• Graph Theory
5.1 Comprehensive Module List

**Note:** This list is currently sorted in alphabetical order w.r.t. the module names. It can be updated semi-automatically by running in `src/sage/combinat`:

```bash
find -name "*.py*" | sed 's|\py\?$||; s|\.| sage/combinat/|' | LANG=en_US.UTF-8 LC_COLLATE=C sort > /tmp/module_list.rst
```

and copy pasting the result back there.

**Todo:** See github issue #17421 for desirable improvements.

5.1.1 Abstract Recursive Trees

The purpose of this class is to help implement trees with a specific structure on the children of each node. For instance, one could want to define a tree in which each node sees its children as linearly (see the [Ordered Trees](#)) or cyclically ordered.

**Tree structures**

Conceptually, one can define a tree structure from any object that can contain others. Indeed, a list can contain lists which contain lists which contain lists, and thus define a tree… The same can be done with sets, or any kind of iterable objects.

While any iterable is sufficient to encode trees, it can prove useful to have other methods available like isomorphism tests (see next section), conversions to DiGraphs objects (see `as_digraph()` or computation of the number of automorphisms constrained by the structure on children. Providing such methods is the whole purpose of the `AbstractTree` class.

As a result, the `AbstractTree` class is not meant to be instantiated, but extended. It is expected that classes extending this one may also inherit from classes representing iterables, for instance `ClonableArray` or `ClonableList`.

**Constrained Trees**

The tree built from a specific container will reflect the properties of the container. Indeed, if A is an iterable class whose elements are linearly ordered, a class B extending both of `AbstractTree` and A will be such that the children of a node will be linearly ordered. If A behaves like a set (i.e. if there is no order on the elements it contains), then two trees will be considered as equal if one can be obtained from the other through permutations between the children of a same node (see next section).
Paths and ID

It is expected that each element of a set of children should be identified by its index in the container. This way, any node of the tree can be identified by a word describing a path from the root node.

Canonical labellings

Equality between instances of classes extending both AbstractTree and A is entirely defined by the equality defined on the elements of A. A canonical labelling of such a tree, however, should be such that two trees a and b satisfying a == b have the same canonical labellings. On the other hand, the canonical labellings of trees a and b satisfying a != b are expected to be different.

For this reason, the values returned by the canonical_labelling method heavily depend on the data structure used for a node’s children and should be overridden by most of the classes extending AbstractTree if it is incoherent with the data structure.

Authors

- Florent Hivert (2010-2011): initial revision
- Frédéric Chapoton (2011): contributed some methods

class sage.combinat.abstract_tree.AbstractClonableTree

    Bases: AbstractTree

Abstract Clonable Tree.

An abstract class for trees with clone protocol (see list_clone). It is expected that classes extending this one may also inherit from classes like ClonableArray or ClonableList depending whether one wants to build trees where adding a child is allowed.

Note: Due to the limitation of Cython inheritance, one cannot inherit here from ClonableElement, because it would prevent us from later inheriting from ClonableArray or ClonableList.

How should this class be extended?

A class extending AbstractClonableTree should satisfy the following assumptions:

- An instantiable class extending AbstractClonableTree should also extend the ClonableElement class or one of its subclasses generally, at least ClonableArray.
- To respect the Clone protocol, the AbstractClonableTree.check() method should be overridden by the new class.

See also the assumptions in AbstractTree.

check()

Check that self is a correct tree.

This method does nothing. It is implemented here because many extensions of AbstractClonableTree also extend sage.structure.list_clone.ClonableElement, which requires it.

It should be overridden in subclasses in order to check that the characterizing property of the respective kind of tree holds (eg: two children for binary trees).

EXAMPLES:

```
sage: OrderedTree([[],[]]).check()
sage: BinaryTree([[],[],[]]).check()
```
class sage.combinat.abstract_tree.AbstractLabelledClonableTree(parent, children, label=None, check=True)

Bases: AbstractLabelledTree, AbstractClonableTree

Abstract Labelled Clonable Tree

This class takes care of modification for the label by the clone protocol.

Note: Due to the limitation of Cython inheritance, one cannot inherit here from ClonableArray, because it would prevent us to inherit later from ClonableList.

map_labels(f)

Apply the function f to the labels of self

This method returns a copy of self on which the function f has been applied on all labels (a label x is replaced by f(x)).

EXAMPLES:

```
sage: LT = LabelledOrderedTree
dsage: t = LT([LT([],label=1),LT([],label=7)],label=3); t
3[1[], 7[]]
dsage: t.map_labels(lambda z:z+1)
4[2[], 8[]]
dsage: LBT = LabelledBinaryTree
dsage: bt = LBT([LBT([],label=1),LBT([],label=4)],label=2); bt
2[1[., .], 4[., .]]
dsage: bt.map_labels(lambda z:z+1)
3[2[., .], 5[., .]]
```

set_label(path, label)

Change the label of subtree indexed by path to label.

INPUT:

- path – None (default) or a path (list or tuple of children index in the tree)
- label – any sage object

OUTPUT: Nothing, self is modified in place

Note: self must be in a mutable state. See sage.structure.list_clone for more details about mutability.

EXAMPLES:

```
sage: t = LabelledOrderedTree([[],[[],[]]])
sage: t.set_label((0,), 4)
Traceback (most recent call last):
... ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t:
....: t.set_label((0,), 4)
```

(continues on next page)
Todo: Do we want to implement the following syntactic sugar:

```python
with t.clone() as tt:
    tt.labels[1,2] = 3
```

```
set_root_label(label)
```

Set the label of the root of `self`.

**INPUT:** `label` – any Sage object

**OUTPUT:** `None`, `self` is modified in place

**Note:** `self` must be in a mutable state. See `sage.structure.list_clone` for more details about mutability.

**EXAMPLES:**

```python
sage: t = LabelledOrderedTree([[],[[],[]]])
sage: t.set_root_label(3)
Traceback (most recent call last):
  ...ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t:
    t.set_root_label(3)
sage: t.label()
3
sage: t
3[None[], None[None[], None[]]]
```

This also works for binary trees:

```python
sage: bt = LabelledBinaryTree([[],[]])
sage: bt.set_root_label(3)
Traceback (most recent call last):
  ...ValueError: object is immutable; please change a copy instead.
sage: with bt.clone() as bt:
    bt.set_root_label(3)
sage: bt.label()
3
sage: bt
3[None[., .], None[., .]]
```
class sage.combinat.abstract_tree.AbstractLabelledTree(parent, children, label=None, check=True)
    Bases: AbstractTree

Abstract Labelled Tree.

Typically a class for labelled trees is constructed by inheriting from a class for unlabelled trees and AbstractLabelledTree.

How should this class be extended?

A class extending AbstractLabelledTree should respect the following assumptions:

• For a labelled tree $T$ the call $T$.parent().unlabelled_trees() should return a parent for unlabelled trees of the same kind: for example,
  - if $T$ is a binary labelled tree, $T$.parent() is LabelledBinaryTrees() and $T$.parent().unlabelled_trees() is BinaryTrees
  - if $T$ is an ordered labelled tree, $T$.parent() is LabelledOrderedTrees() and $T$.parent().unlabelled_trees() is OrderedTrees

• In the same vein, the class of $T$ should contain an attribute _UnLabelled which should be the class for the corresponding unlabelled trees.

See also the assumptions in AbstractTree.

See also:

AbstractTree

as_digraph()

Return a directed graph version of self.

Warning: At this time, the output makes sense only if self is a labelled binary tree with no repeated labels and no None labels.

EXAMPLES:

sage: LT = LabelledOrderedTrees()
sage: t1 = LT([LT([[]],label=6),LT([[]],label=1)],label=9)
sage: t1.as_digraph()
Digraph on 3 vertices

sage: t = BinaryTree([[None, None],[[]],None])
sage: lt = t.canonical_labelling()
sage: lt.as_digraph()
Digraph on 4 vertices

label(path=None)

Return the label of self.

INPUT:

• path – None (default) or a path (list or tuple of children index in the tree)

OUTPUT: the label of the subtree indexed by path

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: t = LabelledOrderedTree([],[], label = 3)
sage: t.label()
3
sage: t[0].label()
sage: t = LabelledOrderedTree([LabelledOrderedTree([], 5), []], label = 3)
sage: t.label()
3
sage: t[0].label()
5
sage: t[1].label()
sage: t.label([0])
5
```

labels()

Return the list of labels of self.

EXAMPLES:

```python
sage: LT = LabelledOrderedTree
sage: t = LT([LT([],label='b'),LT([],label='c')],label='a')
sage: t.labels()
['a', 'b', 'c']
```

leaf_labels()

Return the list of labels of the leaves of self.

In case of a labelled binary tree, these “leaves” are not actually the leaves of the binary trees, but the nodes whose both children are leaves!

EXAMPLES:

```python
sage: LT = LabelledOrderedTree
sage: t = LT([LT([],label='b'),LT([],label='c')],label='a')
sage: t.leaf_labels()
['b', 'c']
```

shape()

Return the unlabelled tree associated to self.

EXAMPLES:

```python
sage: LT = LabelledOrderedTree
sage: t = LT([LT([],label='b'),LT([],label='c')],label='a')
sage: t.shape()
```

```python
sage: LBT = LabelledBinaryTree
sage: bt = LBT([LBT([],label='b'),LBT([],label='c')],label='a')
sage: bt.leaf_labels()
['b', 'c']
```

sage: LBT([]).leaf_labels()
['1']
```

sage: LBT(None).leaf_labels()
[]
```
```python
sage: t = LabelledOrderedTree([],[], label = 25).shape(); t
[[], []]
```
```
sage: LabelledBinaryTree([],[], label = 25).shape()
[[., .], [[., .], [., .]]]
```
```
sage: LRT = LabelledRootedTree
sage: tb = LRT([],label='b')
sage: LRT([tb, tb], label='a').shape()
[[], []]
```

```python
class sage.combinat.abstract_tree.AbstractTree
    Bases: object
    Abstract Tree.
    
    There is no data structure defined here, as this class is meant to be extended, not instantiated.

How should this class be extended?
```
A class extending `AbstractTree` should respect several assumptions:

- For a tree $T$, the call `iter(T)` should return an iterator on the children of the root $T$.
- The `canonical_labelling` method should return the same value for trees that are considered equal (see the “canonical labellings” section in the documentation of the `AbstractTree` class).
- For a tree $T$ the call `T.parent().labelled_trees()` should return a parent for labelled trees of the same kind: for example,
  - if $T$ is a binary tree, `T.parent()` is `BinaryTrees()` and `T.parent().labelled_trees()` is `LabelledBinaryTrees()`
  - if $T$ is an ordered tree, `T.parent()` is `OrderedTrees()` and `T.parent().labelled_trees()` is `LabelledOrderedTrees()`
```

```python
breadth_first_order_traversal(action=None)
```
```
Run the breadth-first post-order traversal algorithm and subject every node encountered to some procedure `action`. The algorithm is:
```
```
the breadth-first order traversal algorithm explores $b$ in the following order of nodes: 3, 1, 7, 2, 5, 8, 4, 6.

canonical_labelling(shift=1)

Return a labelled version of self.

The actual canonical labelling is currently unspecified. However, it is guaranteed to have labels in 1...$n$ where $n$ is the number of nodes of the tree. Moreover, two (unlabelled) trees compare as equal if and only if their canonical labelled trees compare as equal.

EXAMPLES:

```
sage: t = OrderedTree([[], [[]], [[]], [[], []], [[], []], [], []])
sage: t.canonical_labelling()
1[2[., .], 3[4[., .], 5[., .]]]
```

depth()

Return the depth of self.

EXAMPLES:

```
sage: OrderedTree().depth()
1
sage: OrderedTree([]).depth()
1
sage: OrderedTree([[]]).depth()
2
sage: OrderedTree([[[]]]).depth()
3
sage: OrderedTree([[], [[]], [[], []], [[], []], [], []]).depth()
4
```

iterative_post_order_traversal(action=None)

Run the depth-first post-order traversal algorithm (iterative implementation) and subject every node encountered to some procedure action. The algorithm is:

explore each subtree (by the algorithm) from the leftmost one to the rightmost one;
then manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf).

**INPUT:**

- `action` – (optional) a function which takes a node as input, and does something during the exploration

**OUTPUT:**

None. (This is not an iterator.)

**See also:**

- `post_order_traversal_iter()`

**iterative_pre_order_traversal**(action=None)

Run the depth-first pre-order traversal algorithm (iterative implementation) and subject every node encountered to some procedure `action`. The algorithm is:

then manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf); then explore each subtree (by the algorithm) from the leftmost one to the rightmost one.

**INPUT:**

- `action` – (optional) a function which takes a node as input, and does something during the exploration

**OUTPUT:**

None. (This is not an iterator.)

**See also:**

- `pre_order_traversal_iter()`
- `pre_order_traversal()`

**node_number()**

Return the number of nodes of `self`.

**See also:**

`node_number_at_depth()`, `node_number_to_the_right()`

**EXAMPLES:**

```
sage: OrderedTree().node_number()
1
sage: OrderedTree([]).node_number()
1
sage: OrderedTree([[[]]]).node_number()
3
sage: OrderedTree([[], [[]]]).node_number()
4
sage: OrderedTree([[], [[], []], [], [[]], [[]]], []).node_number()
13
```

**EXAMPLES:**
node_number_at_depth(depth)

Return the number of nodes at a given depth.
This counts all nodes that are at the given depth.
Here the root is considered to have depth 0.

INPUT:
• depth – an integer

See also:
node_number(), node_number_to_the_right(), paths_at_depth()

EXAMPLES:

```
sage: T = OrderedTree([[], [[]], [[], []], [], []])
sage: ascii_art(T)
   ___o___
  /     /
 o_   o_ o
 /     /
 o o o o
 |     |
 o o
 |     |
 o

sage: [T.node_number_at_depth(i) for i in range(6)]
[1, 3, 4, 2, 1, 0]
```

node_number_to_the_right(path)

Return the number of nodes at the same depth and to the right of the node identified by path.
This counts the nodes that are at the same depth as the given one, and strictly to its right.

See also:
node_number(), node_number_at_depth(), paths_to_the_right()

EXAMPLES:

```
sage: T = OrderedTree([[], [[]], [[], []], [], []])
sage: ascii_art(T)
   ___o___
  /     /
 o_   o_ o
 /     /
 o o o o
 |     |
 o o
 |     |
 o

sage: T.node_number_to_the_right((0, 1))
3
```
(continues on next page)
paths()

Return a generator for all paths to nodes of self.

OUTPUT:

This method returns a list of sequences of integers. Each of these sequences represents a path from the root node to some node. For instance, \((1, 3, 2, 5, 0, 3)\) represents the node obtained by choosing the 1st child of the root node (in the ordering returned by \(\text{iter}\)), then the 3rd child of its child, then the 2nd child of the latter, etc. (where the labelling of the children is zero-based).

The root element is represented by the empty tuple ()

See also:

paths_at_depth(), paths_to_the_right()

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{list(OrderedTree([]).paths())} \\
& [()] \\
\text{sage: } & \text{list(OrderedTree([[]], []).paths())} \\
& [(), (0,), (1,), (1, 0)] \\
\text{sage: } & \text{list(BinaryTree([[]], []).paths())} \\
& [(), (0,), (1,), (1, 0), (1, 1)]
\end{align*}
\]

paths_at_depth(depth, path=[])

Return a generator for all paths at a fixed depth.

This iterates over all paths for nodes that are at the given depth.

Here the root is considered to have depth 0.

INPUT:

- depth – an integer
- path – optional given path (as a list) used in the recursion
Warning: The path option should not be used directly.

See also:

paths(), paths_to_the_right(), node_number_at_depth()

EXAMPLES:

```python
sage: T = OrderedTree([[], [[]], [], [[]], [], []])
sage: ascii_art(T)
    ______o_______
   /     /     / 
  _o--_ o--o o--o
 / 
o--o o--o
 / / / 
 o o o o
 | | |
 o o

sage: list(T.paths_at_depth(0))
[(0)]
sage: list(T.paths_at_depth(2))
[(0, 0), (0, 1), (2, 0)]
sage: list(T.paths_at_depth(4))
[(0, 1, 1, 0)]
sage: list(T.paths_at_depth(5))
[]

sage: T2 = OrderedTree([])
sage: list(T2.paths_at_depth(0))
[(0)]
```

paths_to_the_right(path)

Return a generator of paths for all nodes at the same depth and to the right of the node identified by path. This iterates over the paths for nodes that are at the same depth as the given one, and strictly to its right.

INPUT:

• path – any path in the tree

See also:

paths(), paths_at_depth(), node_number_to_the_right()

EXAMPLES:

```python
sage: T = OrderedTree([[], [[]], [], [[]], [], []])
sage: ascii_art(T)
    ______o_______
   /     /     / 
  _o--_ o--o o--o
 / 
o--o o--o
 / / / 
 o o o o
 | | |
 o o

sage: T2 = OrderedTree([])
sage: list(T2.paths_at_depth(0))
[(0)]
```

(continues on next page)
post_order_traversal\(\text{(action=\text{None})}\)

Run the depth-first post-order traversal algorithm (recursive implementation) and subject every node encountered to some procedure \text{action}. The algorithm is:

- explore each subtree (by the algorithm) from the leftmost one to the rightmost one;
- then manipulate the root with function `\text{action}` (in the case of a binary tree, only if the root is not a leaf).

INPUT:

- \text{action} – (optional) a function which takes a node as input, and does something during the exploration

OUTPUT:

None. (This is \textit{not} an iterator.)

See also:

- \textit{post_order_traversal\_iter()}
- \textit{iterative\_post_order\_traversal()}

\textbf{post_order_traversal\_iter()}

The depth-first post-order traversal iterator.

This method iters each node following the depth-first post-order traversal algorithm (recursive implementation). The algorithm is:

- explore each subtree (by the algorithm) from the leftmost one to the rightmost one;
- then yield the root (in the case of binary trees, only if it is not a leaf).
EXAMPLES:

For example on the following binary tree $b$:

```
|   3   |
|  /  \ |
| 1   7 |
| /   / |
|2 5 8 |
| /   |
|4 6  |
```

(only the nodes are shown), the depth-first post-order traversal algorithm explores $b$ in the following order of nodes: 2, 1, 4, 6, 5, 8, 7, 3.

For another example, consider the labelled tree:

```
|   1   |
|  / /  |
|2 6 8  |
| | | / / |
|3 7 9 10 |
| / / |
|4 5  |
```

The algorithm explores this tree in the following order: 4, 5, 3, 2, 7, 6, 9, 10, 8, 1.

**pre_order_traversal**(action=None)

Run the depth-first pre-order traversal algorithm (recursive implementation) and subject every node encountered to some procedure *action*. The algorithm is:

- manipulate the root with function `action` (in the case of a binary tree, only if the root is not a leaf);
- then explore each subtree (by the algorithm) from the leftmost one to the rightmost one.

**INPUT:**

- *action* – (optional) a function which takes a node as input, and does something during the exploration

**OUTPUT:**

None. (This is *not* an iterator.)

**EXAMPLES:**

For example, on the following binary tree $b$:

```
|   3   |
|  /  \ |
| 1   7 |
| /   / |
|2 5 8 |
| /   |
|4 6  |
```

the depth-first pre-order traversal algorithm explores $b$ in the following order of nodes: 3, 1, 2, 7, 5, 4, 6, 8.

Another example:
The algorithm explores this tree in the following order: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

See also:

- `pre_order_traversal_iter()`
- `iterative_pre_order_traversal()`

**pre_order_traversal_iter()**

The depth-first pre-order traversal iterator.

This method iterates each node following the depth-first pre-order traversal algorithm (recursive implementation). The algorithm is:

- yield the root (in the case of binary trees, if it is not a leaf);
- then explore each subtree (by the algorithm) from the leftmost one to the rightmost one.

**EXAMPLES:**

For example, on the following binary tree $b$:

(only the nodes shown), the depth-first pre-order traversal algorithm explores $b$ in the following order of nodes: 3, 1, 2, 7, 5, 4, 6, 8.

Another example:

The algorithm explores this labelled tree in the following order: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

**subtrees()**

Return a generator for all nonempty subtrees of $\textit{self}$. 

5.1. Comprehensive Module List
The number of nonempty subtrees of a tree is its number of nodes. (The word “nonempty” makes a difference only in the case of binary trees. For ordered trees, for example, all trees are nonempty.)

EXAMPLES:

```python
sage: list(OrderedTree([]).subtrees())
[[]]

sage: list(OrderedTree([],[]).subtrees())
[[[[], []]], [], [[]], []]

sage: list(OrderedTree([[],[]]).canonical_labelling().subtrees())
[1[2[], 3[4[]]], 2[], 3[4[]], 4[]]

sage: list(BinaryTree([[],[]]).subtrees())
[[[., .], [.[., .], [., .]]], [., .], [[., .], [., .]], [., .], [., .]]

sage: v = BinaryTree([[],[]])
sage: list(v.canonical_labelling().subtrees())
[2[1[., .], 3[., .]], 1[., .], 3[., .]]
```

to_hexacode()

Transform a tree into an hexadecimal string.

The definition of the hexacode is recursive. The first letter is the valence of the root as an hexadecimal (up to 15), followed by the concatenation of the hexacodes of the subtrees.

This method only works for trees where every vertex has valency at most 15.

See `from_hexacode()` for the reverse transformation.

EXAMPLES:

```python
sage: from sage.combinat.abstract_tree import from_hexacode
sage: LT = LabelledOrderedTrees()
sage: from_hexacode('2010', LT).to_hexacode()
'2010'

sage: LT.an_element().to_hexacode()
'3020010'

sage: t = from_hexacode('a0000000000000000', LT)
sage: t.to_hexacode()
'a0000000000'

sage: OrderedTrees(6).an_element().to_hexacode()
'500000'
```
tree_factorial()

Return the tree-factorial of self.

Definition:

The tree-factorial \( T! \) of a tree \( T \) is the product \( \prod_{v \in T} \# \text{children}(v) \).

EXAMPLES:

```python
sage: LT = LabelledOrderedTrees()
sage: t = LT([LT([],label=6),LT([],label=1)],label=9)
sage: t.tree_factorial()
```
sage.combinat.abstract_tree.from_hexacode(ch, parent=None, label='@')

Transform an hexadecimal string into a tree.

INPUT:

- `ch` – an hexadecimal string
- `parent` – kind of trees to be produced. If None, this will be LabelledOrderedTrees
- `label` – a label (default: '@') to be used for every vertex of the tree

See AbstractTree.to_hexacode() for the description of the encoding

See _from_hexacode_aux() for the actual code

EXAMPLES:

```python
sage: from sage.combinat.abstract_tree import from_hexacode
sage: from_hexacode('12000', LabelledOrderedTrees())
@
[@, @]
```

It can happen that only a prefix of the word is used:

```python
sage: from_hexacode('a'+14*'0', LabelledOrderedTrees())
@[, @, @, @, @, @, @, @, @, @]
```

One can choose the label:

```python
sage: from_hexacode('1200', LabelledOrderedTrees(), label='o')
o[o, o]
```

One can also create other kinds of trees:

```python
sage: from_hexacode('1200', OrderedTrees())
[[[], []]]
```

### 5.1.2 Affine Permutations

```python
class sage.combinat.affine_permutation.AffinePermutation(parent, lst, check=True)
Bases: ClonableArray
```

An affine permutation, represented in the window notation, and considered as a bijection from \( \mathbb{Z} \) to \( \mathbb{Z} \).

EXAMPLES:
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]

apply_simple_reflection(i, side='right')

Apply a simple reflection.

INPUT:

• i – an integer

• side – (default: 'right') determines whether to apply the reflection on the 'right' or 'left'

EXAMPLES:

sage: p = AffinePermutationGroup(['A',7,1])((3, -1, 0, 6, 5, 4, 10, 9))
sage: p.apply_simple_reflection(3)
Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
sage: p.apply_simple_reflection(11)
Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
sage: p.apply_simple_reflection(3, 'left')
Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]
sage: p.apply_simple_reflection(11, 'left')
Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]

grassmannian_quotient(i=0, side='right')

Return the Grassmannian quotient.

Factors self into a unique product of a Grassmannian and a finite-type element. Returns a tuple containing the Grassmannian and finite elements, in order according to side.

INPUT:

• i – (default: 0) an element of the index set; the descent checked for

EXAMPLES:

sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: gq=p.grassmannian_quotient()
sage: gq
(Type A affine permutation with window [-1, 0, 3, 4, 5, 6, 9, 10],
Type A affine permutation with window [3, 1, 2, 6, 5, 4, 8, 7])
sage: gq[0].is_i_grassmannian()
True
sage: 0 not in gq[1].reduced_word()
True
sage: prod(gq)==p
True
sage: gqLeft=p.grassmannian_quotient(side='left')
sage: 0 not in gqLeft[0].reduced_word()
True
sage: gqLeft[1].is_i_grassmannian(side='left')
True

(continues on next page)
index_set()

Index set of the affine permutation group.

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A', 7, 1])
sage: A.index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

is_i_grassmannian(i=0, side='right')

Test whether self is i-grassmannian, i.e., either the identity or has i as the sole descent.

INPUT:

- i – an element of the index set
- side – determines the side on which to check the descents

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A', 7, 1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_i_grassmannian()
False
sage: q = A.from_word([3, 2, 1, 0])
sage: q.is_i_grassmannian()
True
sage: q = A.from_word([2, 3, 4, 5])
sage: q.is_i_grassmannian(5)
True
sage: q.is_i_grassmannian(2, side='left')
True
```

is_one()

Tests whether the affine permutation is the identity.

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A', 7, 1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_one()
False
sage: q = A.one()
sage: q.is_one()
True
```

lower_covers(side='right')

Return lower covers of self.

The set of affine permutations of one less length related by multiplication by a simple transposition on the indicated side. These are the elements that self covers in weak order.

EXAMPLES:
Combinatorics, Release 10.1

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.lower_covers()
[Type A affine permutation with window [-1, 3, 0, 6, 5, 4, 10, 9],
 Type A affine permutation with window [3, -1, 0, 5, 6, 4, 10, 9],
 Type A affine permutation with window [3, -1, 0, 6, 4, 5, 10, 9],
 Type A affine permutation with window [3, -1, 0, 6, 5, 4, 9, 10]]

reduced_word()
Returns a reduced word for the affine permutation.

EXAMPLES:
```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.reduced_word()
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
```

signature()
Signature of the affine permutation, \((-1)^l\), where \(l\) is the length of the permutation.

EXAMPLES:
```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.signature()
1
```

to_weyl_group_element()
The affine Weyl group element corresponding to the affine permutation.

EXAMPLES:
```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_weyl_group_element()
[ 0 -1 0 1 0 0 1 0]
[ 1 -1 0 1 0 0 1 -1]
[ 1 -1 0 1 0 0 0 0]
[ 0 0 0 1 0 0 0 0]
[ 0 0 0 1 -1 0 1 0]
[ 0 0 0 0 0 0 1 0]
[ 0 -1 1 0 0 0 1 0]
```

sage.combinat.affine_permutation.AffinePermutationGroup(cartan_type)
Wrapper function for specific affine permutation groups.

These are combinatorial implementations of the affine Weyl groups of types \(A, B, C, D\), and \(G\) as permutations of the set of all integers. the basic algorithms are derived from [BB2005] and [Eri1995].

EXAMPLES:
```
sage: ct = CartanType(['A',7,1])
sage: A = AffinePermutationGroup(ct)
```
sage: A
The group of affine permutations of type ['A', 7, 1]

We define an element of $A$:

```sage
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
```

We find the value $p(1)$, considering $p$ as a bijection on the integers. This is the same as calling the `value()` method:

```sage
sage: p.value(1)
3
sage: p(1) == p.value(1)
True
```

We can also find the position of the integer 3 in $p$ considered as a sequence, equivalent to finding $p^{-1}(3)$:

```sage
sage: p.position(3)
1
sage: (p**-1)(3)
1
```

Since the affine permutation group is a group, we demonstrate its group properties:

```sage
sage: A.one()
Type A affine permutation with window [1, 2, 3, 4, 5, 6, 7, 8]
sage: q = A([0, 2, 3, 4, 5, 6, 7, 9])
sage: p * q
Type A affine permutation with window [1, -1, 0, 6, 5, 4, 10, 11]
sage: q * p
Type A affine permutation with window [3, -1, 1, 6, 5, 4, 10, 8]
sage: p**-1
Type A affine permutation with window [0, -1, 1, 6, 5, 4, 10, 11]
sage: p**-1 * p == A.one()
True
sage: p * p**-1 == A.one()
True
```

If we decide we prefer the Weyl Group implementation of the affine Weyl group, we can easily get it:

```sage
sage: p.to_weyl_group_element()
[ 0 -1  0  1  0  0  1  0]
[ 1 -1  0  1  0  0  1 -1]
[ 1 -1  0  1  0  0  0  0]
[ 0  0  0  1  0  0  0  0]
[ 0  0  0  1  0 -1  1  0]
[ 0  0  0  1 -1  0  1  0]
[ 0  0  0  0  0  0  1  0]
[ 0 -1  1  0  0  0  1  0]
```
We can find a reduced word and do all of the other things one expects in a Coxeter group:

```
sage: p.has_right_descent(1)
True
sage: p.apply_simple_reflection(1)
Type A affine permutation with window [-1, 3, 0, 6, 5, 4, 10, 9]
sage: p.apply_simple_reflection(0)
Type A affine permutation with window [1, -1, 0, 6, 5, 4, 10, 11]
sage: p.reduced_word()
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
sage: p.length()
10
```

The following methods are particular to type $A$. We can check if the element is fully commutative:

```
sage: p.is_fully_commutative()
False
sage: q.is_fully_commutative()
True
```

We can also compute the affine Lehmer code of the permutation, a weak composition with $k+1$ entries:

```
sage: p.to_lehmer_code()
[0, 3, 3, 0, 1, 2, 0, 1]
```

Once we have the Lehmer code, we can obtain a $k$-bounded partition by sorting the Lehmer code, and then reading the row lengths. There is a unique $0$-Grassmanian (dominant) affine permutation associated to this $k$-bounded partition, and a $k$-core as well.

```
sage: p.to_bounded_partition()
[5, 3, 2]
sage: p.to_dominant()
Type A affine permutation with window [-2, -1, 1, 3, 4, 8, 10, 13]
sage: p.to_core()
[5, 3, 2]
```

Finally, we can take a reduced word for $p$ and insert it to find a standard composition tableau associated uniquely to that word:

```
sage: p.tableau_of_word(p.reduced_word())
[[], [1, 6, 9], [2, 7, 10], [], [3], [4, 8], [], [5]]
```

We can also form affine permutation groups in types $B$, $C$, $D$, and $G$:

```
sage: B = AffinePermutationGroup(['B',4,1])
sage: B.an_element()
Type B affine permutation with window [-1, 3, 4, 11]
sage: C = AffinePermutationGroup(['C',4,1])
sage: C.an_element()
Type C affine permutation with window [2, 3, 4, 10]
sage: D = AffinePermutationGroup(['D',4,1])
sage: D.an_element()
```

(continues on next page)
Type D affine permutation with window \([-1, 3, 11, 5]\)

```python
sage: G = AffinePermutationGroup(['G',2,1])
sage: G.an_element()
Type G affine permutation with window [0, 4, -1, 8, 3, 7]
```

```python
class sage.combinat.affine_permutation.AffinePermutationGroupGeneric(cartan_type)
Bases: UniqueRepresentation, Parent

The generic affine permutation group class, in which we define all type-free methods for the specific affine permutation groups.

cartan_matrix()

Returns the Cartan matrix of self.

EXAMPLES:

```python
sage: AffinePermutationGroup(['A',7,1]).cartan_matrix()
[ 2 -1 0 0 0 0 0 -1]
[-1 2 -1 0 0 0 0 0]
[ 0 -1 2 -1 0 0 0 0]
[ 0 0 -1 2 -1 0 0 0]
[ 0 0 0 -1 2 -1 0 0]
[ 0 0 0 0 -1 2 -1 0]
[ 0 0 0 0 0 -1 2 -1]
[-1 0 0 0 0 0 -1 2]
```

cartan_type()

Returns the Cartan type of self.

EXAMPLES:

```python
sage: AffinePermutationGroup(['A',7,1]).cartan_type()
['A', 7, 1]
```

classical()

Returns the finite permutation group.

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: A.classical()
Symmetric group of order 8! as a permutation group
```

from_word(w)

Builds an affine permutation from a given word. Note: Already in category as from_reduced_word, but this is less typing!

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: A.from_word([0, 7, 4, 1, 0, 7, 5, 4, 2, 1])
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
```
Combinatorics, Release 10.1

**index_set()**

EXAMPLES:

```python
sage: AffinePermutationGroup(['A',7,1]).index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

**is_crystallographic()**

Tells whether the affine permutation group is crystallographic.

EXAMPLES:

```python
sage: AffinePermutationGroup(['A',7,1]).is_crystallographic()
True
```

**random_element(n=None)**

Return a random affine permutation of length \( n \).

If \( n \) is not specified, then \( n \) is chosen as a random non-negative integer in \([0, 1000]\).

Starts at the identity, then chooses an upper cover at random. Not very uniform: actually constructs a uniformly random reduced word of length \( n \). Thus we most likely get elements with lots of reduced words!

For the actual code, see `sage.categories.coxeter_group.random_element_of_length()`.

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: A.random_element()  # random
Type A affine permutation with window [-12, 16, 19, -1, -2, 10, -3, 9]
sage: p = A.random_element(10)
sage: p.length() == 10
True
```

**rank()**

Rank of the affine permutation group, equal to \( k + 1 \).

EXAMPLES:

```python
sage: AffinePermutationGroup(['A',7,1]).rank()
8
```

**reflection_index_set()**

EXAMPLES:

```python
sage: AffinePermutationGroup(['A',7,1]).reflection_index_set()
(0, 1, 2, 3, 4, 5, 6, 7)
```

**weyl_group()**

Returns the Weyl Group of the same type as `self`.

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: A.weyl_group()
Weyl Group of type ['A', 7, 1] (as a matrix group acting on the root space)
```
class sage.combinat.affine_permutation.AffinePermutationGroupTypeA(cartan_type)
    Bases: AffinePermutationGroupGeneric
    
    Element
    alias of AffinePermutationTypeA

    from_lehmer_code(C, typ='decreasing', side='right')
    Return the affine permutation with the supplied Lehmer code (a weak composition with \( k + 1 \) parts, at least one of which is 0).
    INPUT:
    • typ – 'increasing' or 'decreasing' (default: 'decreasing'); type of product
    • side – 'right' or 'left' (default: 'right'); whether the decomposition is from the right or left

    EXAMPLES:

    sage: import itertools
    sage: A = AffinePermutationGroup(['A',7,1])
    sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
    sage: p.to_lehmer_code()
    [0, 3, 3, 0, 1, 2, 0, 1]
    sage: A.from_lehmer_code(p.to_lehmer_code()) == p
    True
    sage: orders = ('increasing', 'decreasing')
    sage: sides = ('left', 'right')
    sage: all(A.from_lehmer_code(p.to_lehmer_code(o,s),o,s) == p
    ....:      for o, s in itertools.product(orders, sides))
    True

    one()
    Return the identity element.

    EXAMPLES:

    sage: AffinePermutationGroup(['A',7,1]).one()
    Type A affine permutation with window [1, 2, 3, 4, 5, 6, 7, 8]

class sage.combinat.affine_permutation.AffinePermutationGroupTypeB(cartan_type)
    Bases: AffinePermutationGroupTypeC
    
    Element
    alias of AffinePermutationTypeB

class sage.combinat.affine_permutation.AffinePermutationGroupTypeC(cartan_type)
    Bases: AffinePermutationGroupGeneric
    
    Element
    alias of AffinePermutationTypeC

    one()
    Return the identity element.

    EXAMPLES:
sage: ct=CartanType(['C',4,1])
sage: C = AffinePermutationGroup(ct)
sage: C.one()
Type C affine permutation with window [1, 2, 3, 4]
sage: C.one()*C.one()==C.one()
True

class sage.combinat.affine_permutation.AffinePermutationGroupTypeD(cartan_type)
    Bases: AffinePermutationGroupTypeC
    Element
        alias of AffinePermutationTypeD

class sage.combinat.affine_permutation.AffinePermutationGroupTypeG(cartan_type)
    Bases: AffinePermutationGroupGeneric
    Element
        alias of AffinePermutationTypeG

one()
    Return the identity element.

    EXAMPLES:
    sage: AffinePermutationGroup(['G',2,1]).one()
    Type G affine permutation with window [1, 2, 3, 4, 5, 6]

class sage.combinat.affine_permutation.AffinePermutationTypeA(parent, lst, check=True)
    Bases: AffinePermutation

apply_simple_reflection_left(i)
    Apply the simple reflection to the values $i, i + 1$.

    EXAMPLES:
    sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
    sage: p.apply_simple_reflection_left(3)
    Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]
    sage: p.apply_simple_reflection_left(11)
    Type A affine permutation with window [4, -1, 0, 6, 5, 3, 10, 9]

apply_simple_reflection_right(i)
    Apply the simple reflection to positions $i, i + 1$.

    INPUT:
    • i – an integer

    EXAMPLES:
    sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
    sage: p.apply_simple_reflection_right(3)
    Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
    sage: p.apply_simple_reflection_right(11)
    Type A affine permutation with window [3, -1, 6, 0, 5, 4, 10, 9]
check()

Check that self is an affine permutation.

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p
Type A affine permutation with window [3, -1, 0, 6, 5, 4, 10, 9]
sage: q = A([1,2,3])  # indirect doctest
Traceback (most recent call last):
... ValueError: window does not sum to 36
sage: q = A([1,1,3,4,5,6,7,9])  # indirect doctest
Traceback (most recent call last):
... ValueError: entries must have distinct residues
```

flip_automorphism()

The Dynkin diagram automorphism which fixes \( s_0 \) and reverses all other indices.

EXAMPLES:

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.flip_automorphism()
Type A affine permutation with window [0, -1, 5, 4, 3, 9, 10, 6]
```

has_left_descent(\( i \))

Determine whether there is a descent at \( i \).

INPUT:

• \( i \) – an integer

EXAMPLES:

```python
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.has_left_descent(1)
True
sage: p.has_left_descent(9)
True
sage: p.has_left_descent(0)
True
```

has_right_descent(\( i \))

Determine whether there is a descent at \( i \).

INPUT:

• \( i \) – an integer

EXAMPLES:
is_fully_commutative()
Determine whether self is fully commutative.
This means that it has no reduced word with a braid.
This uses a specific algorithm.

EXAMPLES:

```
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.is_fully_commutative()
False
```

maximal_cyclic_decomposition(typ='decreasing', side='right', verbose=False)
Find the unique maximal decomposition of self into cyclically decreasing/increasing elements.

INPUT:

- `typ` – 'increasing' or 'decreasing' (default: 'decreasing'); chooses whether to find increasing or decreasing sets
- `side` – 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right
- `verbose` – (default: False) print extra information while finding the decomposition

EXAMPLES:

```
sage: p = AffinePermutationGroup(['A',7,1])
sage: p.maximal_cyclic_decomposition()
[[0, 7], [4, 1, 0], [7, 5, 4, 2, 1]]
sage: p.maximal_cyclic_decomposition(side='left')
[[1, 0, 7, 5, 4], [1, 0, 5], [2, 1]]
sage: p.maximal_cyclic_decomposition(typ='increasing', side='right')
[[1], [5, 0, 1, 2], [4, 5, 7, 0, 1]]
sage: p.maximal_cyclic_decomposition(typ='increasing', side='left')
[[0, 1, 2, 4, 5], [4, 7, 0, 1], [7]]
```

maximal_cyclic_factor(typ='decreasing', side='right', verbose=False)
For an affine permutation \(x\), find the unique maximal subset \(A\) of the index set such that \(x = yd_A\) is a reduced product.

INPUT:

- `typ` – 'increasing' or 'decreasing' (default: 'decreasing'); chooses whether to find increasing or decreasing sets
Combinatorics, Release 10.1

• side – 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right
• verbose – True or False. If True, outputs information about how the cyclically increasing element was found.

EXAMPLES:

sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.maximal_cyclic_factor()
[7, 5, 4, 2, 1]

sage: p.maximal_cyclic_factor(side='left')
[1, 0, 7, 5, 4]

sage: p.maximal_cyclic_factor('increasing','right')
[4, 5, 7, 0, 1]

sage: p.maximal_cyclic_factor('increasing','left')
[0, 1, 2, 4, 5]

position(i)

Find the position j such the self.value(j) == i.

EXAMPLES:

sage: A = AffinePermutationGroup(['A',7,1])

sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])

sage: p.position(3)
1

sage: p.position(11)
9

promotion()

The Dynkin diagram automorphism which sends si to si+1.

EXAMPLES:

sage: A = AffinePermutationGroup(['A',7,1])

sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])

sage: p.promotion()

Type A affine permutation with window [2, 4, 0, 1, 7, 6, 5, 11]

tableau_of_word(w, typ='decreasing', side='right', alpha=None)

Finds a tableau on the Lehmer code of self corresponding to the given reduced word.

For a full description of this algorithm, see [Den2012].

INPUT:

• w – a reduced word for self
• typ – 'increasing' or 'decreasing'; the type of Lehmer code used
• side – 'right' or 'left'
• alpha – a content vector; w should be of type alpha; specifying alpha produces semistandard tableaux

EXAMPLES:
\begin{verbatim}
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.tableau_of_word(p.reduced_word())
[[], [1, 6, 9], [2, 7, 10], [], [3], [4, 8], [], [5]]
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: w=p.reduced_word()
sage: w
[0, 7, 4, 1, 0, 7, 5, 4, 2, 1]
sage: alpha=[5,3,2]
sage: p.tableau_of_word(p.reduced_word(), alpha=alpha)
[[], [1, 2, 3], [1, 2, 3], [], [1], [1, 2], [], [1]]
sage: p.tableau_of_word(p.reduced_word(), side='left')
[[1, 4, 9], [6], [], [], [3, 7], [8], [], [2, 5, 10]]
sage: p.tableau_of_word(p.reduced_word(), typ='increasing', side='right')
[[9, 10], [1, 2], [], [], [3, 4], [8], [], [5, 6, 7]]
sage: p.tableau_of_word(p.reduced_word(), typ='increasing', side='left')
[[1, 2], [4, 5, 6], [9, 10], [], [3], [7, 8], [], []]
sage: p.tableau_of_word(p.reduced_word(), typ='decreasing', side='right')

\textbf{to\_bounded\_partition}(\textit{typ='decreasing', side='right'})

Return the $k$-bounded partition associated to the dominant element obtained by sorting the Lehmer code.

\textbf{INPUT:}

- \textit{typ} – ‘increasing’ or ‘decreasing’ (default: ‘decreasing’.) Chooses whether to find increasing or decreasing sets.
- \textit{side} – ‘right’ or ‘left’ (default: ‘right’.) Chooses whether to find maximal sets starting from the left or the right.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = AffinePermutationGroup(['A',2,1])
sage: p=A.from_lehmer_code([4,1,0])
sage: p.to_bounded_partition()
[2, 1, 1, 1]
sage: p.to_core()
[4, 2, 1, 1]
\end{verbatim}

\textbf{to\_core}(\textit{typ='decreasing', side='right'})

Returns the core associated to the dominant element obtained by sorting the Lehmer code.

\textbf{INPUT:}

- \textit{typ} – ‘increasing’ or ‘decreasing’ (default: ‘decreasing’.)
- \textit{side} – ‘right’ or ‘left’ (default: ‘right’.) Chooses whether to find maximal sets starting from the left or the right.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = AffinePermutationGroup(['A',2,1])
sage: p=A.from_lehmer_code([4,1,0])
sage: p.to_bounded_partition()
[2, 1, 1, 1]
sage: p.to_core()
[4, 2, 1, 1]
\end{verbatim}
\end{verbatim}
to_dominant\(\text{(typ='decreasing', side='right')}\)

Finds the Lehmer code and then sorts it. Returns the affine permutation with the given sorted Lehmer code; this element is 0-dominant.

**INPUT:**

- **typ** – 'increasing' or 'decreasing' (default: 'decreasing') chooses whether to find increasing or decreasing sets
- **side** – 'right' or 'left' (default: 'right') chooses whether to find maximal sets starting from the left or the right

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_dominant()
Type A affine permutation with window [-2, -1, 1, 3, 4, 8, 10, 13]
sage: p.to_dominant(typ='increasing', side='left')
Type A affine permutation with window [3, 4, -1, 5, 0, 9, 6, 10]
```

**to_lehmer_code**\(\text{(typ='decreasing', side='right')}\)

Return the affine Lehmer code.

There are four such codes; the options typ and side determine which code is generated. The codes generated are the shape of the maximal cyclic decompositions of self according to the given typ and side options.

**INPUT:**

- **typ** – 'increasing' or 'decreasing' (default: 'decreasing'); chooses whether to find increasing or decreasing sets
- **side** – 'right' or 'left' (default: 'right'); chooses whether to find maximal sets starting from the left or the right

**EXAMPLES:**

```python
sage: import itertools
sage: A = AffinePermutationGroup(['A',7,1])
sage: p=A([3, -1, 0, 6, 5, 4, 10, 9])
sage: orders = ('increasing', 'decreasing')
sage: sides = ('left', 'right')
sage: for o,s in itertools.product(orders, sides):
    ....:     p.to_lehmer_code(o,s)
[2, 3, 2, 0, 1, 2, 0, 0]
[2, 2, 0, 0, 2, 1, 0, 3]
[3, 1, 0, 0, 2, 1, 0, 3]
[0, 3, 3, 0, 1, 2, 0, 1]
sage: for a in itertools.product(orders, sides):
    ....:     A.from_lehmer_code(p.to_lehmer_code(a[0],a[1]), a[0],a[1])==p
True
True
True
True
```

**to_type_a()**

Return an embedding of self into the affine permutation group of type A. (For type A, just returns self.)
EXAMPLES:

```python
sage: p = AffinePermutationGroup(['A',7,1])([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.to_type_a() is p
True
```

**value**(*i*, *base_window=False*)

Return the image of the integer *i* under this permutation.

**INPUT:**

- *base_window* – boolean; indicating whether *i* is in the base window; if True, will run a bit faster, but the method will screw up if *i* is not actually in the index set

**EXAMPLES:**

```python
sage: A = AffinePermutationGroup(['A',7,1])
sage: p = A([3, -1, 0, 6, 5, 4, 10, 9])
sage: p.value(1)
3
sage: p.value(9)
11
```

class **sage.combinat.affine_permutation.AffinePermutationTypeB**(*parent*, *lst*, *check=True*)

Bases: **AffinePermutationTypeC**

**apply_simple_reflection_left**(*i*)

Apply the simple reflection indexed by *i* on values.

**EXAMPLES:**

```python
sage: B = AffinePermutationGroup(['B',4,1])
sage: p=B([-5,1,6,-2])
sage: p.apply_simple_reflection_left(0)
Type B affine permutation with window [-5, -2, 6, 1]
sage: p.apply_simple_reflection_left(2)
Type B affine permutation with window [-5, 1, 7, -3]
sage: p.apply_simple_reflection_left(4)
Type B affine permutation with window [-4, 1, 6, -2]
```

**apply_simple_reflection_right**(*i*)

Apply the simple reflection indexed by *i* on positions.

**EXAMPLES:**

```python
sage: B = AffinePermutationGroup(['B',4,1])
sage: p=B([-5,1,6,-2])
sage: p.apply_simple_reflection_right(1)
Type B affine permutation with window [1, -5, 6, -2]
sage: p.apply_simple_reflection_right(0)
Type B affine permutation with window [-1, 5, 6, -2]
sage: p.apply_simple_reflection_right(4)
Type B affine permutation with window [-5, 1, 6, 11]
```

**check**()

Check that *self* is an affine permutation.
EXAMPLES:

```python
sage: B = AffinePermutationGroup(['B',4,1])
sage: x = B([-5,1,6,-2])
sage: x
Type B affine permutation with window [-5, 1, 6, -2]
```

**has_left_descent**(i)

Determines whether there is a descent at i.

**INPUT:**
- i – an integer

**EXAMPLES:**

```python
sage: B = AffinePermutationGroup(['B',4,1])
sage: p = B([-5,1,6,-2])
sage: [p.has_left_descent(i) for i in B.index_set()]
[True, True, False, False, True]
```

**has_right_descent**(i)

Determines whether there is a descent at index i.

**INPUT:**
- i – an integer

**EXAMPLES:**

```python
sage: B = AffinePermutationGroup(['B',4,1])
sage: p = B([-5,1,6,-2])
sage: [p.has_right_descent(i) for i in B.index_set()]
[True, False, False, True, False]
```

class sage.combinat.affine_permutation.AffinePermutationTypeC(parent, lst, check=True)

Bases: AffinePermutation

**apply_simple_reflection_left**(i)

Apply the simple reflection indexed by i on values.

**EXAMPLES:**

```python
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: for i in C.index_set(): x.apply_simple_reflection_left(i)
Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [-2, 5, 3, 8]
Type C affine permutation with window [-1, 5, 2, 6]
Type C affine permutation with window [-1, 6, 4, 7]
Type C affine permutation with window [-1, 4, 3, 7]
```

**apply_simple_reflection_right**(i)

Apply the simple reflection indexed by i on positions.

**EXAMPLES:**
```python
sage: C = AffinePermutationGroup(['C', 4, 1])
sage: x = C([-1, 5, 3, 7])
sage: for i in C.index_set(): x.apply_simple_reflection_right(i)
Type C affine permutation with window [1, 5, 3, 7]
Type C affine permutation with window [5, -1, 3, 7]
Type C affine permutation with window [-1, 3, 5, 7]
Type C affine permutation with window [-1, 5, 7, 3]
Type C affine permutation with window [-1, 5, 3, 2]
```

**check()**

Check that `self` is an affine permutation.

EXAMPLES:

```python
sage: C = AffinePermutationGroup(['C', 4, 1])
sage: x = C([-1, 5, 3, 7])
sage: x
Type C affine permutation with window [-1, 5, 3, 7]
```

**has_left_descent(i)**

Determine whether there is a descent at `i`.

INPUT:

- `i` – an integer

EXAMPLES:

```python
sage: C = AffinePermutationGroup(['C', 4, 1])
sage: x = C([-1, 5, 3, 7])
sage: for i in C.index_set(): x.has_left_descent(i)
True
False
True
False
True
```

**has_right_descent(i)**

Determine whether there is a descent at index `i`.

INPUT:

- `i` – an integer

EXAMPLES:

```python
sage: C = AffinePermutationGroup(['C', 4, 1])
sage: x = C([-1, 5, 3, 7])
sage: for i in C.index_set(): x.has_right_descent(i)
True
False
True
False
True
```
position(i)

Find the position $j$ such the self.value($j$)=$i$

EXAMPLES:

```
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C.one()
sage: [x.position(i) for i in range(-10,10)] == list(range(-10,10))
True
```

to_type_a()

Return an embedding of self into the affine permutation group of type $A$.

EXAMPLES:

```
sage: C = AffinePermutationGroup(['C',4,1])
sage: x = C([-1,5,3,7])
sage: x.to_type_a()
Type A affine permutation with window [-1, 5, 3, 7, 2, 6, 4, 10, 9]
```

class sage.combinat.affine_permutation.AffinePermutationTypeD(parent, lst, check=True)

Bases: AffinePermutationTypeC

apply_simple_reflection_left(i)

Apply simple reflection indexed by $i$ on values.

EXAMPLES:

```
sage: D = AffinePermutationGroup(['D',4,1])
sage: p=D([-1,-6,5,-2])
sage: p.apply_simple_reflection_left(0)
Type D affine permutation with window [-2, -6, 5, 1]
sage: p.apply_simple_reflection_left(1)
Type D affine permutation with window [2, -6, 5, -1]
sage: p.apply_simple_reflection_left(4)
Type D affine permutation with window [1, -4, 3, -2]
```

apply_simple_reflection_right(i)

Apply the simple reflection indexed by $i$ on positions.

EXAMPLES:

```
sage: D = AffinePermutationGroup(['D',4,1])
sage: p=D([-1,-6,5,-2])
sage: p.apply_simple_reflection_right(0)
Type D affine permutation with window [6, -1, 5, -2]
```
sage: p.apply_simple_reflection_right(1)
Type D affine permutation with window [-6, 1, 5, -2]
sage: p.apply_simple_reflection_right(4)
Type D affine permutation with window [1, -6, 11, 4]

check()

Check that self is an affine permutation.

EXAMPLES:

sage: D = AffinePermutationGroup(['D',4,1])
sage: p = D([1,-6,5,-2])
sage: p
Type D affine permutation with window [1, -6, 5, -2]

has_left_descent(i)

Determine whether there is a descent at i.

INPUT:

• i – an integer

EXAMPLES:

sage: D = AffinePermutationGroup(['D',4,1])
sage: p=D([1,-6,5,-2])
sage: [p.has_left_descent(i) for i in D.index_set()]
[True, True, False, True, True]

has_right_descent(i)

Determine whether there is a descent at index i.

INPUT:

• i – an integer

EXAMPLES:

sage: D = AffinePermutationGroup(['D',4,1])
sage: p=D([1,-6,5,-2])
sage: [p.has_right_descent(i) for i in D.index_set()]
[True, True, False, True, False]

class sage.combinat.affine_permutation.AffinePermutationTypeG(parent, lst, check=True)

Bases: AffinePermutation

apply_simple_reflection_left(i)

Apply simple reflection indexed by i on values.

EXAMPLES:

sage: G = AffinePermutationGroup(['G',2,1])
sage: p=G([2, 10, -5, 12, -3, 5])
sage: p.apply_simple_reflection_left(0)
Type G affine permutation with window [0, 10, -7, 14, -3, 7]
sage: p.apply_simple_reflection_left(1)
Type G affine permutation with window [1, 9, -4, 11, -2, 6]

```sage```
```
p.apply_simple_reflection_left(2)
```
Type G affine permutation with window [3, 11, -5, 12, -4, 4]

apply_simple_reflection_right(i)
Apply the simple reflection indexed by i on positions.

EXAMPLES:

```sage```
```
G = AffinePermutationGroup(['G',2,1])
p = G([2, 10, -5, 12, -3, 5])
p.apply_simple_reflection_right(0)
```
Type G affine permutation with window [-9, -1, -5, 12, 8, 16]

```sage```
```
p.apply_simple_reflection_right(1)
```
Type G affine permutation with window [10, 2, 12, -5, 5, -3]

```sage```
```
p.apply_simple_reflection_right(2)
```
Type G affine permutation with window [2, -5, 10, -3, 12, 5]

check()
Check that self is an affine permutation.

EXAMPLES:

```sage```
```
G = AffinePermutationGroup(['G',2,1])
p = G([2, 10, -5, 12, -3, 5])
p
```
Type G affine permutation with window [2, 10, -5, 12, -3, 5]

has_left_descent(i)
Determines whether there is a descent at i.

INPUT:

- i – an integer

EXAMPLES:

```sage```
```
G = AffinePermutationGroup(['G',2,1])
p = G([2, 10, -5, 12, -3, 5])
[p.has_left_descent(i) for i in G.index_set()]
```
[False, True, False]

has_right_descent(i)
Determines whether there is a descent at index i.

INPUT:

- i – an integer

EXAMPLES:

```sage```
```
G = AffinePermutationGroup(['G',2,1])
p = G([2, 10, -5, 12, -3, 5])
[p.has_right_descent(i) for i in G.index_set()]
```
[False, False, True]
position(i)
Find the position j such the self.value(j) == i.

EXAMPLES:

```
sage: G = AffinePermutationGroup(["G",2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: [p.position(i) for i in p]
[1, 2, 3, 4, 5, 6]
```

to_type_a()
Return an embedding of self into the affine permutation group of type A.

EXAMPLES:

```
sage: G = AffinePermutationGroup(["G",2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: p.to_type_a()
Type A affine permutation with window [2, 10, -5, 12, -3, 5]
```

value(i, base_window=False)
Return the image of the integer i under this permutation.

INPUT:

- base_window – boolean indicating whether i is between 1 and k + 1; if True, will run a bit faster, but the method will screw up if i is not actually in the index set

EXAMPLES:

```
sage: G = AffinePermutationGroup(["G",2,1])
sage: p = G([2, 10, -5, 12, -3, 5])
sage: [p.value(i) for i in [1..12]]
[2, 10, -5, 12, -3, 5, 8, 16, 1, 18, 3, 11]
```

5.1.5 Alternating Sign Matrices

AUTHORS:
- Mike Hansen (2007): Initial version
- Pierre Cange, Luis Serrano (2012): Added monotone triangles
- Travis Scrimshaw (2013-28-03): Added element class for ASM’s and made MonotoneTriangles inherit from GelfandTsetlinPatterns
- Jessica Striker (2013): Added additional methods
- Vincent Delecroix (2017): cleaning

```python
class sage.combinat.alternating_sign_matrix.AlternatingSignMatrices(n)
    Bases: UniqueRepresentation, Parent
    Class of all \( n \times n \) alternating sign matrices.
    An alternating sign matrix of size \( n \) is an \( n \times n \) matrix of 0’s, 1’s and \(-1\)’s such that the sum of each row and column is 1 and the non-zero entries in each row and column alternate in sign.
    Alternating sign matrices of size \( n \) are in bijection with monotone triangles with \( n \) rows.
    INPUT:
    * \( n \) – an integer, the size of the matrices.
    EXAMPLES:
    This will create an instance to manipulate the alternating sign matrices of size 3:

    sage: A = AlternatingSignMatrices(3)
    sage: A
    Alternating sign matrices of size 3
    sage: A.cardinality()
    7

    Notably, this implementation allows to make a lattice of it:

    sage: L = A.lattice()
    sage: L
    Finite lattice containing 7 elements
    sage: L.category()
    Category of facade finite enumerated lattice posets

    Element
    alias of AlternatingSignMatrix
```

5.1. Comprehensive Module List 49
cardinality()

Return the cardinality of self.

The number of $n \times n$ alternating sign matrices is equal to

$$\prod_{k=0}^{n-1} \frac{(3k+1)!}{(n+k)!} = \frac{1!4!7!10!\cdots(3n-2)!}{n!(n+1)!(n+2)!(n+3)\cdots(2n-1)!}$$

EXAMPLES:

```python
sage: [AlternatingSignMatrices(n).cardinality() for n in range(11)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460, 129534272700]
```

cover_relations()

Iterate on the cover relations between the alternating sign matrices.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: for (a,b) in A.cover_relations():
    ....:     eval('a, b')

([0 0 1] [0 0 1]

([0 0 1] [0 1 0]
 [1 -1 1] [0 0 1]
 [0 1 0], [0 1 0])

([0 0 1] [0 1 0]
 [1 -1 1] [0 0 1]
 [0 0 1], [0 1 0])

([0 1 0] [0 0 1]
 [1 0 0] [0 0 1]
 [0 0 1], [0 0 1])

([0 0 1] [0 0 1]
 [0 1 0] [0 1 0]

(continues on next page)
first()
Return the first alternating sign matrix.
EXAMPLES:

```
sage: AlternatingSignMatrices(5).first()
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

from_contre_tableau(comps)
Return an alternating sign matrix from a contre-tableau.
EXAMPLES:

```
sage: ASM = AlternatingSignMatrices(3)
sage: ASM.from_contre_tableau([[1, 2, 3], [1, 2], [1]])
[1 0 0]
[0 1 0]
[0 0 1]
sage: ASM.from_contre_tableau([[1, 2, 3], [2, 3], [3]])
[1 0 0]
[0 1 0]
[0 0 1]
```

from_corner_sum(corner)
Return an alternating sign matrix from a corner sum matrix.
EXAMPLES:

```
sage: A = AlternatingSignMatrices(3)
sage: A.from_corner_sum(matrix([[0,0,0,0],[0,1,1,1],[0,1,2,2],[0,1,2,3]]))
[1 0 0]
[0 1 0]
[0 0 1]
sage: A.from_corner_sum(matrix([[0,0,0,0],[0,0,1,1],[0,1,1,2],[0,1,2,3]]))
[0 1 0]
[1 -1 1]
[0 1 0]
```

from_height_function(height)
Return an alternating sign matrix from a height function.
EXAMPLES:
Combinatorics, Release 10.1

sage: A = AlternatingSignMatrices(3)
sage: A.from_height_function(matrix([[0,1,2,3],[1,2,1,2],[2,3,2,1],[3,2,1,0]]))
[0 0 1]
[1 0 0]
[0 1 0]
sage: A.from_height_function(matrix([[0,1,2,3],[1,2,1,2],[2,1,2,1],[3,2,1,0]]))
[ 0 1 0]
[ 1 -1 1]
[ 0 1 0]
from_monotone_triangle(triangle, check=True)
Return an alternating sign matrix from a monotone triangle.
EXAMPLES:
sage: A = AlternatingSignMatrices(3)
sage: A.from_monotone_triangle([[3, 2, 1], [2, 1], [1]])
[1 0 0]
[0 1 0]
[0 0 1]
sage: A.from_monotone_triangle([[3, 2, 1], [3, 2], [3]])
[0 0 1]
[0 1 0]
[1 0 0]

sage: A.from_monotone_triangle([[3, 2, 1], [2, 2], [1]])
Traceback (most recent call last):
...
ValueError: not a valid triangle
gyration_orbit_sizes()
Return the sizes of gyration orbits of self.
EXAMPLES:
sage: AlternatingSignMatrices(3).gyration_orbit_sizes()
[3, 2, 2]
sage: AlternatingSignMatrices(4).gyration_orbit_sizes()
[4, 8, 2, 8, 8, 8, 2, 2]
sage:
sage:
....:
....:
sage:
True

A = AlternatingSignMatrices(5)
li = [5,10,10,10,10,10,2,5,10,10,10,10,10,10,10,10,10,10,10,10,
4,10,10,10,10,10,10,4,5,10,10,10,10,10,10,10,2,4,5,10,10,10,10,10,10,
4,5,10,10,2,2]
A.gyration_orbit_sizes() == li

gyration_orbits()
Return the list of gyration orbits of self.
EXAMPLES:

52

Chapter 5. Comprehensive Module List


### AlternatingSignMatrices

*Example*

```python
sage: AlternatingSignMatrices(3).gyration_orbits()
((
    [1 0 0] [0 0 1] [ 0 1 0]
    [0 1 0] [0 1 0] [ 1 -1 1]
    [0 0 1], [1 0 0], [ 0 1 0]
),
  (
    [0 1 0] [1 0 0]
    [1 0 0] [0 0 1]
    [0 0 1], [0 1 0]
  ),
  (
    [0 0 1] [0 1 0]
    [1 0 0] [0 0 1]
    [0 1 0], [1 0 0]
  ))
```

### last()

Return the last alternating sign matrix.

**Examples:**

```python
sage: AlternatingSignMatrices(5).last()
[0 0 0 0 1]
[0 0 0 1 0]
[0 0 1 0 0]
[0 1 0 0 0]
[1 0 0 0 0]
```

### lattice()

Return the lattice of the alternating sign matrices of size $n$, created by `LatticePoset`.

**Examples:**

```python
sage: A = AlternatingSignMatrices(3)
sage: L = A.lattice()
sage: L
Finite lattice containing 7 elements
```

### matrix_space()

Return the underlying matrix space.

**Examples:**

```python
sage: A = AlternatingSignMatrices(3)
sage: A.matrix_space()
sage: A.matrix_space()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
```

### random_element()

Return a uniformly random alternating sign matrix.

**Examples:**

```python
```
This is done using a modified version of Propp and Wilson’s “coupling from the past” algorithm. It creates a uniformly random Gelfand-Tsetlin triangle with top row \([n, n-1, \ldots, 2, 1]\), and then converts it to an alternating sign matrix.

\[
\text{size()}
\]

Return the size of the matrices in \(\text{self}\).

\begin{verbatim}
class sage.combinat.alternating_sign_matrixAlternatingSignMatrix(parent, asm)
    Bases: Element
    An alternating sign matrix.
    An alternating sign matrix is a square matrix of 0’s, 1’s and –1’s such that the sum of each row and column is 1 and the non-zero entries in each row and column alternate in sign.
    These were introduced in [MRR1983].

    ASM_compatible(B)
    Return True if \(\text{self}\) and B are compatible alternating sign matrices in the sense of [EKLP1992]. (If \(\text{self}\) is of size \(n\), B must be of size \(n+1\)).
    In [EKLP1992], there is a notion of a pair of ASM’s with sizes differing by 1 being compatible, in the sense that they can be combined to encode a tiling of the Aztec Diamond.
    EXAMPLES:

    sage: A = AlternatingSignMatrix(matrix([[0,0,1],[0,1,-1,1],[1,0,0,0],[0,0,1,-1]]))
    sage: B = AlternatingSignMatrix(matrix([[0,0,1,0],[0,0,0,1],[1,0,0,-1],[0,1,0,0]]))
    sage: AASM_compatible(B)
    True
    sage: A = AlternatingSignMatrix(matrix([[0,1],[1,-1],[0,1]]))
    sage: B = AlternatingSignMatrix(matrix([[0,0,1],[0,0,0],[1,0,0,0],[0,1,0,-1]]))
    sage: AASM_compatible(B)
    False

    ASM_compatible_bigger()
    Return all ASM’s compatible with \(\text{self}\) that are of size one greater than \(\text{self}\).
    Given an \(n \times n\) alternating sign matrix A, there are as many ASM’s of size \(n+1\) compatible with A as 2 raised to the power of the number of 1’s in A [EKLP1992].
    EXAMPLES:

\end{verbatim}
sage: A = AlternatingSignMatrix([[1,0],[0,1]])
sage: A.ASM_compatible_bigger()

[[ 0 1 0] [1 0 0] [0 1 0] [1 0 0]
 [1 -1 1] [0 0 1] [1 0 0] [0 1 0]
 [0 1 0], [0 1 0], [0 0 1], [0 0 1]]
sage: B = AlternatingSignMatrix([[0,1],[1,0]])
sage: B.ASM_compatible_bigger()

[[0 0 1] [0 0 1] [0 1 0] [ 0 1 0]
 [0 1 0] [1 0 0] [0 0 1] [ 1 -1 1]
 [1 0 0], [0 1 0], [1 0 0], [ 0 1 0]]
sage: B = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
sage: len(B.ASM_compatible_bigger()) == 2**4
True

ASM_compatible_smaller()

Return the list of all ASMs compatible with self that are of size one smaller than self.

Given an alternating sign matrix \( A \) of size \( n \), there are as many ASM’s of size \( n - 1 \) compatible with it as 2 raised to the power of the number of \(-1\)’s in \( A \) [EKLP1992].

EXAMPLES:

sage: A = AlternatingSignMatrix(matrix([[0,0,1,0],[0,1,-1,1],[1,0,0,0],[0,0,1,0]]))
sage: A.ASM_compatible_smaller()

[[0 0 1] [ 0 1 0]
 [1 0 0] [ 1 -1 1]
 [0 1 0], [ 0 1 0]]
sage: B = AlternatingSignMatrix(matrix([[1,0,0],[0,0,1],[0,1,0]]))
sage: B.ASM_compatible_smaller()

[[1 0]
 [0 1]]

corner_sum_matrix()

Return the corner sum matrix of self.

EXAMPLES:

sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).corner_sum_matrix()

[0 0 0 0]
[0 1 1 1]
[0 1 2 2]
[0 1 2 3]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])

(continues on next page)
gyration()

Return the alternating sign matrix obtained by applying gyration to the height function in bijection with self.

Gyration acts on height functions as follows. Go through the entries of the matrix, first those for which the sum of the row and column indices is even, then for those for which it is odd, and increment or decrement the squares by 2 wherever possible such that the resulting matrix is still a height function. Gyration was first defined in [Wie2000] as an action on fully-packed loops.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).gyration()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.gyration()
[1 0 0]
[0 1 0]
[0 0 1]
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).gyration().gyration()
[ 0 1 0]
[ 1 -1 1]
[ 0 1 0]
sage: A = AlternatingSignMatrices(4)
sage: M = A([[0,0,1,0],[1,0,0,0],[0,1,-1,1],[0,0,1,0]])
sage: for i in range(5):
....:     M = M.gyration()
sage: M
```
sage: a0 = a = AlternatingSignMatrices(5).random_element()
sage: for i in range(20):
    ....:     a = a.gyration()
sage: a == a0
True

**gyration_orbit()**

Return the gyration orbit of self (including self).

EXAMPLES:

```python
sage: AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]]).gyration_orbit()
[[ 0 1 0] [1 0 0] [0 0 1]
 [ 1 -1 1] [0 1 0] [0 1 0]
 [ 0 1 0], [0 0 1], [1 0 0]]
```

```python
sage: AlternatingSignMatrix([[0,1,0,0],[1,-1,1,0],[0,1,-1,1],[0,0,1,0]]).gyration_orbit()
[[ 0 1 0 0] [1 0 0 0] [ 0 0 1 0] [0 0 0 1]
 [ 1 -1 1 0] [0 1 0 0] [ 0 1 -1 1] [0 1 0 0]
 [ 0 1 -1 1] [0 0 1 0] [ 1 -1 1 0] [0 1 0 0]
 [ 0 0 1 0], [0 0 0 1], [ 0 1 0 0], [1 0 0 0]]
```

```python
sage: len(AlternatingSignMatrix([[0,1,0,0,0,0],[0,0,1,0,0,0],[1,-1,0,0,0,1],
                               [0,1,0,0,0,0],[0,0,0,1,0,0],[0,0,0,0,1,0]]).gyration_orbit())
12
```

**height_function()**

Return the height function from self.

A height function corresponding to an \(n \times n\) ASM is an \((n+1) \times (n+1)\) matrix such that the first row is 0, 1, ..., \(n\), the last row is \(n, n-1, \ldots, 1, 0\), and the difference between adjacent entries is 1.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).height_function()
[0 1 2 3]
[1 0 1 2]
[2 1 0 1]
[3 2 1 0]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.height_function()
[0 1 2 3]
```

(continues on next page)
Combinatorics, Release 10.1

(continued from previous page)

```
[1 2 1 2]
[2 1 2 1]
[3 2 1 0]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.height_function()
[0 1 2 3]
[1 2 1 2]
[2 3 2 1]
[3 2 1 0]
sage: A = AlternatingSignMatrices(4)
sage: all(A.from_height_function(a.height_function()) == a for a in A)
True
```

**inversion_number()**

Return the inversion number of self.

If we denote the entries of the alternating sign matrix as $a_{i,j}$, the inversion number is defined as $\sum_{i > k} \sum_{j < l} a_{i,j} a_{k,l}$. When restricted to permutation matrices, this gives the usual inversion number of the permutation.

This definition is equivalent to the one given in [MRR1983].

**EXAMPLES:**

```
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).inversion_number()
0
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.inversion_number()
2
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]])
sage: asm.inversion_number()
2
sage: P = Permutations(5)
sage: all(p.number_of_inversions()==AlternatingSignMatrix(p.to_matrix()).˓
→inversion_number() for p in P)
True
```

**is_permutation()**

Return True if self is a permutation matrix and False otherwise.

**EXAMPLES:**

```
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0,1,0],[1,0,0],[0,0,1]])
sage: asm.is_permutation()
True
sage: asm = A([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.is_permutation()
False
```

**left_key()**

Return the left key of the alternating sign matrix self.
The left key of an alternating sign matrix was defined by Lascoux in [Lasc] and is obtained by successively removing all the $-1$’s until what remains is a permutation matrix. This notion corresponds to the notion of left key for semistandard tableaux. So our algorithm proceeds as follows: we map self to its corresponding monotone triangle, view that monotone triangle as a semistandard tableau, take its left key, and then map back through monotone triangles to the permutation matrix which is the left key.

See also [Ava2007].

EXAMPLES:

```sage
A = AlternatingSignMatrices(3)
sage: A([[0,0,1],[1,0,0],[0,1,0]]).left_key()
[0 0 1]
[1 0 0]
[0 1 0]
sage: t = A([[0,1,0],[1,-1,1],[0,1,0]]).left_key(); t
[1 0 0]
[0 0 1]
[0 1 0]
sage: parent(t)
Alternating sign matrices of size 3
```

left_key_as_permutation()

Return the permutation of the left key of self.

See also:

• left_key()

EXAMPLES:

```sage
A = AlternatingSignMatrices(3)
sage: A([[0,0,1],[1,0,0],[0,1,0]]).left_key_as_permutation()
[3, 1, 2]
sage: t = A([[0,1,0],[1,-1,1],[0,1,0]]).left_key_as_permutation(); t
[1, 3, 2]
sage: parent(t)
Standard permutations
```

link_pattern()

Return the link pattern corresponding to the fully packed loop corresponding to self.

EXAMPLES:

We can extract the underlying link pattern (a non-crossing partition) from a fully packed loop:

```sage
A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: A.link_pattern()
[(1, 2), (3, 6), (4, 5)]
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: B.link_pattern()
[(1, 6), (2, 5), (3, 4)]
```

number_negative_ones()

Return the number of entries in self equal to -1.
EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0,1,0],[1,0,0],[0,0,1]])
sage: asm.number_negative_ones()
0
sage: asm = A([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.number_negative_ones()
1
```

rotate_ccw()  
Return the counterclockwise quarter turn rotation of self.

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).rotate_ccw()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.rotate_ccw()
[1 0 0]
[0 0 1]
[0 1 0]
```

rotate_cw()  
Return the clockwise quarter turn rotation of self.

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).rotate_cw()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.rotate_cw()
[0 1 0]
[1 0 0]
[0 0 1]
```

to_dyck_word(algorithm)  
Return a Dyck word determined by the specified algorithm.

The algorithm ‘last_diagonal’ uses the last diagonal of the monotone triangle corresponding to self. The algorithm ‘link_pattern’ returns the Dyck word in bijection with the link pattern of the fully packed loop.

Note that these two algorithms in general yield different Dyck words for a given alternating sign matrix.

INPUT:

- algorithm - either 'last_diagonal' or 'link_pattern'

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[0,1,0],[1,0,0],[0,0,1]]).to_dyck_word(algorithm = 'last_diagonal')
[1, 1, 0, 0, 1, 0]
sage: d = A([[0,1,0],[1,-1,1],[0,1,0]]).to_dyck_word(algorithm = 'last_diagonal'); d
[1, 1, 0, 1, 0, 0]
sage: parent(d)
Complete Dyck words
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0,1,0],[1,0,0],[0,0,1]])
sage: asm.to_dyck_word(algorithm = 'link_pattern')
[1, 0, 1, 0, 1, 0]
sage: asm = A([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.to_dyck_word(algorithm = 'link_pattern')
[1, 0, 1, 1, 0, 0]
sage: A = AlternatingSignMatrices(4)
sage: asm = A([[0,0,1,0],[1,0,0,0],[0,1,-1,1],[0,0,1,0]])
sage: asm.to_dyck_word(algorithm = 'link_pattern')
[1, 1, 0, 1, 1, 0, 0]
sage: asm.to_dyck_word()  Traceback (most recent call last):
... TypeError: ...to_dyck_word() ...argument...
sage: asm.to_dyck_word(algorithm = 'notamethod')
Traceback (most recent call last):
... ValueError: unknown algorithm 'notamethod'
```

to_fully_packed_loop()

Return the fully packed loop configuration from self.

See also:

FullyPackedLoop

EXAMPLES:

```python
sage: asm = AlternatingSignMatrix([[1,0,0],[0,1,0],[0,0,1]])
sage: fpl = asm.to_fully_packed_loop()
sage: fpl
+ + -- +
| |
+ + -- +
| |
-- + + + --
| |
-- + + +
| |
```

to_matrix()

Return self as a regular matrix.

5.1. Comprehensive Module List 61
EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[1, 0, 0],[0, 1, 0],[0, 0, 1]])
sage: m = asm.to_matrix(); m
[1 0 0]
[0 1 0]
[0 0 1]
sage: m.parent()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
```

**to_monotone_triangle()**

Return a monotone triangle from self.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).to_monotone_triangle()
[[3, 2, 1], [2, 1], [1]]
sage: asm = A([[0, 1, 0],[1, -1, 1],[0, 1, 0]]).to_monotone_triangle()
[[3, 2, 1], [3, 1], [2]]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]]).to_monotone_triangle()
[[3, 2, 1], [3, 1], [3]]
sage: A.from_monotone_triangle(asm.to_monotone_triangle()) == asm
True
```

**to_permutation()**

Return the corresponding permutation if self is a permutation matrix.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: asm = A([[0,1,0],[1,0,0],[0,0,1]])
sage: p = asm.to_permutation(); p
[2, 1, 3]
sage: parent(p)
Standard permutations
sage: asm = A([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.to_permutation()
Traceback (most recent call last):
...
ValueError: not a permutation matrix
```

**to_semistandard_tableau()**

Return the semistandard tableau corresponding the monotone triangle corresponding to self.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: t = A([[0,1,0],[1,-1,1],[0,1,0]]).to_semistandard_tableau(); t
[[1, 1, 2], [2, 3], [3]]
```
Semistandard tableaux

to six vertex model()

Return the six vertex model configuration from self.

This method calls sage.combinat.six_vertex_model.from_alternating_sign_matrix().

EXAMPLES:

```python
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
sage: asm.to_six_vertex_model()
```

```
^ ^ ^
| | |
--> # -> # <- # <--
^ | | ^
| V |
--> # <- # -> # <--
| ^ |
V | V
--> # -> # <- # <--
| | |
V V V
```

transpose()

Return self transposed.

EXAMPLES:

```python
sage: A = AlternatingSignMatrices(3)
sage: A([[1, 0, 0],[0, 1, 0],[0, 0, 1]]).transpose()
[1 0 0]
[0 1 0]
[0 0 1]
sage: asm = A([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: asm.transpose()
[0 1 0]
[0 0 1]
[1 0 0]
```

class sage.combinat.alternating_sign_matrix.ContreTableaux

Bases: Parent

Factory class for the combinatorial class of contre tableaux of size n.

EXAMPLES:

```python
sage: ct4 = ContreTableaux(4); ct4
Contre tableaux of size 4
sage: ct4.cardinality()
42
```

class sage.combinat.alternating_sign_matrix.ContreTableaux_n(n)

Bases: ContreTableaux
class sage.combinat.alternating_sign_matrix.MonotoneTriangles(n)

Bases: GelfandTsetlinPatternsTopRow

Monotone triangles with n rows.

A monotone triangle is a number triangle \((a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq i}\) on \(\{1, \ldots, n\}\) such that:

- \(a_{i,j} < a_{i,j+1}\)
- \(a_{i+1,j} < a_{i,j} \leq a_{i+1,j+1}\)

This notably requires that the bottom column is \([1, \ldots, n]\).

Alternatively a monotone triangle is a strict Gelfand-Tsetlin pattern with top row \((n, \ldots, 2, 1)\).

INPUT:
- \(n\) – The number of rows in the monotone triangles

EXAMPLES:

This represents the monotone triangles with base \([3,2,1]\):

```
sage: M = MonotoneTriangles(3)
sage: M
Monotone triangles with 3 rows
sage: M.cardinality()
7
```

The monotone triangles are a lattice:

```
sage: M.lattice()
Finite lattice containing 7 elements
```

Monotone triangles can be converted to alternating sign matrices and back:

```
sage: M = MonotoneTriangles(5)
sage: A = AlternatingSignMatrices(5)
sage: all(A.from_monotone_triangle(m).to_monotone_triangle() == m for m in M)
True
```

cardinality()

Cardinality of self.

The number of monotone triangles with \(n\) rows is equal to

\[
\prod_{k=0}^{n-1} \frac{(3k + 1)!}{(n + k)!} = \frac{1!4!7!10! \cdots (3n - 2)!}{n!(n+1)!(n+2)!(n+3)! \cdots (2n-1)!}
\]

EXAMPLES:

```
sage: M = MonotoneTriangles(4)
sage: M.cardinality()
42
```
cover_relations()

Iterate on the cover relations in the set of monotone triangles with \( n \) rows.

EXAMPLES:

```python
sage: M = MonotoneTriangles(3)
sage: for (a,b) in M.cover_relations():
    ....:   eval('a, b')
([[3, 2, 1], [2, 1], [1]], [[3, 2, 1], [2, 1], [2]])
([[3, 2, 1], [2, 1], [1]], [[3, 2, 1], [3, 1], [1]])
([[3, 2, 1], [2, 1], [2]], [[3, 2, 1], [3, 1], [2]])
([[3, 2, 1], [3, 1], [1]], [[3, 2, 1], [3, 1], [2]])
([[3, 2, 1], [3, 1], [2]], [[3, 2, 1], [3, 2], [2]])
([[3, 2, 1], [3, 1], [3]], [[3, 2, 1], [3, 2], [3]])
([[3, 2, 1], [3, 2], [2]], [[3, 2, 1], [3, 2], [3]])
```

lattice()

Return the lattice of the monotone triangles with \( n \) rows.

EXAMPLES:

```python
sage: M = MonotoneTriangles(3)
sage: P = M.lattice()
sage: P
Finite lattice containing 7 elements
```

class sage.combinat.alternating_sign_matrix.TruncatedStaircases

Bases: Parent

Factory class for the combinatorial class of truncated staircases of size \( n \) with last column last_column.

EXAMPLES:

```python
sage: t4 = TruncatedStaircases(4, [2,3]); t4
Truncated staircases of size 4 with last column [2, 3]
sage: t4.cardinality()
4
```

class sage.combinat.alternating_sign_matrix.TruncatedStaircases_nlastcolumn(n, last_column)

Bases: TruncatedStaircases

cardinality()

EXAMPLES:

```python
sage: T = TruncatedStaircases(4, [2,3])
sage: T.cardinality()
4
```
5.1.6 Backtracking

This library contains a generic tool for constructing large sets whose elements can be enumerated by exploring a search space with a (lazy) tree or graph structure.

- **GenericBacktracker**: Depth first search through a tree described by a children function, with branch pruning, etc.

This module has mostly been superseded by `RecursivelyEnumeratedSet`.

```python
class sage.combinat.backtrack.GenericBacktracker(initial_data, initial_state):
    Bases: object
    A generic backtrack tool for exploring a search space organized as a tree, with branch pruning, etc.
    See also `RecursivelyEnumeratedSet_forest` for handling simple special cases.

class sage.combinat.backtrack.PositiveIntegerSemigroup:
    Bases: UniqueRepresentation, RecursivelyEnumeratedSet_forest
    The commutative additive semigroup of positive integers.
    This class provides an example of algebraic structure which inherits from `RecursivelyEnumeratedSet_forest`. It builds the positive integers a la Peano, and endows it with its natural commutative additive semigroup structure.

    EXAMPLES:

    ```python
    sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
    sage: PP = PositiveIntegerSemigroup()
    sage: PP.category()
    Join of Category of monoids and Category of commutative additive semigroups and...
    sage: PP.cardinality()
    +Infinity
    sage: PP.one()
    1
    sage: PP.an_element()
    1
    sage: some_elements = list(PP.some_elements()); some_elements
    [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23,...
    24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43,...
    44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63,...
    64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83,...
    84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100]
```

**children(x)**

Return the single child \(x+1\) of the integer \(x\)

```python
from sage.combinat.backtrack import PositiveIntegerSemigroup
PP = PositiveIntegerSemigroup()
list(PP.children(1))
[2]
list(PP.children(42))
[43]
```
example:

```python
sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
sage: PP = PositiveIntegerSemigroup()
sage: PP.one()
1
```

Return the single root of self.

EXAMPLES:

```python
sage: from sage.combinat.backtrack import PositiveIntegerSemigroup
sage: PP = PositiveIntegerSemigroup()
sage: list(PP.roots())
[1]
```

**5.1.7 Baxter permutations**

class `sage.combinat.baxter_permutations.BaxterPermutations`

Bases: `UniqueRepresentation`, `Parent`

The combinatorial class of Baxter permutations.

A Baxter permutation is a permutation avoiding the generalized permutation patterns $2 - 41 - 3$ and $3 - 14 - 2$. In other words, a permutation $\sigma$ is a Baxter permutation if for any subword $u := u_1 u_2 u_3 u_4$ of $\sigma$ such that the letters $u_2$ and $u_3$ are adjacent in $\sigma$, the standardized version of $u$ is neither $2413$ nor $3142$.

INPUT:

- `n` – (default: `None`) a nonnegative integer, the size of the permutations.

OUTPUT:

Return the combinatorial class of the Baxter permutations of size $n$ if $n$ is not `None`. Otherwise, return the combinatorial class of all Baxter permutations.

EXAMPLES:

```python
sage: BaxterPermutations(5)
Baxter permutations of size 5
sage: BaxterPermutations()
Baxter permutations
```

class `sage.combinat.baxter_permutations.BaxterPermutations_all`

Bases: `DisjointUnionEnumeratedSets`, `BaxterPermutations`

The enumerated set of all Baxter permutations.

See `BaxterPermutations` for the definition of Baxter permutations.

EXAMPLES:
```python
sage: from sage.combinat.baxter_permutations import BaxterPermutations_all
sage: BaxterPermutations_all()

Baxter permutations

to_pair_of_twin_binary_trees(p)

Apply a bijection between Baxter permutations of size self._n and the set of pairs of twin binary trees with self._n nodes.

INPUT:

• p – a Baxter permutation.

OUTPUT:

The pair of twin binary trees \((T_L, T_R)\) where \(T_L\) (resp. \(T_R\)) is obtained by inserting the letters of \(p\) from left to right (resp. right to left) following the binary search tree insertion algorithm. This is called the Baxter \(P\)-symbol in [Gir2012] Definition 4.1.

Note: This method only works when \(p\) is a permutation. For words with repeated letters, it would return two “right binary search trees” (in the terminology of [Gir2012]), which conflicts with the definition in [Gir2012].

EXAMPLES:

```python
sage: BaxterPermutations().to_pair_of_twin_binary_trees(Permutation([]))
(., .)
sage: BaxterPermutations().to_pair_of_twin_binary_trees(Permutation([1, 2, 3]))
(1[., 2[., 3[., .]], 3[2[1[., .], .], .]], .)
sage: BaxterPermutations().to_pair_of_twin_binary_trees(Permutation([3, 4, 1, 2]))
(3[1[., 2[., .]], 4[., .]], 2[1[., .], 4[3[., .], .]])
```
```
5.1.8 A bijectionist’s toolkit

A guided tour

Consider the following combinatorial statistics on a permutation:

- \( wex \), the number of weak excedences,
- \( fix \), the number of fixed points,
- \( des \), the number of descents (after appending 0),
- \( adj \), the number of adjacencies (after appending 0), and
- \( llis \), the length of a longest increasing subsequence.

Moreover, let \( rot \) be action of rotation on a permutation, i.e., the conjugation with the long cycle.

It is known that there must exist a statistic \( s \) on permutations, which is equidistributed with \( llis \) but additionally invariant under \( rot \). However, at least very small cases do not contradict the possibility that one can even find a statistic \( s \), invariant under \( rot \) and such that \( (s, wex, fix) \sim (llis, des, adj) \). Let us check this for permutations of size at most 3:
sage: N = 3
sage: A = B = [pi for n in range(N+1) for pi in Permutations(n)]

sage: def alpha1(p):
    return len(p.weak_excedences())

sage: def alpha2(p):
    return len(p.fixed_points())

sage: def beta1(p):
    return len(p.descents(final_descent=True)) if p else 0

sage: def beta2(p):
    return len([e for (e, f) in zip(p, p[1:]+[0]) if e == f+1])

sage: def rotate_permutation(p):
    
    cycle = Permutation(tuple(range(1, len(p)+1)))
    return Permutation([cycle.inverse()(p(cycle(i))) for i in range(1, len(p)+1)])

sage: tau = Permutation.longest_increasing_subsequence_length

sage: def bijectionist(A, B, tau):

   bij = Bijectionist(A, B, tau)

sage: bij.set_statistics((len, len), (alpha1, beta1), (alpha2, beta2))

sage: a, b = bij.statistics_table()

sage: table(a, header_row=True, frame=True)

<table>

sage: from sage.combinat.cyclic_sieving_phenomenon import orbit_decomposition
sage: bij.set_constant_blocks(orbit_decomposition(A, rotate_permutation))

sage: bij.constant_blocks()
{{[1, 3, 2], [2, 1, 3], [3, 2, 1]}}

sage: next(bij.solutions_iterator())
{
[ ]: 0,
[1]: 1,
[1, 2]: 1,
[1, 2, 3]: 1,
[1, 3, 2]: 2,
[2, 1]: 2,
[2, 1, 3]: 2,
[2, 3, 1]: 2,
[3, 1, 2]: 3,
[3, 2, 1]: 2
}

On the other hand, we can check that there is no rotation invariant statistic on non-crossing set partitions which is equidistributed with the Strahler number on ordered trees:

```
sage: N = 8
sage: A = [SetPartition(d.to_noncrossing_partition()) for n in range(N) for d in DyckWords(n)]
```

```
sage: B = [t for n in range(1, N+1) for t in OrderedTrees(n)]
```

```
sage: def theta(m):
....:     return SetPartition([[i % m.size() + 1 for i in b] for b in m])
```

```
sage: from sage.combinat.cyclic_sieving_phenomenon import orbit_decomposition
sage: bij.set_constant_blocks(orbit_decomposition(A, theta))
```

Code for the Strahler number can be obtained from FindStat. The following code is equivalent to \( \tau = \text{findstat}(397) \):

```
sage: def tau(T):
....:     if len(T) == 0:
....:         return 1
....:     else:
....:         l = [tau(S) for S in T]
....:         m = max(l)
....:         if l.count(m) == 1:
....:             return m
....:         else:
....:             return m+1
```

```
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((lambda a: a.size(), lambda b: b.node_number()-1))
sage: from sage.combinat.cyclic_sieving_phenomenon import orbit_decomposition
sage: bij.set_constant_blocks(orbit_decomposition(A, theta))
```
Next we demonstrate how to search for a bijection, instead.

An example identifying $s$ and $S$:

```python
sage: N = 4
sage: A = [dyck_word for n in range(1, N) for dyck_word in DyckWords(n)]

sage: B = [binary_tree for n in range(1, N) for binary_tree in BinaryTrees(n)]

sage: concat_path = lambda D1, D2: DyckWord(list(D1) + list(D2))

sage: concat_tree = lambda B1, B2: concat_path(B1.to_dyck_word(), B2.to_dyck_word()).to_binary_tree()

sage: bij = Bijectionist(A, B)

sage: bij.set_intertwining_relations((2, concat_path, concat_tree))

sage: bij.set_statistics((lambda d: d.semilength(), lambda t: t.node_number()))

sage: for D in sorted(bij.minimal_subdistributions_iterator(), key=lambda x: x):
    ascii_art(D)
```

The output is in a form suitable for FindStat:

```python
sage: findmap(list(bij.minimal_subdistributions_iterator()))
# optional --
internet
0: Mp00034 (quality [100])
1: Mp00061oMp0023 (quality [100])
2: Mp00018oMp0140 (quality [100])
```

**class** `sage.combinat.bijectionist.Bijectionist(A, B, tau=None, alpha_beta=(), P=None, pi_rho=(), phi_psi=(), Q=None, elements_distributions=(), value_restrictions=(), solver=None, key=None)`
Bases: `SageObject`

A toolbox to list all possible bijections between two finite sets under various constraints.

**INPUT:**

- **A, B** – sets of equal size, given as a list
- **tau** – (optional) a function from **B** to **Z**, in case of `None`, the identity map `lambda x: x` is used
- **alpha_beta** – (optional) a list of pairs of statistics `alpha` from **A** to **W** and `beta` from **B** to **W**
- **P** – (optional) a partition of **A**
- **pi_rho** – (optional) a list of triples `(k, pi, rho)`, where
  - `pi` – a k-ary operation composing objects in **A** and
  - `rho` – a k-ary function composing statistic values in **Z**
- **elements_distributions** – (optional) a list of pairs `(tA, tZ)`, specifying the distributions of `tA`
- **value_restrictions** – (optional) a list of pairs `(a, tZ)`, restricting the possible values of `a`
- **solver** – (optional) the backend used to solve the mixed integer linear programs

**W** and **Z** can be arbitrary sets. As a natural example we may think of the natural numbers or tuples of integers.

We are looking for a statistic \( s: A \rightarrow Z \) and a bijection \( S: A \rightarrow B \) such that

- \( s = \tau \circ S \): the statistics \( s \) and \( \tau \) are equidistributed and \( S \) is an intertwining bijection.
- \( \alpha = \beta \circ S \): the statistics \( \alpha \) and \( \beta \) are equidistributed and \( S \) is an intertwining bijection.
- \( s \) is constant on the blocks of \( P \).
- \( s(\pi(a_1,\ldots,a_k)) = \rho(s(a_1),\ldots,s(a_k)) \).

Additionally, we may require that

- \( s(a) \in Z_a \) for specified sets \( Z_a \subseteq Z \), and
- \( s|_\tilde{A} \) has a specified distribution for specified sets \( \tilde{A} \subset A \).

If \( \tau \) is the identity, the two unknown functions \( s \) and \( S \) coincide. Although we do not exclude other bijective choices for \( \tau \), they probably do not make sense.

If we want that \( S \) is graded, i.e., if elements of \( A \) and \( B \) have a notion of size and \( S \) should preserve this size, we can add grading statistics as \( \alpha \) and \( \beta \). Since \( \alpha \) and \( \beta \) will be equidistributed with \( S \) as an intertwining bijection, \( S \) will then also be graded.

In summary, we have the following two commutative diagrams, where \( s \) and \( S \) are unknown functions.

\[
\begin{array}{cc}
  A & A^k \\
  \downarrow^{\alpha} & \downarrow^{\pi} \\
  W & A^k \\
  \hline
  s & s^k \\
  B & Z \\
  \hline
  \end{array}
\]

\[
\begin{array}{cc}
  A & Z \\
  \downarrow^{\pi} & \downarrow^{\rho} \\
  A^k & Z^k \\
  \hline
  s & \beta \\
  s^k & Z^k \\
  \hline
  \end{array}
\]

**Note:** If \( \tau \) is the identity map, the partition \( P \) of \( A \) necessarily consists only of singletons.

**Note:** The order of invocation of the methods with prefix `set`, i.e., `set_statistics()`, `set_intertwining_relations()`, `set_constant_blocks()`, etc., is irrelevant. Calling any of these methods a second time overrides the previous specification.
constant_blocks\((singletons=False, \text{optimal}=False)\)

Return the set partition \(P\) of \(A\) such that \(s : A \to Z\) is known to be constant on the blocks of \(P\).

**INPUT:**

- **singletons** – (optional, default: False) whether or not to include singleton blocks in the output
- **optimal** – (optional, default: False) whether or not to compute the coarsest possible partition

**Note:** computing the coarsest possible partition may be computationally expensive, but may speed up generating solutions.

**EXAMPLES:**

```sage
A = B = ['a', 'b', 'c']
sage: bij = Bijectionist(A, B, lambda x: 0)
sage: bij.set_constant_blocks([["a", "b"]])
sage: bij.constant_blocks()
{\{'a', 'b'\}}
```

minimal_subdistributions_blocks_iterator()

Return all representatives of minimal subsets \(\tilde{P}\) of \(P\) together with submultisets \(\tilde{Z}\) with \(s(\tilde{P}) = \tilde{Z}\) as multisets.

**Warning:** If there are several solutions with the same support (i.e., the sets of block representatives are the same), only one of these will be found, even if the distributions are different, see the doctest below. To find all solutions, use `minimal_subdistributions_iterator()`, which is, however, computationally more expensive.

**EXAMPLES:**

```sage
A = B = [permutation for n in range(3) for permutation in Permutations(n)]
sage: bij = Bijectionist(A, B, len)
sage: bij.set_statistics((len, len))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(solution)
{{}: 0, {1}: 1, {1, 2}: 2, {2, 1}: 2}
sage: sorted(bij.minimal_subdistributions_blocks_iterator())
[[[]], [[0]], [[1]], [[1, 1]], [[1, 2]], [[2]], [[2, 1]], [[2, 2]]]
```

Another example:

```sage
N = 2; A = B = [dyck_word for n in range(N+1) for dyck_word in DyckWords(n)]
sage: def tau(D):
    return D.number_of_touch_points()
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((lambda d: d.semilength(), lambda d: d.semilength()))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(solution)
```
....:  print(solution)
[[]: 0, [1, 0]: 1, [1, 0, 1, 0]: 1, [1, 1, 0, 0]: 2]
[[[[]]: 0, [1, 0]: 1, [1, 0, 1, 0]: 1, [1, 1, 0, 0]: 1]]

sage: for subdistribution in bij.minimal_subdistributions_blocks_iterator(): ....:  print(subdistribution)
([[]], [0])
([[[1, 0]]], [1])
([[[1, 0, 1, 0], [1, 1, 0, 0]]], [1, 2])

An example with two elements of the same block in a subdistribution:

sage: A = B = ['a', 'b', 'c', 'd', 'e']
sage: tau = {'a': 1, 'b': 1, 'c': 2, 'd': 2, 'e': 3}.get
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_constant_blocks(['a', 'b'])
sage: bij.constant_blocks(optimal=True)
{"a", "e"}

sage: list(bij.minimal_subdistributions_blocks_iterator())
([['b', 'b', 'c', 'd', 'e'], [1, 1, 2, 2, 3]])

An example with overlapping minimal subdistributions:

sage: A = B = ['a', 'b', 'c', 'd', 'e']
sage: tau = {'a': 1, 'b': 1, 'c': 2, 'd': 2, 'e': 3}.get
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_distributions(('a', [1, 2]), ('a', [1, 2, 3]))
sage: sorted(bij.solutions_iterator(), key=...)
[{'a': 1, 'b': 2, 'c': 2, 'd': 3, 'e': 1},
 {'a': 1, 'b': 2, 'c': 3, 'd': 2, 'e': 1},
 {'a': 2, 'b': 1, 'c': 1, 'd': 3, 'e': 2},
 {'a': 2, 'b': 1, 'c': 3, 'd': 1, 'e': 2}]

Fedor Petrov’s example from https://mathoverflow.net/q/424187:

sage: A = B = ['a'+str(i) for i in range(1, 9)] + ['b'+str(i) for i in range(3, 9)] + ['d']
sage: tau = {b: 0 if i < 10 else 1 for i, b in enumerate(B)}.get
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_constant_blocks(['a'+str(i), 'b'+str(i)] for i in range(1, 9) if 'b'+str(i) in A])
sage: d = [0]*8+[1]*4
sage: sorted({'a': 1, 'b': 2, 'c': 2, 'd': 3, 'e': 1},
 {'a': 1, 'b': 2, 'c': 3, 'd': 2, 'e': 1},
 {'a': 2, 'b': 1, 'c': 1, 'd': 3, 'e': 2},
 {'a': 2, 'b': 1, 'c': 3, 'd': 1, 'e': 2})

sage: bij.constant_blocks(optimal=True)
{"a", "e"}

sage: list(bij.minimal_subdistributions_blocks_iterator())
([['b', 'b', 'c', 'd', 'e'], [1, 1, 2, 2, 3]])

5.1. Comprehensive Module List 75
[1, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1, 0],
[1, 0, 0, 1, 0, 0, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0],
[1, 0, 1, 0, 0, 0, 0, 1, 1, 0, 0, 0, 0, 1, 0],
[1, 0, 1, 0, 0, 0, 1, 0, 1, 0, 0, 0, 1, 0, 0],
[1, 1, 0, 0, 0, 1, 0, 0, 0, 0, 0, 1, 0, 0, 1],
[1, 1, 0, 0, 1, 0, 0, 0, 0, 0, 1, 0, 0, 0, 1]

sage: sorted(bij.minimal_subdistributions_blocks_iterator())  # random
[[['a1', 'a2', 'a3', 'a4', 'a5', 'a6', 'a7', 'a8'],
  [0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1]],
 [['a3', 'a4', 'd'], [0, 0, 1]],
 [['a7', 'a8', 'd'], [0, 0, 1]]]

The following solution is not found, because it happens to have the same support as the other:

sage: D = set(A).difference(['b7', 'b8', 'd'])
sage: sorted(a.replace("b", "a") for a in D)
[['a1', 'a2', 'a3', 'a4', 'a5', 'a6', 'a7', 'a8'],
 [0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1]],
 [['a3', 'a4', 'd'], [0, 0, 1]],
 [['a7', 'a8', 'd'], [0, 0, 1]]]

But it is, by design, included here:

sage: sorted(D) in [d for d, _ in bij.minimal_subdistributions_iterator()]
True

minimal_subdistributions_iterator()

Return all minimal subsets \( \tilde{\mathcal{A}} \) of \( \mathcal{A} \) together with submultisets \( \tilde{\mathcal{Z}} \) with \( s(\tilde{\mathcal{A}}) = \tilde{\mathcal{Z}} \) as multisets.

EXAMPLES:

sage: A = B = [permutation for n in range(3) for permutation in Permutations(n)]
sage: bij = Bijectionist(A, B, len)
sage: bij.set_statistics((len, len))
sage: for sol in bij.solutions_iterator():
    ....:     print(sol)
    {{[]: 0, [1]: 1, [1, 2]: 2, [2, 1]: 2}}

sage: sorted(bij.minimal_subdistributions_iterator())
[([[]], [0]), ([1], [1]), ([1, 2], [2]), ([2, 1], [2])]

Another example:

sage: N = 2; A = B = [dyck_word for n in range(N+1) for dyck_word in DyckWords(n)]
sage: def tau(D):
    return D.number_of_touch_points()
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((lambda d: d.semilength(), lambda d: d.semilength()))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ....:     print(solution)
    {{[]: 0, [1, 0]: 1, [1, 0, 1, 0]: 1, [1, 1, 0, 0]: 2}}
    {{[]: 0, [1, 0]: 1, [1, 0, 1, 0]: 2, [1, 1, 0, 0]: 1}}

sage: for subdistribution in bij.minimal_subdistributions_iterator():

(continues on next page)
An example with two elements of the same block in a subdistribution:

```
sage: A = B = ["a", "b", "c", "d", "e"]
sage: tau = {"a": 1, "b": 1, "c": 2, "d": 2, "e": 3}.get
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_constant_blocks(["a", "b"])
sage: bij.set_value_restrictions("a", [1, 2])
sage: bij.constant_blocks(optimal=True)
{"a", 'b'}
sage: list(bij.minimal_subdistributions_iterator())
[[["a", "b", "c", "d", "e"], [1, 1, 2, 2, 3]]]
```

**possible_values** *(p=None, optimal=False)*  
Return for each block the values of \(s\) compatible with the imposed restrictions.

**INPUT:**
- \(p\) – (optional) a block of \(P\), or an element of a block of \(P\), or a list of these
- \(optimal\) – (default: False) whether or not to compute the minimal possible set of statistic values

**Note:** Computing the minimal possible set of statistic values may be computationally expensive.

**Todo:** currently, calling this method with \(optimal=True\) does not update the internal dictionary, because this would interfere with the variables of the MILP.

**EXAMPLES:**

```
sage: A = B = ["a", "b", "c", "d"]
sage: tau = {"a": 1, "b": 1, "c": 1, "d": 2}.get
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_constant_blocks(["a", "b"])
sage: bij.possible_values(A)
{'a': {1, 2}, 'b': {1, 2}, 'c': {1, 2}, 'd': {1, 2}}
sage: bij.possible_values(A, optimal=True)
{'a': {1}, 'b': {1}, 'c': {1, 2}, 'd': {1, 2}}
```

The internal dictionary is not updated:

```
sage: bij.possible_values(A)
{'a': {1, 2}, 'b': {1, 2}, 'c': {1, 2}, 'd': {1, 2}}
```

**set_constant_blocks** *(P)*  
Declare that \(s : A \to Z\) is constant on each block of \(P\).
**Warning:** Any restriction imposed by a previous invocation of `set_constant_blocks()` will be overwritten, including restrictions discovered by `set_intertwining_relations()` and `solutions_iterator()`!

A common example is to use the orbits of a bijection acting on $A$. This can be achieved using the function `orbit_decomposition()`.

**INPUT:**
- $P$ – a set partition of $A$, singletons may be omitted

**EXAMPLES:**
Initially the partitions are set to singleton blocks. The current partition can be reviewed using `constant_blocks()`:

```python
sage: A = B = 'abcd'
sage: bij = Bijectionist(A, B, lambda x: B.index(x) % 2)
sage: bij.constant_blocks()
{}

sage: bij.set_constant_blocks([[ 'a', 'c' ]])
sage: bij.constant_blocks()
{ 'a', 'c' }
```

We now add a map that combines some blocks:

```python
sage: def pi(p1, p2): return 'abcdefgh'[A.index(p1) + A.index(p2)]
sage: def rho(s1, s2): return (s1 + s2) % 2
sage: bij.set_intertwining_relations((2, pi, rho))
sage: list(bij.solutions_iterator())
[[{'a': 0, 'b': 1, 'c': 0, 'd': 1}]]

sage: bij.constant_blocks()
{ 'a', 'c' }, { 'b', 'd' }
```

Setting constant blocks overrides any previous assignment:

```python
sage: bij.set_constant_blocks([[ 'a', 'b' ]])
sage: bij.constant_blocks()
{ 'a', 'b' }
```

If there is no solution, and the coarsest partition is requested, an error is raised:

```python
sage: bij.constant_blocks[optimal=True]
Traceback (most recent call last):
... StopIteration
```

**set_distributions(**elements_distributions)**
Specify the distribution of $s$ for a subset of elements.

**Warning:** Any restriction imposed by a previous invocation of `set_distributions()` will be overwritten!
INPUT:

- one or more pairs of \((\tilde{A}, \tilde{Z})\), where \(\tilde{A} \subseteq A\) and \(\tilde{Z}\) is a list of values in \(Z\) of the same size as \(\tilde{A}\)

This method specifies that \(\{s(a)\mid a \in \tilde{A}\}\) equals \(\tilde{Z}\) as a multiset for each of the pairs.

When specifying several distributions, the subsets of \(A\) do not have to be disjoint.

ALGORITHM:

We add

\[
\sum_{a \in \tilde{A}} x_{p(a), z} t^z = \sum_{z \in \tilde{Z}} t^z,
\]

where \(p(a)\) is the block containing \(a\), for each given distribution as a vector equation to the MILP.

EXAMPLES:

```
sage: A = B = [permutation for n in range(4) for permutation in Permutations(n)]
sage: tau = Permutation.longest_increasing_subsequence_length
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((len, len))
sage: bij.set_distributions(((Permutation([1, 2, 3]), Permutation([1, 3, 2])), \rightarrow [1, 3]))
sage: for sol in sorted(list(bij.solutions_iterator()), key=lambda d:\n   tuple(sorted(d.items()))):
   ....:    print(sol)
   \rightarrow [2, 3, 1] : 2, [3, 1, 2] : 2, [2, 3, 1] : 2,
   [{0, 1, 2}] : 1, [1, 2] : 2, [2, 1] : 1, [1, 2, 3] : 1, [1, 3, 2] : 3, [2, 1, 3] : 1,
sage: bij.constant_blocks(optimal=True)
{{[2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]}}
sage: sorted(bij.minimal_subdistributions_blocks_iterator(), key=lambda d:\n   (len(d[0]), d[0]))
[([], [0]), ([1], [1]), ([2, 1, 3], [2]), ([1, 2], [2, 1], [1, 2]), ([1, 2, 3], [1, 3, 2]), ([1, 3, 2], [1, 3, 2])]
```

We may also specify multiple, possibly overlapping distributions:

```
sage: bij.set_distributions(((Permutation([1, 2, 3]), Permutation([1, 3, 2])), \rightarrow [1, 3]),
   ....:   (Permutation([1, 3, 2]), Permutation([3, 2, 1]))
sage: for sol in sorted(list(bij.solutions_iterator()), key=lambda d:\n   tuple(sorted(d.items()))):
   ....:    print(sol)
   \rightarrow [2, 3, 1] : 2, [3, 1, 2] : 2, [2, 3, 1] : 2
   ({0, 1, 2}) : 1, [1, 2] : 2, [2, 1] : 1, [1, 2, 3] : 1, [1, 3, 2] : 3, [2, 1, 3] : 1,
```
\[ \{[2, 3, 1]: 2, [3, 1, 2]: 2, [3, 2, 1]: 2\} \]

\[ \{[\]: 0, [1]: 1, [1, 2]: 2, [2, 1]: 1, [1, 2, 3]: 3, [1, 3, 2]: 1, [2, 1, 3]: 2, [2, 3, 1]: 2, [3, 1, 2]: 2, [3, 2, 1]: 2\} \]

\[ \text{sage: bij.constant_blocks(optimal=\text{True})} \]
\[ \{\{1\}, [1, 3, 2]\}, \{[2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]\}\]
\[ \text{sage: sorted(bij.minimal_subdistributions_blocks_iterator(), key=\text{lambda d:\}} \]
\[ \text{(len(d[0]), d[0]))} \]
\[\{\{\}, [0]\}, \{[1]\}, \{[1, 2, 3]\}, [3]\}, \{[2, 3, 1]\}, [2\}, \{[1, 2], [2, 1]\}, [1, 2]\}\]

**set_homomesic\(Q\)**

Assert that the average of \(s\) on each block of \(Q\) is constant.

**INPUT:**

- \(Q\) – a set partition of \(A\)

**EXAMPLES:**

\[ \text{sage: A = B = [1,2,3]} \]
\[ \text{sage: bij = Bijectionist(A, B, \text{lambda b: b \% 3})} \]
\[ \text{sage: bij.set_homomesic([\{1,2\}, [3]\])} \]
\[ \text{sage: list(bij.solutions_iterator())} \]
\[\{1: 2, 2: 0, 3: 1\}, \{1: 0, 2: 2, 3: 1\}\]

**set_intertwining_relations\(*\pi\_rho\)**

Add restrictions of the form \(s(\pi(a_1,\ldots,a_k)) = \rho(s(a_1),\ldots,s(a_k))\).

**Warning:** Any restriction imposed by a previous invocation of **set_intertwining_relations\()** will be overwritten!

**INPUT:**

- \(\pi\_rho\) – one or more tuples \((k, \pi: A^k \to A, \rho: Z^k \to Z, \tilde{A})\) where \(\tilde{A}\) (optional) is a \(k\)-ary function that returns true if and only if a \(k\)-tuple of objects in \(A\) is in the domain of \(\pi\)

**ALGORITHM:**

The relation

\[ s(\pi(a_1,\ldots,a_k)) = \rho(s(a_1),\ldots,s(a_k)) \]

for each pair \((\pi, \rho)\) implies immediately that \(s(\pi(a_1,\ldots,a_k))\) only depends on the blocks of \(a_1,\ldots,a_k\).

The MILP formulation is as follows. Let \(a_1,\ldots,a_k \in A\) and let \(a = \pi(a_1,\ldots,a_k)\). Let \(z_1,\ldots,z_k \in Z\) and let \(z = \rho(z_1,\ldots,z_k)\). Suppose that \(a_i \in p_i\) for all \(i\) and that \(a \in p\).

We then want to model the implication

\[ x_{p_1,z_1} = 1, \ldots, x_{p_k,z_k} = 1 \implies x_{p,z} = 1. \]
We achieve this by requiring
\[ x_{p, z} \geq 1 - k + \sum_{i=1}^{k} x_{p_i, z_i}. \]

Note that \( z \) must be a possible value of \( p \) and each \( z_i \) must be a possible value of \( p_i \).

**EXAMPLES:**

We can concatenate two permutations by increasing the values of the second permutation by the length of the first permutation:

```python
def concat(p1, p2):
    return Permutation(p1 + [i + len(p1) for i in p2])
```

We may be interested in statistics on permutations which are equidistributed with the number of fixed points, such that concatenating permutations corresponds to adding statistic values:

```python
A = B = [permutation for n in range(4) for permutation in Permutations(n)]
bij = Bijectionist(A, B, Permutation.number_of_fixed_points)
bij.set_intertwining_relations((2, concat, lambda x, y: x + y))
```

The domain of the composition may be restricted. E.g., if we concatenate only permutations starting with a 1, we obtain fewer forced elements:

```python
in_domain = lambda p1, p2: (not p1 or p1(1) == 1) and (not p2 or p2(1) == 1)
bij.set_intertwining_relations((2, concat, lambda x, y: x + y, in_domain))
```
We can also restrict according to several composition functions. For example, we may additionally concatenate permutations by incrementing the elements of the first:

```python
sage: skew_concat = lambda p1, p2: Permutation([i + len(p2) for i in p1]) + list(p2)
sage: bij.set_intertwining_relations((2, skew_concat, lambda x, y: x + y))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    print(solution)
{[0]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 1, [3, 1, 2]: 1, [3, 2, 1]: 0}
{[0]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 1, [3, 1, 2]: 1, [3, 2, 1]: 0}
{[0]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 1, [3, 1, 2]: 0, [3, 2, 1]: 1}
{[0]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 1, [3, 2, 1]: 1}
{[0]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 0, [3, 2, 1]: 1}
{[0]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 0, [3, 2, 1]: 1}
{[0]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 0, [3, 1, 2]: 0, [3, 2, 1]: 0}
```

However, this yields no solution:

```python
sage: bij.set_intertwining_relations((2, concat, lambda x, y: x + y), (2, skew_concat, lambda x, y: x + y))
sage: list(bij.solutions_iterator())
[]
```

**set_quadratic_relation** *(\texttt{\#phi\_psi})*

Add restrictions of the form $s \circ \psi \circ s = \phi$.

**INPUT:**

- \texttt{phi\_psi} – (optional) a list of pairs $(\phi, \rho)$ where $\phi : A \to Z$ and $\psi : Z \to A$

**ALGORITHM:**

We add

$$x_{p(a), z} = x_{p(\psi(z)), \phi(a)}$$

for $a \in A$ and $z \in Z$ to the MILP, where $\phi : A \to Z$ and $\psi : Z \to A$. Note that, in particular, $\phi$ must be constant on blocks.
EXAMPLES:

```sage
A = B = DyckWords(3)
sage: bij = Bijectionist(A, B)
sage: bij.set_statistics((
    lambda D: D.number_of_touch_points(),
    lambda D: D.
    →number_of_initial_rises()))
sage: ascii_art(sorted(bij.minimal_subdistributions_iterator()))
```

```
[ ( [ /
  ] ) ]
[ ( [ /
      / ] ) [ [ /
        / ] )
[ [ [ /
            / ] ], [ [ /
```

```sage
bij.set_quadratic_relation((
    lambda D: D,
    lambda D: D))
sage: ascii_art(sorted(bij.minimal_subdistributions_iterator()))
```

```
[ ( [ /
  ] ) ]
[ ( [ /
      / ] ) [ [ /
        / ] )
[ [ [ /
            / ] ], [ [ /
```

```python
set_semi_conjugacy(*pi_rho)
```

Add restrictions of the form \( s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_k)) \).

**Warning:** Any restriction imposed by a previous invocation of `set_intertwining_relations()` will be overwritten!

**INPUT:**

- `pi_rho` – one or more tuples \((k, \pi : A^k \to A, \rho : Z^k \to Z, \tilde{A})\) where \(\tilde{A}\) (optional) is a \(k\)-ary function that returns true if and only if a \(k\)-tuple of objects in \(A\) is in the domain of \(\pi\)

**ALGORITHM:**

The relation

\[
s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_k))
\]

for each pair \((\pi, \rho)\) implies immediately that \(s(\pi(a_1, \ldots, a_k))\) only depends on the blocks of \(a_1, \ldots, a_k\).

The MILP formulation is as follows. Let \(a_1, \ldots, a_k \in A\) and let \(a = \pi(a_1, \ldots, a_k)\). Let \(z_1, \ldots, z_k \in Z\) and let \(z = \rho(z_1, \ldots, z_k)\). Suppose that \(a_i \in p_i\) for all \(i\) and that \(a \in p\).

We then want to model the implication

\[
x_{p_1, z_1} = 1, \ldots, x_{p_k, z_k} = 1 \Rightarrow x_{p, z} = 1.
\]
We achieve this by requiring

\[ x_{p, z} \geq 1 - k + \sum_{i=1}^{k} x_{p_i, z_i}. \]

Note that \( z \) must be a possible value of \( p \) and each \( z_i \) must be a possible value of \( p_i \).

EXAMPLES:

We can concatenate two permutations by increasing the values of the second permutation by the length of the first permutation:

```python
sage: def concat(p1, p2): return Permutation(p1 + [i + len(p1) for i in p2])
```

We may be interested in statistics on permutations which are equidistributed with the number of fixed points, such that concatenating permutations corresponds to adding statistic values:

```python
sage: A = B = [permutation for n in range(4) for permutation in Permutations(n)]
sage: bij = Bijectionist(A, B, Permutation.number_of_fixed_points)
sage: bij.set_statistics((len, len))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
  print(solution)
...
{[\:]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 0, [2, 3, 1]: 1, [3, 1, 2]: 1, [3, 2, 1]: 3}
...
```

The domain of the composition may be restricted. E.g., if we concatenate only permutations starting with a 1, we obtain fewer forced elements:

```python
sage: in_domain = lambda p1, p2: (not p1 or p1(1) == 1) and (not p2 or p2(1) == 1)
sage: bij.set_intertwining_relations((2, concat, lambda x, y: x + y, in_domain))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
  print(solution)
...
{[\:]: 0, [1]: 1, [1, 2]: 0, [2, 1]: 2, [1, 2, 3]: 1, [1, 3, 2]: 0, [2, 1, 3]: 1, [2, 3, 1]: 1, [3, 1, 2]: 0, [3, 2, 1]: 0}
(continues on next page)
```
We can also restrict according to several composition functions. For example, we may additionally concatenate permutations by incrementing the elements of the first:

```python
sage: skew_concat = lambda p1, p2: Permutation([i + len(p2) for i in p1]) + list(p2)
sage: bij.set_intertwining_relations((2, skew_concat, lambda x, y: x + y))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ...:     print(solution)
{[1]: 0, [1, 2]: 2, [2, 1]: 3, [3, 1, 2]: 0, [3, 2, 1]: 0}
{[1]: 0, [1, 2]: 2, [2, 1]: 3, [3, 1, 2]: 0, [3, 2, 1]: 0}
{[1]: 0, [1, 2]: 2, [2, 1]: 3, [3, 1, 2]: 0, [3, 2, 1]: 0}
{[1]: 0, [1, 2]: 2, [2, 1]: 3, [3, 1, 2]: 0, [3, 2, 1]: 0}
{[1]: 0, [1, 2]: 2, [2, 1]: 3, [3, 1, 2]: 0, [3, 2, 1]: 0}
{[1]: 0, [1, 2]: 2, [2, 1]: 3, [3, 1, 2]: 0, [3, 2, 1]: 0}
```

However, this yields no solution:

```python
sage: bij.set_intertwining_relations((2, concat, lambda x, y: x + y), (2, skew_concat, lambda x, y: x + y))
sage: list(bij.solutions_iterator())
[]
```

```python
set_statistics(*alpha_beta)

Set constraints of the form $\alpha = \beta \circ S$.

**Warning:** Any restriction imposed by a previous invocation of `set_statistics()` will be overwritten!
```

INPUT:
- `alpha_beta` – one or more pairs $(\alpha: A \to W, \beta: B \to W)$

If the statistics $\alpha$ and $\beta$ are not equidistributed, an error is raised.

ALGORITHM:
We add
\[ \sum_{a \in A, z \in Z} x_{p(a), z} s^x t^{\alpha(a)} = \sum_{b \in B} s^x t^{\beta(b)} \]
as a matrix equation to the MILP.

EXAMPLES:
We look for bijections \( S \) on permutations such that the number of weak exceedences of \( S(\pi) \) equals the number of descents of \( \pi \), and statistics \( s \), such that the number of fixed points of \( S(\pi) \) equals \( s(\pi) \):

```python
sage: N = 4; A = B = [permutation for n in range(N) for permutation in Permutations(n)]
sage: def wex(p):
    return len(p.weak_excedences())
sage: def fix(p):
    return len(p.fixed_points())
sage: def des(p):
    return len(p.descents(final_descent=True)) if p else 0
sage: def adj(p):
    return len([e for (e, f) in zip(p, p[1:]+[0]) if e == f+1])

sage: bij = Bijectionist(A, B, fix)
sage: bij.set_statistics((wex, des), (len, len))
sage: for solution in sorted(list(bij.solutions_iterator()), key=lambda d: tuple(sorted(d.items()))):
    ....: print(solution)

Calling this with non-equidistributed statistics yields an error:

```python
sage: bij = Bijectionist(A, B, fix)
sage: bij.set_statistics((wex, fix))
Traceback (most recent call last):
  ...
ValueError: statistics alpha and beta are not equidistributed
```
**set_value_restrictions**(*value_restrictions*)

Restrict the set of possible values \(s(a)\) for a given element \(a\).

**Warning:** Any restriction imposed by a previous invocation of **set_value_restrictions**() will be overwritten!

**INPUT:**

- **value_restrictions** – one or more pairs \((a \in A, Z \subseteq Z)\)

**EXAMPLES:**

We may want to restrict the value of a given element to a single or multiple values. We do not require that the specified values are in the image of \(\tau\). In some cases, the restriction may not be able to provide a better solution, as for size 3 in the following example.

```python
sage: A = B = [permutation for n in range(4) for permutation in Permutations(n)]
sage: tau = Permutation.longest_increasing_subsequence_length
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((len, len))
sage: bij.set_value_restrictions((Permutation([1, 2]), [1]),
    (Permutation([3, 2, 1]), [2, 3, 4]))
sage: for sol in sorted(bij.solutions_iterator(), key=lambda d: sorted(d.
\rightarrow items())):
    print(sol)
```

(continues on next page)
However, an error occurs if the set of possible values is empty. In this example, the image of $\tau$ under any legal bijection is disjoint to the specified values.

`solutions_iterator()`

An iterator over all solutions of the problem.

OUTPUT: An iterator over all possible mappings $s : A \to Z$

ALGORITHM:

We solve an integer linear program with a binary variable $x_{p,z}$ for each partition block $p \in P$ and each statistic value $z \in Z$:

- $x_{p,z} = 1$ if and only if $s(a) = z$ for all $a \in p$.

Then we add the constraint $\sum_{x \in V} x < |V|$, where $V$ is the set containing all $x$ with $x = 1$, that is, those indicator variables representing the current solution. Therefore, a solution of this new program must be different from all those previously obtained.

INTEGER LINEAR PROGRAM:

- Let $m_w(p)$, for a block $p$ of $P$, be the multiplicity of the value $w$ in $W$ under $\alpha$, that is, the number of elements $a \in p$ with $\alpha(a) = w$.

- Let $n_w(z)$ be the number of elements $b \in B$ with $\beta(b) = w$ and $\tau(b) = z$ for $w \in W, z \in Z$.

- Let $k$ be the arity of a pair $(\pi, \rho)$ in an intertwining relation.

and the following constraints:

- because every block is assigned precisely one value, for all $p \in P$,

$$\sum_z x_{p,z} = 1.$$ 

- because the statistics $s$ and $\tau$ and also $\alpha$ and $\beta$ are equidistributed, for all $w \in W$ and $z \in Z$,
\[ \sum_p \sum_{w(p)} m_w(p) x_{p,z} = n_w(z). \]

- for each intertwining relation \( s(\pi(a_1, \ldots, a_k)) = \rho(s(a_1), \ldots, s(a_r)) \), and for all \( k \)-combinations of blocks \( p_i \in P \) such that there exist \((a_1, \ldots, a_k) \in p_1 \times \cdots \times p_k \) with \( \pi(a_1, \ldots, a_k) \in W \) and \( z = \rho(z_1, \ldots, z_k) \),

\[ x_{p,z} \geq 1 - k + \sum_{i=1}^k x_{p_i,z_i}. \]

- for each distribution restriction, i.e. a set of elements \( \hat{A} \) and a distribution of values given by integers \( d_z \) representing the multiplicity of each \( z \in Z \), and \( r_p = |p \cap \hat{A}| \) indicating the relative size of block \( p \) in the set of elements of the distribution,

\[ \sum_p r_p x_{p,z} = d_z. \]

**EXAMPLES:**

```python
sage: A = B = 'abc'
sage: bij = Bijectionist(A, B, lambda x: B.index(x) % 2, solver="GLPK")
sage: next(bij.solutions_iterator())
{'a': 0, 'b': 1, 'c': 0}
sage: list(bij.solutions_iterator())
[{'a': 0, 'b': 1, 'c': 0},
 {'a': 1, 'b': 0, 'c': 0},
 {'a': 0, 'b': 0, 'c': 1}]
sage: N = 4
sage: A = B = [permutation for n in range(N) for permutation in Permutations(n)]
```

Let \( \tau \) be the number of non-left-to-right-maxima of a permutation:

```python
sage: def tau(pi):
    ...:     pi = list(pi)
    ...:     i = count = 0
    ...:     for j in range(len(pi)):
    ...:         if pi[j] > i:
    ...:             i = pi[j]
    ...:         else:
    ...:             count += 1
    ...:     return count
```

We look for a statistic which is constant on conjugacy classes:

```python
sage: P = [list(a) for n in range(N) for a in Permutations(n).conjugacy_classes()]
sage: bij = Bijectionist(A, B, tau, solver="GLPK")
sage: bij.set_statistics((len, len))
sage: bij.set_constant_blocks(P)
sage: for solution in bij.solutions_iterator():
    ...:     print(solution)
{[ ]: 0, [1]: 0, [1, 2]: 1, [2, 1]: 0, [1, 2, 3]: 0, [1, 3, 2]: 1, [2, 1, 3]: 1, ...
, [3, 2, 1]: 1, [2, 3, 1]: 2, [3, 1, 2]: 2}
```

(continues on next page)
Changing or re-setting problem parameters clears the internal cache. Setting the verbosity prints the MILP which is solved:

```
sage: set_verbose(2)
sage: bij.set_constant_blocks(P)
sage: _ = list(bij.solutions_iterator())
```

Constraints are:

- block [ ]: 1 <= x_0 <= 1
- block [1]: 1 <= x_1 <= 1
- block [2, 1]: 1 <= x_2 + x_3 <= 1
- block [1, 2]: 1 <= x_6 + x_7 + x_8 <= 1

\textbf{sage: } set\_verbose(0)

\textbf{statistics\_fibers()}

Return a dictionary mapping statistic values in $W$ to their preimages in $A$ and $B$.

This is a (computationally) fast way to obtain a first impression which objects in $A$ should be mapped to which objects in $B$.

\textbf{EXAMPLES:}

\textbf{sage: } A = B = [\textit{permutation} \textit{for} n \textit{in} \textit{range}(4) \textit{for} \textit{permutation} \textit{in} \textit{Permutations}(n)]
\textbf{sage: } tau = \textit{Permutation}.\textit{longest\_increasing\_subsequence\_length}
\textbf{sage: } \textit{def} \textit{wex}(p): \textit{return} \textit{len}(p.\textit{weak\_excedences}())
\textbf{sage: } \textit{def} \textit{fix}(p): \textit{return} \textit{len}(p.\textit{fixed\_points}())

\textbf{(continues on next page)}
sage: def des(p):
    return len(p.descents(final_descent=True)) if p else 0
sage: def adj(p):
    return len([e for (e, f) in zip(p, p[1:]+[0]) if e == f+1])
sage: bij = Bijectionist(A, B, tau)
sage: bij.set_statistics((wex, des), (fix, adj))
sage: table([[key, AB[0], AB[1]] for key, AB in bij.statistics_fibers().items()])
(0, 0, 0) [] []
(1, 1, 1) [[1]]
(2, 2, 2) [[1, 2]]
(2, 1, 0) [[2, 1]]
(3, 3, 3) [[1, 2, 3]]
(3, 2, 1) [[1, 3, 2], [2, 1, 3], [3, 2, 1]]
(3, 2, 0) [[2, 3, 1]]
(3, 1, 0) [[3, 1, 2]]

statistics_table(header=True)

Provide information about all elements of $A$ with corresponding $\alpha$ values and all elements of $B$ with corresponding $\beta$ and $\tau$ values.

**INPUT:**

- header – (default: True) whether to include a header with the standard Greek letters

**OUTPUT:**

A pair of lists suitable for table, where

- the first contains the elements of $A$ together with the values of $\alpha$
- the second contains the elements of $B$ together with the values of $\tau$ and $\beta$

**EXAMPLES:**

sage: A = B = [permutation for n in range(4) for permutation in Permutations(n)]
sage: tau = Permutation.longest_increasing_subsequence_length
sage: def wex(p):
    return len(p.weak_excedences())

sage: def fix(p):
    return len(p.fixed_points())

sage: def des(p):
    return len(p.descents(final_descent=True)) if p else 0

sage: def adj(p):
    return len([e for (e, f) in zip(p, p[1:]+[0]) if e == f+1])

sage: bij = Bijectionist(A, B, tau)

### 5.1.9 Binary Recurrence Sequences

This class implements several methods relating to general linear binary recurrence sequences, including a sieve to find perfect powers in integral linear binary recurrence sequences.

**EXAMPLES:**

sage: R = BinaryRecurrenceSequence(1,1)  # the Fibonacci sequence
sage: R(137)  # the 137th term of the Fibonacci sequence
19134702400093278081449423917
sage: R(137) == fibonacci(137)
True
sage: [R(i) % 4 for i in range(12)]
[0, 1, 1, 2, 3, 1, 0, 1, 1, 2, 3, 1]

(continues on next page)
sage: R.period(4)  # the period of the fibonacci sequence modulo 4
6
sage: R.pthpowers(2, 10**10)  # long time (7 seconds) -- in fact these are all squares, c.f. [BMS06]
[0, 1, 2, 12]
sage: S = BinaryRecurrenceSequence(8, 1)  # a Lucas sequence
sage: S.period(73)
148
sage: S(5) % 73 == S(5 +148) %73
True
sage: S.pthpowers(3, 10**10)  # long time (3 seconds) -- provably finds the indices of all 3rd powers less than 10^10
[0, 1, 2]
sage: T = BinaryRecurrenceSequence(2, 0, 1, 2)
sage: [T(i) for i in range(10)]
[1, 2, 4, 8, 16, 32, 64, 128, 256, 512]
sage: T.is_degenerate()
True
sage: T.is_geometric()
True
sage: T.pthpowers(7, 10**30)  # optional - sage.symbolic
Traceback (most recent call last):
...
ValueError: the degenerate binary recurrence sequence is geometric or quasigeometric and has many pth powers

AUTHORS:

• Isabel Vogt (2013): initial version

See [SV2013], [BMS2006], and [SS1983].

class sage.combinat.binary_recurrence_sequences.BinaryRecurrenceSequence(b, c, u0=0, u1=1)

Bases: sageObject

Create a linear binary recurrence sequence defined by initial conditions \( u_0 \) and \( u_1 \) and recurrence relation \( u_{n+2} = b \cdot u_{n+1} + c \cdot u_n \).

INPUT:

• \( b \) – an integer (partially determining the recurrence relation)
• \( c \) – an integer (partially determining the recurrence relation)
• \( u_0 \) – an integer (the 0th term of the binary recurrence sequence)
• \( u_1 \) – an integer (the 1st term of the binary recurrence sequence)

OUTPUT:

• An integral linear binary recurrence sequence defined by \( u_0, u_1, \) and \( u_{n+2} = b \cdot u_{n+1} + c \cdot u_n \)

See also:

fibonacci(), lucas_number1(), lucas_number2()
EXAMPLES:

```
sage: R = BinaryRecurrenceSequence(3,3,2,1)
```
```
sage: R
```
```
Binary recurrence sequence defined by: u_n = 3 * u_{n-1} + 3 * u_{n-2};
With initial conditions: u_0 = 2, and u_1 = 1
```

`is_arithmetic()`

Decide whether the sequence is degenerate and an arithmetic sequence.

The sequence is arithmetic if and only if
\[ u_1 - u_0 = u_2 - u_1 = u_3 - u_2. \]
This corresponds to the matrix \( F = [[0, 1], [c, b]] \) being nondiagonalizable and \( \alpha/\beta = 1 \).

EXAMPLES:

```
sage: S = BinaryRecurrenceSequence(2,-1)
```
```
sage: [S(i) for i in range(10)]
```
```
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```
```
sage: S.is_arithmetic()
```
```
True
```

`is_degenerate()`

Decide whether the binary recurrence sequence is degenerate.

Let \( \alpha \) and \( \beta \) denote the roots of the characteristic polynomial \( p(x) = x^2 - bx - c \). Let \( a = u_1 - u_0 \beta / (\beta - \alpha) \) and \( b = u_1 - u_0 \alpha / (\beta - \alpha) \). The sequence is, thus, given by \( u_n = a \alpha^n - b \beta^n \). Then we say that the sequence is nondegenerate if and only if \( a * b * \alpha * \beta \neq 0 \) and \( \alpha/\beta \) is not a root of unity.

More concretely, there are 4 classes of degeneracy, that can all be formulated in terms of the matrix \( F = [[0, 1], [c, b]] \):

- \( F \) is singular – this corresponds to \( c = 0 \), and thus \( \alpha * \beta = 0 \). This sequence is geometric after term \( u_0 \) and so we call it quasigeometric.
- \( v = [[u_0], [u_1]] \) is an eigenvector of \( F \) – this corresponds to a geometric sequence with \( a * b = 0 \).
- \( F \) is nondiagonalizable – this corresponds to \( \alpha = \beta \). This sequence will be the point-wise product of an arithmetic and geometric sequence.
- \( F^k \) is scalar, for some \( k > 1 \) – this corresponds to \( \alpha/\beta \) a \( k \) th root of unity. This sequence is a union of several geometric sequences, and so we again call it quasigeometric.

EXAMPLES:

```
sage: S = BinaryRecurrenceSequence(0,1)
```
```
sage: S.is_degenerate()
```
```
True
```
```
sage: S.is_geometric()
```
```
False
```
```
sage: S.is_quasigeometric()
```
```
True
```
```
sage: R = BinaryRecurrenceSequence(3,-2)
```
```
sage: R.is_degenerate()
```
```
False
```
```
sage: T = BinaryRecurrenceSequence(2,-1)
```
```
(continues on next page)
Combinatorics, Release 10.1

(continued from previous page)

```python
sage: T.is_degenerate()
True
sage: T.is_arithmetic()
True
```

is_geometric()

Decide whether the binary recurrence sequence is geometric - ie a geometric sequence.

This is a subcase of a degenerate binary recurrence sequence, for which \(ab = 0\), i.e. \(u_n/u_{n-1} = r\) for some value of \(r\).

See is_degenerate() for a description of degeneracy and definitions of \(a\) and \(b\).

EXAMPLES:

```python
sage: S = BinaryRecurrenceSequence(2,0,1,2)
sage: [S(i) for i in range(10)]
[1, 2, 4, 8, 16, 32, 64, 128, 256, 512]
sage: S.is_geometric()
True
```

is_quasigeometric()

Decide whether the binary recurrence sequence is degenerate and similar to a geometric sequence, i.e. the union of multiple geometric sequences, or geometric after term \(u_0\).

If \(\alpha/\beta\) is a \(k\) th root of unity, where \(k > 1\), then necessarily \(k = 2, 3, 4, 6\). Then \(F = [[0, 1], [c, b]]\) is diagonalizable, and \(F^k = [[\alpha^k, 0], [0, \beta^k]]\) is scaler matrix. Thus for all values of \(j\) mod \(k\), the \(j\) mod \(k\) terms of \(u_n\) form a geometric series.

If \(\alpha\) or \(\beta\) is zero, this implies that \(c = 0\). This is the case when \(F\) is singular. In this case, \(u_1, u_2, u_3, \ldots\) is geometric.

EXAMPLES:

```python
sage: S = BinaryRecurrenceSequence(0,1)
sage: [S(i) for i in range(10)]
[0, 1, 0, 1, 0, 1, 0, 1, 0, 1]
sage: S.is_quasigeometric()
True
```

period\((m)\)

Return the period of the binary recurrence sequence modulo an integer \(m\).

If \(n_1\) is congruent to \(n_2\) modulo period\((m)\), then \(u_{n_1}\) is is congruent to \(u_{n_2}\) modulo \(m\).

INPUT:

- \(m\) – an integer (modulo which the period of the recurrence relation is calculated).

OUTPUT:

- The integer (the period of the sequence modulo \(m\))
EXAMPLES:
If \( p = \pm 1 \) \text{ mod } 5, then the period of the Fibonacci sequence mod \( p \) is \( p - 1 \) (c.f. Lemma 3.3 of [BMS2006]).

```python
sage: R = BinaryRecurrenceSequence(1,1)
sage: R.period(31)
30
sage: [R(i) % 4 for i in range(12)]
[0, 1, 1, 2, 3, 1, 0, 1, 1, 2, 3, 1]
sage: R.period(4)
6
```

This function works for degenerate sequences as well.

```python
sage: S = BinaryRecurrenceSequence(2,0,1,2)
sage: S.is_degenerate()
True
sage: S.is_geometric()
True
sage: [S(i) % 17 for i in range(16)]
[1, 2, 4, 8, 16, 15, 13, 9, 1, 2, 4, 8, 16, 15, 13, 9]
sage: S.period(17)
8
```

**Note:** The answer is cached.

**pthpowers**\((p, \text{Bound})\)

Find the indices of proveably all \( p \)th powers in the recurrence sequence bounded by \( \text{Bound} \).

Let \( u_n \) be a binary recurrence sequence. A \( p \)th power in \( u_n \) is a solution to \( u_n = y^p \) for some integer \( y \). There are only finitely many \( p \)th powers in any recurrence sequence [SS1983].

**INPUT:**
- \( p \) - a rational prime integer (the fixed \( p \) in \( u_n = y^p \))
- \( \text{Bound} \) - a natural number (the maximum index \( n \) in \( u_n = y^p \) that is checked).

**OUTPUT:**
- A list of the indices of all \( p \)th powers less bounded by \( \text{Bound} \). If the sequence is degenerate and there are many \( p \)th powers, raises `ValueError`.

**EXAMPLES:**

```python
sage: R = BinaryRecurrenceSequence(1,1)  # the Fibonacci sequence
sage: R.pthpowers(2, 10**10)  # long time (7 seconds) -- in fact these are all squares, c.f. [BMS2006]
[0, 1, 2, 12]
sage: S = BinaryRecurrenceSequence(8,1) # a Lucas sequence
sage: S.pthpowers(3, 10**10)  # long time (3 seconds) -- provably finds the indices of all 3rd powers less than 10^10
[0, 1, 2]
```

(continues on next page)
sage: Q = BinaryRecurrenceSequence(3,3,2,1)
sage: Q.pthpowers(11,10**10)  # long time (7.5 seconds)
[1]

If the sequence is degenerate, and there are no p\(th\) powers, returns \([\]
\). Otherwise, if there are many p\(th\) powers, raises ValueError.

sage: T = BinaryRecurrenceSequence(2,0,1,2)
sage: T.is_degenerate()
True
sage: T.is_geometric()
True
sage: T.pthpowers(7, 10**30)  # optional - sage.symbolic
Traceback (most recent call last):
... ValueError: the degenerate binary recurrence sequence is geometric or
quasigeometric and has many p\(th\) powers

sage: L = BinaryRecurrenceSequence(4,0,2,2)
sage: [L(i).factor() for i in range(10)]
[2, 2, 2^3, 2^5, 2^7, 2^9, 2^11, 2^13, 2^15, 2^17]
sage: L.is_quasigeometric()
True
sage: L.pthpowers(2, 10**30)  # optional - sage.symbolic
[]

Note: This function is primarily optimized in the range where Bound is much larger than p.

5.1.10 Binary Trees

This module deals with binary trees as mathematical (in particular immutable) objects.

Note: If you need the data-structure for example to represent sets or hash tables with AVL trees, you should have a look at sage.misc.sagex_ds.

AUTHORS:

- Florent Hivert (2010-2011): initial implementation.

class sage.combinat.binary_tree.BinaryTree(parent, children=None, check=True)

Bases: AbstractClonableTree, ClonableArray

Binary trees.

Binary trees here mean ordered (a.k.a. plane) finite binary trees, where “ordered” means that the children of each node are ordered.
Binary trees contain nodes and leaves, where each node has two children while each leaf has no children. The number of leaves of a binary tree always equals the number of nodes plus 1.

INPUT:

- **children** – None (default) or a list, tuple or iterable of length 2 of binary trees or convertible objects. This corresponds to the standard recursive definition of a binary tree as either a leaf or a pair of binary trees. Syntaxic sugar allows leaving out all but the outermost calls of the `BinaryTree()` constructor, so that, e.g., `BinaryTree([BinaryTree(None), BinaryTree(None)])` can be shortened to `BinaryTree([None, None])`. It is also allowed to abbreviate `[None, None]` by `[]`.

- **check** – (default: True) whether check for binary should be performed or not.

EXAMPLES:

```python
sage: BinaryTree()
```
```python
sage: BinaryTree(None)
```
```python
sage: BinaryTree([])
```
```python
sage: BinaryTree([None, None])
```
```python
sage: BinaryTree([None, []])
```
```python
sage: BinaryTree([None, BinaryTree([None, None])])
```
```python
sage: BinaryTree([[], []])
```
```python
traceback (most recent call last):
...
ValueError: this is not a binary tree
```

**as_ordered_tree**(with_leaves=True)

Return the same tree seen as an ordered tree. By default, leaves are transformed into actual nodes, but this can be avoided by setting the optional variable `with_leaves` to `False`.

EXAMPLES:

```python
sage: bt = BinaryTree([]); bt
[., .]
sage: bt.as_ordered_tree()
[[], []]
sage: bt.as_ordered_tree(with_leaves = False)
[]
sage: bt = bt.canonical_labelling(); bt
1[., .]
sage: bt.as_ordered_tree()
1[None[], None[]]
sage: bt.as_ordered_tree(with_leaves=False)
1[]
```
**canonical_labelling**(shift=1)

Return a labelled version of self.

The canonical labelling of a binary tree is a certain labelling of the nodes (not the leaves) of the tree. The actual canonical labelling is currently unspecified. However, it is guaranteed to have labels in 1...n where n is the number of nodes of the tree. Moreover, two (unlabelled) trees compare as equal if and only if their canonical labelled trees compare as equal.

**EXAMPLES:**

```
sage: BinaryTree().canonical_labelling()
...
```

```
sage: BinaryTree([[]]).canonical_labelling()
1[., .]
```

```
sage: BinaryTree([[[], None], [[], []]]).canonical_labelling()
5[2[1[., .], 4[3[., .], .]], 7[6[., .], 8[., .]]]
```

**canopee()**

Return the canopee of self.

The canopee of a non-empty binary tree T with n internal nodes is the list t of 0 and 1 of length n – 1 obtained by going along the leaves of T from left to right except the two extremal ones, writing 0 if the leaf is a right leaf and 1 if the leaf is a left leaf.

**EXAMPLES:**

```
sage: BinaryTree([]).canopee()
[]
```

```
sage: BinaryTree([None, []]).canopee()
[1]
```

```
sage: BinaryTree([[], None]).canopee()
[0]
```

```
sage: BinaryTree([[], [[]]]).canopee()
[0, 1]
```

```
sage: BinaryTree([[[], None], [[]]]).canopee()
[0, 1, 0, 0, 1, 0, 1]
```

The number of pairs (t1, t2) of binary trees of size n such that the canopee of t1 is the complementary of the canopee of t2 is also the number of Baxter permutations (see [DG1994], see also OEIS sequence A001181). We check this in small cases:

```
sage: [len([[u,v] for u in BinaryTrees(n) for v in BinaryTrees(n) if [1 - x for x in u.canopee()] == v.canopee()]) for n in range(1, 5)]
[1, 2, 6, 22]
```

Here is a less trivial implementation of this:

```
sage: from sage.sets.finite_set_map_cy import fibers
sage: def baxter(n):
    ....:     f = fibers(lambda t: tuple(t.canopee()), BinaryTrees(n))
    ....:     return sum(len(f[i])*len(f[tuple(1-x for x in i)]) for i in f)
sage: [baxter(n) for n in range(1, 7)]
[1, 2, 6, 22, 92, 422]
```
check()

Check that `self` is a binary tree.

EXAMPLES:

```python
sage: BinaryTree([[], []])  # indirect doctest
[[., .], [., .]]
sage: BinaryTree([[], [], []])  # indirect doctest
Traceback (most recent call last):
  ...  
ValueError: this is not a binary tree
sage: BinaryTree([[]])  # indirect doctest
Traceback (most recent call last):
  ...  
ValueError: this is not a binary tree
```

comb(`side='left'`)

Return the comb of a tree.

There are two combs in a binary tree: a left comb and a right comb.

Consider all the vertices of the leftmost (resp. rightmost) branch of the root. The left (resp. right) comb is the list of right (resp. left) subtrees of each of these vertices.

INPUT:

- `side` – (default: ‘left’) set to ‘left’ to obtain a left comb, and to ‘right’ to obtain a right comb.

OUTPUT:

A list of binary trees.

See also:

`over_decomposition()`, `under_decomposition()`

EXAMPLES:

```python
sage: BT = BinaryTree( '. ')
sage: [BT.comb('left'), BT.comb('right')]
[[], []]
sage: BT = BinaryTree( '[...]' )
sage: [BT.comb('left'), BT.comb('right')]
[[], []]
sage: BT = BinaryTree( '[[[[., .], .], [], .], .]')
sage: BT.comb('left')
[., .]
sage: BT.comb('right')
[.]
sage: BT = BinaryTree( '[[[[., .], .], .], .]')
```

```python
sage: ascii_art(BT)
________o________
/         
__o__ o
/ \
 o __o___ o
/ / /
(continues on next page)
```
dendriform_shuffle(other)

Return the list of terms in the dendriform product.

This is the list of all binary trees that can be obtained by identifying the rightmost path in self and the leftmost path in other. Every term corresponds to a shuffle of the vertices on the rightmost path in self and the vertices on the leftmost path in other.

EXAMPLES:

sage: u = BinaryTree()
sage: g = BinaryTree([[]])
sage: l = BinaryTree([[g, u]])
sage: r = BinaryTree([u, g])

sage: list(g.dendriform_shuffle(g)) # optional - sage.combinat
[[[., .], .], [., [., .]]]

sage: list(l.dendriform_shuffle(l)) # optional - sage.combinat
[[[[., .], .], .], [[[., .], [., .]], .], [[., .], [[., .], .]], [[., .], [., .]]]

sage: list(l.dendriform_shuffle(r)) # optional - sage.combinat
graph(with_leaves=True)

Convert self to a digraph.

By default, this graph contains both nodes and leaves, hence is never empty. To obtain a graph which contains only the nodes, the with_leaves optional keyword variable has to be set to False.

The resulting digraph is endowed with a combinatorial embedding, in order to be displayed correctly.

INPUT:

• with_leaves – (default: True) a Boolean, determining whether the resulting graph will be formed from the leaves and the nodes of self (if True), or only from the nodes of self (if False)

EXAMPLES:

```
sage: t1 = BinaryTree([[], None])
sage: t1.graph()  
Digraph on 5 vertices  
sage: t1.graph(with_leaves=False)
Digraph on 2 vertices

sage: t1 = BinaryTree([[], [[], None]])
sage: t1.graph()  
Digraph on 9 vertices  
sage: t1.graph().edges(sort=True)
[(0, 1, None), (0, 4, None), (1, 2, None), (1, 3, None), (4, 5, None), (4, 8, None), (5, 6, None), (5, 7, None)]
sage: t1.graph(with_leaves=False)
Digraph on 4 vertices

sage: t1.graph(with_leaves=False).edges(sort=True)
[(0, 1, None), (0, 2, None), (2, 3, None)]

sage: t1 = BinaryTree()

sage: t1.graph()  
Digraph on 1 vertex  
sage: t1.graph(with_leaves=False)
Digraph on 0 vertices

sage: BinaryTree([]).graph()
Digraph on 3 vertices

sage: BinaryTree([]).graph(with_leaves=False)
Digraph on 1 vertex

sage: t1 = BinaryTree([[], [[]], []])
sage: t1.graph(with_leaves=False)
Digraph on 5 vertices

sage: t1.graph(with_leaves=False).edges(sort=True)
[(0, 1, None), (0, 2, None), (2, 3, None), (2, 4, None)]
```

hook_number()

Return the number of hooks.

Recalling that a branch is a path from a vertex of the tree to a leaf, the leftmost (resp. rightmost) branch of a vertex $v$ is the branch from $v$ made only of left (resp. right) edges.
The hook of a vertex $v$ is a set of vertices formed by the union of $v$, and the vertices of its leftmost and rightmost branches.

There is a unique way to partition the set of vertices in hooks. The number of hooks in such a partition is the hook number of the tree.

We can obtain this partition recursively by extracting the root’s hook and iterating the processus on each tree of the remaining forest.

EXAMPLES:

```python
sage: BT = BinaryTree( '.' )
sage: BT.hook_number()
0
sage: BT = BinaryTree( '[.,]' )
sage: BT.hook_number()
1
sage: BT = BinaryTree( '[[.,], [.,]]', ascii_art(BT)
   
   o
   / \
  o  o
  /
  
sage: BT.hook_number()
1
sage: BT = BinaryTree( '[[[.,], [.,]], [.,]]', ascii_art(BT)
   
   __o__
  / \ \
 o  __o___
 / \
 o  o
 / \
 o  o
/ \ / \
 o  o  o  o
/ \
 o  o
/ \
 o  o
/ \
 o  o
sage: BT.hook_number()
6
```

**in_order_traversal** *(node_action=None, leaf_action=None)*

Explore the binary tree self using the depth-first infix-order traversal algorithm, executing the node_action function whenever traversing a node and executing the leaf_action function whenever traversing a leaf.

In more detail, what this method does to a tree $T$ is the following:

```python
if the root of `T` is a node:
    apply in_order_traversal to the left subtree of `T`
    (with the same node_action and leaf_action);
    apply node_action to the root of `T`;
```

(continues on next page)
apply in_order_traversal to the right subtree of `T`  
   (with the same node_action and leaf_action);
else:
   apply leaf_action to the root of `T`.

For example on the following binary tree $T$, where we denote leaves by $a, b, c, \ldots$ and nodes by $1, 2, 3, \ldots$:

```
  ___3___
 /      \
1   ___7___  
 /     /     \  
a 2   _5_   8  
 /  /\     /\  
b c4 6 h i
 /\  \  
d e f g
```

this method first applies leaf_action to $a$, then applies node_action to 1, then leaf_action to $b$, then node_action to 2, etc., with the vertices being traversed in the order $a, 1, b, 2, c, 3, d, 4, e, 5, f, 6, g, 7, h, 8, i$.

See in_order_traversal_iter() for a version of this algorithm which only iterates through the vertices rather than applying any function to them.

**INPUT:**

- **node_action** – (optional) a function which takes a node in input and does something during the exploration
- **leaf_action** – (optional) a function which takes a leaf in input and does something during the exploration

**in_order_traversal_iter()**

The depth-first infix-order traversal iterator for the binary tree self.

This method iterates each vertex (node and leaf alike) of the given binary tree following the depth-first infix order traversal algorithm.

The depth-first infix order traversal algorithm iterates through a binary tree as follows:

iterate through the left subtree (by the depth-first infix order traversal algorithm);
yield the root;
iterate through the right subtree (by the depth-first infix order traversal algorithm).

For example on the following binary tree $T$, where we denote leaves by $a, b, c, \ldots$ and nodes by $1, 2, 3, \ldots$:

```
  ___3___
 /      \
1   ___7___  
 /     /     \  
a 2   _5_   8  
 /  /\     /\  
b c4 6 h i
 /\  \  
d e f g
```

(continues on next page)
the depth-first infix-order traversal algorithm iterates through the vertices of $T$ in the following order: 
$a, 1, b, 2, c, 3, d, 4, e, 5, f, 6, g, 7, h, 8, i$.

See `in_order_traversal()` for a version of this algorithm which not only iterates through, but actually does something at the vertices of tree.

**is_complete()**

Return `True` if `self` is complete, else return `False`.

In a nutshell, a complete binary tree is a perfect binary tree except possibly in the last level, with all nodes in the last level “flush to the left”.

In more detail: A complete binary tree (also called binary heap) is a binary tree in which every level, except possibly the last one (the deepest), is completely filled. At depth $n$, all nodes must be as far left as possible.

For example:

```
| ___o___ |  
| / \   |  
| _o_ o |  
| / \   |  
| o o   |  
| / \   |  
| o o   |  
| / \   |  
| o o   |  
```

is not complete but the following ones are:

```
| ___o___ ___o___ ___o___ |  
| / \ / \ / \   |  
| o o o o o o _o_ o   |  
| / \ / \ / \ / \   |  
| o o o o o o , o o o o   |  
| / \ / \   |  
| o o o   |  
```

**EXAMPLES:**

```
sage: def lst(i):
.....:     return [bt for bt in BinaryTrees(i) if bt.is_complete()]
sage: for i in range(8): ascii_art(lst(i)) # long time

[ ]
[ o ]
[   ]
[ o ]
[   ]
[ o ]
[   ]
[ o ]
[ o ]
```

(continues on next page)
is_empty()

Return whether self is empty.

The notion of emptiness employed here is the one which defines a binary tree to be empty if its root is a leaf. There is precisely one empty binary tree.

EXAMPLES:

```python
sage: BinaryTree().is_empty()
True
sage: BinaryTree([]).is_empty()
False
sage: BinaryTree([[], None]).is_empty()
False
```

is_full()

Return True if self is full, else return False.

A full binary tree is a tree in which every node either has two child nodes or has two child leaves.

This is also known as proper binary tree or 2-tree or strictly binary tree.

For example:

```plaintext
       __o__
      /   \
    o     o
   /     /
  o     o
 /     /
 o     o
```

is not full but the next one is:

```plaintext
       ___o___
      /   \
    __o__ 0
   /   /
   o   o
```

(continues on next page)
EXAMPLES:

```
sage: BinaryTree([[[[]],None],[None,[]]], []).is_full()
False
sage: BinaryTree([[[[]],[[]]],[]], []).is_full()
True
sage: ascii_art([bt for bt in BinaryTrees(5) if bt.is_full()])
[   _o_ , _o_   ]
[ / \ / \   ]
[ o o o o   ]
```

### is_perfect()

Return True if self is perfect, else return False.

A perfect binary tree is a full tree in which all leaves are at the same depth.

For example:

```
| ___o___ |
| / \    |
| __o__ o |
| / \    |
| o o    |
| / \    |
| o o o o |
```

is not perfect but the next one is:

```
| --o-- |
| / \   |
| o o   |
| / \   |
| o o o o |
```

EXAMPLES:

```
sage: def lst(i):
    ....:     return [bt for bt in BinaryTrees(i) if bt.is_perfect()]
sage: for i in range(8): ascii_art(lst(i)) # long time
[ ]
[ o ]
[ ]
[ o ]
[ / \ ]
[ o o ]
[ ]
[ ]
[ ]
```
left_border_symmetry()

Return the tree where a symmetry has been applied recursively on all left borders. If a tree is made of three trees \([T_1, T_2, T_3]\) on its left border, it becomes \([T'_3, T'_2, T'_1]\) where same symmetry has been applied to \(T_1, T_2, T_3\).

EXAMPLES:

```python
sage: BinaryTree().left_border_symmetry()
```

```python
sage: BinaryTree([]).left_border_symmetry()
```

```python
sage: bt = BinaryTree([None, [None, []], None]).left_border_symmetry()
sage: bt
```

```python
sage: bt = BinaryTree([None, [None, [None, []]], None]).leftBorder_symmetry()
sage: bt
```

```python
sage: bt = BinaryTree([None, [None, [None, []]], None]).canonical_labelling()
sage: bt
```

left_children_node_number\(\text{(direction=}'\text{left}'\text{)}\)

Return the number of nodes which are left children in self.

Every node (except the root) is either the left child or the right child of its parent node. The total number of nodes is 1 plus the number of left-children nodes plus the number of right-children nodes.

INPUT:

- direction – either 'left' (default) or 'right'; if set to 'right', instead count nodes that are right children

EXAMPLES:

```python
sage: bt = BinaryTree([None, [[None, []], None], [None, [None, []]]])
sage: ascii_art(bt)
```

```python
sage: bt.left_children_node_number('left')
```

```python
sage: bt.left_children_node_number('right')
```
sage: all(5 == 1 + bt.left_children_node_number()
.....:          + bt.left_children_node_number('right')
.....:          for bt in BinaryTrees(5))
True

left_right_symmetry()

Return the left-right symmetrized tree of self.

EXAMPLES:

sage: BinaryTree().left_right_symmetry()
.
sage: BinaryTree([]).left_right_symmetry()
[.., ..]
sage: BinaryTree([[],None]).left_right_symmetry()
[.., [.., .]]
sage: BinaryTree([[],[],None]).left_right_symmetry()
[.., [[.., .], .]]

left_rotate()

Return the result of left rotation applied to the binary tree self.

Left rotation on binary trees is defined as follows: Let $T$ be a binary tree such that the right child of the root of $T$ is a node. Let $A$ be the left child of the root of $T$, and let $B$ and $C$ be the left and right children of the right child of the root of $T$. (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Then, the left rotation of $T$ is the binary tree in which the right child of the root is $C$, whereas the left child of the root is a node whose left and right children are $A$ and $B$. In pictures:

```
| * * |
| / \ / |
| A * -left-rotate-> * C |
| / \ / |
| B C A B |
```

where asterisks signify a single node each (but $A$, $B$ and $C$ might be empty).

For example,

```
| _o_ o |
| / \ / |
| o o -left-rotate-> o |
| / / |
| o o o |

<BLANKLINE>
```

| __o__ o |
| / \ / |
| o o -left-rotate-> o |
| / / |
| o o o |

| o o |
| / |
| o o |
Left rotation is the inverse operation to right rotation \((right\_rotate())\).

See also:

\(right\_rotate()\)

EXAMPLES:

```sage
sage: b = BinaryTree([[],[[],None]]); ascii_art([b])
[   _o_   ]
[   /\    ]
[   o   o ]
[   /     ]
[   o     ]
sage: ascii_art([b.left_rotate()])
[ o ]
[ / ]
[ o ]
[ / \ ]
[ o   ]
sage: b.left_rotate().right_rotate() == b
True
```

\(make\_leaf()\)

Modify self so that it becomes a leaf (i.e., an empty tree).

**Note:** self must be in a mutable state.

See also:

\(make\_node\)

EXAMPLES:

```sage
sage: t = BinaryTree([None, None])
sage: t.make_leaf()
Traceback (most recent call last):
  ...
ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t1:
    ....: t1.make_leaf()
sage: t, t1
([., .], .)
```

\(make\_node(child\_list=[None, None])\)

Modify self so that it becomes a node with children child\_list.

**INPUT:**

- child\_list – a pair of binary trees (or objects convertible to)

**Note:** self must be in a mutable state.

See also:

\(make\_leaf\)
EXAMPLES:

```python
sage: t = BinaryTree()
sage: t.make_node([None, None])
Traceback (most recent call last):
  ... ValueError: object is immutable; please change a copy instead.
sage: with t.clone() as t1:
    ....: t1.make_node([None, None])
sage: t, t1
(., [., .])
sage: with t.clone() as t:
    ....: t.make_node([BinaryTree(), BinaryTree(), BinaryTree([])])
Traceback (most recent call last):
  ...
ValueError: the list must have length 2
sage: with t1.clone() as t2:
    ....: t2.make_node([t1, t1])
```

over(\(bt\))

Return self over \(bt\), where “over” is the over (\(\backslash\)) operation.

If \(T\) and \(T'\) are two binary trees, then \(T\) over \(T'\) (written \(T/T'\)) is defined as the tree obtained by grafting \(T'\) on the rightmost leaf of \(T\). More precisely, \(T/T'\) is defined by identifying the root of the \(T'\) with the rightmost leaf of \(T\). See section 4.5 of [HNT2005].

If \(T\) is empty, then \(T/T' = T'\).

The definition of this “over” operation goes back to Loday-Ronco [LR0102066] (Definition 2.2), but it is denoted by \(\backslash\) and called the “under” operation there. In fact, trees in sage have their root at the top, contrary to the trees in [LR0102066] which are growing upwards. For this reason, the names of the over and under operations are swapped, in order to keep a graphical meaning. (Our notation follows that of section 4.5 of [HNT2005].)

See also:

under()

EXAMPLES:

Showing only the nodes of a binary tree, here is an example for the over operation:

A Sage example:
Combinatorics, Release 10.1

```python
sage: b1 = BinaryTree([[],[[],[]]])
sage: b2 = BinaryTree([[None, []],[]])
sage: ascii_art((b1, b2, b1/b2))
( _o_ , _o_ , _o_ )
( / \ / \ / \ )
( o o o o o o _o_ )
( / \ / \ )
( o o o o o )
( \ )
( _o_ )
( / \ )
( o o )
( \ )
( o )
```

**over_decomposition()**

Return the unique maximal decomposition as an over product.

This means that the tree is cut along all edges of its rightmost path.

Beware that the factors are ordered starting from the root.

See also:

*`comb()`, `under_decomposition()`*

**EXAMPLES:**

```python
sage: g = BinaryTree([])
sage: r = g.over(g); r
[., [., .]]
sage: l = g.under(g); l
[[., .], .]
sage: r.over_decomposition()
[[., .], [., .]]
sage: l.over_decomposition() == [l]
True
sage: x = g.over(l).over(l).over(g).over(g)
sage: ascii_art(x)
    _o_  
   /   /  
  o   o   o
sage: x.over_decomposition() == [g,l,l,g,g]
True
```

**prune()**

Return the binary tree obtained by deleting each leaf of `self`.

The operation of pruning is the left inverse of attaching as many leaves as possible to each node of a binary tree. That is to say, for all binary trees `bt`, we have:

```python
bt == bt.to_full().prune()
```
However, it is only a right inverse if and only if $bt$ is a full binary tree:

```python
bt == bt.prune().to_full()
```

**OUTPUT:**
A binary tree.

**See also:**
to_full()

**EXAMPLES:**

```python
sage: bt = BinaryTree([[None, []], [], [], []])
sage: ascii_art(bt)
   o
  / 
__o__ 
/   
  o   o   o
/ \   
  o   o   o
```

We check the relationship with to_full():

```python
sage: bt = BinaryTree([[[], [[None, []], [], []], [], []]])
sage: bt == bt.to_full().prune()
True
sage: bt == bt.prune().to_full()
False
```

Pruning the empty tree is again the empty tree:

```python
sage: bt = BinaryTree(None)
sage: bt.prune()
```

**q_hook_length_fraction**(q=None, q_factor=False)
Compute the $q$-hook length fraction of the binary tree self, with an additional “q-factor” if desired.

If $T$ is a (plane) binary tree and $q$ is a polynomial indeterminate over some ring, then the $q$-hook length fraction $h_q(T)$ of $T$ is defined by

$$h_q(T) = \frac{[[T]]_q!}{\prod_{t \in T} |T_t|_q},$$
Combinatorics, Release 10.1

where the product ranges over all nodes \( t \) of \( T \), where \( T_t \) denotes the subtree of \( T \) consisting of \( t \) and its all descendants, and where for every tree \( S \), we denote by \(|S|\) the number of nodes of \( S \). While this definition only shows that \( h_q(T) \) is a rational function in \( T \), it is in fact easy to show that \( h_q(T) \) is actually a polynomial in \( T \), and thus makes sense when any element of a commutative ring is substituted for \( q \). This can also be explicitly seen from the following recursive formula for \( h_q(T) \):

\[
h_q(T) = \binom{|T| - 1}{|T_1|}_q h_q(T_1) h_q(T_2),
\]

where \( T \) is any nonempty binary tree, and \( T_1 \) and \( T_2 \) are the two child trees of the root of \( T \), and where \( \binom{a}{b}_q \) denotes a \( q \)-binomial coefficient.

A variation of the \( q \)-hook length fraction is the following "\( q \)-hook length fraction with \( q \)-factor":

\[
f_q(T) = h_q(T) \cdot \prod_{t \in T} q^{|T_{\text{right}}(t)|},
\]

where for every node \( t \), we denote by \( \text{right}(t) \) the right child of \( t \). This \( f_q(T) \) differs from \( h_q(T) \) only in a multiplicative factor, which is a power of \( q \).

When \( q = 1 \), both \( f_q(T) \) and \( h_q(T) \) equal the number of permutations whose binary search tree (see [HNT2005] for the definition) is \( T \) (after dropping the labels). For example, there are 20 permutations which give a binary tree of the following shape:

```
|   __o__   |
|  /     \  |
| o     o  |
| /       /|
| o   o   o|
| o   o   o|
```

by the binary search insertion algorithm, in accordance with the fact that this tree satisfies \( f_1(T) = 20 \).

When \( q \) is considered as a polynomial indeterminate, \( f_q(T) \) is the generating function for all permutations whose binary search tree is \( T \) (after dropping the labels) with respect to the number of inversions (i. e., the Coxeter length) of the permutations.

Objects similar to \( h_q(T) \) also make sense for general ordered forests (rather than just binary trees), see e. g. [BW1988], Theorem 9.1.

INPUT:

- \( q \) – a ring element which is to be substituted as \( q \) into the \( q \)-hook length fraction (by default, this is set to be the indeterminate \( q \) in the polynomial ring \( \mathbb{Z}[q] \))

- \( q\_factor \) – a Boolean (default: False) which determines whether to compute \( h_q(T) \) or to compute \( f_q(T) \) (namely, \( h_q(T) \) is obtained when \( q\_factor \ == \ True \) and \( f_q(T) \) is obtained when \( q\_factor \ == \ True \))

EXAMPLES:

Let us start with a simple example. Actually, let us start with the easiest possible example – the binary tree with only one vertex (which is a leaf):

```
sage: b = BinaryTree()
sage: b.q_hook_length_fraction() #optional - sage.combinat
1
sage: b.q_hook_length_fraction(q_factor=True) #optional - sage.combinat
1
```
Nothing different for a tree with one node and two leaves:

```python
sage: b = BinaryTree([[]]); b
[., .]
sage: b.q_hook_length_fraction() # optional - sage.combinat
1
sage: b.q_hook_length_fraction(q_factor=True) # optional - sage.combinat
1
```

Let us get to a more interesting tree:

```python
sage: b = BinaryTree([[[],[]],[[None],[]]]); b
[[[., .], [., .]], [., .]]
sage: b.q_hook_length_fraction()(q=1) # optional - sage.combinat
20
sage: b.q_hook_length_fraction() # optional - sage.combinat
q^7 + 2*q^6 + 3*q^5 + 4*q^4 + 4*q^3 + 3*q^2 + 2*q + 1
sage: b.q_hook_length_fraction(q_factor=True) # optional - sage.combinat
q^10 + 2*q^9 + 3*q^8 + 4*q^7 + 4*q^6 + 3*q^5 + 2*q^4 + q^3
sage: b.q_hook_length_fraction(q=2) # optional - sage.combinat
465
sage: b.q_hook_length_fraction(q=2, q_factor=True) # optional - sage.combinat
3720
```

Let us check the fact that $f_q(T)$ is the generating function for all permutations whose binary search tree is $T$ (after dropping the labels) with respect to the number of inversions of the permutations:

```python
sage: def q_hook_length_fraction_2(T):
    ....:     P = PolynomialRing(ZZ, 'q').gen()
    ....:     q = P.gen()
    ....:     res = P.zero()
    ....:     for w in T.sylvester_class():
    ....:         res += q ** Permutation(w).length()
    ....:     return res
sage: def test_genfun(i):
    ....:     return all( q_hook_length_fraction_2(T)
    ....:                   == T.q_hook_length_fraction(q_factor=True)
    ....:                   for T in BinaryTrees(i) )
sage: test_genfun(4) # optional - sage.combinat
True
```

```
right_rotate()  
Return the result of right rotation applied to the binary tree self.
```

Right rotation on binary trees is defined as follows: Let $T$ be a binary tree such that the left child of the root of $T$ is a node. Let $C$ be the right child of the root of $T$, and let $A$ and $B$ be the left and right children of the left child of the root of $T$. (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Then, the right rotation of $T$ is the binary tree in which the left child of the root is $A$, whereas the right child of the root is a node whose left and right children are $B$ and $C$. In pictures:

```
| * * |   * |
| / \ |   / \ |
| * C -right-rotate-> A * |
| / \   / \   |
| A B   B C   |
```

where asterisks signify a single node each (but $A$, $B$ and $C$ might be empty).

For example,

```
| o _o_ |   _o_ |
| / / \
| o -right-rotate-> o o |
| / \
| o o   o   |
```

Right rotation is the inverse operation to left rotation ($\text{left\_rotate()}$).

The right rotation operation introduced here is the one defined in Definition 2.1 of [CP2012].

See also:

$\text{left\_rotate()}$

EXAMPLES:

```
sage: b = BinaryTree([[[],[]], None]); ascii_art([b])
[ o ]
[ / ]
[ o ]
[ / ]
o o
```

```
sage: ascii_art([b.right_rotate()])
[ _o_ ]
[ / \ ]
o o o
[ / ]
o o
```

```
sage: b = BinaryTree([[None],[None,[[]], []]]; ascii_art([b])
[  _o_  ]
[ / \ ]
o o o
[ / ]
o o
```

(continues on next page)
show (with_leaves=False)

Show the binary tree show, with or without leaves depending on the Boolean keyword variable with_leaves.

Warning: For a labelled binary tree, the labels shown in the picture are not (in general) the ones given by the labelling!

Use _latex_(), view, _ascii_art_() or pretty_print for more faithful representations of the data of the tree.

single_edge_cut_shapes()

Return the list of possible single-edge cut shapes for the binary tree.

This is used in sage.combinat.interval_posets.TamariIntervalPoset.is_new().

OUTPUT:

a list of triples \((m, i, n)\) of integers

This is a list running over all inner edges (i.e., edges joining two non-leaf vertices) of the binary tree. The removal of each inner edge defines two binary trees (connected components), the root-tree and the sub-tree. Thus, to every inner edge, we can assign three positive integers: \(m\) is the node number of the root-tree \(R\), and \(n\) is the node number of the sub-tree \(S\). The integer \(i\) is the index of the leaf of \(R\) on which \(S\) is grafted to obtain the original tree. The leaves of \(R\) are numbered starting from 1 (from left to right), hence \(1 \leq i \leq m + 1\).

In fact, each of \(m\) and \(n\) determines the other, as the total node number of \(R\) and \(S\) is the node number of self.

EXAMPLES:

```python
sage: BT = BinaryTrees(3)
sage: [t.single_edge_cut_shapes() for t in BT]
[[[2, 3, 1], (1, 2, 2)],
 [[2, 2, 1], (1, 2, 2)],
 [[2, 1, 1], (2, 3, 1)],
 [[2, 2, 1], (1, 1, 2)],
 [[2, 1, 1], (1, 1, 2)]]
```

```python
sage: BT = BinaryTrees(2)
sage: [t.single_edge_cut_shapes() for t in BT]
```
sylvester_class(left_to_right=False)

Iterate over the sylvester class corresponding to the binary tree self.

The sylvester class of a tree $T$ is the set of permutations $\sigma$ whose right-to-left binary search tree (a notion defined in [HNT2005], Definition 7) is $T$ after forgetting the labels. This is an equivalence class of the sylvester congruence (the congruence on words which holds two words $uacvbw$ and $ucavbw$ congruent whenever $a, b, c$ are letters satisfying $a \leq b < c$, and extends by transitivity) on the symmetric group.

For example the following tree’s sylvester class consists of the permutations $(1, 3, 2)$ and $(3, 1, 2)$:

```
      o
     / \              o
    o   o
```

(only the nodes are drawn here).

The right-to-left binary search tree of a word is constructed by an RSK-like insertion algorithm which proceeds as follows: Start with an empty labelled binary tree, and read the word from right to left. Each time a letter is read from the word, insert this letter in the existing tree using binary search tree insertion (binary_search_insert()). This is what the binary_search_tree() method computes if it is given the keyword left_to_right=False.

Here are two more descriptions of the sylvester class of a binary search tree:

- The sylvester class of a binary search tree $T$ is the set of all linear extensions of the poset corresponding to $T$ (that is, of the poset whose Hasse diagram is $T$, with the root on top), provided that the nodes of $T$ are labelled with $1, 2, \ldots, n$ in a binary-search-tree way (i.e., every left descendant of a node has a label smaller than that of the node, and every right descendant of a node has a label higher than that of the node).

- The sylvester class of a binary search tree $T$ (with vertex labels $1, 2, \ldots, n$) is the interval $[u, v]$ in the right permutohedron order (permutohedron_lequal()), where $u$ is the 312-avoiding permutation corresponding to $T$ (to_312_avoiding_permutation()), and where $v$ is the 132-avoiding permutation corresponding to $T$ (to_132_avoiding_permutation()).

If the optional keyword variable left_to_right is set to True, then the left sylvester class of self is returned instead. This is the set of permutations $\sigma$ whose left-to-right binary search tree (that is, the result of the binary_search_tree() with left_to_right set to True) is self. It is an equivalence class of the left sylvester congruence.

Warning: This method yields the elements of the sylvester class as raw lists, not as permutations!

EXAMPLES:

Verifying the claim that the right-to-left binary search trees of the permutations in the sylvester class of a tree $t$ all equal $t$:

```
sage: def test_bst_of_sc(n, left_to_right):
    ....:     for t in BinaryTrees(n):
```

(continues on next page)
for p in t.sylvester_class(left_to_right=left_to_right):
    p_per = Permutation(p)
    tree = p_per.binary_search_tree(left_to_right=left_to_right)
    if not BinaryTree(tree) == t:
        return False
    return True

sage: test_bst_of_sc(4, False)                        # optional - sage.combinat
True

sage: test_bst_of_sc(5, False) # long time            # optional - sage.combinat
True

The same with the left-to-right version of binary search:

sage: test_bst_of_sc(4, True)                          # optional - sage.combinat
True

sage: test_bst_of_sc(5, True) # long time              # optional - sage.combinat
True

Checking that the sylvester class is the set of linear extensions of the poset of the tree:

sage: all( sorted(t.canonical_labelling().sylvester_class())
         == sorted(list(v) for v in t.canonical_labelling().to_poset().linear_extensions())
       for t in BinaryTrees(4) )
True

tamari_greater()

The list of all trees greater or equal to self in the Tamari order.
This is the order filter of the Tamari order generated by self.
See tamari_lequal() for the definition of the Tamari poset.

See also:
tamari_smaller()

EXAMPLES:

For example, the tree:

```
|   __o__   |
| /  /   /  |
| o o   o o |
```

has these trees greater or equal to it:
Return the Tamari interval between \texttt{self} and \texttt{other} as a \texttt{TamariIntervalPoset}.

A “Tamari interval” is an interval in the Tamari poset. See \texttt{tamari_lequal()} for the definition of the Tamari poset.

INPUT:

- \texttt{other} – a binary tree greater or equal to \texttt{self} in the Tamari order

EXAMPLES:

\begin{verbatim}
    sage: bt = BinaryTree([[None, [], None], None])
    sage: ip = bt.tamari_interval(BinaryTree([[None, [], None]])); ip
    The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)]
    sage: ip.lower_binary_tree()
    [[., [[]], .], .]
    sage: ip.upper_binary_tree()
    [[., [[., .]], .]]
    sage: ip.interval_cardinality()
    4
    sage: ip.number_of_tamari_inversions()
    2
    sage: list(ip.binary_trees())
    [[., [[., .], .]],
    [[., [[., .]], .]],
    [[., [[[., .], .]], .]]
\end{verbatim}
**tamari_join(other)**

Return the join of the binary trees self and other (of equal size) in the $n$-th Tamari poset (where $n$ is the size of these trees).

The $n$-th Tamari poset (defined in `tamari_lequal()`) is known to be a lattice, and the map from the $n$-th symmetric group $S_n$ to the $n$-th Tamari poset defined by sending every permutation $p \in S_n$ to the binary search tree of $p$ (more precisely, to $p$.binary_search_tree_shape()) is a lattice homomorphism. (See Theorem 6.2 in [Rea2004].)

See also:

tamari_lequal(), tamari_meet().

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014; Frédéric Chapoton, 9 January 2018.

EXAMPLES:

```python
sage: a = BinaryTree([None, [None, []]])
sage: b = BinaryTree([None, [[], None]])
sage: c = BinaryTree([None, [], None])
sage: d = BinaryTree([[], None, None])
sage: e = BinaryTree([], [])
sage: a.tamari_join(c) == a
True
sage: b.tamari_join(c) == b
True
sage: c.tamari_join(e) == a
True
sage: d.tamari_join(e) == e
True
sage: e.tamari_join(b) == a
True
sage: e.tamari_join(a) == a
True
sage: b1 = BinaryTree([None, [[], None, None]])
sage: b2 = BinaryTree([[], None, []])
sage: b1.tamari_join(b2)
[., [[., .], [., .]]]
sage: b3 = BinaryTree([[], None, None])
sage: b1.tamari_join(b3)
[., [[., .], [., .]]]
sage: b2.tamari_join(b3)
[., [., [., .]]]
```

The universal property of the meet operation is satisfied:
```python
sage: def test_uni_join(p, q):
....:     j = p.tamari_join(q)
....:     if not p.tamari_lequal(j):
....:         return False
....:     if not q.tamari_lequal(j):
....:         return False
....:     for r in p.tamari_greater():
....:         if q.tamari_lequal(r) and not j.tamari_lequal(r):
....:             return False
....:     return True
sage: all(test_uni_join(p, q) for p in BinaryTrees(3) for q in BinaryTrees(3))
True
sage: p = BinaryTrees(6).random_element()
    # optional - sage.combinat
sage: q = BinaryTrees(6).random_element()
    # optional - sage.combinat
sage: test_uni_join(p, q)
    # optional - sage.combinat
True
```

Border cases:

```python
sage: b = BinaryTree(None)
sage: b.tamari_join(b)
```

```python
tamari_lequal(t2)
Return True if self is less or equal to another binary tree t2 (of the same size as self) in the Tamari order.

The Tamari order on binary trees of size n is the partial order on the set of all binary trees of size n generated by the following requirement: If a binary tree T' is obtained by right rotation (see right_rotate()) from a binary tree T, then T < T'. This not only is a well-defined partial order, but actually is a lattice structure on the set of binary trees of size n, and is a quotient of the weak order on the n-th symmetric group (also known as the right permutahedron order, see permutahedron_lequal()). See [CP2012]. The set of binary trees of size n equipped with the Tamari order is called the n-th Tamari poset.

The Tamari order can equivalently be defined as follows:

If T and S are two binary trees of size n, then the following four statements are equivalent:

- We have T ≤ S in the Tamari order.
- There exist elements t and s of the Sylvester classes (sylvester_class()) of T and S, respectively, such that t ≤ s in the weak order on the symmetric group.
- The 132-avoiding permutation corresponding to T (see to_132_avoiding_permutation()) is ≤ to the 132-avoiding permutation corresponding to S in the weak order on the symmetric group.
- The 312-avoiding permutation corresponding to T (see to_312_avoiding_permutation()) is ≤ to the 312-avoiding permutation corresponding to S in the weak order on the symmetric group.

See also:
tamari_smaller(), tamari_greater(), tamari_pred(), tamari_succ(), tamari_interval()
EXAMPLES:

This tree:

```
  o
 / \
o o
 / 
o
 / \
o o
```

is Tamari-≤ to the following tree:

```
_ o_
/ \
o o
/ \ o o
```

Checking this:

```
sage: b = BinaryTree([[[], []], None, []])
sage: c = BinaryTree([[[],[]],[None,[]]])
sage: b.tamari_lequal(c)
True
```

*tamari_meet (other, side='right')*

Return the meet of the binary trees self and other (of equal size) in the $n$-th Tamari poset (where $n$ is the size of these trees).

The $n$-th Tamari poset (defined in *tamari_lequal()*) is known to be a lattice, and the map from the $n$-th symmetric group $S_n$ to the $n$-th Tamari poset defined by sending every permutation $p \in S_n$ to the binary search tree of $p$ (more precisely, to $p$.binary_search_tree_shape()) is a lattice homomorphism. (See Theorem 6.2 in [Rea2004].)

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```
sage: a = BinaryTree([None, [None, []]])
sage: b = BinaryTree([None, [], None]])
sage: c = BinaryTree([None, [], None])
sage: d = BinaryTree([[], None, None])
sage: e = BinaryTree([[], []])
sage: a.tamari_meet(c) == c
True
sage: b.tamari_meet(c) == c
True
sage: c.tamari_meet(e) == d
True
```

(continues on next page)
sage: d.tamari_meet(e) == d
True
sage: e.tamari_meet(b) == d
True
sage: e.tamari_meet(a) == e
True

sage: b1 = BinaryTree([None, [[], None], None])
sage: b2 = BinaryTree([[], None, []])

sage: b1.tamari_meet(b2)
[[[., .], .], ., .]

sage: b3 = BinaryTree([[], [], None])

sage: b1.tamari_meet(b3)
[[[., .], .], ., .]

sage: b2.tamari_meet(b3)
[[[., .], .], ., .]

The universal property of the meet operation is satisfied:

sage: def test_uni_meet(p, q):
....:     m = p.tamari_meet(q)
....:     if not m.tamari_lequal(p):
....:         return False
....:     if not m.tamari_lequal(q):
....:         return False
....:     for r in p.tamari_smaller():
....:         if r.tamari_lequal(q) and not r.tamari_lequal(m):
....:             return False
....:     return True

sage: all( test_uni_meet(p, q) for p in BinaryTrees(3) for q in BinaryTrees(3) )
True

Border cases:

sage: b = BinaryTree(None)
sage: b.tamari_meet(b)
[., .]

tamari_pred()

Compute the list of predecessors of self in the Tamari poset.

This list is computed by performing all left rotates possible on its nodes.

See tamari_lequal() for the definition of the Tamari poset.
EXAMPLES:

For this tree:
```
| __o__ |
| / \ |
| o o |
| / \ / |
| o o o |
```

the list is:
```
| o , _o_ |
| / / \ |
| _o_ o o |
| / \ / / |
| o o o o |
| / \ / |
| o o o |
| / |
| o |
```

**tamari_smaller()**

The list of all trees smaller or equal to `self` in the Tamari order.

This is the order ideal of the Tamari order generated by `self`.

See **tamari_lequal()** for the definition of the Tamari poset.

**See also:**

**tamari_greater()**

**EXAMPLES:**

The tree:
```
| __o__ |
| / \ |
| o o |
| / \ / |
| o o o |
```

has these trees smaller or equal to it:
```
| __o__ , _o_ , o , o , o , o |
| / / \ / / / / |
| o o o _o_ o o o |
| / / / / / / / |
| o o o o o o o o |
| / / |
| o o |
| / |
```

**tamari_sorting_tuple(reverse=False)**

Return the Tamari sorting tuple of `self` and the size of `self`. 
This is a pair \((w, n)\), where \(n\) is the number of nodes of \(\text{self}\), and \(w\) is an \(n\)-tuple whose \(i\)-th entry is the number of all nodes among the descendants of the right child of the \(i\)-th node of \(\text{self}\). Here, the nodes of \(\text{self}\) are numbered from left to right.

**INPUT:**

- `reverse` – boolean (default `False`) if `True`, return instead the result for the left-right symmetric of the binary tree

**OUTPUT:**

a pair \((w, n)\), where \(w\) is a tuple of integers, and \(n\) the size

Two binary trees of the same size are comparable in the Tamari order if and only if the associated tuples \(w\) are componentwise comparable. (This is essentially the Theorem in [HT1972].) This is used in `tamari_lequal()`.

**EXAMPLES:**

```sage
sage: [t.tamari_sorting_tuple() for t in BinaryTrees(3)]

[((2, 1, 0), 3),
 (2, 0, 0), 3),
 ((0, 1, 0), 3),
 ((0, 0, 0), 3),
 ((0, 0, 0), 3)]
```

```sage
sage: t = BinaryTrees(10).random_element()  # _optional - sage.combinat
sage: u = t.left_right_symmetry()  # _optional - sage.combinat
sage: t.tamari_sorting_tuple(True) == u.tamari_sorting_tuple()  # _optional - sage.combinat
True
```

**REFERENCES:**

- [HT1972]

**tamari_succ()**

Compute the list of successors of \(\text{self}\) in the Tamari poset.

This is the list of all trees obtained by a right rotate of one of its nodes.

See `tamari_lequal()` for the definition of the Tamari poset.

**EXAMPLES:**

The list of successors of:

```
|   _o_   |
|   / \   |
| o o   o |
| / \ /   |
| o o o   |
```

is:

```
|   _o_   ,   _o_   ,   _o_   |
|   / \   / _o_   \   / \   |
```

(continues on next page)
to_132_avoiding_permutation()

Return a 132-avoiding permutation corresponding to the binary tree.

The linear extensions of a binary tree form an interval of the weak order called the sylvester class of the tree. This permutation is the maximal element of this sylvester class.

EXAMPLES:

```
sage: bt = BinaryTree([[],[]])
sage: bt.to_132_avoiding_permutation()
[3, 1, 2]
sage: bt = BinaryTree([[[], [[], None], []], [], []])
sage: bt.to_132_avoiding_permutation()
[8, 6, 7, 3, 4, 1, 2, 5]
```

to_312_avoiding_permutation()

Return a 312-avoiding permutation corresponding to the binary tree.

The linear extensions of a binary tree form an interval of the weak order called the sylvester class of the tree. This permutation is the minimal element of this sylvester class.

EXAMPLES:

```
sage: bt = BinaryTree([[],[]])
sage: bt.to_312_avoiding_permutation()
[1, 3, 2]
sage: bt = BinaryTree([[[], [[], None], []], [], []])
sage: bt.to_312_avoiding_permutation()
[1, 3, 4, 2, 6, 8, 7, 5]
```

to_dyck_word(usemap='1L0R')

Return the Dyck word associated with self using the given map.

INPUT:

• usemap – a string, either 1L0R, 1R0L, L1R0, R1L0

The bijection is defined recursively as follows:

• a leaf is associated to the empty Dyck Word

• a tree with children $l, r$ is associated with the Dyck word described by usemap where $L$ and $R$ are respectively the Dyck words associated with the trees $l$ and $r$.

EXAMPLES:

```
sage: BinaryTree().to_dyck_word()  # optional - sage.combinat
[]
sage: BinaryTree([]).to_dyck_word()  # optional - sage.combinat
[]
```

[1, 0]
sage: BinaryTree([[[], []], None], [[], []]).to_dyck_word() #...
-> optional - sage.combinat
[1, 1, 1, 0, 1, 1, 0, 1, 1, 0, 1, 0]
sage: BinaryTree([None, []], None).to_dyck_word() #...
-> optional - sage.combinat
[1, 0, 1, 0, 0]
sage: BinaryTree([None, []], None).to_dyck_word("1R0L") #...
-> optional - sage.combinat
[1, 1, 0, 1, 0, 0]
sage: BinaryTree([None, []], None).to_dyck_word("L1R0") #...
-> optional - sage.combinat
[1, 0, 1, 0, 0]
sage: BinaryTree([None, []], None).to_dyck_word("R1L0") #...
-> optional - sage.combinat
[1, 1, 0, 1, 0, 0]
sage: BinaryTree([None, []], None).to_dyck_word("R10L") #...
-> optional - sage.combinat
Traceback (most recent call last):
...
ValueError: R10L is not a correct map
to_dyck_word_tamari()

Return the Dyck word associated with self in consistency with the Tamari order on Dyck words and binary trees.

The bijection is defined recursively as follows:
- a leaf is associated with an empty Dyck word;
- a tree with children $l$, $r$ is associated with the Dyck word $T(l)1T(r)0$.

EXAMPLES:

sage: BinaryTree().to_dyck_word_tamari() #...
-> optional - sage.combinat
[]

sage: BinaryTree([]).to_dyck_word_tamari() #...
-> optional - sage.combinat
[1, 0]

sage: BinaryTree([None, []], None).to_dyck_word_tamari() #...
-> optional - sage.combinat
[1, 1, 0, 1, 0, 0]

to_full()

Return the full binary tree constructed from self.

Let $T$ be a binary tree with $n$ nodes. We construct a full binary tree $F$ from $T$ by attaching a leaf to each node of $T$ which does not have 2 children. The resulting tree will have $2n + 1$ nodes.

OUTPUT:

A full binary tree. See is_full() for the definition of full.
See also:

prune()

EXAMPLES:

```python
sage: bt = BinaryTree([[None, []], None])
sage: bt.to_full().is_full()
True
sage: ascii_art(bt)
   o
 / \
 o  

sage: ascii_art(bt.to_full())
   _o_        
  /   \
_o_     o
 /    \
  o    o

sage: bt = BinaryTree([[[], []]])
sage: ascii_art(bt)
   o
 /\ \\
 o   o

sage: ascii_art(bt.to_full())
   _o_        
  /   \
_o_     o
 /    \
  o    o

sage: BinaryTree(None).to_full()
[., .]
```

to_ordered_tree_left_branch()

Return an ordered tree of size \(n + 1\) by the following recursive rule:

• if \(x\) is the left child of \(y\), \(x\) becomes the left brother of \(y\)
• if \(x\) is the right child of \(y\), \(x\) becomes the last child of \(y\)

EXAMPLES:

```python
sage: bt = BinaryTree([[[], []]])
sage: bt.to_ordered_tree_left_branch()
[[[], []]]
sage: bt = BinaryTree([[[], [], None], [[], []]])
sage: bt.to_ordered_tree_left_branch()
[[[], [], []], [[], [], []]]
```

to_ordered_tree_right_branch()

Return an ordered tree of size \(n + 1\) by the following recursive rule:
• if $x$ is the right child of $y$, $x$ becomes the right brother of $y$

• if $x$ is the left child of $y$, $x$ becomes the first child of $y$

EXAMPLES:

```python
sage: bt = BinaryTree([[], []])
sage: bt.to_ordered_tree_right_branch()
[[[[]], []]]
sage: bt = BinaryTree([[], [], [None], []])
sage: bt.to_ordered_tree_right_branch()
[[[[[]], []], []], [[]], []]
```

`to_poset` *(with_leaves=False, root_to_leaf=False)*

Return the poset obtained by interpreting the tree as a Hasse diagram.

The default orientation is from leaves to root but you can pass root_to_leaf=True to obtain the inverse orientation.

Leaves are ignored by default, but one can set with_leaves to True to obtain the poset of the complete tree.

INPUT:

• with_leaves – (default: False) a Boolean, determining whether the resulting poset will be formed from the leaves and the nodes of self (if True), or only from the nodes of self (if False)

• root_to_leaf – (default: False) a Boolean, determining whether the poset orientation should be from root to leaves (if True) or from leaves to root (if False).

EXAMPLES:

```python
sage: bt = BinaryTree([])
sage: bt.to_poset()
Finite poset containing 1 elements
sage: bt.to_poset(with_leaves=True)
Finite poset containing 3 elements
sage: P1 = bt.to_poset(with_leaves=True)
sage: len(P1.maximal_elements())
1
sage: len(P1.minimal_elements())
2
sage: bt = BinaryTree([])
sage: P2 = bt.to_poset(with_leaves=True, root_to_leaf=True)
sage: len(P2.maximal_elements())
2
sage: len(P2.minimal_elements())
1
```

If the tree is labelled, we use its labelling to label the poset. Otherwise, we use the poset canonical labelling:

```python
sage: bt = BinaryTree([[], [None, []]]).canonical_labelling()
sage: bt
2[[[., .], [., [., .]]], [., [., [., .]]]]
sage: bt.to_poset().cover_relations()
[[[4, 3], [3, 2], [1, 2]]
```

Let us check that the empty binary tree is correctly handled:
sage: bt = BinaryTree()
sage: bt.to_poset()
Finite poset containing 0 elements
sage: bt.to_poset(with_leaves=True)
Finite poset containing 1 elements

**to_tilting()**

Transform a binary tree into a tilting object.

Let \( t \) be a binary tree with \( n \) nodes. There exists a unique depiction of \( t \) (above the diagonal) such that all leaves are regularly distributed on the diagonal line from \((0,0)\) to \((n,n)\) and all edges are either horizontal or vertical. This method provides the coordinates of this depiction, with the root as the top-left vertex.

**OUTPUT:**

a list of pairs of integers.

Every vertex of the binary tree is mapped to a pair of integers. The conventions are the following. The root has coordinates \((0, n)\) where \(n\) is the node number. If a vertex is the left (right) son of another vertex, they share the first (second) coordinate.

**EXAMPLES:**

```python
sage: t = BinaryTrees(1)[0]
sage: t.to_tilting()
[(0, 1)]

sage: for t in BinaryTrees(2):
    ....:     print(t.to_tilting())
[(1, 2), (0, 2)]
[(0, 1), (0, 2)]

sage: from sage.combinat.abstract_tree import from_hexacode
sage: t = from_hexacode('2020222002000', BinaryTrees())
sage: print(t.to_tilting())
[(0, 1), (2, 3), (4, 5), (6, 7), (4, 7), (8, 9), (10, 11),
(8, 11), (4, 11), (12, 13), (4, 13), (2, 13), (0, 13)]
```

```python
sage: w = DyckWord([1,1,1,1,0,1,1,0,0,0,1,1,0,1,0,1,1,0,0,0,0,0,0])
# optional - sage.combinat
sage: t2 = w.to_binary_tree()
# optional - sage.combinat
sage: len(t2.to_tilting()) == t2.node_number()
# optional - sage.combinat
True
```

**to_undirected_graph**(with_leaves=False)

Return the undirected graph obtained from the tree nodes and edges.

Leaves are ignored by default, but one can set with_leaves to True to obtain the graph of the complete tree.

**INPUT:**

- with_leaves – (default: False) a Boolean, determining whether the resulting graph will be formed from the leaves and the nodes of self (if True), or only from the nodes of self (if False)

**EXAMPLES:**
If the tree is labelled, we use its labelling to label the graph. Otherwise, we use the graph canonical labelling which means that two different trees can have the same graph.

**EXAMPLES:**

```
sage: bt = BinaryTree([[],[None,[]]])
sage: bt.canonical_labelling().to_undirected_graph() == bt.to_undirected_graph()
False
sage: BinaryTree([[],[]]).to_undirected_graph() == BinaryTree([[[None, None]], None]).to_undirected_graph()
True
```

**twisting_number()**

Return a pair (number of maximal left branches, number of maximal right branches).

Recalling that a branch of a vertex $v$ is a path from a vertex of the tree to a leaf, a left (resp. right) branch is a branch made only of left (resp. right) edges. The length of a branch is the number of edges composing it. A left (resp. right) branch is maximal if it is not included in a strictly longer left (resp. right) branch.

**OUTPUT:**

A list of two integers

**EXAMPLES:**

```
sage: BT = BinaryTree( '.' )
sage: BT.twisting_number()
[0, 0]
sage: BT = BinaryTree( '[..]' )
sage: BT.twisting_number()
[0, 0]
sage: BT = BinaryTree( '[[[..], .], [[..]]]' ); ascii_art(BT)
  o
 /\  
o  o
 /  
 o
sage: BT.twisting_number()
[1, 1]
sage: BT = BinaryTree( '[[[[..], [., .]], [., .]], [[., .], [., .]], [., .]]', '[]', '[[[..], [., .]], [., [., .]], [[., .], [., .]], [., .]]' )
sage: ascii_art(BT)
________o________
(continues on next page)
under \((bt)\)

Return \(self\) under \(bt\), where “under” is the \(\backslash\) operation.

If \(T\) and \(T'\) are two binary trees, then \(T\) under \(T'\) (written \(T \backslash T'\)) is defined as the tree obtained by grafting \(T\) on the leftmost leaf of \(T'\). More precisely, \(T \backslash T'\) is defined by identifying the root of \(T\) with the leftmost leaf of \(T'\).

If \(T'\) is empty, then \(T \backslash T' = T\).

The definition of this “under” operation goes back to Loday-Ronco [LR0102066] (Definition 2.2), but it is denoted by \(\backslash\) and called the “over” operation there. In fact, trees in sage have their root at the top, contrary to the trees in [LR0102066] which are growing upwards. For this reason, the names of the over and under operations are swapped, in order to keep a graphical meaning. (Our notation follows that of section 4.5 of [HNT2005].)

See also:

\(over()\)

EXAMPLES:

Showing only the nodes of a binary tree, here is an example for the under operation:
under_decomposition()

Return the unique maximal decomposition as an under product.
This means that the tree is cut along all edges of its leftmost path.
Beware that the factors are ordered starting from the root.

See also:

\texttt{comb()}, \texttt{over\_decomposition()}

EXAMPLES:

\begin{verbatim}
sage: g = BinaryTree([])
sage: r = g.over(g); r
[., [., .]]
sage: l = g.under(g); l
[[., .], .]
sage: l.under_decomposition()
[[., .], [., .]]
sage: r.under_decomposition() == [r]
True

sage: x = r.under(g).under(r).under(g)
sage: ascii_art(x)
 o
 / 
 o  o
 / 
 o  
 o
sage: x.under_decomposition() == [g,r,g,r]
True
\end{verbatim}

\texttt{class sage.combinat.binary_tree.BinaryTrees}

\texttt{Bases: UniqueRepresentation, Parent}

Factory for binary trees.

A binary tree is a tree with at most 2 children. The binary trees considered here are also ordered (a.k.a. planar),
that is to say, their children are ordered.

A full binary tree is a binary tree with no nodes with 1 child.

INPUT:
- \texttt{size} – (optional) an integer
- \texttt{full} – (optional) a boolean

OUTPUT:
The set of all (full if \texttt{full=True}) binary trees (of the given \texttt{size} if specified).

See also:

\texttt{BinaryTree}, \texttt{BinaryTree.is\_full()}

EXAMPLES:
Combinatorics, Release 10.1

sage: BinaryTrees()
Binary trees

sage: BinaryTrees(2)
Binary trees of size 2

sage: BinaryTrees(full=True)
Full binary trees

sage: BinaryTrees(3, full=True)
Full binary trees of size 3

sage: BinaryTrees(4, full=True)
Traceback (most recent call last):
...
ValueError: n must be 0 or odd

Note: This is a factory class whose constructor returns instances of subclasses.

Note: The fact that BinaryTrees is a class instead of a simple callable is an implementation detail. It could be changed in the future and one should not rely on it.

leaf()
Return a leaf tree with self as parent.

EXAMPLES:

sage: BinaryTrees().leaf()

class sage.combinat.binary_tree.BinaryTrees_all
Bases: DisjointUnionEnumeratedSets, BinaryTrees

Element
alias of BinaryTree

labelled_trees()
Return the set of labelled trees associated to self.

EXAMPLES:

sage: BinaryTrees().labelled_trees()
Labelled binary trees

unlabelled_trees()
Return the set of unlabelled trees associated to self.

EXAMPLES:

sage: BinaryTrees().unlabelled_trees()
Binary trees
class sage.combinat.binary_tree.BinaryTrees_size(size)
Bases: BinaryTrees
The enumerated sets of binary trees of given size.
cardinality()
   The cardinality of self
   This is a Catalan number.
random_element()
   Return a random BinaryTree with uniform probability.
   This method generates a random DyckWord and then uses a bijection between Dyck words and binary trees.

EXAMPLES:
sage: BinaryTrees(5).random_element() # random
[., [., [., [., [., .]]]]]#

sage: BinaryTrees(0).random_element()#

sage: BinaryTrees(1).random_element()#
[., .]

class sage.combinat.binary_tree.FullBinaryTrees_all
Bases: DisjointUnionEnumeratedSets, BinaryTrees
All full binary trees.
class sage.combinat.binary_tree.FullBinaryTrees_size(size)
Bases: BinaryTrees
Full binary trees of a fixed size (number of nodes).
cardinality()
   The cardinality of self
   This is a Catalan number.
random_element()
   Return a random FullBinaryTree with uniform probability.
   This method generates a random DyckWord of size \((s - 1)/2\), where \(s\) is the size of self, which uses a bijection between Dyck words and binary trees to get a binary tree, and convert it to a full binary tree.

EXAMPLES:
sage: BinaryTrees(5, full=True).random_element() # random
[[], [[], [[]]]]#

sage: BinaryTrees(0, full=True).random_element()#

sage: BinaryTrees(1, full=True).random_element()#
[., .]
class sage.combinat.binary_tree.LabelledBinaryTree(parent, children, label=None, check=True)

Bases: AbstractLabelledClonableTree, BinaryTree

Labelled binary trees.

A labelled binary tree is a binary tree (see BinaryTree for the meaning of this) with a label assigned to each node. The labels need not be integers, nor are they required to be distinct. None can be used as a label.

**Warning:** While it is possible to assign values to leaves (not just nodes) using this class, these labels are disregarded by various methods such as `labels()`, `map_labels()`, and (ironically) `leaf_labels()`.

**INPUT:**

- children – None (default) or a list, tuple or iterable of length 2 of labelled binary trees or convertible objects. This corresponds to the standard recursive definition of a labelled binary tree as being either a leaf, or a pair of:
  - a pair of labelled binary trees,
  - and a label.

(The label is specified in the keyword variable `label`; see below.)

Syntactic sugar allows leaving out all but the outermost calls of the `LabelledBinaryTree()` constructor, so that, e.g., `LabelledBinaryTree([[LabelledBinaryTree(None), LabelledBinaryTree(None)])` can be shortened to `LabelledBinaryTree([None, None])`. However, using this shorthand, it is impossible to label any vertex of the tree other than the root (because there is no way to pass a `label` variable without calling `LabelledBinaryTree` explicitly).

It is also allowed to abbreviate `[None, None]` by `[]` if one does not want to label the leaves (which one should not do anyway!).

- label – (default: None) the label to be put on the root of this tree.
- check – (default: True) whether checks should be performed or not.

**Todo:** It is currently not possible to use `LabelledBinaryTree()` as a shorthand for `LabelledBinaryTree(None)` (in analogy to similar syntax in the BinaryTree class).

**EXAMPLES:**

```
sage: LabelledBinaryTree(None)
...
'sage: LabelledBinaryTree(None, label="ae")  # not well supported
'ae'
sage: LabelledBinaryTree([])
None[[]]
sage: LabelledBinaryTree([], label=3)  # not well supported
3[[,]]
sage: LabelledBinaryTree([None, None])
None[[],]
sage: LabelledBinaryTree([None, None], label=5)
5[[,]]
sage: LabelledBinaryTree([None, []])
None[[], None[[]]]
sage: LabelledBinaryTree([None, []], label=4)
...
```
binary_search_insert(letter)

Return the result of inserting a letter letter into the right strict binary search tree self.

INPUT:
• letter – any object comparable with the labels of self

OUTPUT:
The right strict binary search tree self with letter inserted into it according to the binary search insertion algorithm.

Note: self is supposed to be a binary search tree. This is not being checked!

A right strict binary search tree is defined to be a labelled binary tree such that for each node n with label x, every descendant of the left child of n has a label ≤ x, and every descendant of the right child of n has a label > x. (Here, only nodes count as descendants, and every node counts as its own descendant too.) Leaves are assumed to have no labels.

Given a right strict binary search tree t and a letter i, the result of inserting i into t (denoted Ins(i, t) in the following) is defined recursively as follows:

• If t is empty, then Ins(i, t) is the tree with one node only, and this node is labelled with i.

• Otherwise, let j be the label of the root of t. If i > j, then Ins(i, t) is obtained by replacing the right child of t by Ins(i, r) in t, where r denotes the right child of t. If i ≤ j, then Ins(i, t) is obtained by replacing the left child of t by Ins(i, l) in t, where l denotes the left child of t.

See, for example, [HNT2005] for properties of this algorithm.

Warning: If t is nonempty, then inserting i into t does not change the root label of t. Hence, as opposed to algorithms like Robinson-Schensted-Knuth, binary search tree insertion involves no bumping.

EXAMPLES:
The example from Fig. 2 of [HNT2005]:
Combinatorics, Release 10.1

```python
sage: LBT = LabelledBinaryTree
sage: x = LBT(None)
sage: x
...
sage: x = x.binary_search_insert("b"); x
b[., .]
sage: x = x.binary_search_insert("d"); x
b[., d[., .]]
sage: x = x.binary_search_insert("e"); x
b[., d[., e[., .]]]
sage: x = x.binary_search_insert("a"); x
b[a[., .], d[., e[., .]]]
sage: x = x.binary_search_insert("b"); x
b[a[., b[., .]], d[., e[., .]]]
sage: x = x.binary_search_insert("d"); x
b[a[., b[., .]], d[d[., .], e[., .]]]
sage: x = x.binary_search_insert("a"); x
b[a[a[., .], b[., .]], d[d[., .], e[., .]]]
sage: x = x.binary_search_insert("c"); x
b[a[a[., .], b[., .]], d[d[c[., .], .], e[., .]]]
```

Other examples:

```python
sage: LBT = LabelledBinaryTree
sage: LBT(None).binary_search_insert(3)
3[., .]
sage: LBT([], label = 1).binary_search_insert(3)
1[., 3[., .]]
sage: LBT([], label = 3).binary_search_insert(1)
3[1[., .], .]
sage: res = LBT(None)
sage: for i in [3,1,5,2,4,6]:
    ....:    res = res.binary_search_insert(i)
sage: res
3[1[., 2[., .]], 5[4[., .], 6[., .]]]
```

```python
heap_insert(l)
```

Return the result of inserting a letter `l` into the binary heap (tree) `self`.

A binary heap is a labelled complete binary tree such that for each node, the label at the node is greater or equal to the label of each of its child nodes. (More precisely, this is called a max-heap.)

For example:

```
  _______7__
 /       \__
| 5       |
|    6    |
|         |
| 3  4    |
```

is a binary heap.

See [Wikipedia article Binary_heap#Insert](https://en.wikipedia.org/wiki/Binary_heap#Insert) for a description of how to insert a letter into a binary heap. The result is another binary heap.

INPUT:
• letter – any object comparable with the labels of self

Note: self is assumed to be a binary heap (tree). No check is performed.

left_rotate()

Return the result of left rotation applied to the labelled binary tree self.

Left rotation on labelled binary trees is defined as follows: Let T be a labelled binary tree such that the right child of the root of T is a node. Let A be the left child of the root of T, and let B and C be the left and right children of the right child of the root of T. (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Furthermore, let x be the label at the root of T, and y be the label at the right child of the root of T. Then, the left rotation of T is the labelled binary tree in which the root is labelled y, the right child of the root is C, whereas the left child of the root is a node labelled x whose left and right children are A and B. In pictures:

<table>
<thead>
<tr>
<th>y</th>
<th>x</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ \</td>
<td>/ \</td>
</tr>
<tr>
<td>x</td>
<td>C</td>
</tr>
<tr>
<td>/ \</td>
<td>/ \</td>
</tr>
<tr>
<td>A B</td>
<td>B C</td>
</tr>
</tbody>
</table>

Left rotation is the inverse operation to right rotation (right_rotate()).

right_rotate()

Return the result of right rotation applied to the labelled binary tree self.

Right rotation on labelled binary trees is defined as follows: Let T be a labelled binary tree such that the left child of the root of T is a node. Let C be the right child of the root of T, and let A and B be the left and right children of the left child of the root of T. (Keep in mind that nodes of trees are identified with the subtrees consisting of their descendants.) Furthermore, let y be the label at the root of T, and x be the label at the left child of the root of T. Then, the right rotation of T is the labelled binary tree in which the root is labelled x, the left child of the root is A, whereas the right child of the root is a node labelled y whose left and right children are B and C. In pictures:

<table>
<thead>
<tr>
<th>y</th>
<th>x</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ \</td>
<td>/ \</td>
</tr>
<tr>
<td>x</td>
<td>C</td>
</tr>
<tr>
<td>/ \</td>
<td>/ \</td>
</tr>
<tr>
<td>A B</td>
<td>B C</td>
</tr>
</tbody>
</table>

Right rotation is the inverse operation to left rotation (left_rotate()).

semistandard_insert(letter)

Return the result of inserting a letter letter into the semistandard tree self using the bumping algorithm.

INPUT:
• letter – any object comparable with the labels of self

OUTPUT:
The semistandard tree self with letter inserted into it according to the bumping algorithm.

Note: self is supposed to be a semistandard tree. This is not being checked!
A semistandard tree is defined to be a labelled binary tree such that for each node $n$ with label $x$, every descendant of the left child of $n$ has a label $> x$, and every descendant of the right child of $n$ has a label $\geq x$. (Here, only nodes count as descendants, and every node counts as its own descendant too.) Leaves are assumed to have no labels.

Given a semistandard tree $t$ and a letter $i$, the result of inserting $i$ into $t$ (denoted $\text{Ins}(i, t)$ in the following) is defined recursively as follows:

1. If $t$ is empty, then $\text{Ins}(i, t)$ is the tree with one node only, and this node is labelled with $i$.
2. Otherwise, let $j$ be the label of the root of $t$. If $i \geq j$, then $\text{Ins}(i, t)$ is obtained by replacing the right child of $t$ by $\text{Ins}(i, r)$ in $t$, where $r$ denotes the right child of $t$. If $i < j$, then $\text{Ins}(i, t)$ is obtained by replacing the label at the root of $t$ by $i$, and replacing the left child of $t$ by $\text{Ins}(j, l)$ in $t$, where $l$ denotes the left child of $t$.

This algorithm is similar to the Robinson-Schensted-Knuth insertion algorithm for semistandard Young tableaux.

AUTHORS:

- Darij Grinberg (10 Nov 2013).

EXAMPLES:

```python
sage: LBT = LabelledBinaryTree
sage: x = LBT(None)
sage: x
.
sage: x = x.semistandard_insert("b"); x
b[., .]
sage: x = x.semistandard_insert("d"); x
b[., d[., .]]
sage: x = x.semistandard_insert("e"); x
b[., d[., e[., .]]]
sage: x = x.semistandard_insert("a"); x
a[b[., .], d[., e[., .]]]
sage: x = x.semistandard_insert("b"); x
a[b[., .], b[d[., .], e[., .]]]
sage: x = x.semistandard_insert("d"); x
a[b[., .], b[d[., .], d[e[., .], .]]]
sage: x = x.semistandard_insert("a"); x
a[b[., .], a[b[d[., .], .], d[e[., .], .]]]
sage: x = x.semistandard_insert("c"); x
a[b[., .], a[b[d[., .], .], c[d[e[., .], .], .]]]
```

Other examples:

```python
sage: LBT = LabelledBinaryTree
sage: x = LBT(None).semistandard_insert(3)
3[., .]
sage: LBT([[], label = 1]).semistandard_insert(3)
1[., 3[., .]]
sage: LBT([[], label = 3]).semistandard_insert(1)
1[3[., .], .]
sage: res = LBT(None)
sage: for i in [3,1,5,2,4,6]:
    ....:     res = res.semistandard_insert(i)
```

(continues on next page)
sage: res
1[3[., .], 2[5[., .], 4[., 6[., .]]]]

class sage.combinat.binary_tree.LabelledBinaryTrees(category=None)

Bases: LabelledOrderedTrees

This is a parent stub to serve as a factory class for trees with various labels constraints.

Element

alias of LabelledBinaryTree

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

sage: LabelledBinaryTrees().labelled_trees()
Labelled binary trees

unlabelled_trees()

Return the set of unlabelled trees associated to self.

EXAMPLES:

sage: LabelledBinaryTrees().unlabelled_trees()
Binary trees

This is used to compute the shape:

sage: t = LabelledBinaryTrees().an_element().shape(); t
[[[., .], [., .]], [[., .], [., .]]]
sage: t.parent()
Binary trees

sage.combinat.binary_tree.binary_search_tree_shape(w, left_to_right=True)

Direct computation of the binary search tree shape of a list of integers.

INPUT:

- w – a list of integers
- left_to_right – boolean (default True)

OUTPUT: a non labelled binary tree

This is used under the same name as a method for permutations.

EXAMPLES:

sage: from sage.combinat.binary_tree import binary_search_tree_shape
sage: binary_search_tree_shape([1,4,3,2])
[., [[[., .], .], .]]
sage: binary_search_tree_shape([5,1,3,2])
[[., [[., .], .]], .]

By passing the option left_to_right=False one can have the insertion going from right to left:
Combinatorics, Release 10.1

```sage
sage: binary_search_tree_shape([1,6,4,2], False)
[[., .], [., [., .]]]
```

`sage.combinat.binary_tree.from_tamari_sorting_tuple(key)`

Return a binary tree from its Tamari-sorting tuple.

See `tamari_sorting_tuple()`

**INPUT:**

- `key` – a tuple of integers

**EXAMPLES:**

```sage
sage: from sage.combinat.binary_tree import from_tamari_sorting_tuple
sage: t = BinaryTrees(60).random_element()  # optional - sage.combinat
sage: from_tamari_sorting_tuple(t.tamari_sorting_tuple()[0]) == t  # optional - sage.combinat
True
```

### 5.1.11 Blob Algebras

**AUTHORS:**

- Travis Scrimshaw (2020-05-16): Initial version

**class** `sage.combinat.blob_algebra.BlobAlgebra(k, q1, q2, q3, base_ring, prefix)`

Bases: `CombinatorialFreeModule`

The blob algebra.

The **blob algebra** (also known as the Temperley-Lieb algebra of type $B$ in [ILZ2018], but is a quotient of the Temperley-Lieb algebra of type $B$ defined in [Graham1985]) is a diagram-type algebra introduced in [MS1994] whose basis consists of **Temperley-Lieb diagrams**, noncrossing perfect matchings, that may contain blobs on strands that can be deformed so that the blob touches the left side (which we can think of as a frozen pole).

The form we give here has 3 parameters, the natural one from the **Temperley-Lieb algebra**, one for the idempotent relation, and one for a loop with a blob.

**INPUT:**

- `k` – the order
- `q1` – the loop parameter
- `q2` – the idempotent parameter
- `q3` – the blob loop parameter

**EXAMPLES:**

```sage
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B = sorted(B4.basis())
sage: B[14]
B({{-4, -3}}, {{-2, -1}, {1, 2}, {3, 4}})
sage: B[40]
B({{3, 4}}, {{-4, -3}, {-2, -1}, {1, 2}})
```

(continues on next page)
REFERENCES:

• [MS1994]
• [ILZ2018]

one_basis()

Return the index of the basis element 1.

EXAMPLES:

```python
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B4.one_basis()
({}, {{-4, 4}, {-3, 3}, {-2, 2}, {-1, 1}})
```

order()

Return the order of self.

The order of a partition algebra is defined as half of the number of nodes in the diagrams.

EXAMPLES:

```python
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B4.order()
4
```

product_on_basis(top, bot)

Return the product of the basis elements indexed by top and bot.

EXAMPLES:

```python
sage: R.<q,r,s> = ZZ[]
sage: B4 = algebras.Blob(4, q, r, s)
sage: B = B4.basis()
sage: BD = sorted(B.keys())
sage: BD[14]({{-4, -3}}, {{-2, -1}, {1, 2}, {3, 4}})
sage: BD[40]({{3, 4}}, {{-4, -3}, {-2, -1}, {1, 2}, {3, 4}})
sage: B4.product_on_basis(BD[14], BD[40])
q*r*s*B({}, {{-4, -3}, {-2, -1}, {1, 2}, {3, 4}})
sage: all(len((x*y).support()) == 1 for x in B for y in B)
True
```

class sage.combinat.blob_algebra.BlobDiagram(parent, marked, unmarked)

Bases: Element

A blob diagram.

A blob diagram consists of a perfect matching of the set \(\{1, \ldots, n\} \cup \{-1, \ldots, -n\}\) such that the result is a noncrossing matching (a *Temperley-Lieb diagram*), divided into two sets of pairs: one for the pairs with
blobs and one for those without. The blobed pairs must either be either the leftmost propagating strand or to the
left of it and not nested.

```python
temperley_lieb_diagram()
```

Return the Temperley-Lieb diagram corresponding to self.

```python
sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: B = BD4([[1,-3]], [[2,-4], [3,4], [-1,-2]])
sage: B.temperley_lieb_diagram()
{{-4, 2}, {-3, 1}, {-2, -1}, {3, 4}}
```

```python
class sage.combinat.blob_algebra.BlobDiagrams(n)
```

Bases: Parent, UniqueRepresentation

The set of all blob diagrams.

```python
Element
```

alias of BlobDiagram

```python
base_set()
```

Return the base set of self.

```python
sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: sorted(BD4.base_set())
[-4, -3, -2, -1, 1, 2, 3, 4]
```

```python
cardinality()
```

Return the cardinality of self.

```python
sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: BD4.cardinality()
70
```

```python
order()
```

Return the order of self.

```python
sage: from sage.combinat.blob_algebra import BlobDiagrams
sage: BD4 = BlobDiagrams(4)
sage: BD4.order()
4
```
5.1.12 Cartesian Products

```python
class sage.combinat.cartesian_product.CartesianProduct_iters(*iters)
    Bases: EnumeratedSetFromIterator

Cartesian product of finite sets.

This class will soon be deprecated (see github issue #18411 and github issue #19195). One should instead use the functorial construction cartesian_product. The main differences in behavior are:

• construction: CartesianProduct takes as many argument as there are factors whereas cartesian_product takes a single list (or iterable) of factors;
• representation of elements: elements are represented by plain Python list for CartesianProduct versus a custom element class for cartesian_product;
• membership testing: because of the above, plain Python lists are not considered as elements of a cartesian_product.

All of these is illustrated in the examples below.

EXAMPLES:
```

```python
sage: F1 = ['a', 'b']
sage: F2 = [1, 2, 3, 4]
sage: F3 = Permutations(3)  #
    # optional - sage.combinat
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: C = CartesianProduct_iters(F1, F2, F3)  #
    # optional - sage.combinat
sage: c = cartesian_product([F1, F2, F3])  #
    # optional - sage.combinat
sage: type(C.an_element())  #
    # optional - sage.combinat
<class 'list'>
sage: type(c.an_element())  #
    # optional - sage.combinat
<class 'sage.sets.cartesian_product.CartesianProduct_with_category.element_class'>
sage: l = ['a', 1, Permutation([3, 2, 1])]  #
    # optional - sage.combinat
sage: l in C  #
    # optional - sage.combinat
True
sage: l in c  #
    # optional - sage.combinat
False
sage: elt = c(l)  #
    # optional - sage.combinat
sage: elt  #
    # optional - sage.combinat
('a', 1, [3, 2, 1])
sage: elt in c  #
    # optional - sage.combinat
True
```

(continues on next page)
cardinality()

Returns the number of elements in the Cartesian product of everything in *iters.

EXAMPLES:

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(range(2), range(3)).cardinality()
6
sage: CartesianProduct_iters(range(2), range(3)).cardinality()
6
sage: CartesianProduct_iters(range(2), range(3), range(4)).cardinality()
24
```

This works correctly for infinite objects:

```python
sage: CartesianProduct_iters(ZZ, QQ).cardinality()
+Infinity
sage: CartesianProduct_iters(ZZ, []).cardinality()
0
```

is_finite()

The Cartesian product is finite if all of its inputs are finite, or if any input is empty.

EXAMPLES:

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(ZZ, []).is_finite()
True
sage: CartesianProduct_iters(4,4).is_finite()
Traceback (most recent call last):
  ... ValueError: unable to determine whether this product is finite
```

list()

Returns

EXAMPLES:

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: CartesianProduct_iters(range(3), range(3)).list()
[[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2], [2, 0], [2, 1], [2, 2]]
sage: CartesianProduct_iters('dog', 'cat').list()
[['d', 'c'], ['d', 'a'], ['d', 't'], ['o', 'c'], ['o', 'a'], ['o', 't'], ['g', 'c'],

```
random_element()

Return a random element from the Cartesian product of *iters.

EXAMPLES:

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: c = CartesianProduct_iters('dog', 'cat').random_element()
sage: c in CartesianProduct_iters('dog', 'cat')
True
```

unrank(x)

For finite Cartesian products, we can reduce unrank to the constituent iterators.

EXAMPLES:

```python
sage: from sage.combinat.cartesian_product import CartesianProduct_iters
sage: C = CartesianProduct_iters(range(1000), range(1000), range(1000))
sage: C[238792368]
[238, 792, 368]
```

Check for github issue #15919:

```python
sage: FF = IntegerModRing(29)
sage: C = CartesianProduct_iters(FF, FF, FF)
sage: C.unrank(0)
[0, 0, 0]
```

### 5.1.13 Enumerated sets of partitions, tableaux, ...

**Partitions**

- Integer partitions
- Skew Partitions
- Partition tuples
- Super Partitions
- TableauTuples
- Skew Tableaux
- Ribbons
- Ribbon Tableaux
- Strong and weak tableaux
- Shifted primed tableaux
- Residue sequences of tableaux
Combinatorics, Release 10.1

RSK

- Robinson-Schensted-Knuth correspondence
- Growth diagrams and dual graded graphs

5.1.14 Combinatorial Hopf algebras

- Symmetric Functions
  - Non-commutative symmetric functions and quasi-symmetric functions
  - Symmetric functions in non-commuting variables
  - Schubert Polynomials
- Poirier-Reutenauer Hopf algebra of standard tableaux
- Free Quasi-symmetric functions
- Grossman-Larson Hopf Algebras
- Word Quasi-symmetric functions

5.1.15 Poirier-Reutenauer Hopf algebra of standard tableaux

AUTHORS:

- Franco Saliola (2012): initial implementation
- Travis Scrimshaw (2018-04-11): added missing doctests and reorganization

```python
class sage.combinat.chas.fsym.FSymBases(parent_with_realization):
    Bases: Category_realization_of_parent

    The category of graded bases of $FSym$ and $FSym^*$ indexed by standard tableaux.

class ElementMethods
    Bases: object

    duality_pairing(other)
    
    Compute the pairing between self and an element other of the dual.

    EXAMPLES:

    sage: FSym = algebras.FSym(QQ)
    sage: G = FSym.G()
    sage: F = G.dual_basis()
    sage: elt = G[[1,3],[2]] - 3*G[[1,2],[3]]
    sage: elt.duality_pairing(F[[1,3],[2]])
    1
    sage: elt.duality_pairing(F[[1,2],[3]])
    -3
    sage: elt.duality_pairing(F[[1,2]])
    0
```

class ParentMethods
    Bases: object
basis($degree=None$)
The basis elements (optionally: of the specified degree).

OUTPUT: Family

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: TG = FSym.G()
sage: TG.basis()
Lazy family (Term map from Standard tableaux to Hopf algebra of standard→tableaux
over the Rational Field in the Fundamental basis(i))_{i in Standard→tableaux}
sage: TG.basis().keys()
Standard tableaux
sage: TG.basis(degree=3).keys()
Standard tableaux of size 3
sage: TG.basis(degree=3).list()
[G[123], G[13|2], G[12|3], G[1|2|3]]
```

degree_on_basis($t$)
Return the degree of a standard tableau in the algebra of free symmetric functions.
This is the size of the tableau $t$.

EXAMPLES:

```
sage: G = algebras.FSym(QQ).G()
sage: t = StandardTableau([[1,3],[2]])
sage: G.degree_on_basis(t)
3
sage: u = StandardTableau([[1,3,4,5],[2]])
sage: G.degree_on_basis(u)
5
```

duality_pairing($x, y$)
The canonical pairing between $FSym$ and $FSym^*$. 

EXAMPLES:

```
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: F = G.dual_basis()
sage: t1 = StandardTableau([[1,3,5],[2,4]])
sage: t2 = StandardTableau([[1,3],[2,5],[4]])
sage: G.duality_pairing(G[t1], F[t2])
0
sage: G.duality_pairing(G[t1], F[t1])
1
sage: G.duality_pairing(G[t2], F[t2])
1
sage: F.duality_pairing(F[t2], G[t2])
1
sage: z = G[[1,3,5],[2,4]]
```

(continues on next page)
sage: all(F.duality_pairing(F[p1] * F[p2], z) == c
    ....:   for ((p1, p2), c) in z.coproduct())
True

duality_pairing_matrix(basis, degree)
The matrix of scalar products between elements of FSym and elements of FSym*.

INPUT:
• basis – a basis of the dual Hopf algebra
• degree – a non-negative integer

OUTPUT:
• the matrix of scalar products between the basis self and the basis basis in the dual Hopf algebra of degree degree

EXAMPLES:

sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: G.duality_pairing_matrix(G.dual_basis(), 3)
[[1 0 0 0]
 [0 1 0 0]
 [0 0 1 0]
 [0 0 0 1]]

one_basis()
Return the basis index corresponding to 1.

EXAMPLES:

sage: FSym = algebras.FSym(QQ)
sage: TG = FSym.G()
sage: TG.one_basis()
[]

super_categories()
The super categories of self.

EXAMPLES:

sage: from sage.combinat.chas.fsym import FSymBases
sage: FSym = algebras.FSym(ZZ)
sage: bases = FSymBases(FSym)
sage: bases.super_categories()
[Category of realizations of Hopf algebra of standard tableaux over the Integer Ring,
 Join of Category of realizations of hopf algebras over Integer Ring
 and Category of graded algebras over Integer Ring
 and Category of graded coalgebras over Integer Ring,
 Category of graded connected hopf algebras with basis over Integer Ring]

class sage.combinat.chas.fsym.FSymBasis_abstract(alg, graded=True):
    Bases: CombinatorialFreeModule, BindableClass

    Abstract base class for graded bases of FSym and of FSym* indexed by standard tableaux.
    This must define the following attributes:
Combinatorics, Release 10.1

- 

some_elements()
Return some elements of self.

EXAMPLES:

```
sage: G = algebras.FSym(QQ).G()
sage: G.some_elements()
```

class sage.combinat.chas.fsym.FreeSymmetricFunctions(base_ring)

Bases: UniqueRepresentation, Parent

The free symmetric functions.

The free symmetric functions is a combinatorial Hopf algebra defined using tableaux and denoted \( FSym \).

Consider the Hopf algebra \( FQSym \) (FreeQuasisymmetricFunctions) over a commutative ring \( R \), and its bases \( (F_w) \) and \( (G_w) \) (where \( w \), in both cases, ranges over all permutations in all symmetric groups \( S_0, S_1, S_2, \ldots \)). For each word \( w \), let \( P(w) \) be the P-tableau of \( w \) (that is, the first of the two tableaux obtained by applying the RSK algorithm to \( w \); see RSK()). If \( t \) is a standard tableau of size \( n \), then we define \( G_t \in FQSym \) to be the sum of the \( F_w \) with \( w \) ranging over all permutations of \( \{1, 2, \ldots, n\} \) satisfying \( P(w) = t \). Equivalently, \( G_t \) is the sum of the \( G_w \) with \( w \) ranging over all permutations of \( \{1, 2, \ldots, n\} \) satisfying \( Q(w) = t \) (where \( Q(w) \) denotes the Q-tableau of \( w \)).

The \( R \)-linear span of the \( G_t \) (for \( t \) ranging over all standard tableaux) is a Hopf subalgebra of \( FQSym \), denoted by \( FSym \) and known as the free symmetric functions or the Poirier-Reutenauer Hopf algebra of tableaux. It has been introduced in [PoiReu95], where it was denoted by \( (ZT, *, \delta) \). (What we call \( G_t \) has just been called \( t \) in [PoiReu95].) The family \( (G_t) \) (with \( t \) ranging over all standard tableaux) is a basis of \( FSym \), called the Fundamental basis.

EXAMPLES:

As explained above, \( FSym \) is constructed as a Hopf subalgebra of \( FQSym \):

```
sage: G = algebras.FSym(QQ).G()
sage: F = algebras.FQSym(QQ).F()
sage: G[[1,3],[2]]
G[13|2]
sage: G[[1,3],[2]].to_fqsym()
G[2, 1, 3] + G[3, 1, 2]
sage: F(G[[1,3],[2]])
F[2, 1, 3] + F[2, 3, 1]
```

This embedding is a Hopf algebra morphism:

```
sage: all(F(G[t1] * G[t2]) == F(G[t1]) * F(G[t2])
....:    for t1 in StandardTableaux(2)
....:    for t2 in StandardTableaux(3))
True
```

```
sage: FF = F.tensor_square()
sage: all(FF(G[t].coproduct()) == F(G[t]).coproduct()
....:    for t in StandardTableaux(4))
True
```

5.1. Comprehensive Module List
There is a Hopf algebra map from $FSym$ onto the Hopf algebra of symmetric functions, which maps a tableau $t$ to the Schur function indexed by the shape of $t$:

```sage
sage: TG = algebras.FSym(QQ).G()
sage: t = StandardTableau([[1,3],[2,4],[5]])
sage: TG[t]
G[13|24|5]
sage: TG[t].to_symmetric_function()
s[2, 2, 1]
```

```python
class Fundamental(Alg, graded=True):
    Bases: FSymBasis_abstract

    The Hopf algebra of tableaux on the Fundamental basis.

    EXAMPLES:

    ```sage
    sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: TG = G; G
    Hopf algebra of standard tableaux over the Rational Field
    in the Fundamental basis
    ```

    Elements of the algebra look like:

    ```sage
    sage: TG.an_element()
    ```

```python
class Element
    Bases: IndexedFreeModuleElement

    to_fqsym()
    Return the image of self under the natural inclusion map to $FQSym$.

    EXAMPLES:

    ```sage
    sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[1,3],[2,4],[5]])
sage: G[t].to_fqsym()
    ```

```python
to_symmetric_function()
    Return the image of self under the natural projection map to $Sym$.

    The natural projection map $FSym \to Sym$ sends each standard tableau $t$ to the Schur function $s_\lambda$, where $\lambda$ is the shape of $t$. This map is a surjective Hopf algebra homomorphism.

    EXAMPLES:

    ```sage
    sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[1,3],[2,4],[5]])
sage: G[t].to_symmetric_function()
s[2, 2, 1]
    ```
**coproduct_on_basis**(t)

Return the coproduct of the basis element indexed by t.

**EXAMPLES:**

```python
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t = StandardTableau([[1,2,5], [3,4]])
sage: G.coproduct_on_basis(t)
```

**dual_basis()**

Return the dual basis to self.

**EXAMPLES:**

```python
sage: G = algebras.FSym(QQ).G()
sage: G.dual_basis()
Dual Hopf algebra of standard tableaux over the Rational Field
  in the FundamentalDual basis
```

**product_on_basis**(t1, t2)

Return the product of basis elements indexed by t1 and t2.

**EXAMPLES:**

```python
sage: FSym = algebras.FSym(QQ)
sage: G = FSym.G()
sage: t1 = StandardTableau([[1,2], [3]])
sage: t2 = StandardTableau([[1,2,3]])
sage: G.product_on_basis(t1, t2)
sage: t1 = StandardTableau([[1],[2]])
sage: t2 = StandardTableau([[1],[2]])
sage: G.product_on_basis(t1, t2)
sage: t1 = StandardTableau([[1,2],[3]])
sage: t2 = StandardTableau([[1],[2]])
sage: G.product_on_basis(t1, t2)
```

**G**

alias of **Fundamental**

**a_realization()**

Return a particular realization of self (the Fundamental basis).

**EXAMPLES:**
sage: FSym = algebras.FSym(QQ)
sage: FSym.a_realization()
Hopf algebra of standard tableaux over the Rational Field
in the Fundamental basis

dual()

Return the dual Hopf algebra of $FSym$.

EXAMPLES:

sage: algebras.FSym(QQ).dual()
Dual Hopf algebra of standard tableaux over the Rational Field

class sage.combinat.chas.fsym.FreeSymmetricFunctions_Dual(
    base_ring)

Bases: UniqueRepresentation, Parent

The Hopf dual $FSym^*$ of the free symmetric functions $FSym$.

See FreeSymmetricFunctions for the definition of the latter.

Recall that the fundamental basis of $FSym$ consists of the elements $G_t$ for $t$ ranging over all standard tableaux.
The dual basis of this is called the dual fundamental basis of $FSym^*$, and is denoted by $(G_t^*)$. The Hopf dual $FSym^*$ is isomorphic to the Hopf algebra $(\mathbb{Z}T, \ast', \delta')$ from [PoiReu95]; the isomorphism sends a basis element $G_t^*$ to $t$.

EXAMPLES:

sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: TF[1,2] * TF[[1],[2]]
sage: TF[[1,2],[3]].coproduct()

The Hopf algebra $FSym^*$ is a Hopf quotient of $FQSym$; the canonical projection sends $F_w$ (for a permutation $w$) to $G_{Q(w)}^*$, where $Q(w)$ is the $Q$-tableau of $w$. This projection is implemented as a coercion:

sage: FQSym = algebras.FQSym(QQ)
sage: F = FQSym.F()
sage: TF(F[[1, 3, 2]])
F[12|3]
sage: TF(F[[5, 1, 4, 2, 3]])
F[135|2|4]

F

alias of FundamentalDual

class FundamentalDual(\text{alg}, \text{graded}=\text{True})

Bases: FSymBasis_abstract

The dual to the Hopf algebra of tableaux, on the fundamental dual basis.

EXAMPLES:

sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
Elements of the algebra look like:

```
sage: TF.an_element()
```

class Element

Bases: IndexedFreeModuleElement

**to_quasisymmetric_function()**

Return the image of self under the canonical projection $FSym^* \rightarrow QSym$ to the ring of quasisymmetric functions.

This projection is the adjoint of the canonical injection $NSym \rightarrow FSym$ (see `to_fsym()`). It sends each tableau $t$ to the fundamental quasi-symmetric function $F_\alpha$, where $\alpha$ is the descent composition of $t$.

**EXAMPLES:**

```
sage: F = algebras.FSym(QQ).dual().F()
sage: F[[1,3,5],[2,4]].to_quasisymmetric_function()
F[1, 2, 2]
```

coproduct_on_basis($t$)

**EXAMPLES:**

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: t = StandardTableau([[1,2,5], [3,4]])
sage: TF.coproduct_on_basis(t)
```

dual_basis()

Return the dual basis to self.

**EXAMPLES:**

```
sage: F = algebras.FSym(QQ).dual().F()
sage: F.dual_basis()
Hopf algebra of standard tableaux over the Rational Field
in the Fundamental basis
```

product_on_basis($t_1, t_2$)

**EXAMPLES:**

```
sage: FSym = algebras.FSym(QQ)
sage: TF = FSym.dual().F()
sage: t1 = StandardTableau([[1,2]])
sage: TF.product_on_basis(t1, t1)
```
Combinatorics, Release 10.1

(continued from previous page)

```python
sage: t0 = StandardTableau([])
sage: TF.product_on_basis(t1, t0) == TF[t1] == TF.product_on_basis(t0, t1)
True
```

**a_realization()**

Return a particular realization of self (the Fundamental dual basis).

**EXAMPLES:**

```python
sage: FSym = algebras.FSym(QQ).dual()
sage: FSym.a_realization()
Dual Hopf algebra of standard tableaux over the Rational Field in the FundamentalDual basis
```

**dual()**

Return the dual Hopf algebra of self, which is $F \text{Sym}$.

**EXAMPLES:**

```python
sage: D = algebras.FSym(QQ).dual()
sage: D.dual()
Hopf algebra of standard tableaux over the Rational Field
```

sage.combinat.chas.fsym.ascent_set(t)

Return the ascent set of a standard tableau $t$ (encoded as a sorted list).

The ascent set of a standard tableau $t$ is defined as the set of all entries $i$ of $t$ such that the number $i + 1$ either appears to the right of $i$ or appears in a row above $i$ or does not appear in $t$ at all.

**EXAMPLES:**

```python
sage: from sage.combinat.chas.fsym import ascent_set
sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])
sage: ascent_set(t)
[2, 3, 5, 6, 8]
sage: ascent_set(StandardTableau([]))
[]
sage: ascent_set(StandardTableau([[1, 2, 3]]))
[1, 2, 3]
sage: ascent_set(StandardTableau([[1, 2, 4], [3]]))
[1, 3, 4]
sage: ascent_set([[1, 3, 5], [2, 4]])
[2, 4, 5]
```

sage.combinat.chas.fsym.descent_composition(t)

Return the descent composition of a standard tableau $t$.

This is the composition of the size of $t$ whose partial sums are the elements of the descent set of $t$ (see `descent_set()`).

**EXAMPLES:**

```python
sage: from sage.combinat.chas.fsym import descent_composition
sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])
sage: descent_composition(t)
```
sage.combinat.chas.fsym.descent_set(t)

Return the descent set of a standard tableau t (encoded as a sorted list).

The descent set of a standard tableau $t$ is defined as the set of all entries $i$ of $t$ such that the number $i + 1$ appears in a row below $i$ in $t$.

EXAMPLES:

```python
sage: from sage.combinat.chas.fsym import descent_set
sage: t = StandardTableau([[1,3,4,7],[2,5,6],[8]])
sage: descent_set(t)
[1, 4, 7]
sage: descent_set(StandardTableau([]))
[]
sage: descent_set(StandardTableau([[1, 2, 3]]))
[]
sage: descent_set(StandardTableau([[1, 2, 4], [3]]))
[2]
sage: descent_set([[1, 3, 5], [2, 4]])
[1, 3]
```

sage.combinat.chas.fsym.standardize(t)

Return the standard tableau corresponding to a given semistandard tableau $t$ with no repeated entries.

**Note:** This is an optimized version of `Tableau.standardization()` for computations in $FSym$ by using the assumption of no repeated entries in $t$.

EXAMPLES:

```python
sage: from sage.combinat.chas.fsym import standardize
sage: t = Tableau([[1,3,5,7],[2,4,8],[9]])
sage: standardize(t)
[[1, 3, 5, 6], [2, 4, 7], [8]]
sage: t = Tableau([[3,8,9,15],[5,10,12],[133]])
sage: standardize(t)
[[1, 3, 4, 7], [2, 5, 6], [8]]
```

### 5.1.16 Word Quasi-symmetric functions

**AUTHORS:**

- Travis Scrimshaw (2018-04-09): initial implementation
- Darij Grinberg and Amy Pang (2018-04-12): further bases and methods

**class** `sage.combinat.chas.wqsym.WQSymBases(base, graded)`

Bases: `Category_realization_of_parent`

The category of bases of $WQSym$. 

---

[1, 3, 3, 1]
sage: descent_composition([[1, 3, 5], [2, 4]])
[1, 2, 2]
class ElementMethods
Bases: object

algebraic_complement()

Return the image of the element self of WQSym under the algebraic complement involution.

If \( u = (u_1, u_2, \ldots, u_n) \) is a packed word that contains the letters 1, 2, \ldots, \( k \) and no others, then the complement of \( u \) is defined to be the packed word \( \overline{u} := (k + 1 - u_1, k + 1 - u_2, \ldots, k + 1 - u_n) \).

The algebraic complement involution is defined as the linear map \( WQSym \to WQSym \) that sends each basis element \( M_\mu \) of the monomial basis of \( WQSym \) to the basis element \( M_\pi \). This is a graded algebra automorphism and a coalgebra anti-automorphism of \( WQSym \). Denoting by \( \overline{f} \) the image of an element \( f \in WQSym \) under the algebraic complement involution, it can be shown that every packed word \( u \) satisfies

\[
M_\mu = M_\pi, \quad X_u = X_\pi,
\]

where standard notations for classical bases of \( WQSym \) are being used (that is, \( M \) for the monomial basis, and \( X \) for the characteristic basis).

This can be restated in terms of ordered set partitions: For any ordered set partition \( R = (R_1, R_2, \ldots, R_k) \), let \( R^c \) denote the ordered set partition \( (R_k, R_{k-1}, \ldots, R_1) \); this is known as the reversal of \( R \). Then,

\[
M_A = M_{A^c}, \quad X_A = X_{A^c}
\]

for any ordered set partition \( A \).

The formula describing algebraic complements on the Q basis (\texttt{WordQuasiSymmetricFunctions.StronglyCoarser}) is more complicated, and requires some definitions. We define a partial order \( \leq \) on the set of all ordered set partitions as follows: \( A \leq B \) if and only if \( A \) is strongly finer than \( B \) (see \texttt{is_strongly_finer()} for a definition of this). The length \( \ell(R) \) of an ordered set partition \( R \) shall be defined as the number of parts of \( R \). Use the notation \( Q \) for the Q basis. For any ordered set partition \( A \) of \([n]\), we have

\[
Q_A = \sum_p c_{A,p} Q_p,
\]

where the sum is over all ordered set partitions \( P \) of \([n]\), and where the coefficient \( c_{A,p} \) is defined as follows:

- If there exists an ordered set partition \( R \) satisfying \( R \leq P \) and \( A \leq R^c \), then this \( R \) is unique, and \( c_{A,p} = (-1)^{\ell(R) - \ell(P)} \).
- If there exists no such \( R \), then \( c_{A,p} = 0 \).

The formula describing algebraic complements on the \( \Phi \) basis (\texttt{WordQuasiSymmetricFunctions.StronglyFiner}) is identical to the above formula for the Q basis, except that the \( \leq \) sign has to be replaced by \( \geq \) in the definition of the coefficients \( c_{A,p} \). In fact, both formulas are particular cases of a general formula for involutions: Assume that \( V \) is an (additive) abelian group, and that \( I \) is a poset. For each \( i \in I \), let \( M_i \) be an element of \( V \). Also, let \( \omega \) be an involution of the set \( I \) (not necessarily order-preserving or order-reversing), and let \( \omega' \) be an involutive group endomorphism of \( V \) such that each \( i \in I \) satisfies \( \omega'(M_i) = M_{\omega(i)} \). For each \( i \in I \), let \( F_i = \sum_{j \geq i} M_j \), where we assume that the sum is finite. Then, each \( i \in I \) satisfies

\[
\omega'(F_i) = \sum_j \sum_{k \leq j; \omega(k) \geq i} \mu(k; j) F_j,
\]

where \( \mu \) denotes the Möbius function. This formula becomes particularly useful when the \( k \) satisfying \( k \leq j \) and \( \omega(k) \geq i \) is unique (if it exists). In our situation, \( V \) is \( WQSym \), and \( I \) is the set of ordered
set partitions equipped either with the \( \leq \) partial order defined above or with its opposite order. The \( M_i \) is the \( M_A \), whereas the \( F_i \) is either \( Q_i \) or \( \Phi_i \).

If we denote the star involution (`star_involution()`) of the quasisymmetric functions by \( f \mapsto f^* \), and if we let \( \pi \) be the canonical projection \( WQSym \to QSym \), then each \( f \in WQSym \) satisfies \( \pi(f) = (\pi(f))^* \).

**See also:**

`coalgebraic_complement()`, `star_involution()`

**EXAMPLES:**

Recall that the index set for the bases of \( WQSym \) is given by ordered set partitions, not packed words. Translated into the language of ordered set partitions, the algebraic complement involution acts on the Monomial basis by reversing the ordered set partition. In other words, we have

\[
M(\{P_1, P_2, \ldots, P_k\}) = M(\{P_k, P_{k-1}, \ldots, P_1\})
\]

for any standard ordered set partition \((P_1, P_2, \ldots, P_k)\). Let us check this in practice:

```python
sage: WQSym = algebras.WQSym(ZZ)
sage: M = WQSym.M()
sage: M[[1,3],[2]].algebraic_complement() M[[2], {1, 3}]
sage: M[[1,4],[2,5],[3,6]].algebraic_complement() M[[3, 6], {2, 5}, {1, 4}]
sage: (3*M[[1]] - 4*M[[2]] + 5*M[[1],[2]]).algebraic_complement() -4*M[{} + 3*M[{} + 5*M[{} + 1}]
sage: X = WQSym.X()
sage: X[[1,3],[2]].algebraic_complement() X[2], {1, 3}]
sage: C = WQSym.C()
sage: C[[1,3],[2]].algebraic_complement() -C[{} + 1, 2, 3] - C[{} + 1, 3] + C[2], {1, 3}]
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].algebraic_complement() Q[{} + 1, 2, 3, 5, 6] + Q[{} + 1, 2, 3, 4, 5, 6] - Q[{} + 1, 2, 3, 5, 6]
```

The algebraic complement involution intertwines the antipode and the inverse of the antipode:

```python
sage: all( M[I].antipode().algebraic_complement().antipode() == M[I].algebraic_complement() for I in OrderedSetPartitions(4) )
True
```

Testing the \( \pi(f) = (\pi(f))^* \) relation:

```python
sage: all( M[I].algebraic_complement().to_quasisymmetric_function() == M[I].to_quasisymmetric_function().star_involution() for I in OrderedSetPartitions(4) )
True
```
Todo: Check further commutative squares.

```python
coalgebraic_complement()
```

Return the image of the element `self` of `WQSym` under the coalgebraic complement involution.

If \( u = (u_1, u_2, \ldots, u_n) \) is a packed word, then the `reversal` of \( u \) is defined to be the packed word \((u_n, u_{n-1}, \ldots, u_1)\). This reversal is denoted by \( u^r \).

The coalgebraic complement involution is defined as the linear map \( WQSym \to WQSym \) that sends each basis element \( M_u \) of the monomial basis of \( WQSym \) to the basis element \( M_{u^r} \). This is a graded coalgebra automorphism and an algebra anti-automorphism of \( WQSym \). Denoting by \( f^r \) the image of an element \( f \in WQSym \) under the coalgebraic complement involution, it can be shown that every packed word \( u \) satisfies

\[
(M_u)^r = M_{u^r}, \quad (X_u)^r = X_{u^r},
\]

where standard notations for classical bases of \( WQSym \) are being used (that is, \( M \) for the monomial basis, and \( X \) for the characteristic basis).

This can be restated in terms of ordered set partitions: For any ordered set partition \( R \) of \([n]\), let \( \overline{R} \) denote the complement of \( R \) (defined in `complement()`). Then,

\[
(M_A)^r = M_{\overline{A}}, \quad (X_A)^r = X_{\overline{A}}
\]

for any ordered set partition \( A \).

Recall that \( WQSym \) is a subring of the ring of all bounded-degree noncommutative power series in countably many indeterminates. The latter ring has an obvious continuous algebra anti-endomorphism which sends each letter \( x_i \) to \( x_i \) (and thus sends each monomial \( x_{i_1}x_{i_2}\cdots x_{i_n} \) to \( x_{i_n}x_{i_{n-1}}\cdots x_{i_1} \)). This anti-endomorphism is actually an involution. The coalgebraic complement involution is simply the restriction of this involution to the subring \( WQSym \).

The formula describing coalgebraic complements on the Q basis (`WordQuasiSymmetricFunctions. StronglyCoarser`) is more complicated, and requires some definitions. We define a partial order \( \leq \) on the set of all ordered set partitions as follows: \( A \leq B \) if and only if \( A \) is strongly finer than \( B \) (see `is_strongly_finer()` for a definition of this). The length \( \ell(R) \) of an ordered set partition \( R \) shall be defined as the number of parts of \( R \). Use the notation \( Q \) for the Q basis. For any ordered set partition \( A \) of \([n]\), we have

\[
(Q_A)^r = \sum_P c_{A,P} Q_P,
\]

where the sum is over all ordered set partitions \( P \) of \([n]\), and where the coefficient \( c_{A,P} \) is defined as follows:

- If there exists an ordered set partition \( R \) satisfying \( R \leq P \) and \( A \leq \overline{R} \), then this \( R \) is unique, and \( c_{A,P} = (-1)^{\ell(R) - \ell(P)} \).
- If there exists no such \( R \), then \( c_{A,P} = 0 \).

The formula describing coalgebraic complements on the \( \Phi \) basis (`WordQuasiSymmetricFunctions. StronglyFiner`) is identical to the above formula for the Q basis, except that the \( \leq \) sign has to be replaced by \( \geq \) in the definition of the coefficients \( c_{A,P} \). In fact, both formulas are particular cases of the general formula for involutions described in the documentation of `algebraic_complement()`.

If we let \( \pi \) be the canonical projection \( WQSym \to QSym \), then each \( f \in WQSym \) satisfies \( \pi(f^r) = \pi(f) \).

See also:

`algebraic_complement()`, `star_involution()`
EXAMPLES:
Recall that the index set for the bases of $WQSym$ is given by ordered set partitions, not packed words.
Translated into the language of ordered set partitions, the coalgebraic complement involution acts on the Monomial basis by complementing the ordered set partition. In other words, we have

$$(M_A)^r = M_{\pi}$$

for any standard ordered set partition $P$. Let us check this in practice:

```python
sage: WQSym = algebras.WQSym(ZZ)
sage: M = WQSym.M()
sage: M[[1,3],[2]].coalgebraic_complement()
M[[1,3],[2]]
sage: M[[1,2],[3]].coalgebraic_complement()
M[[2,3],[1]]
sage: M[[1],[4],[2,3]].coalgebraic_complement()
M[[4],[1],[2,3]]
sage: M[[1,4],[2,5],[3,6]].coalgebraic_complement()
M[[3,6],[2,5],[1,4]]
sage: (3*M[[1]] - 4*M[[1],[2]] + 5*M[[1],[2],[3]]).coalgebraic_complement()
-4*M[[1]] + 3*M[[1]] + 5*M[[2],[1]]
sage: X = WQSym.X()
sage: X[[1,3],[2]].coalgebraic_complement()
X[[1,3],[2]]
sage: C = WQSym.C()
sage: C[[1,3],[2]].coalgebraic_complement()
C[[1,3],[2]]
sage: Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].coalgebraic_complement()
Q[[2],[1,3],[6,5]]
sage: Phi = WQSym.Phi()
sage: Phi[[2],[1,3]].coalgebraic_complement()
-Phi[[2],[1,3]] + Phi[[2],[1,3]] + Phi[[2],[3],[1]]
```

The coalgebraic complement involution intertwines the antipode and the inverse of the antipode:

```python
sage: all( M[I].antipode().coalgebraic_complement().antipode() == M[I].coalgebraic_complement() for I in OrderedSetPartitions(4) )
True
```

Testing the $\pi(f^r) = \pi(f)$ relation above:

```python
sage: all( M[I].coalgebraic_complement().to_quasisymmetric_function() == M[I].to_quasisymmetric_function() for I in OrderedSetPartitions(4) )
True
```

Todo: Check further commutative squares.

**star_involution()**

Return the image of the element `self` of $WQSym$ under the star involution.
The star involution is the composition of the algebraic complement involution \( \text{algebraic_complement()} \) with the coalgebraic complement involution \( \text{coalgebraic_complement()} \). The composition can be performed in either order, as the involutions commute.

The star involution is a graded Hopf algebra anti-automorphism of \( W_{QS} \). Let \( f^* \) denote the image of an element \( f \in W_{QS} \) under the star involution. Let \( M, X, Q \) and \( \Phi \) stand for the monomial, characteristic, Q and Phi bases of \( W_{QS} \). For any ordered set partition \( A \) of \( [n] \), we let \( A^* \) denote the complement \( (\text{complement()} \) of the reversal \( (\text{reversed()} \) of \( A \). Then, for any ordered set partition \( A \) of \( [n] \), we have

\[
(M_A)^* = M_{A^*}, \quad (X_A)^* = X_{A^*}, \quad (Q_A)^* = Q_{A^*}, \quad (\Phi_A)^* = \Phi_{A^*}.
\]

The star involution \( \text{star_involution()} \) on the ring of noncommutative symmetric functions is a restriction of the star involution on \( W_{QS} \).

If we denote the star involution \( \text{star_involution()} \) of the quasisymmetric functions by \( f \mapsto f^* \), and if we let \( \pi \) be the canonical projection \( W_{QS} \to QS \), then each \( f \in W_{QS} \) satisfies \( \pi(f^*) = (\pi(f))^* \).

**Todo:** More commutative diagrams? FQSym and FSym need their own \text{star_involution} methods defined first.

---

**See also:**

\text{algebraic_complement()}, \text{coalgebraic_complement()}

**EXAMPLES:**

Keep in mind that the default input method for basis keys of \( W_{QS} \) is by entering an ordered set partition, not a packed word. Let us check the basis formulas for the star involution:

```python
sage: WQSym = algebras.WQSym(ZZ)
sage: M = WQSym.M()
sage: M[[1,3], [2,4,5]].star_involution()
M[{1, 2, 4}, {3, 5}]
sage: M[[1,3],[2]].star_involution()
M[{2}, {1, 3}]
sage: M[[1,4],[2,5],[3,6]].star_involution()
M[{1, 4}, {2, 5}, {3, 6}]
sage: (3*M[[1]] - 4*M[[]] + 5*M[[1],[2]]).star_involution()
-4*M[[]] + 3*M[[1]] + 5*M[{1}, {2}]
sage: X = WQSym.X()
sage: X[[1,3],[2]].star_involution()
X[{2}, {1, 3}]
sage: C = WQSym.C()
sage: C[[1,3],[2]].star_involution()
-C[{{1, 2, 3}}] - C[{{1, 3}, {2}}] + C[{{2}, {1, 3}}]
sage: Q = WQSym.Q()
sage: Q[[1,3], [2,4,5]].star_involution()
Q[{1, 2, 4}, {3, 5}]
sage: Phi = WQSym.Phi()
sage: Phi[[1,3], [2,4,5]].star_involution()
Phi[{1, 2, 4}, {3, 5}]
```

Testing the formulas for \((Q_A)^*\) and \((\Phi_A)^*\):
The star involution commutes with the antipode:

```
sage: all(M[I].antipode().star_involution() == M[I].star_involution().antipode() 
       for I in OrderedSetPartitions(4) )
True
```

Testing the \( \pi(\pi^*) = (\pi^*)^\pi \) relation:

```
sage: all( M[I].star_involution().to_quasisymmetric_function() 
       == M[I].to_quasisymmetric_function().star_involution() 
       for I in OrderedSetPartitions(4) )
True
```

Testing the fact that the star involution on the noncommutative symmetric functions is a restriction of
the star involution on \( W \mathcal{Q} \text{Sym} \):

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: R = NCSF.R()
sage: all(R[I].star_involution().to_fqsym().to_wqsym() 
       == R[I].to_fqsym().to_wqsym().star_involution() 
       for I in Compositions(4) )
True
```

**Todo:** Check further commutative squares.

to_quasisymmetric_function()

The projection of \texttt{self} to the ring \( \mathcal{Q} \text{Sym} \) of quasisymmetric functions.

There is a canonical projection \( \pi : W \mathcal{Q} \text{Sym} \to \mathcal{Q} \text{Sym} \) that sends every element \( M_P \) of the monomial basis of \( W \mathcal{Q} \text{Sym} \) to the monomial quasisymmetric function \( M_c \), where \( c \) is the composition whose parts are the sizes of the blocks of \( P \). This \( \pi \) is a ring homomorphism.

**OUTPUT:**

- an element of the quasisymmetric functions in the monomial basis

**EXAMPLES:**

```
sage: M = algebras.WQSym(QQ).M()
sage: M[[1,3],[2]].to_quasisymmetric_function()
M[2, 1]
sage: (M[[1,3],[2]] + 3*M[[2,3],[1]] - M[[1,2,3],]).to_quasisymmetric_ 
    function()
sage: X, Y = M[[1,3],[2]], M[[1,2,3],]
sage: X.to_quasisymmetric_function() * Y.to_quasisymmetric_function() == 
    (X*Y).to_quasisymmetric_function()
```

(continues on next page)
True

```python
sage: C = algebras.WQSym(QQ).C()
sage: C[[2,3],[1,4]].to_quasisymmetric_function() == M(C[[2,3],[1,4]]).to_quasisymmetric_function()
True

sage: C2 = algebras.WQSym(GF(2)).C()
sage: C2[[1,2],[3,4]].to_quasisymmetric_function()
M[2, 2]
sage: C2[[2,3],[1,4]].to_quasisymmetric_function()
M[4]
```

```python
class ParentMethods
Bases: object
degree_on_basis(t)

Return the degree of an ordered set partition in the algebra of word quasi-symmetric functions. This is the sum of the sizes of the blocks of the ordered set partition.

EXAMPLES:

```python
sage: A = algebras.WQSym(QQ).M()
sage: u = OrderedSetPartition([[2,1],])
sage: A.degree_on_basis(u)
2
sage: u = OrderedSetPartition([[2], [1]])
sage: A.degree_on_basis(u)
2
```

is_commutative()

Return whether self is commutative.

EXAMPLES:

```python
sage: M = algebras.WQSym(ZZ).M()
sage: M.is_commutative()
False
```

is_field(proof=True)

Return whether self is a field.

EXAMPLES:

```python
sage: M = algebras.WQSym(QQ).M()
sage: M.is_field()
False
```

one_basis()

Return the index of the unit.

EXAMPLES:
super_categories()

The super categories of self.

EXAMPLES:

```python
sage: from sage.combinat.chas.wqsym import WQSymBases
sage: WQSym = algebras.WQSym(ZZ)
```

```python
sage: bases = WQSymBases(WQSym, True)
sage: bases.super_categories()
[Category of realizations of Word Quasi-symmetric functions over Integer Ring,
 Join of Category of realizations of hopf algebras over Integer Ring
 and Category of graded algebras over Integer Ring
 and Category of graded coalgebras over Integer Ring,
 Category of graded connected hopf algebras with basis over Integer Ring]
```

```python
sage: bases = WQSymBases(WQSym, False)
sage: bases.super_categories()
[Category of realizations of Word Quasi-symmetric functions over Integer Ring,
 Join of Category of realizations of hopf algebras over Integer Ring
 and Category of graded algebras over Integer Ring
 and Category of graded coalgebras over Integer Ring,
 Join of Category of filtered connected hopf algebras with basis over Integer Ring
 and Category of graded algebras over Integer Ring
 and Category of graded coalgebras over Integer Ring]
```

class sage.combinat.chas.wqsym.WQSymBasis_abstract(alg, graded=True)

Bases: CombinatorialFreeModule, BindableClass

Abstract base class for bases of WQSym.

This must define two attributes:

• _prefix – the basis prefix
• _basis_name – the name of the basis (must match one of the names that the basis can be constructed from WQSym)

an_element()

Return an element of self.

EXAMPLES:

```python
sage: M = algebras.WQSym(QQ).M()
sage: M.an_element()
M[{1}] + 2*M[{1}, {2}]
```

options = Current options for WordQuasiSymmetricFunctions element - display: normal - objects: compositions

some_elements()

Return some elements of the word quasi-symmetric functions.
EXAMPLES:
```
sage: M = algebras.WQSym(QQ).M()
sage: M.some_elements()
[[], [1], [1, 2], [1] + [1, 2], [] + 1/2*[1]]
```

```python
class sage.combinat.chas.wqsym.WordQuasiSymmetricFunctions(R)
Bases: UniqueRepresentation, Parent
```

The word quasi-symmetric functions.

The ring of word quasi-symmetric functions can be defined as a subring of the ring of all bounded-degree non

commutative power series in countably many indeterminates (i.e., elements in \( R\langle\langle x_1, x_2, x_3, \ldots \rangle\rangle \) of bounded
degree). Namely, consider words over the alphabet \( \{1, 2, 3, \ldots \} \); every noncommutative power series is an in

finite \( R \)-linear combination of these words. For each such word \( w \), we define the packing of \( w \) to be the word

pack\( (w) \) that is obtained from \( w \) by replacing the smallest letter that appears in \( w \) by \( 1 \), the second-smallest

letter that appears in \( w \) by \( 2 \), etc. (for example, pack(4112774) = 3112443). A word \( w \) is said to be packed if

pack\( (w) = w \). For each packed word \( u \), we define the noncommutative power series \( M_u = \sum w \), where the

sum ranges over all words \( w \) satisfying pack\( (w) = u \). The span of these power series \( M_u \) is a subring of the

ring of all noncommutative power series; it is called the ring of word quasi-symmetric functions, and is denoted

by \( WQSym \).

For each nonnegative integer \( n \), there is a bijection between packed words of length \( n \) and ordered set partitions

of \( \{1, 2, \ldots, n\} \). Under this bijection, a packed word \( u = (u_1, u_2, \ldots, u_n) \) of length \( n \) corresponds to the

ordered set partition \( P = (P_1, P_2, \ldots, P_k) \) of \( \{1, 2, \ldots, n\} \) whose \( i \)-th part \( P_i \) (for each \( i \)) is the set of all

\( j \in \{1, 2, \ldots, n\} \) such that \( u_j = i \).

The basis element \( M_u \) is also denoted as \( M_P \) in this situation. The basis \( (M_P)_P \) is called the Monomial basis

and is implemented as Monomial.

Other bases are the cone basis (aka C basis), the characteristic basis (aka X basis), the Q basis and the Phi basis.

Bases of \( WQSym \) are implemented (internally) using ordered set partitions. However, the user may access specific basis vectors using either packed words or ordered set partitions. See the examples below, noting especially the section on ambiguities.

\( WQSym \) is endowed with a connected graded Hopf algebra structure (see Section 2.2 of [NoThWi08], Section

1.1 of [FoiMal14] and Section 4.3.2 of [MeNoTh11]) given by

\[
\Delta(M(P_1, \ldots, P_k)) = \sum_{i=0}^{k} M_{st(P_1, \ldots, P_i)} \otimes M_{st(P_{i+1}, \ldots, P_k)}.
\]

Here, for any ordered set partition \( (Q_1, \ldots, Q_k) \) of a finite set \( Z \) of integers, we let \( st(Q_1, \ldots, Q_k) \) denote the

set partition obtained from \( Z \) by replacing the smallest element appearing in it by 1, the second-smallest element

by 2, and so on.

A rule for multiplying elements of the monomial basis relies on the quasi-shuffle product of two ordered set

partitions. The quasi-shuffle product \( \square \) is given by ShuffleProduct_overlapping with the + operation in the

overlapping of the shuffles being the union of the sets. The product \( M_P \circ M_Q \) for two ordered set partitions \( P \) and

\( Q \) of \( [n] \) and \( [m] \) is then given by

\[
M_P \circ M_Q = \sum_{R\in P\square Q^+} M_R,
\]

where \( Q^+ \) means \( Q \) with all numbers shifted upwards by \( n \).

Sometimes, \( WQSym \) is also denoted as NCQSym.
EXAMPLES:

Constructing the algebra and its Monomial basis:

```
sage: WQSym = algebras.WQSym(ZZ)
sage: WQSym
Word Quasi-symmetric functions over Integer Ring
sage: M = WQSym.M()
sage: M
Word Quasi-symmetric functions over Integer Ring in the Monomial basis
sage: M[[[]]]
M[[]]
```

Calling basis elements using packed words:

```
sage: x = M[[1,2,1]]; x
M[[1, 3], {2}]
sage: x == M[[1,2,1]] == M[Word([1,2,1])]  
True
sage: y = M[[1,1,2]] - M[[1,2,2]]; y
-M[{1}, {2, 3}] + M[{1, 2}, {3}]
```

Calling basis elements using ordered set partitions:

```
sage: z = M[[1,2,3]]; z
M[[1, 2, 3]]
sage: z == M[[[1,2,3]]] == M[OrderedSetPartition([[1,2,3]])]  
True
sage: M[[1,2],[3]]
M[[1, 2], {3}]
```

Note that expressions above are output in terms of ordered set partitions, even when input as packed words. Output as packed words can be achieved by modifying the global options. (See `OrderedSetPartitions.options()` for further details.):

```
sage: M.options.objects = "words"
sage: y
-M[1, 2, 2] + M[1, 1, 2]
sage: M.options.display = "compact"
sage: y
-M[122] + M[112]
sage: z
M[111]
```

The options should be reset to display as ordered set partitions:
Illustration of the Hopf algebra structure:

```python
sage: M[[2, 3], [5], [6], [4], [1]].coproduct()
M[] # M[[2, 3], {5}, {6}, {4}, {1}] + M[{1, 2}] # M[{3}, {4}, {2}, {1}]
+ M[{1, 2}, {3}] # M[{3}, {2}, {1}] + M[{1, 2}, {3}, {4}] # M[{2}, {1}]
+ M[{1, 2}, {4}, {5}, {3}] # M({1}) + M[{2, 3}, {5}, {6}, {4}, {1}] # M[]
sage: _ == M[5,1,1,4,2,3].coproduct()
True
```

```python
sage: M[[1,1,1]] * M[[1,1,2]]  # packed words
M[[1, 2, 3], {4, 5}, {6}] + M[{1, 2, 3, 4, 5}, {6}]
+ M[{4, 5}, {1, 2, 3}, {6}] + M[{4, 5}, {1, 2, 3, 6}]
+ M[{4, 5}, {6}, {1, 2, 3}]
```

```python
sage: M[[1,2,3]].antipode()  # ordered set partition
-M[[1, 2, 3]]
```

```python
sage: x = M[[1,2,3]] + 3*M[[2,1]]
sage: x.counit()
0
```

**Ambiguities**

Some ambiguity arises when accessing basis vectors with the dictionary syntax, i.e., $M[...]$. A common example is when referencing an ordered set partition with one part. For example, in the expression $M[[1,2]]$, does $[[1,2]]$ refer to an ordered set partition or does $[1,2]$ refer to a packed word? We choose the latter: if the received arguments do not behave like a tuple of iterables, then view them as describing a packed word. (In the running example, one argument is received, which behaves as a tuple of integers.) Here are a variety of ways to get the same basis vector:

```python
sage: x = M[1,1]; x
M[[1, 2]]
sage: x == M[[1,1]]  # treated as word
True
sage: x == M[[1,2,1]] == M[[[1,2]]]  # treated as ordered set partitions
True
```

```python
sage: M[[1,3],[2]]  # treat as ordered set partition
M[[1, 3], {2}]
sage: M[[1,3],[2]] == M[1,2,1]  # treat as word
True
```

**Todo:**

- Dendriform structure.
alias of \texttt{Cone}\

class \texttt{Characteristic(alg)}\
Bases: \texttt{WQSymBasis\_abstract}\

The Characteristic basis of \texttt{WQSym}.\

The \textit{Characteristic basis} is a graded basis \((X_P)\) of \texttt{WQSym}, indexed by ordered set partitions \(P\). It is defined by

\[ X_P = (-1)^{\ell(P)} M_P, \]

where \((M_P)_P\) denotes the Monomial basis, and where \(\ell(P)\) denotes the number of blocks in an ordered set partition \(P\).

EXAMPLES:

\begin{verbatim}
    sage: WQSym = algebras.WQSym(QQ)
    sage: X = WQSym.X(); X
    Word Quasi-symmetric functions over Rational Field in the Characteristic basis
    sage: X[[[1,2,3]]] * X[[1,2],[3]]
    X[[1, 2, 3], {4, 5}, {6}] - X[[1, 2, 3, 4, 5}, {6}]
    + X[{4, 5}, {1, 2, 3}, {6}] - X[{4, 5}, {1, 2, 3, 6}]
    + X[{4, 5}, {6}, {1, 2, 3}]
    sage: X[[1, 4], [3], [2]].coproduct()
    X[] # X[[1, 4], {3}, {2}] + X[[1, 2]] # X[{2}, {1}]
    + X[{1, 3}, {2}] # X[[1]] + X[{1, 4}, {3}, {2}] # X[]
    sage: M = WQSym.M()
    sage: M(X[[[1, 2, 3],]])
    -M[{{1, 2, 3}}]
    sage: M(X[[[1, 3], [2]]])
    M[{{1}, {3}}, {2}]
    sage: X(M[[[1, 2, 3],]])
    -X[{{1, 2, 3}}]
    sage: X(M[[[1, 3], [2]]])
    X[{{1}, {3}}, {2}]
\end{verbatim}

class \texttt{Element}\
Bases: \texttt{IndexedFreeModuleElement}\

\texttt{algebraic\_complement()}\n
Return the image of the element \texttt{self} of \texttt{WQSym} under the algebraic complement involution.\n
See \texttt{WQSymBases.ElementMethods.algebraic\_complement()} for a definition of the involution and for examples.\n
See also: \texttt{coalgebraic\_complement()}, \texttt{star\_involution()}\n
EXAMPLES:
class Cone(alg)

Bases: WQSymBasis_abstract

The Cone basis of WQSym.

Let \((X_P)_P\) denote the Characteristic basis of WQSym. Denote the quasi-shuffle of two ordered set partitions \(A\) and \(B\) by \(A \triangleleft B\). For an ordered set partition \(P = (P_1, \ldots, P_\ell)\), we form a list of ordered set partitions \([P] := (P_1', \ldots, P_k')\) as follows. Define a strictly decreasing sequence of integers \(\ell + 1 = i_0 > i_1 > \cdots > i_k = 1\) recursively by requiring that \(\min P_{i_j} \leq \min P_a\) for all \(a < i_{j-1}\). Set \(P_j' = (P_{i_j}, \ldots, P_{i_{j-1}})\).
The Cone basis $(C_P)_P$ is defined by

$$C_P = \sum_Q X_Q,$$

where the sum is over all elements $Q$ of the quasi-shuffle product $P'_1 \square P'_2 \square \ldots \square P'_k$ with $[P] = (P'_1, \ldots, P'_k)$.

**EXAMPLES:**

```sage
sage: WQSym = algebras.WQSym(QQ)
sage: C = WQSym.C()
sage: C
Word Quasi-symmetric functions over Rational Field in the Cone basis

sage: X = WQSym.X()
sage: X(C[[2,3],[1,4]])
X[{1, 2, 3, 4}] + X[{1, 4}, {2, 3}] + X[{2, 3}, {1, 4}]

sage: X(C[[1,4],[2,3]])
X[{1, 4}, {2, 3}]

sage: X(C[[2,3],[1],[4]])
X[{1}, {2, 3}, {4}] + X[{1}, {2, 3, 4}] + X[{1}, {4}, {2, 3}]
+ X[{1, 2, 3}, {4}] + X[{2, 3}, {1}, {4}]

sage: X(C[[3],[2,5],[1],[4]])
X[{1, 2, 3, 4, 5}] + X[{1, 2, 4, 5}, {3}] + X[{1, 3, 4}, {2, 5}]
+ X[{1, 4}, {2, 3, 5}] + X[{1, 4}, {2, 5}, {3}]
+ X[{2, 3, 5}, {1, 4}] + X[{2, 3, 5}, {1, 4}, {3}]
+ X[{2, 5}, {1, 2, 4, 5}] + X[{2, 5}, {1, 4}, {3}]
+ X[{3, 1, 2, 4, 5}] + X[{3}, {2, 5}, {1, 4}]

sage: C(X[[2,3],[1,4]])
-C[{1, 2, 3, 4}] - C[{1, 4}, {2, 3}] + C[{2, 3}, {1, 4}]
```

**REFERENCES:**

- Section 4 of [Early2017]

**Todo:** Experiments suggest that `algebraic_complement()`, `coalgebraic_complement()`, and `star_involution()` should have reasonable formulas on the C basis; at least the coefficients of the outputs on any element of the C basis seem to be always 0, 1, −1. Is this true? What is the formula?

**some_elements()**

Return some elements of the word quasi-symmetric functions in the Cone basis.

**EXAMPLES:**

```sage
sage: C = algebras.WQSym(QQ).C()
sage: C.some_elements()
[C[], C[{1}], C[{1, 2}], C[] + 1/2*C[{1}]]
```

**M**

alias of `Monomial`

**class Monomial(alg, graded=True)**

Bases: `WQSymBasis_abstract`
The Monomial basis of $WQSym$.

The family $(M_u)$, as defined in `WordQuasiSymmetricFunctions` with $u$ ranging over all packed words, is a basis for the free $R$-module $WQSym$ and called the Monomial basis. Here it is labelled using ordered set partitions.

**EXAMPLES:**

```python
sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); M
Word Quasi-symmetric functions over Rational Field in the Monomial basis
sage: sorted(M.basis(2))
[[1], [2]], [[2], [1]], [[1, 2]]
```

**coproduct_on_basis**$(x)$

Return the coproduct of `self` on the basis element indexed by the ordered set partition $x$.

**EXAMPLES:**

```python
sage: M = algebras.WQSym(QQ).M()
sage: M.coproduct(M.one())  # indirect doctest
M[[1]] # M[]
```

**product_on_basis**$(x,y)$

Return the (associative) $*$ product of the basis elements of `self` indexed by the ordered set partitions $x$ and $y$.

This is the shifted quasi-shuffle product of $x$ and $y$.

**EXAMPLES:**

```python
sage: A = algebras.WQSym(QQ).M()
sage: x = OrderedSetPartition([[1], [2, 3]])
sage: y = OrderedSetPartition([[1, 2]])
sage: z = OrderedSetPartition([[1, 2], [3]])
sage: A.product_on_basis(x, y)
M[[1], [2, 3], [4, 5]] + M[[1], [2, 3, 4, 5]]
```

174 Chapter 5. Comprehensive Module List
**Phi**
alias of *StronglyFiner*

**Q**
alias of *StronglyCoarser*

class *StronglyCoarser*(alg)

Bases: *WQSymBasis_abstract*

The Q basis of \(\text{WQSym}\).

We define a partial order \(\leq\) on the set of all ordered set partitions as follows: \(A \leq B\) if and only if \(A\) is strongly finer than \(B\) (see `is_strongly_finer()` for a definition of this).

The \(Q\) basis \((Q_P)_{P}\) is a basis of \(\text{WQSym}\) indexed by ordered set partitions, and is defined by

\[
Q_P = \sum M_W,
\]

where the sum is over ordered set partitions \(W\) satisfying \(P \leq W\).

EXAMPLES:

```python
sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); Q = WQSym.Q()
sage: Q
Word Quasi-symmetric functions over Rational Field in the Q basis

sage: Q(M[[2,3],[1,4]])
Q[2, 3, {1, 4}]
sage: Q(M[[1,2],[3,4]])
Q[1, 2, {3, 4}]

sage: M(Q[[1,2],[3,4]])
M[1, 2, {3, 4}] + M[1, 2, {3, 4}]
sage: M(Q[[2,3],[1],[4]])
M[2, 3, {1}, {4}] + M[2, 3, {1}, {4}]
sage: M(Q[[3],[2],[5],[1,4]])
M[3, {2, 5}, {1, 4}]
sage: M(Q[[1,4],[2,3],[5],[6]])
M[1, 4, {2, 3, 5, 6}] + M[1, 4, {2, 3, 5, 6}]

sage: Q([[1, 3], [2]] * Q([[1], [2]])
Q[1, 3, {2, 4, 5}] + Q[[1, 3], {4}, {2}, {5}]
+ Q[1, 3, {4}, {2}, {5}] + Q[4, {1, 3}, {2}, {5}]
+ Q[4, {1, 3}, {2}, {5}] + Q[4, {1, 3}, {2}]

sage: Q([[1, 3], [2]]).coproduct()
Q[] # Q[1, 3, {2}] + Q[1, 2] # Q[1] + Q[1, 3, {2}] # Q[]
```

- Section 6 of [BerZab05]

class *Element*

Bases: *IndexedFreeModuleElement*
algebraic_complement()  
Return the image of the element self of \(WQSym\) under the algebraic complement involution.  
See `WQSymBases.ElementMethods.algebraic_complement()` for a definition of the involution and for examples.  
See also:  
coalgebraic_complement(), star_involution()  
EXAMPLES:

```sage
WQSym = algebras.WQSym(ZZ)
Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].algebraic_complement()
Q[{3, 4}, {1, 2, 5, 6}] + Q[{3, 4}, {5, 6}, {1, 2}]
- Q[{3, 4, 5, 6}, {1, 2}]
sage: Q[[3], [1, 2], [4]].algebraic_complement()
Q[{3}, {1, 2}, {4}]
```

coalgebraic_complement()  
Return the image of the element self of \(WQSym\) under the coalgebraic complement involution.  
See `WQSymBases.ElementMethods.coalgebraic_complement()` for a definition of the involution and for examples.  
See also:  
algebraic_complement(), star_involution()  
EXAMPLES:

```sage
WQSym = algebras.WQSym(ZZ)
Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].coalgebraic_complement()
Q[{1, 2, 5, 6}, {3, 4}] + Q[{5, 6}, {1, 2}, {3, 4}] - Q[{5, 6}, {1, 2, 3, 4}]
sage: Q[[3], [1, 2], [4]].coalgebraic_complement()
Q[{2}, {1, 3, 4}]
```

star_involution()  
Return the image of the element self of \(WQSym\) under the star involution.  
See `WQSymBases.ElementMethods.star_involution()` for a definition of the involution and for examples.  
See also:  
algebraic_complement(), coalgebraic_complement()  
EXAMPLES:

```sage
WQSym = algebras.WQSym(ZZ)
Q = WQSym.Q()
sage: Q[[1,2],[5,6],[3,4]].star_involution()
Q[{3, 4}, {1, 2}, {5, 6}]
sage: Q[[3], [1, 2], [4]].star_involution()
Q[{1}, {3, 4}, {2}]
```
coproduct_on_basis(x)

Return the coproduct of self on the basis element indexed by the ordered set partition x.

EXAMPLES:

```python
sage: Q = algebras.WQSym(QQ).Q()
sage: Q.coproduct(Q.one()) # indirect doctest
Q[] # Q[]
sage: Q.coproduct( Q([[1]]) ) # indirect doctest
Q[] # Q[[1]] + Q[[]] # Q[]
sage: Q.coproduct( Q([1,2]]) )
Q[] # Q[[1, 2]] + Q[[1, 2]] # Q[]
sage: Q.coproduct( Q([1], [2])) )
Q[] # Q[[1], {2}] + Q[{1}] # Q[[]] + Q[[]] # Q[]
sage: Q.coproduct( Q([1,2],[3],[4]).coproduct() )
Q[] # Q[[1, 2], {3}, {4}] + Q[[1, 2]] # Q[[]] + Q[[]] # Q[] + Q[[1, 2], {3}] # Q[[1]] + Q[[1, 2], {3}, {4}] # Q[]
```

product_on_basis(x, y)

Return the (associative) \(*\) product of the basis elements of the Q basis self indexed by the ordered set partitions \(x\) and \(y\).

This is the shifted shuffle product of \(x\) and \(y\).

EXAMPLES:

```python
sage: A = algebras.WQSym(QQ).Q()
sage: x = OrderedSetPartition([[1],[2,3]])
sage: y = OrderedSetPartition([[[1],[2]]])
sage: z = OrderedSetPartition([[1,2],[3]])
sage: A.product_on_basis(x, y)
Q[[1], {2, 3}, {4}, {5}] + Q[[1], {4}, {5}, {2}, 3] + Q[4, 5, {1}, {2}, {3}]
sage: A.product_on_basis(x, z)
Q[[1], {2, 3}, {4}, {5}, {6}] + Q[[1], {4}, {5}, {2}, {3}, {6}] + Q[4, 5, {1}, {2}, {3}, {6}] + Q[4, 5, {1}, {6}, {2}, {3}] + Q[4, 5, {6}, {1}, {2}, {3}]
sage: A.product_on_basis(y, y)
Q[[1, 2], {3}, {4}] + Q[3, 4, {1}, 2]
```

some_elements()

Return some elements of the word quasi-symmetric functions in the Q basis.

EXAMPLES:

```python
sage: Q = algebras.WQSym(QQ).Q()
sage: Q.some_elements()
[Q[], Q[[1]], Q[[1, 2]], Q[] + 1/2*Q[[1]]]
```

class StronglyFiner(alg)

Bases: WQSymBasis_abstract

The Phi basis of \(WQSym\).

We define a partial order \(\leq\) on the set of all ordered set partitions as follows: \(A \leq B\) if and only if \(A\) is strongly finer than \(B\) (see \texttt{is_strongly_finer()} for a definition of this).
The \textit{Phi basis} \( (\Phi_P) \) is a basis of \( WQS(y)m \) indexed by ordered set partitions, and is defined by

\[
\Phi_P = \sum M_W,
\]

where the sum is over ordered set partitions \( W \) satisfying \( W \leq P \).

Novelli and Thibon introduced this basis in [NovThi06] Section 2.7.2, and called it the quasi-ribbon basis. It later reappeared in [MeNoTh11] Section 4.3.2.

**EXAMPLES:**

```python
sage: WQSym = algebras.WQSym(QQ)
sage: M = WQSym.M(); Phi = WQSym.Phi()
sage: Phi
Word Quasi-symmetric functions over Rational Field in the Phi basis
sage: Phi(M[[2,3],[1,4]])
Phi\{2\}, \{3\}, \{1\}, \{4\} - Phi\{2\}, \{3\}, \{1, 4\}
  - Phi\{2, 3\}, \{1\}, \{4\} + Phi\{2, 3\}, \{1, 4\}
sage: Phi(M[[1,2],[3,4]])
Phi\{1\}, \{2\}, \{3\}, \{4\} - Phi\{1\}, \{2\}, \{3, 4\}
  - Phi\{1, 2\}, \{3\}, \{4\} + Phi\{1, 2\}, \{3, 4\}
sage: M(Phi[[2,3],[1],[4]])
M\{2\}, \{3\}, \{1\}, \{4\} + M\{2, 3\}, \{1\}, \{4\}
+ M\{2, 3\}, \{1\}, \{4\} + M\{2, 3\}, \{1, 4\}
sage: Phi[[1,],[1],[4]]
Phi\{1\} * Phi\{1\} * Phi\{1\}
Phi\{1, 2\}, \{4\} + Phi\{2, 1\}, \{4\}
  + Phi\{1\}, \{2\}, \{4\} + Phi\{1\}, \{2\}, \{4\}
  + Phi\{1\}, \{2\}, \{4\} + Phi\{1\}, \{2\}, \{4\}
sage: M(Phi[[3,5],[1,4],[2]].coproduct())
Phi\{3\}, \{5\}, \{1, 4\}, \{2\}
  + Phi\{3\}, \{5\}, \{1\}, \{4\}, \{2\}
  + Phi\{3\}, \{5\}, \{1\}, \{4\}, \{2\}
  + Phi\{3\}, \{5\}, \{1\}, \{4\}, \{2\}
```

- Section 2.7.2 of [NovThi06]

**class Element**

**Bases:** IndexedFreeModuleElement

**algebraic_complement()**

Return the image of the element \textit{self} of \( WQS(y)m \) under the algebraic complement involution.

See \textit{WQSymBases.ElementMethods.algebraic_complement()} for a definition of the involution and for examples.
See also:

*coalgebraic_complement(), star_involution()

EXAMPLES:

```python
codeblock
sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1],[2,4],[3]].algebraic_complement()
-Phi[{3}, {2}, {4}, {1}] + Phi[{3}, {2, 4}, {1}] + Phi[{3}, {4}, {2}, {1}]
sage: Phi[[1],[2,3],[4]].algebraic_complement()
-Phi[{4}, {2}, {3}, {1}] + Phi[{4}, {2, 3}, {1}] + Phi[{4}, {3}, {2}, {1}]
```

**coalgebraic_complement()**

Return the image of the element `self` of `WQSym` under the coalgebraic complement involution.

See `WQSymBases.ElementMethods.coalgebraic_complement()` for a definition of the involution and for examples.

See also:

*algebraic_complement(), star_involution()

EXAMPLES:

```python
codeblock
sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1,2],[5,6],[3,4]].coalgebraic_complement()
Phi[{3, 4}, {1, 2}, {5, 6}]
sage: Phi[[3], [1, 2], [4]].star_involution()
Phi[{1}, {3, 4}, {2}]
```

**star_involution()**

Return the image of the element `self` of `WQSym` under the star involution.

See `WQSymBases.ElementMethods.star_involution()` for a definition of the involution and for examples.

See also:

*algebraic_complement(), coalgebraic_complement()

EXAMPLES:

```python
codeblock
sage: WQSym = algebras.WQSym(ZZ)
sage: Phi = WQSym.Phi()
sage: Phi[[1],[2,4],[3]].algebraic_complement()
-Phi[{3}, {2}, {4}, {1}] + Phi[{3}, {2, 4}, {1}] + Phi[{3}, {4}, {2}, {1}]
sage: Phi[[1],[2,3],[4]].algebraic_complement()
-Phi[{4}, {2}, {3}, {1}] + Phi[{4}, {2, 3}, {1}] + Phi[{4}, {3}, {2}, {1}]
```

**coproduct_on_basis()**

Return the coproduct of `self` on the basis element indexed by the ordered set partition `x`.

5.1. Comprehensive Module List
The coproduct of the basis element $\Phi_x$ indexed by an ordered set partition $x$ of $[n]$ can be computed by the following formula ([NovThi06]):

$$\Delta \Phi_x = \sum \Phi_y \otimes \Phi_z,$$

where the sum ranges over all pairs $(y, z)$ of ordered set partitions $y$ and $z$ such that:
- $y$ and $z$ are ordered set partitions of two complementary subsets of $[n]$;
- $x$ is obtained either by concatenating $y$ and $z$, or by first concatenating $y$ and $z$ and then merging the two “middle blocks” (i.e., the last block of $y$ and the first block of $z$); in the latter case, the maximum of the last block of $y$ has to be smaller than the minimum of the first block of $z$ (so that when merging these blocks, their entries don’t need to be sorted).

EXAMPLES:

```sage
sage: Phi = algebras.WQSym(QQ).Phi()
sage: Phi.coproduct(Phi.one())
# indirect doctest
Phi[] # Phi[]
sage: Phi.coproduct( Phi([[1]]) )  # indirect doctest
Phi[] # Phi([1]) + Phi([1]) # Phi[]
sage: Phi.coproduct( Phi([[1,2]]) )
Phi[] # Phi([1, 2]) + Phi([1]) # Phi([1]) + Phi([1, 2]) # Phi[]
sage: Phi.coproduct( Phi([[1],[2]]) )
Phi[] # Phi([1], [2]) + Phi([1]) # Phi([1]) + Phi([1], [2]) # Phi[]
sage: Phi.coproduct( Phi([[1,2],[3],[4]]) )
Phi[] # Phi([1, 2], [3], [4]) + Phi([1]) # Phi([1]) + Phi([1], [2], [3]) + Phi([1, 2]) # Phi([1]) + Phi([1], [2], [3]) # Phi([1]) + Phi([1, 2], [3], [4]) # Phi[]
```

product_on_basis($x, y$)

Return the (associative) $\ast$ product of the basis elements of the Phi basis self indexed by the ordered set partitions $x$ and $y$.

This is obtained by the following algorithm (going back to [NovThi06]):

Let $x$ be an ordered set partition of $[m]$, and $y$ an ordered set partition of $[n]$. Transform $x$ into a list $u$ of all the $m$ elements of $[m]$ by writing out each block of $x$ (in increasing order) and putting bars between each two consecutive blocks; this is called a barred permutation. Do the same for $y$, but also shift each entry of the resulting barred permutation by $m$. Let $v$ be the barred permutation of $[m+n] \setminus [m]$ thus obtained. Now, shuffle the two barred permutations $u$ and $v$ (ignoring the bars) in all the $\binom{m+n}{n}$ possible ways. For each shuffle obtained, place bars between some entries of the shuffle, according to the following rule:
- If two consecutive entries of the shuffle both come from $u$, then place a bar between them if the corresponding entries of $u$ had a bar between them.
- If the first of two consecutive entries of the shuffle comes from $v$ and the second from $u$, then place a bar between them.

This results in a barred permutation of $[m+n]$. Transform it into an ordered set partition of $[m+n]$, by treating the bars as dividers separating consecutive blocks.

The product $\Phi_x \Phi_y$ is the sum of $\Phi_p$ with $p$ ranging over all ordered set partitions obtained this way.

EXAMPLES:

```sage
sage: A = algebras.WQSym(QQ).Phi()
sage: x = OrderedSetPartition([[1],[2,3]])
sage: y = OrderedSetPartition([[1,2]])
sage: z = OrderedSetPartition([[1,2],[3]])
```

(continues on next page)
some_elements()

Return some elements of the word quasi-symmetric functions in the Phi basis.

EXAMPLES:

```
sage: Phi = algebras.WQSym(QQ).Phi()
sage: Phi.some_elements()
[Phi[], Phi[1], Phi[1, 2], Phi[], 1/2*Phi[1]]
```

X

alias of Characteristic

a_realization()

Return a particular realization of self (the $M$-basis).

EXAMPLES:

```
sage: WQSym = algebras.WQSym(QQ)
sage: WQSym.a_realization()
Word Quasi-symmetric functions over Rational Field in the Monomial basis
```

options = Current options for WordQuasiSymmetricFunctions element - display: normal - objects: compositions
5.1.17 Cluster algebras and quivers

- A compendium on the cluster algebra and quiver package in Sage [MS2011]
- Quiver mutation types
- Quiver
- ClusterSeed

5.1.18 ClusterSeed

A cluster seed is a pair \((B, x)\) with \(B\) being a skew-symmetrizable \((n + m) \times n\)-matrix and with \(x\) being an \(n\)-tuple of independent elements in the field of rational functions in \(n\) variables.

For the compendium on the cluster algebra and quiver package see [MS2011].

See also:
For mutation types of cluster seeds, see `sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType()`. Cluster seeds are closely related to `sage.combinat.cluster_algebra_quiver.quiver.ClusterQuiver()`.

```python
class sage.combinat.cluster_algebra_quiver.cluster_seed.ClusterSeed(data, frozen=None, is_principal=False, user_labels=None, user_labels_prefix='x'):
```

Bases: `SageObject`

The cluster seed associated to an exchange matrix.

INPUT:

- `data` – can be any of the following:

```python
* `:class:`QuiverMutationType`
```

- `str` – a string representing a `QuiverMutationType` or a common quiver type (see Examples)
- `ClusterQuiver`
- `Matrix` – a skew-symmetrizable matrix
- `DiGraph` – must be the input data for a quiver
- `List of edges` – must be the edge list of a digraph for a quiver
EXAMPLES:

```python
sage: S = ClusterSeed(['A', 5]); S
A seed for a cluster algebra of rank 5 of type ['A', 5]

sage: S = ClusterSeed(['A', [2, 5], 1]); S
A seed for a cluster algebra of rank 7 of type ['A', [2, 5], 1]

sage: T = ClusterSeed(S); T
A seed for a cluster algebra of rank 7

sage: T = ClusterSeed(S._M); T
A seed for a cluster algebra of rank 7

sage: T = ClusterSeed(S.quiver()._digraph); T
A seed for a cluster algebra of rank 7

sage: T = ClusterSeed(S.quiver()._digraph.edges(sort=True)); T
A seed for a cluster algebra of rank 7

sage: S = ClusterSeed(['B', 2]); S
A seed for a cluster algebra of rank 2 of type ['B', 2]

sage: S = ClusterSeed(['C', 2]); S
A seed for a cluster algebra of rank 2 of type ['B', 2]

sage: S = ClusterSeed(['A', [5, 0], 1]); S
A seed for a cluster algebra of rank 5 of type ['D', 5]

sage: S = ClusterSeed(['GR', [3, 7]]); S
A seed for a cluster algebra of rank 6 of type ['E', 6]

sage: S = ClusterSeed(['F', 4, [2, 1]]); S
A seed for a cluster algebra of rank 6 of type ['F', 4, [1, 2]]

sage: S = ClusterSeed(['A', 4]); S._use_fpolys
True
sage: S._use_d_vec
True
sage: S._use_g_vec
True
sage: S._use_c_vec
True

sage: S = ClusterSeed(['A', 4]); S.use_fpolys(False); S._use_fpolys
False

sage: S = ClusterSeed(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']]),
.....:    frozen=['c']); S
A seed for a cluster algebra of rank 4 with 1 frozen variable

sage: S = ClusterSeed(['D', 4], user_labels=[-1, 0, 1, 2]); S
A seed for a cluster algebra of rank 4 of type ['D', 4]

LLM_gen_set(size_limit=-1)
```

5.1. Comprehensive Module List
Produce a list of upper cluster algebra elements corresponding to all vectors in \(\{0, 1\}^n\).

**INPUT:**

- \(B\) – a skew-symmetric matrix.
- `size_limit` – a limit on how many vectors you want the function to return.

**OUTPUT:**

An array of elements in the upper cluster algebra.

**EXAMPLES:**

```python
sage: B = matrix([[0, 1, 0, 0], [-1, 0, -1, 0], [0, -1, 0], [1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: C = ClusterSeed(B)
sage: C.LLM_gen_set()
[1, (x1 + x3)/x0, (x0*x4 + x2)/x1, (x0*x3*x4 + x1*x2 + x2*x3)/(x0*x1), (x1*x5 + 1)/x2, (x1^2*x5 + x1*x3*x5 + x1 + x3)/(x0*x2), (x0*x1*x4*x5 + x0*x4 + x2)/(x1*x2), (x0*x1*x3*x4*x5 + x0*x3*x4 + x1*x2 + x2*x3)/(x0*x1*x2)]
```

**b_matrix()**

Return the \(B\)-matrix of `self`.

**EXAMPLES:**

```python
sage: ClusterSeed(['A', 4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]
sage: ClusterSeed(['B', 4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -2 0]
sage: ClusterSeed(['D', 4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 -1]
[ 0 1 0 0]
[ 0 1 0 0]
sage: ClusterSeed(QuiverMutationType([['A', 2], ['B', 2]])).b_matrix()
[ 0 1 0 0]
[-1 0 0 0]
[ 0 0 0 1]
[ 0 0 -2 0]
```

**b_matrix_class**(\(\text{depth} = +\text{Infinity}, \text{up_to_equivalence} = \text{True})}
Return all $B$-matrices in the mutation class of self.

**INPUT:**

- `depth` – (default: infinity) integer or infinity, only seeds with distance at most $\text{depth}$ from self are returned
- `up_to_equivalence` – (default: True) if True, only $B$-matrices up to equivalence are considered.

**EXAMPLES:**

- for examples see `b_matrix_class_iter()`

### `b_matrix_class_iter(depth=+Infinity, up_to_equivalence=True)`

Return an iterator through all $B$-matrices in the mutation class of self.

**INPUT:**

- `depth` – (default: infinity) integer or infinity, only seeds with distance at most $\text{depth}$ from self are returned
- `up_to_equivalence` – (default: True) if True, only $B$-matrices up to equivalence are considered.

**EXAMPLES:**

A standard finite type example:

```python
sage: S = ClusterSeed(['A',4])
sage: it = S.b_matrix_class_iter()
sage: for T in it: print(T)
[ 0 0 0 1]
[ 0 0 1 1]
[ 0 -1 0 0]
[-1 -1 0 0]
[ 0 0 0 1]
[ 0 0 1 0]
[ 0 -1 0 1]
[-1 0 -1 0]
[ 0 0 1 1]
[ 0 0 0 -1]
[-1 0 0 0]
[-1 1 0 0]
[ 0 0 0 1]
[ 0 0 -1 1]
[ 0 1 0 -1]
[-1 -1 1 0]
[ 0 0 0 1]
[ 0 0 -1 0]
[ 0 1 0 -1]
[-1 0 1 0]
[ 0 0 0 -1]
[ 0 0 -1 1]
[ 0 1 0 -1]
[ 1 -1 1 0]
```

A finite type example with given depth:
```
sage: it = S.b_matrix_class_iter(depth=1)
sage: for T in it: print(T)
[ 0 0 0 1]
[ 0 0 1 1]
[ 0 -1 0 0]
[-1 -1 0 0]
[ 0 0 0 1]
[ 0 0 1 0]
[ 0 -1 0 1]
[-1 0 -1 0]
[ 0 0 1 1]
[ 0 0 0 -1]
[-1 0 0 0]
[-1 1 0 0]
```

Finite type example not considered up to equivalence:

```
sage: S = ClusterSeed(['A',3])
sage: it = S.b_matrix_class_iter(up_to_equivalence=False)
sage: b_matrix_class = list(it)
sage: len(b_matrix_class)
14
sage: b_matrix_class[0]
[ 0 1 0]
[-1 0 -1]
[ 0 1 0]
```

Infinite (but finite mutation) type example:

```
sage: S = ClusterSeed(['A',[1,2],1])
sage: it = S.b_matrix_class_iter()
sage: for T in it: print(T)
[ 0 1 1]
[-1 0 1]
[-1 -1 0]
[ 0 -2 1]
[ 2 0 -1]
[-1 1 0]
```

Infinite mutation type example:

```
sage: S = ClusterSeed(['E',10])
sage: it = S.b_matrix_class_iter(depth=3)
sage: len ([T for T in it])
266
```

For a cluster seed from an arbitrarily labelled digraph:

```
sage: dg = DiGraph([('a', 'b'), ('b', 'c')], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['b'])
sage: S.b_matrix_class()
[ [ 0 0 ] [ 0 0 ] [0 0]
```

(continues on next page)
c_matrix(show_warnings=True)

Return all \(c\)-vectors of self.

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.c_matrix()
[ 1 0 0]
[ 0 0 -1]
[ 0 -1 0]
sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False)
sage: S.use_c_vectors(False); S.use_d_vectors(False); S.track_mutations(False)
sage: S.c_matrix()
Traceback (most recent call last):
... ValueError: Unable to calculate c-vectors. Need to use c vectors.
```

c_vector\((k)\)

Return the \(k\)-th \(c\)-vector of self. It is obtained as the \(k\)-th column vector of the bottom part of the \(B\)-matrix of self.

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.c_vector(k) for k in range(3)]
[(1, 0, 0), (0, 0, -1), (0, -1, 0)]
sage: S = ClusterSeed(Matrix([[0,1],[-1,0],[1,0],[-1,1]])); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
sage: S.c_vector(0)
(1, 0)
sage: S = ClusterSeed(Matrix([[0,1],[-1,0],[1,0],[-1,1]]))
sage: S.use_c_vectors(bot_is_c=True); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
```

(continues on next page)
cluster()

Return a copy of the cluster of self.

EXAMPLES:

```sage
S = ClusterSeed(['A', 3])
S.cluster()
[x0, x1, x2]
```

```sage
S.mutate(1)
S.cluster()
[x0, (x0*x2 + 1)/x1, x2]
```

```sage
S.mutate(2)
S.cluster()
[x0, (x0*x2 + 1)/x1, (x0*x2 + x1 + 1)/(x1*x2)]
```

```sage
S.mutate([2, 1])
S.cluster()
[x0, x1, x2]
```

class_cluster(depth=+Infinity, show_depth=False, up_to_equivalence=True)

Return the cluster class of self with respect to certain constraints.

INPUT:

- **depth** – (default: infinity) integer, only seeds with distance at most depth from self are returned
- **return_depth** – (default: False) - if True, ignored if depth is set; returns the depth of the mutation class, i.e., the maximal distance from self of an element in the mutation class
- **up_to_equivalence** – (default: True) if True, only clusters up to equivalence are considered.

EXAMPLES:

- for examples see `cluster_class_iter()`

cluster_class_iter(depth=+Infinity, show_depth=False, up_to_equivalence=True)

Return an iterator through all clusters in the mutation class of self.

INPUT:

- **depth** – (default: infinity) integer or infinity, only seeds with distance at most depth from self are returned
- **show_depth** – (default: False) if True, ignored if depth is set; returns the depth of the mutation class, i.e., the maximal distance from self of an element in the mutation class
- **up_to_equivalence** – (default: True) if True, only clusters up to equivalence are considered.

EXAMPLES:

A standard finite type example:
Combinatorics, Release 10.1

\begin{verbatim}
sage: S = ClusterSeed(['A',3])
sage: it = S.cluster_class_iter()
sage: cluster_class = list(it)
sage: len(cluster_class)
14
sage: cluster_class[0]
[x0, x1, x2]

A finite type example with given depth:

sage: it = S.cluster_class_iter(depth=1)
sage: for T in it: print(T)
[x0, x1, x2]
[x0, x1, (x1 + 1)/x2]
[x0, (x0*x2 + 1)/x1, x2]
[(x1 + 1)/x0, x1, x2]

A finite type example where the depth is returned while computing:

sage: it = S.cluster_class_iter(show_depth=True)
sage: _ = list(it)
Depth: 0 found: 1 Time: ... s
Depth: 1 found: 4 Time: ... s
Depth: 2 found: 9 Time: ... s
Depth: 3 found: 13 Time: ... s
Depth: 4 found: 14 Time: ... s

Finite type examples not considered up to equivalence:

sage: it = S.cluster_class_iter(up_to_equivalence=False)
sage: len([T for T in it])
84

sage: it = ClusterSeed(['A',2]).cluster_class_iter(up_to_equivalence=False)
sage: cluster_class = list(it)
sage: len(cluster_class)
10
sage: cluster_class[0]
[x0, x1]
sage: cluster_class[-1]
[x1, x0]

Infinite type examples:

sage: S = ClusterSeed(['A',[1,1],1])
sage: it = S.cluster_class_iter()
sage: next(it)
[x0, x1]
sage: next(it)
[x0, (x0^2 + 1)/x1]
sage: next(it)
[(x1^2 + 1)/x0, x1]
sage: next(it)
[(x1^2 + 1)/x0, x1]
\end{verbatim}
For a cluster seed from an arbitrarily labelled digraph:

```python
sage: dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['b'])
sage: S.cluster_class()
[[a, c], [a, (b + 1)/c], [(b + 1)/a, c], [(b + 1)/a, (b + 1)/c]]
sage: S2 = ClusterSeed(dg, frozen=[])
sage: S2.cluster_class()[0]
[a, b, c]
```

**cluster_index(cluster_str)**

Return the index of a cluster if use_fpolys is on.

**INPUT:**

- cluster_str – the string to look for in the cluster

**OUTPUT:**

An integer or None if the string is not a cluster variable

**EXAMPLES:**

```python
sage: S = ClusterSeed([('A', 4), user_labels=['x', 'y', 'z', 'w'])); S.mutate('x')
sage: S.cluster_index('x')
sage: S.cluster_index('(y+1)/x')
0
```

**cluster_variable(k)**

Generates a cluster variable using F-polynomials

**EXAMPLES:**

```python
sage: S = ClusterSeed((['A', 3])
sage: S.mutate([0,1])
sage: S.cluster_variable(0)
(x1 + 1)/x0
sage: S.cluster_variable(1)
(x0*x2 + x1 + 1)/(x0*x1)
```
coefficient\( (k) \)
Return the coefficient of self at index \( k \), or vertex \( k \) if \( k \) is not an index.

EXAMPLES:

```sage
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.coefficient(k) for k in range(3)]
[y0, 1/y2, 1/y1]
```

coefficients()
Return all coefficients of self.

EXAMPLES:

```sage
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.coefficients()
y0, 1/y2, 1/y1
```

d_matrix\( (\text{show\_warnings=True}) \)
Return the matrix of \( d \)-vectors of self.

EXAMPLES:

```sage
sage: S = ClusterSeed(['A',4]); S.d_matrix()
[-1  0  0  0]
[ 0 -1  0  0]
[ 0  0 -1  0]
[ 0  0  0 -1]
sage: S.mutate([1,2,1,0,1,3]); S.d_matrix()
[ 1  1  0  1]
[ 1  1  1  1]
[ 1  0  1  1]
[ 0  0  0  1]
```

d_vector\( (k) \)
Return the \( k \)-th \( d \)-vector of self. This is the exponent vector of the denominator of the \( k \)-th cluster variable.

EXAMPLES:

```sage
sage: S = ClusterSeed(['A',3])
sage: S.mutate([2,1,2])
sage: [S.d_vector(k) for k in range(3)]
[(-1, 0, 0), (0, 1, 1), (0, 1, 0)]
```

echangeable_part()
Return the restriction to the principal part (i.e. the exchangeable variables) of self.

EXAMPLES:

```sage
sage: S = ClusterSeed(['A',4])
sage: T = ClusterSeed(S.quiver().digraph().edges(sort=True), frozen=[3])
sage: T.quiver().digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]
```
sage: T.exchangeable_part().quiver().digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1))]

### f_polynomial(k)

Return the $k$-th $F$-polynomial of self. It is obtained from the $k$-th cluster variable by setting all $x_i$ to 1.

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

**EXAMPLES:**

```python
code
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.f_polynomial(k) for k in range(3)]
[1, y1*y2 + y2 + 1, y1 + 1]
sage: S = ClusterSeed(Matrix([[0,1],[-1,0],[1,0],[-1,1]]))
sage: S.use_c_vectors(bot_is_c=True); S
A seed for a cluster algebra of rank 2 with 2 frozen variables
sage: T = ClusterSeed(Matrix([[0,1],[-1,0]])).principal_extension(); T
A seed for a cluster algebra of rank 2 with principal coefficients
sage: S.mutate(0)
sage: T.mutate(0)
sage: S.f_polynomials()
[y0 + y1, 1]
sage: T.f_polynomials()
[y0 + 1, 1]
```

### f_polynomials()

Return all $F$-polynomials of self. These are obtained from the cluster variables by setting all $x_i$’s to 1.

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

**EXAMPLES:**

```python
code
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.f_polynomials()
[1, y1*y2 + y2 + 1, y1 + 1]
```

### find_upper_bound(verbos=False)

Return the upper bound of the given cluster algebra as a quotient ring.

The upper bound is the intersection of the Laurent polynomial rings of the initial cluster and its neighboring clusters. As such, it always contains both the cluster algebra and the upper cluster algebra. This function uses the algorithm from [MM2015].

When the initial seed is totally coprime (for example, when the unfrozen part of the exchange matrix has full rank), the upper bound is equal to the upper cluster algebra by [BFZ2005].
**Warning:** The computation time grows rapidly with the size of the seed and the number of steps. For most seeds larger than four vertices, the algorithm may take an infeasible amount of time. Additionally, it will run forever without terminating whenever the upper bound is infinitely-generated (such as the example in [Spe2013]).

**INPUT:**

- verbose – (default: False) if True, prints output during the computation.

**EXAMPLES:**

- **finite type:**

  ```python
  sage: S = ClusterSeed(['A',3])
  sage: S.find_upper_bound()  # doctest: +NORMALIZE_WHITESPACE
  Quotient of Multivariate Polynomial Ring in x0, x1, x2, x0p, x1p, x2p, z0 over Rational Field
  by the ideal (x0^2 - x1 - 1, x1^2 - x0^2 - x2 - 1, x2^2 - x0 - x1, x0*z0 - x2, x1*z0 - x1p, x2*z0 - x0p, x0p*x1p + z0 - x0p*x1p*x2p + x1 + 1)
  ```

- **Markov:**

  ```python
  sage: B = matrix([[0,2,-2],[[-2,0,2],[2,-2,0]])
  sage: S = ClusterSeed(B)
  sage: S.find_upper_bound()  # doctest: +NORMALIZE_WHITESPACE
  Quotient of Multivariate Polynomial Ring in x0, x1, x2, x0p, x1p, x2p, z0 over Rational Field
  by the ideal (x0^2 + x2 - x1 - 1, x1^2 - x0^2 - x2 - 1, x2^2 - x0 - x1 - 1, x0^3 - x1^3 - x2, x0^2 - x1^2 - x2^2, x0^*3 - x1^*3 - x2^*3 - x0^*2 - x1^*2 - x2^*2, x0^*2 - x1^*2 - x2^*2, x0^* - x1^* - x2^*, x0^* - x1^* - x2^*, x0^* - x1^* - x2^*)
  ```

**first_green_vertex()**

Return the first green vertex of `self`.

A vertex is defined to be green if its c-vector has all non-positive entries. More information on green vertices can be found at [BDP2013]

**EXAMPLES:**

```python
sage: ClusterSeed(['A',3]).principal_extension().first_green_vertex()
0
sage: ClusterSeed(['A',3,3],1).principal_extension().first_green_vertex()
0
```

**first_red_vertex()**

Return the first red vertex of `self`.

A vertex is defined to be red if its c-vector has all non-negative entries. More information on red vertices can be found at [BDP2013].

**EXAMPLES:**

```python
sage: ClusterSeed(['A',3]).principal_extension().first_red_vertex()
0
sage: ClusterSeed(['A',3,3],1).principal_extension().first_red_vertex()
0
```
first_urban_renewal()

Return the first urban renewal vertex.

An urban renewal vertex is one in which there are two arrows pointing toward the vertex and two arrows pointing away.

EXAMPLES:

```python
sage: G = ClusterSeed(['GR', [4, 9]]); G.first_urban_renewal()
5
```

free_vertices()

Return the list of exchangeable vertices of self.

EXAMPLES:

```python
sage: S = ClusterSeed(DiGraph([
'a', 'b'], [
'c', 'b'], [
'c', 'd'], [
'e', 'd'])),
....:
    frozen=['b', 'd'])
sage: S.free_vertices()
['a', 'c', 'e']
sage: S = ClusterSeed(DiGraph([[5, 'b']]))
sage: S.free_vertices()
[5, 'b']
```

frozen_vertices()

Return the list of frozen vertices of self.

EXAMPLES:

```python
sage: S = ClusterSeed(DiGraph([
'a', 'b'], [
'c', 'b'], [
'c', 'd'], [
'e', 'd'])),
....:
    frozen=['b', 'd'])
sage: sorted(S.frozen_vertices())
['b', 'd']
```

g_matrix(show_warnings=True)

Return the matrix of all g-vectors of self. These are the degree vectors of the cluster variables after setting all \( y_i \)'s to 0.

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

EXAMPLES:
```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: S.g_matrix()
[ 1  0  0]
[ 0  0 -1]
[ 0 -1  0]
sage: S = ClusterSeed(['A',3])
sage: S.mutate([0,1])
sage: S.g_matrix()
[-1 -1  0]
[ 1  0  0]
[ 0  0  1]
sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False); S.g_matrix()
[1  0  0  0]
[0  1  0  0]
[0  0  1  0]
[0  0  0  1]
sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_c_vectors(False); S.use_fpolys(False)
sage: S.track_mutations(False); S.g_matrix()
Traceback (most recent call last):
  ... 
ValueError: Unable to calculate g-vectors. Need to use g vectors.
```

### `g_vector(k)`

Return the k-th *g-vector* of *self*. This is the degree vector of the k-th cluster variable after setting all $y_i$'s to 0.

**Warning:** This method assumes the sign-coherence conjecture and that the input seed is sign-coherent (has an exchange matrix with columns of like signs). Otherwise, computational errors might arise.

#### EXAMPLES:

```python
sage: S = ClusterSeed(['A',3]).principal_extension()
sage: S.mutate([2,1,2])
sage: [S.g_vector(k) for k in range(3)]
[(1, 0, 0), (0, 0, -1), (0, -1, 0)]
```

### `get_upper_cluster_algebra_element(a)`

Compute an element in the upper cluster algebra of $B$ corresponding to the vector $a \in \mathbb{Z}^n$.

See [LLM2014] for more details.

**INPUT:**

- B – a skew-symmetric matrix. Must have the same number of columns as the length of the vectors in $vd$.
- a – a vector in $\mathbb{Z}^n$ where $n$ is the number of columns in $B$. 

---

5.1. Comprehensive Module List
OUTPUT:

Return an element in the upper cluster algebra. Depending on the input it may or may not be irreducible.

EXAMPLES:

```
sage: B = matrix([[0,3,-3],[-3,0,3],[3,-3,0],[1,0,0],[0,1,0],[0,0,1]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,0])
(x0^3*x2^3*x3*x4 + x2^6*x3 + x1^3*x2^3)/(x0*x1)
sage: C.get_upper_cluster_algebra_element([1,1,1])
x0^2*x1^2*x2^2*x3*x4*x5 + x0^2*x1^2*x2^2
```

```
sage: B = matrix([[0,3,0],[-3,0,3],[0,-3,0]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,0])
(x1^3*x2^3 + x0^3 + x2^3)/(x0*x1)
sage: C.get_upper_cluster_algebra_element([1,1,1])
(x0^3*x1^3 + x1^3*x2^3 + x0^3 + x2^3)/(x0*x1^3*x2)
```

```
sage: B = matrix([[0,2],[-3,0],[4,-5]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1])
(x2^9 + x1^3*x2^5 + x0^2*x2^4)/(x0*x1)
```

```
sage: B = matrix([[0,3,-5],[-3,0,4],[5,-4,0]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,1])
x0^4*x1^2*x2^3 + x0^2*x1^3*x2^4
```

```
return an element in the upper cluster algebra. Depending on the input it may or may not be irreducible.
```

```
EXAMPLES:

```
sage: B = matrix([[0,3,-3],[-3,0,3],[3,-3,0],[1,0,0],[0,1,0],[0,0,1]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,0])
(x0^3*x2^3*x3*x4 + x2^6*x3 + x1^3*x2^3)/(x0*x1)
sage: C.get_upper_cluster_algebra_element([1,1,1])
x0^2*x1^2*x2^2*x3*x4*x5 + x0^2*x1^2*x2^2
```

```
sage: B = matrix([[0,3,0],[-3,0,3],[0,-3,0]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,0])
(x1^3*x2^3 + x0^3 + x2^3)/(x0*x1)
sage: C.get_upper_cluster_algebra_element([1,1,1])
(x0^3*x1^3 + x1^3*x2^3 + x0^3 + x2^3)/(x0*x1^3*x2)
```

```
sage: B = matrix([[0,2],[-3,0],[4,-5]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1])
(x2^9 + x1^3*x2^5 + x0^2*x2^4)/(x0*x1)
```

```
sage: B = matrix([[0,3,-5],[-3,0,4],[5,-4,0]])
sage: C = ClusterSeed(B)
sage: C.get_upper_cluster_algebra_element([1,1,1])
x0^4*x1^2*x2^3 + x0^2*x1^3*x2^4
```

```
Example:

```
sage: S = ClusterSeed(['R2', [3, 3]])
sage: S.greedy(4, 4)
(x0^12 + x1^12 + 4*x0^9 + 4*x1^9 + 6*x0^6
 + 4*x0^3*x1^3 + 6*x1^6 + 4*x0^3 + 4*x1^3 + 1)/(x0^4*x1^4)
sage: S.greedy(4, 4, 'by_combinatorics')
(x0^12 + x1^12 + 4*x0^9 + 4*x1^9 + 6*x0^6
 + 4*x0^3*x1^3 + 6*x1^6 + 4*x0^3 + 4*x1^3 + 1)/(x0^4*x1^4)
sage: S.greedy(4, 4, 'just_numbers')
35
```

```
sage: S = ClusterSeed(['R2', [2, 2]])
sage: S.greedy(1, 2)
(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2)
sage: S.greedy(1, 2, 'by_combinatorics')
(x0^4 + 2*x0^2 + x1^2 + 1)/(x0*x1^2)
```
green_vertices()
Return the list of green vertices of self.
A vertex is defined to be green if its c-vector has all non-positive entries. More information on green vertices can be found at [BDP2013]

OUTPUT:
The green vertices as a list of integers.

EXAMPLES:
```
sage: ClusterSeed(['A',3]).principal_extension().green_vertices()
[0, 1, 2]
sage: ClusterSeed(['A',[3,3],1]).principal_extension().green_vertices()
[0, 1, 2, 3, 4, 5]
```

ground_field()
Return the ground field of the cluster of self.

EXAMPLES:
```
sage: S = ClusterSeed(['A',3])
sage: S.ground_field()
Multivariate Polynomial Ring in x0, x1, x2, y0, y1, y2 over Rational Field
```

highest_degree_denominator(filter=None)
Return the vertex of the cluster polynomial with highest degree in the denominator.

INPUT:
- filter – a list or iterable

OUTPUT:
An integer.

EXAMPLES:
```
sage: B = matrix([[0,-1,0,-1,1,1],
               [1,0,1,0,-1,-1],
               [0,-1,0,-1,1,1],
               [1,0,1,0,-1,-1],
               [-1,1,-1,1,0,0],
               [-1,1,-1,1,0,0]])
sage: C = ClusterSeed(B).principal_extension(); C.mutate([0,1,2,4,3,2,5,4,3])
sage: C.highest_degree_denominator()
5
```

interact(fig_size=1, circular=True)
Start an interactive window for cluster seed mutations.
Only in Jupyter notebook mode.

INPUT:
- fig_size – (default: 1) factor by which the size of the plot is multiplied.
- circular – (default: True) if True, the circular plot is chosen, otherwise >>spring<< is used.

is_acyclic()
Return True iff self is acyclic (i.e., if the underlying quiver is acyclic).

EXAMPLES:
**is_acyclic()**

Return True if the quiver is acyclic.

**is_bipartite(return_bipartition=False)**

Return True if the underlying quiver is bipartite.

**is_finite()**

Return True if the quiver is of finite type.

**is_mutation_finite(nr_of_checks=None, return_path=False)**

Return True if the quiver is of finite mutation type.

**ALGORITHM:**

- A cluster seed is mutation infinite if and only if every $b_{ij} * b_{ji} > -4$. Thus, we apply random mutations in random directions.

**Warning:**

- Uses a non-deterministic method by random mutations in various directions.
In theory, it can return a wrong True.

EXAMPLES:

```python
sage: S = ClusterSeed(['A', 10])
sage: S._mutation_type = None
sage: S.is_mutation_finite()
True
sage: S = ClusterSeed([(0,1),(1,2),(2,3),(3,4),(4,5),(5,6),(6,7),(7,8),(2,9)])
sage: S.is_mutation_finite()
False
```

Return the number of frozen variables of self.

EXAMPLES:

```python
sage: S = ClusterSeed(['A', 3])
sage: S.n()
3
sage: S.m()
0
sage: S = S.principal_extension()
sage: S.m()
3
```

Return the vertex that will produce the most decrease in denominator degrees after mutation

EXAMPLES:

```python
sage: S = ClusterSeed(['A', 5])
sage: S.mutate([0,2,3,1,2,3,1,2,0,2,3])
sage: S.most_decreased_denominator_after_mutation()
2
```

Return the vertex that will produce the least degrees after mutation

EXAMPLES:

```python
sage: S = ClusterSeed(['A', 5])
sage: S.mutate([0,2,3,1,2,3,1,2,0,2,3])
sage: S.most_decreased_edge_after_mutation()
2
```

Mutate self at a vertex or a sequence of vertices.

INPUT:
• sequence – a vertex of self, an iterator of vertices of self, a function which takes in the ClusterSeed and returns a vertex or an iterator of vertices, or a string representing a type of vertices to mutate

• inplace – (default: True) if False, the result is returned, otherwise self is modified

• input_type – (default: None) indicates the type of data contained in the sequence

Possible values for vertex types in sequence are:

• "first_source": mutates at first found source vertex,

• "sources": mutates at all sources,

• "first_sink": mutates at first sink,

• "sinks": mutates at all sink vertices,

• "green": mutates at the first green vertex,

• "red": mutates at the first red vertex,

• "urban_renewal" or "urban": mutates at first urban renewal vertex,

• "all_urban_renewals" or "all_urban": mutates at all urban renewal vertices.

For input_type, if no value is given, preference will be given to vertex names, then indices, then cluster variables. If all input is not of the same type, an error is given. Possible values for input_type are:

• "vertices": interprets the input sequence as vertices

• "indices": interprets the input sequence as indices

• "cluster_vars": interprets the input sequence as cluster variables this must be selected if inputting a sequence of cluster variables.

EXAMPLES:

```python
sage: S = ClusterSeed(['A',4]); S.b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]
sage: S.mutate(0); S.b_matrix()
[ 0 -1 0 0]
[ 1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]
sage: T = S.mutate(0, inplace=False); T
A seed for a cluster algebra of rank 4 of type ['A', 4]
sage: S.mutate(0)
sage: S == T
True
sage: S.mutate([0,1,0])
sage: S.b_matrix()
[ 0 -1 1 0]
[ 1 0 0 0]
```

[(x0 + 1)/xneg1, (x0*x1 + xneg1 + x1)/(xneg1*x0), x1]

mutation_analysis(options=['all'], filter=None)

Runs an analysis of all potential mutation options. Note that this might take a long time on large seeds.
Note: Edges are only returned if we have a non-valued quiver. Green and red vertices are only returned if the cluster is principal.

INPUT:
• options – (default: ['all']) a list of mutation options.
• filter – (default: None) A vertex or interval of vertices to limit our search to

Possible options are:
• "all" - All options below
• "edges" - Number of edges (works with skew-symmetric quivers)
• "edge_diff" - Edges added/deleted (works with skew-symmetric quivers)
• "green_vertices" - List of green vertices (works with principals)
• "green_vertices_diff" - Green vertices added/removed (works with principals)
• "red_vertices" - List of red vertices (works with principals)
• "red_vertices_diff" - Red vertices added/removed (works with principals)
• "urban_renewals" - List of urban renewal vertices
• "urban_renewals_diff" - Urban renewal vertices added/removed
• "sources" - List of source vertices
• "sources_diff" - Source vertices added/removed
• "sinks" - List of sink vertices
• "sinks_diff" - Sink vertices added/removed
• "denominators" - List of all denominators of the cluster variables

OUTPUT:
Outputs a dictionary indexed by the vertex numbers. Each vertex will itself also be a dictionary with each desired option included as a key in the dictionary. As an example you would get something similar to: {0: {'edges': 1}, 1: {'edges': 2}}. This represents that if you were to do a mutation at the current seed then mutating at vertex 0 would result in a quiver with 1 edge and mutating at vertex 0 would result in a quiver with 2 edges.

EXAMPLES:

```
sage: B = [[0, 4, 0, -1],[4,0, 3, 0],[0, -3, 0, 1],[1, 0, -1, 0]]
sage: S = ClusterSeed(matrix(B)); S.mutate([2,3,1,2,1,3,0,2])
sage: S.mutation_analysis()

mutation_class(\text{\texttt{depth=+Infinity, show\_depth=False, return\_paths=False, up\_to\_equivalence=True, only\_sink\_source=False}})

Return the mutation class of self with respect to certain constraints.

\underline{Note:} Vertex labels are not tracked in this method.

See also:

\text{\texttt{mutation\_class\_iter()}}

INPUT:

- \text{\texttt{depth}} – (default: infinity`) integer, only seeds with distance at most depth from self are returned
- \text{\texttt{show\_depth}} – (default: False) if True, the actual depth of the mutation is shown
- \text{\texttt{return\_paths}} – (default: False) if True, a shortest path of mutation sequences from self to the given quiver is returned as well
- \text{\texttt{up\_to\_equivalence}} – (default: True) if True, only seeds up to equivalence are considered
- \text{\texttt{sink\_source}} – (default: False) if True, only mutations at sinks and sources are applied

EXAMPLES:

- for examples see \text{\texttt{mutation\_class\_iter()}}

mutation_class_iter(\text{\texttt{depth=+Infinity, show\_depth=False, return\_paths=False, up\_to\_equivalence=True, only\_sink\_source=False}})

Return an iterator for the mutation class of self with respect to certain constraints.

INPUT:

- \text{\texttt{depth}} – (default: infinity) integer or infinity, only seeds with distance at most depth from self are returned.
- \text{\texttt{show\_depth}} – (default: False) if True, the current depth of the mutation is shown while computing.
- \text{\texttt{return\_paths}} – (default: False) if True, a shortest path of mutations from self to the given quiver is returned as well.
- \text{\texttt{up\_to\_equivalence}} – (default: True) if True, only one seed up to simultaneous permutation of rows and columns of the exchange matrix is recorded.
- \text{\texttt{sink\_source}} – (default: False) if True, only mutations at sinks and sources are applied.

EXAMPLES:

A standard finite type example:

```
sage: S = ClusterSeed(['A',3])
sage: it = S.mutation_class_iter()
sage: for T in it: print(T)
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
```
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]
A seed for a cluster algebra of rank 3 of type ['A', 3]

A finite type example with given depth:

```python
sage: it = S.mutation_class_iter(depth=1)
sage: for T in it: print(T)
```

A finite type example where the depth is shown while computing:

```python
sage: it = S.mutation_class_iter(show_depth=True)
sage: for T in it: pass
```

A finite type example with shortest paths returned:

```python
sage: it = S.mutation_class_iter(return_paths=True)
sage: mutation_class = list(it)
sage: len(mutation_class)
14
```

Finite type examples not considered up to equivalence:

```python
sage: it = S.mutation_class_iter(up_to_equivalence=False)
sage: len([T for T in it])
84
```

Check that github issue #14638 is fixed:
Infinite type examples:

```python
sage: S = ClusterSeed(['A',[1,1],1])
sage: it = S.mutation_class_iter()
sage: next(it)
A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1]
sage: next(it)
A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1]
sage: next(it)
A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1]
sage: next(it)
A seed for a cluster algebra of rank 2 of type ['A', [1, 1], 1]
```

`mutation_sequence(sequence, show_sequence=False, fig_size=1.2, return_output='seed')`

Return the seeds obtained by mutating `self` at all vertices in `sequence`.

**INPUT:**

- `sequence` – an iterable of vertices of `self`.
- `show_sequence` – (default: `False`) if `True`, a png containing the associated quivers is shown.
- `fig_size` – (default: 1.2) factor by which the size of the plot is multiplied.
- `return_output` – (default: 'seed') determines what output is to be returned:
  - if 'seed', outputs all the cluster seeds obtained by the `sequence` of mutations.
  - if 'matrix', outputs a list of exchange matrices.
  - if 'var', outputs a list of new cluster variables obtained at each step.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A',2])
sage: for T in S.mutation_sequence([0,1,0]):
    ....:     print(T.b_matrix())
[ 0 -1]
[ 1 0]
[ 0 1]
[-1 0]
[ 0 -1]
[ 1 0]
```
mutation_type()

Return the mutation type of each connected component of self, if it can be determined.

Otherwise, the mutation type of this component is set to be unknown.

The mutation types of the components are ordered by vertex labels.

Warning:

- All finite types can be detected,
- All affine types can be detected, except affine type D (the algorithm is not yet implemented)
- All exceptional types can be detected.
- Might fail to work if it is used within different Sage processes simultaneously (that happened in the doctesting).

EXAMPLES:

- finite types:

  sage: S = ClusterSeed(['A',5])
sage: S._mutation_type = S._quiver._mutation_type = None
sage: S.mutation_type()
['A', 5]

  sage: S = ClusterSeed([(0,1),(1,2),(2,3),(3,4)])
sage: S.mutation_type()
['A', 5]

  sage: S = ClusterSeed(DiGraph([['a','b'],['c','b'],['c','d'],['e','d']],
                            frozen=['c']))
sage: S.mutation_type()

[ ['A', 2], ['A', 2] ]

- affine types:

  sage: S = ClusterSeed(['E',8,[1,1]]); S
A seed for a cluster algebra of rank 10 of type ['E', 8, [1, 1]]
sage: S._mutation_type = S._quiver._mutation_type = None; S
A seed for a cluster algebra of rank 10
sage: S.mutation_type() # long time
['E', 8, [1, 1]]

- the not yet working affine type D:

  sage: S = ClusterSeed(['D',4,1])
sage: S._mutation_type = S._quiver._mutation_type = None
\textbf{Combinatorics, Release 10.1}

(continued from previous page)

\begin{verbatim}
\textbf{sage}: S.mutation_type() # todo: not implemented
["D", 4, 1]
\end{verbatim}

- the exceptional types:

\begin{verbatim}
\textbf{sage}: S = ClusterSeed(['X',6])
\textbf{sage}: S._mutation_type = S._quiver._mutation_type = None
\textbf{sage}: S.mutation_type() # long time
['X', 6]
\end{verbatim}

- infinite types:

\begin{verbatim}
\textbf{sage}: S = ClusterSeed(['GR',[4,9]])
\textbf{sage}: S._mutation_type = S._quiver._mutation_type = None
\textbf{sage}: S.mutation_type()
'undetermined infinite mutation type'
\end{verbatim}

\textbf{mutations()}

Return the list of mutations \texttt{self} has undergone if they are being tracked.

\textbf{EXAMPLES:}

\begin{verbatim}
\textbf{sage}: S = ClusterSeed(['A',3])
\textbf{sage}: S.mutations()
[]
\textbf{sage}: S.mutate([0,1,0,2])
\textbf{sage}: S.mutations()
[0, 1, 0, 2]
\textbf{sage}: S.track_mutations(False)
\textbf{sage}: S.mutations()
Traceback (most recent call last):
...
ValueError: Not recording mutation sequence. Need to track mutations.
\end{verbatim}

\textbf{n()}

Return the number of exchangeable variables of \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
\textbf{sage}: S = ClusterSeed(['A',3])
\textbf{sage}: S.n()
3
\end{verbatim}

\textbf{oriented_exchange_graph()}

Return the oriented exchange graph of \texttt{self} as a directed graph.

The seed must be a cluster seed for a cluster algebra of finite type with principal coefficients (the corresponding quiver must have mutable vertices 0, 1, ..., \(n - 1\)).

\textbf{EXAMPLES:}
```python
sage: S = ClusterSeed(['A', 2]).principal_extension()
sage: G = S.oriented_exchange_graph(); G
Digraph on 5 vertices
sage: G.out_degree_sequence()
[2, 1, 1, 1, 0]

sage: S = ClusterSeed(['B', 2]).principal_extension()
sage: G = S.oriented_exchange_graph(); G
Digraph on 6 vertices
sage: G.out_degree_sequence()
[2, 1, 1, 1, 1, 0]
```

```python
plot(circular=False, mark=None, save_pos=False, force_c=False, with_greens=False, add_labels=False)
```

Return the plot of the quiver of self.

**INPUT:**

- circular – (default: False) if True, the circular plot is chosen, otherwise `spring` is used.
- mark – (default: None) if set to i, the vertex i is highlighted.
- save_pos – (default: False) if True, the positions of the vertices are saved.
- force_c – (default: False) if True, will show the frozen vertices even if they were never initialized
- with_greens – (default: False) if True, will display the green vertices in green
- add_labels – (default: False) if True, will use the initial variables as labels

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A', 5])
sage: S.plot()  # needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
```

```python
sage: S.plot(circular=True)  # needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
```

```python
sage: S.plot(circular=True, mark=1)  # needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
```

```python
principal_extension()
```

Return the principal extension of self, yielding a $2n \times n$ matrix.

Raises an error if the input seed has a non-square exchange matrix. In this case, the method instead adds $n$ frozen variables to any previously frozen variables. I.e., the seed obtained by adding a frozen variable to every exchangeable variable of self.

**EXAMPLES:**

```python
sage: S = ClusterSeed([[0,1],[1,2],[2,3],[2,4]]); S
A seed for a cluster algebra of rank 5
sage: T = S.principal_extension(); T
A seed for a cluster algebra of rank 5 with principal coefficients
```
```
sage: T.b_matrix()
[ 0 1 0 0 0]
[-1 0 1 0 0]
[ 0 -1 0 1 1]
[ 0 0 -1 0 0]
[ 0 0 -1 0 0]
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ 0 0 1 0 0]
[ 0 0 0 1 0]
[ 0 0 0 0 1]

sage: S = ClusterSeed(['A', 4], user_labels=['a', 'b', 'c', 'd'])
sage: T = S.principal_extension()
sage: T.cluster()
[a, b, c, d]
sage: T.coefficients()
y0, y1, y2, y3
sage: S2 = ClusterSeed(['A', 4], user_labels={0: 'a', 1: 'b', 2: 'c', 3: 'd'})
sage: S2 == S
True
sage: T2 = S2.principal_extension()
sage: T2 == T
True
```

**quiver()**

Return the *quiver* associated to *self*.

EXAMPLES:

```
sage: S = ClusterSeed(['A',3])
sage: S.quiver()
Quiver on 3 vertices of type ['A', 3]
```

**red_vertices()**

Return the list of red vertices of *self*.

A vertex is defined to be red if its c-vector has all non-negative entries. More information on red vertices can be found at [BDP2013].

OUTPUT:

The red vertices as a list of integers.

EXAMPLES:

```
sage: ClusterSeed(['A',3]).principal_extension().red_vertices()
[]
sage: ClusterSeed(['A', [3, 3], 1]).principal_extension().red_vertices()
[]
sage: Q = ClusterSeed(['A', [3, 3], 1]).principal_extension()
sage: Q.mutate(1)
```

(continues on next page)
 sage: Q.red_vertices()

[1]

**reorient**(data)

Reorients self with respect to the given total order, or with respect to an iterator of ordered pairs.

**Warning:**
- This operation might change the mutation type of self.
- Ignores ordered pairs \((i, j)\) for which neither \((i, j)\) nor \((j, i)\) is an edge of self.

**INPUT:**
- data – an iterator defining a total order on self.vertices(), or an iterator of ordered pairs in self defining the new orientation of these edges.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A', [2, 3], 1])
sage: S.mutation_type()
['A', [2, 3], 1]
sage: S.reorient(((0, 1), (2, 3)))
sage: S.mutation_type()
['D', 5]
```

**reset_cluster()**

Reset the cluster of self to the initial cluster.

**EXAMPLES:**

```python
sage: S = ClusterSeed(['A', 3])
sage: S.mutate([1, 2, 1])
sage: S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]
sage: S.reset_cluster()
sage: S.cluster()
[x0, x1, x2]
```
sage: T.cluster()  
\[x_0, (x_1 x_2 + x_0)/x_2, (x_1 x_1 y_2 + x_0 y_1 + x_2)/(x_1 x_2)\]

sage: T.reset_cluster()  
sage: T.cluster()  
\[x_0, x_1, x_2\]

sage: S = ClusterSeed(['B',3], user_labels=[[1,2],[2,3],[3,4]],  
..................  
user_labels_prefix='p')  
sage: S.mutate([0,1])  
sage: S.cluster()  
\[(p_{2 \cdot 3} + 1)/p_{1 \cdot 2}, (p_{1 \cdot 2} p_{3 \cdot 4}^2 + p_{2 \cdot 3} + 1)/(p_{1 \cdot 2} p_{2 \cdot 3}), p_{3 \cdot 4}\]

sage: S.reset_cluster()  
sage: S.cluster()  
\[p_{1 \cdot 2}, p_{2 \cdot 3}, p_{3 \cdot 4}\]

sage: S.g_matrix()  
\[[1 \ 0 \ 0]\]  
\[[0 \ 1 \ 0]\]  
\[[0 \ 0 \ 1]\]

sage: S.f_polynomials()  
\[1, 1, 1\]

reset_coefficients()

Reset the coefficients of self to the frozen variables but keep the current cluster.
This raises an error if the number of frozen variables is different from the number of exchangeable variables.

**Warning:** This command to be phased out since `use_c_vectors()` does this more effectively.

EXAMPLES:

sage: S = ClusterSeed(['A',3]).principal_extension()  
sage: S.b_matrix()  
\[[0 \ 1 \ 0]\]  
\[[-1 \ 0 \ -1]\]  
\[[0 \ 1 \ 0]\]  
\[[1 \ 0 \ 0]\]  
\[[0 \ 1 \ 0]\]  
\[[0 \ 0 \ 1]\]

sage: S.mutate([1,2,1])  
sage: S.b_matrix()  
\[[0 \ 1 \ -1]\]  
\[[-1 \ 0 \ 1]\]  
\[[1 \ -1 \ 0]\]  
\[[1 \ 0 \ 0]\]  
\[[0 \ 1 \ -1]\]  
\[[0 \ 0 \ -1]\]

sage: S.reset_coefficients()  
sage: S.b_matrix()  
\[[0 \ 1 \ -1]\]
save_image(filename, circular=False, mark=None, save_pos=False)

Save the plot of the underlying digraph of the quiver of self.

INPUT:

- filename – the filename the image is saved to.
- circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
- mark – (default: None) if set to i, the vertex i is highlighted.
- save_pos – (default: False) if True, the positions of the vertices are saved.

EXAMPLES:

```python
sage: S = ClusterSeed(['F',4,[1,2]])
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix=".png") as f:
    # needs sage.plot sage.symbolic
    ....:     S.save_image(f.name)
```

set_c_matrix(data)

Will force set the c-matrix according to a matrix, a quiver, or a seed.

INPUT:

- data – The matrix to set the c-matrix to. Also allowed to be a quiver or cluster seed, in which case the b-matrix is used.

EXAMPLES:

```python
sage: S = ClusterSeed(['A',3])
sage: X = matrix([[0,0,1],[0,1,0],[1,0,0]])
sage: S.set_c_matrix(X)
sage: S.c_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: Y = matrix([[-1,0,1],[0,1,0],[1,0,0]])
sage: S.set_c_matrix(Y)
C matrix does not look to be valid - there exists a column containing positive and negative entries.
Continuing...
sage: Z = matrix([[1,0,1],[0,1,0],[2,0,2]])
sage: S.set_c_matrix(Z)
C matrix does not look to be valid - not a linearly independent set.
Continuing...
```
**set_cluster** *(cluster, force=False)*

Sets the cluster for *self* to *cluster*.

**Warning:** Initialization may lead to inconsistent data.

**INPUT:**

- **cluster** – an iterable defining a cluster for *self*.

**EXAMPLES:**

```
sage: S = ClusterSeed(['A',3])
sage: cluster = S.cluster()
sage: S.mutate([1,2,1])
sage: S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]
sage: cluster2 = S.cluster()
sage: S.set_cluster(cluster)
Warning: using set_cluster at this point could lead to inconsistent seed data.
sage: S.set_cluster(cluster, force=True)
sage: S.cluster()
[x0, x1, x2]
sage: S.set_cluster(cluster2, force=True)
sage: S.cluster()
[x0, (x1 + 1)/x2, (x0*x2 + x1 + 1)/(x1*x2)]
sage: S = ClusterSeed(['A',3]); S.use_fpolys(False)
sage: S.set_cluster([1,1,1])
Warning: clusters not being tracked so this command is ignored.
```

**show**(fig_size=1, circular=False, mark=None, save_pos=False, force_c=False, with_greens=False, add_labels=False)

Shows the plot of the quiver of *self*.

**INPUT:**

- **fig_size** – (default: 1) factor by which the size of the plot is multiplied.
- **circular** – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
- **mark** – (default: None) if set to i, the vertex i is highlighted.
- **save_pos** – (default: False) if True, the positions of the vertices are saved.
- **force_c** – (default: False) if True, will show the frozen vertices even if they were never initialized
- **with_greens** – (default: False) if True, will display the green vertices in green
- **add_labels** – (default: False) if True, will use the initial variables as labels

**smallest_c_vector**()

Return the vertex with the smallest c-vector.

**OUTPUT:** An integer.

**EXAMPLES:**
track_mutations(use=True)

Begin tracking the mutation path.

**Warning:** May initialize all other data to ensure that all c-, d-, and g-vectors agree on the start of mutations.

**INPUT:**

- use – (default: True) If True, will begin filling the mutation path

**EXAMPLES:**

```sage
sage: S = ClusterSeed(['A',4]); S.track_mutations(False)
sage: S.mutate(0)
sage: S.mutations()
Traceback (most recent call last):
... ValueError: Not recording mutation sequence. Need to track mutations.
```

```sage
sage: S.track_mutations(True)
sage: S.g_matrix()
[[1 0 0 0]
 [0 1 0 0]
 [0 0 1 0]
 [0 0 0 1]]
```

universal_extension()

Return the universal extension of self.

This is the initial seed of the associated cluster algebra with universal coefficients, as defined in section 12 of [FZ2007].

This method works only if self is a bipartite, finite-type seed.

Due to some limitations in the current implementation of CartanType, we need to construct the set of almost positive coroots by hand. As a consequence their ordering is not the standard one (the rows of the bottom part of the exchange matrix might be a shuffling of those you would expect).

**EXAMPLES:**

```sage
sage: S = ClusterSeed(['A',2])
sage: T = S.universal_extension()
sage: T.b_matrix()
[  0  1]
[-1  0]
```

(continues on next page)

\end{bmatrix}
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & S = \text{ClusterSeed}(['A', 5], \text{user_labels}=[-2, -1, 0, 1 ,2]) \\
\text{sage: } & U = S.\text{universal_extension()} \\
\text{sage: } & U.\text{b_matrix()} == \text{ClusterSeed}(['A', 5]).\text{universal_extension().b_matrix()} \\
& \text{True}
\end{align*}
\]

urban_renewals(return_first=False)

Return the list of the urban renewal vertices of self.

An urban renewal vertex is one in which there are two arrows pointing toward the vertex and two arrows pointing away.

INPUT:

- return_first – (default: False) if True, will return the first urban renewal

OUTPUT:

A list of vertices (as integers)

EXAMPLES:
sage: G = ClusterSeed(['GR',[4,9]]); G.urban_renewals()
[5, 6]

use_c_vectors(use=True, bot_is_c=False, force=False)
Reconstruct c-vectors from other data or initialize if no usable data exists.

Warning: Initialization may lead to inconsistent data.

INPUT:
• use – (default: True) If True, will use c-vectors
• bot_is_c – (default: False) If True and ClusterSeed self has self._m == self._n, then will assume bottom half of the extended exchange matrix is the c-matrix. If True, lets the ClusterSeed know c-vectors can be calculated.

EXAMPLES:

```sage
sage: S = ClusterSeed(['A',4])
sage: S.use_c_vectors(False); S.use_g_vectors(False)
sage: S.use_fpolys(False); S.track_mutations(False)
sage: S.use_c_vectors(True)
Warning: Initializing c-vectors at this point could lead to inconsistent seed data.
sage: S.use_c_vectors(True, force=True)
sage: S.c_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

use_d_vectors(use=True, force=False)
Reconstruct d-vectors from other data or initialize if no usable data exists.

Warning: Initialization may lead to inconsistent data.

INPUT:
• use – (default: True) If True, will use d-vectors

EXAMPLES:
```python
sage: S = ClusterSeed(['A',4])
sage: S.use_d_vectors(True)
sage: S.d_matrix()
[-1 0 0 0]
[ 0 -1 0 0]
[ 0 0 -1 0]
[ 0 0  0 -1]

sage: S = ClusterSeed(['A',4]); S.use_d_vectors(False)
sage: S.track_mutations(False); S.mutate(1); S.d_matrix()
[-1 0 0 0]
[ 0 1 0 0]
[ 0 0 -1 0]
[ 0 0  0 -1]

Warning: Initializing d-vectors at this point could lead to inconsistent seed data.

sage: S.use_d_vectors(True, force=True)
sage: S.d_matrix()
[-1 0 0 0]
[ 0 -1 0 0]
[ 0 0 -1 0]
[ 0 0  0 -1]

sage: S = ClusterSeed(['A',4]); S.mutate(1); S.d_matrix()
[-1 0 0 0]
[ 0 1 0 0]
[ 0 0 -1 0]
[ 0 0  0 -1]

use_fpolys(use=True, user_labels=None, user_labels_prefix=None)
Use F-polynomials in our Cluster Seed
Note: This will automatically try to recompute the cluster variables if possible

5.1. Comprehensive Module List 221
INPUT:

• use – (default: True) If True, will use F-polynomials
• user_labels – (default: None) If set, will overwrite the default cluster variable labels
• user_labels_prefix – (default: None) If set, will overwrite the default

EXAMPLES:

```
sage: S = ClusterSeed(['A',4]); S.use_fpolys(False); S._cluster
sage: S.use_fpolys(True)
sage: S.cluster()
[x0, x1, x2, x3]
sage: S = ClusterSeed(['A',4]); S.use_fpolys(False); S.track_mutations(False)
sage: S.mutate(1)
sage: S.use_fpolys(True)
Traceback (most recent call last):
... ValueError: F-polynomials and Cluster Variables cannot be reconstructed
from given data.
sage: S.cluster()
Traceback (most recent call last):
... ValueError: Clusters not being tracked
```

use_g_vectors(\texttt{use=True,} \texttt{force=False})

Reconstruct g-vectors from other data or initialize if no usable data exists.

\textbf{Warning:} Initialization may lead to inconsistent data.

INPUT:

• use – (default: True) If True, will use g-vectors

EXAMPLES:

```
sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False)
sage: S.use_g_vectors(True)
sage: S.g_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: S = ClusterSeed(['A',4])
sage: S.use_g_vectors(False); S.use_fpolys(False)
sage: S.mutate(1)
sage: S.use_g_vectors(True)
sage: S.g_matrix()
[ 1 0 0 0]
[ 0 -1 0 0]
[ 0 0 1 0]
```

(continues on next page)
variable_class\( (depth=+\infty, \text{ignore\_bipartite\_belt}=\text{False}) \)

Return all cluster variables in the mutation class of \texttt{self}.

INPUT:

- \texttt{depth} – (default: infinity) integer, only seeds with distance at most \texttt{depth} from \texttt{self} are returned
- \texttt{ignore\_bipartite\_belt} – (default: False) if True, the algorithm does not use the bipartite belt

EXAMPLES:

- for examples see \texttt{variable\_class\_iter()}

variable_class_iter\( (depth=+\infty, \text{ignore\_bipartite\_belt}=\text{False}) \)

Return an iterator for all cluster variables in the mutation class of \texttt{self}.

INPUT:

- \texttt{depth} – (default: infinity) integer, only seeds with distance at most \texttt{depth} from \texttt{self} are returned
- \texttt{ignore\_bipartite\_belt} – (default: False) if True, the algorithm does not use the bipartite belt

EXAMPLES:

A standard finite type example:
Finite type examples with given depth:

```python
sage: it = S.variable_class_iter(depth=1)
sage: for T in it: print(T)

Found a bipartite seed - restarting the depth counter at zero and constructing the variable class using its bipartite belt.

x0
x1
x2
(x1 + 1)/x0
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2)
(x1 + 1)/x2
(x0*x2 + x1 + 1)/(x0*x1)
(x0*x2 + 1)/x1
(x0*x2 + x1 + 1)/(x1*x2)
```

Note that the notion of `depth` depends on whether a bipartite seed is found or not, or if it is manually ignored:

```python
sage: it = S.variable_class_iter(depth=1, ignore_bipartite_belt=True)
sage: for T in it: print(T)

x0
x1
x2
(x1 + 1)/x0
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2)
(x1 + 1)/x2
(x0*x2 + x1 + 1)/(x0*x1)
(x0*x2 + 1)/x1
(x0*x2 + x1 + 1)/(x1*x2)
```

Infinite type examples:

```python
sage: S = ClusterSeed(['A',[1,1],1])
sage: it = S.variable_class_iter(depth=2)
sage: for T in it: print(T)

Found a bipartite seed - restarting the depth counter at zero and constructing the variable class using its bipartite belt.

x0
x1
x2
(x1 + 1)/x0
(x1^2 + x0*x2 + 2*x1 + 1)/(x0*x1*x2)
(x1 + 1)/x2
(x0*x2 + x1 + 1)/(x0*x1)
```

(continues on next page)
\(x(k)\)

Return the \(k\)-th initial cluster variable for the associated cluster seed, or the cluster variable of the corresponding vertex in \texttt{self.quiver}.

**EXAMPLES:**

\[
sage: S = ClusterSeed(['A', 3])
sage: S.mutate([2, 1])
sage: S.x(0)
x0
sage: S.x(1)
x1
sage: S.x(2)
x2
sage: dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['c'])
sage: S.x('a')
a
\]

\(y(k)\)

Return the \(k\)-th initial coefficient (frozen variable) for the associated cluster seed, or the cluster variable of the corresponding vertex in \texttt{self.quiver}.

**EXAMPLES:**

\[
sage: S = ClusterSeed(['A', 3]).principal_extension()
sage: S.mutate([2, 1])
sage: S.y(0)
y0
sage: S.y(1)
y1
sage: S.y(2)
y2
\]
sage: dg = DiGraph([['a', 'b'], ['b', 'c']], format="list_of_edges")
sage: S = ClusterSeed(dg, frozen=['c'])
sage: S.y(0)
c
sage: S.y('c')
c

class sage.combinat.cluster_algebra_quiver.cluster_seed.ClusterVariable(parent, numerator, denominator, coerce=True, reduce=True, mutation_type=None, variable_type=None, xdim=0)

Bases: FractionFieldElement

This class is a thin wrapper for cluster variables in cluster seeds.

It provides the extra feature to store if a variable is frozen or not.

- the associated positive root:

```
sage: S = ClusterSeed(['A',3])
sage: for T in S.variable_class_iter():
....:     print("{} {}\n".format(T, T.almost_positive_root()))
x0 -alpha[1]
x1 -alpha[2]
x2 -alpha[3]
(x1 + 1)/x0 alpha[1]
(x1^2 + x0*x2 + 2*x1 + 1)/(x0^2*x1*x2) alpha[1] + alpha[2] + alpha[3]
(x1 + 1)/x2 alpha[3]
(x0*x2 + x1 + 1)/(x0*x1) alpha[1] + alpha[2]
(x0*x2 + 1)/x1 alpha[2]
(x0*x2 + x1 + 1)/(x1*x2) alpha[2] + alpha[3]
```

\texttt{almost_positive_root()}

Return the \textit{almost positive root} associated to \texttt{self} if \texttt{self} is of finite type.

\textbf{EXAMPLES:}

```
sage: S = ClusterSeed(['A',3])
sage: for T in S.variable_class_iter():
....:     print("{} {}\n".format(T, T.almost_positive_root()))
x0 -alpha[1]
x1 -alpha[2]
x2 -alpha[3]
(x1 + 1)/x0 alpha[1]
(x1^2 + x0*x2 + 2*x1 + 1)/(x0^2*x1*x2) alpha[1] + alpha[2] + alpha[3]
(x1 + 1)/x2 alpha[3]
(x0*x2 + x1 + 1)/(x0*x1) alpha[1] + alpha[2]
(x0*x2 + 1)/x1 alpha[2]
(x0*x2 + x1 + 1)/(x1*x2) alpha[2] + alpha[3]
```

\texttt{sage.combinat.cluster_algebra_quiver.cluster_seed.PathSubset(n, m)}

Encode a \textit{maximal} Dyck path from \((0,0)\) to \((n,m)\) (for \(n \geq m \geq 0\)) as a subset of \(\{0, 1, 2, ..., 2n - 1\}\).
The encoding is given by indexing horizontal edges by odd numbers and vertical edges by evens.

The horizontal between \((i, j)\) and \((i + 1, j)\) is indexed by the odd number \(2 * i + 1\). The vertical between \((i, j)\) and \((i, j + 1)\) is indexed by the even number \(2 * j\).

**EXAMPLES:**

```
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import PathSubset
sage: PathSubset(4,0)
{1, 3, 5, 7}
sage: PathSubset(4,1)
{1, 3, 5, 6, 7}
sage: PathSubset(4,2)
{1, 2, 3, 5, 6, 7}
sage: PathSubset(4,3)
{1, 2, 3, 4, 5, 6, 7}
sage: PathSubset(4,4)
{0, 1, 2, 3, 4, 5, 6, 7}
```

sage.combinat.cluster_algebra_quiver.cluster_seed.SetToPath(T)

Rearrange the encoding for a *maximal* Dyck path (as a set) so that it is a list in the proper order of the edges.

**EXAMPLES:**

```
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import PathSubset
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import SetToPath
sage: SetToPath(PathSubset(4,0))
[1, 3, 5, 7]
sage: SetToPath(PathSubset(4,1))
[1, 3, 5, 7, 6]
sage: SetToPath(PathSubset(4,2))
[1, 3, 2, 5, 7, 6]
sage: SetToPath(PathSubset(4,3))
[1, 3, 2, 5, 4, 7, 6]
sage: SetToPath(PathSubset(4,4))
[1, 0, 3, 2, 5, 4, 7, 6]
```

sage.combinat.cluster_algebra_quiver.cluster_seed.coeff_recurs(p, q, a1, a2, b, c)

Coefficients in Laurent expansion of greedy element, as defined by recursion.

**EXAMPLES:**

```
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import coeff_recurs
sage: coeff_recurs(1, 1, 5, 5, 3, 3)
10
```

sage.combinat.cluster_algebra_quiver.cluster_seed.get_green_vertices(C)

Get the green vertices from a matrix.

Will go through each column and return the ones where no entry is greater than 0.

**INPUT:**

- \(C\) – The C-matrix to check

**EXAMPLES:**
sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import get_green_vertices
sage: S = ClusterSeed(['A',4]); S.mutate([1,2,3,2,0,1,2,0,3])
[0, 3]

sage.combinat.cluster_algebra_quiver.cluster_seed.get_red_vertices(C)

Get the red vertices from a matrix.

Will go through each column and return the ones where no entry is less than 0.

INPUT:

• C – The C-matrix to check

EXAMPLES:

sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import get_red_vertices
sage: S = ClusterSeed(['A',4]); S.mutate([1,2,3,2,0,1,2,0,3])
[1, 2]

sage.combinat.cluster_algebra_quiver.cluster_seed.is_LeeLiZel_allowable(T, n, m, b, c)

Check if the subset $T$ contributes to the computation of the greedy element $x[m,n]$ in the rank two $(b,c)$-cluster algebra.

This uses the conditions of Lee-Li-Zelevinsky’s paper [LLZ2014].

EXAMPLES:

sage: from sage.combinat.cluster_algebra_quiver.cluster_seed import is_LeeLiZel_allowable
sage: is_LeeLiZel_allowable({1,2},3,2,4,2,6,6)
True

5.1.19 mutation_class

This file contains helper functions for compute the mutation class of a cluster algebra or quiver.

For the compendium on the cluster algebra and quiver package see [MS2011]

AUTHORS:

• Gregg Musiker
• Christian Stump
5.1.20 Helper functions for mutation types of quivers

This file contains helper functions for detecting the mutation type of a cluster algebra or quiver.

For the compendium on the cluster algebra and quiver package see [MS2011]

AUTHORS:

• Gregg Musiker
• Christian Stump

\begin{verbatim}
sage.combinat.cluster_algebra_quiver.mutation_type.is_mutation_finite(M, nr_of_checks=None)
\end{verbatim}

Use a non-deterministic method by random mutations in various directions. Can result in a wrong answer.

**Warning:** This method modifies the input matrix \( M \)!

**INPUT:**

• \( nr_of_checks \) – (default: None) number of mutations applied. Standard is \( 500^\times \) (number of vertices of \( self \)).

**ALGORITHM:**

A quiver is mutation infinite if and only if every edge label \((a,-b)\) satisfy \( a \times b > 4 \). Thus, we apply random mutations in random directions

**EXAMPLES:**

\begin{verbatim}
sage: from sage.combinat.cluster_algebra_quiver.mutation_type import is_mutation_finite

sage: Q = ClusterQuiver(['A',10])
sage: M = Q.b_matrix() # needs sage.modules
sage: is_mutation_finite(M) # needs sage.modules
(\text{True}, \text{None})

sage: Q = ClusterQuiver([(0,1),(1,2),(2,3),(3,4),(4,5),(5,6),(6,7),(7,8),(2,9)])
sage: M = Q.b_matrix() # needs sage.modules
sage: is_mutation_finite(M) # random
(\text{False}, [9, 6, 9, 8, 9, 4, 0, 4, 5, 2, 1, 0, 1, 0, 7, 1, 9, 2, 5, 7, 8, 6, 3, 0, 2,\n5, 4, 2, 6, 9, 2, 7, 3, 5, 3, 7, 9, 5, 9, 0, 2, 7, 9, 2, 4, 2, 1, 6, 9, 4, 3, 5,\n0, 8, 2, 9, 5, 3, 7, 0, 1, 8, 3, 7, 2, 7, 3, 4, 8, 0, 4, 9, 5, 2, 8, 4, 8, 1, 7,\n8, 9, 1, 5, 0, 8, 7, 4, 8, 9, 8, 0, 7, 4, 7, 1, 2, 8, 6, 1, 3, 9, 3, 9, 1, 3, 2,\n4, 9, 5, 1, 2, 9, 4, 8, 5, 3, 4, 6, 8, 9, 2, 5, 9, 4, 6, 2, 1, 4, 9, 6, 0, 9, 8,\n0, 4, 7, 9, 2, 1, 6])
\end{verbatim}

Check that github issue #19495 is fixed:

\begin{verbatim}
sage: dg = DiGraph(); dg.add_vertex(0); S = ClusterSeed(dg); S # needs sage.modules
A seed for a cluster algebra of rank 1
\end{verbatim}

(continues on next page)
sage: S.is_mutation_finite() # needs sage.modules
True

sage.combinat.cluster_algebra_quiver.mutation_type.load_data(user=True)

Load a dict with keys being tuples representing exceptional QuiverMutationTypes, and with values being lists or sets containing all mutation equivalent quivers as dig6 data.

We check

- the data stored by the user (unless user=False was given)
- and the data installed by the optional package database_mutation_class.

INPUT:

- user – boolean (default: True) whether to look at user data. If not, only consider the optional package.

EXAMPLES:

sage: from sage.combinat.cluster_algebra_quiver.mutation_type import load_data
sage: load_data(2) # random - depends on the data the user has stored
{('G', 2): [(['AO', ((0, 1), (1, -3))],), ('AO', ((0, 1), (3, -1))),]}

5.1.21 Quiver

A quiver is an oriented graph without loops, two-cycles, or multiple edges. The edges are labelled by pairs \((i, -j)\) (with \(i\) and \(j\) being positive integers) such that the matrix \(M = (m_{ab})\) with \(m_{ab} = i, m_{ba} = -j\) for an edge \((i, -j)\) between vertices \(a\) and \(b\) is skew-symmetrizable.

**Warning:** This is not the standard definition of a quiver. Normally, in cluster algebra theory, a quiver is defined as an oriented graph without loops and two-cycles but with multiple edges allowed; the edges are unlabelled. This notion of quivers, however, can be seen as a particular case of our notion of quivers. Namely, if we have a quiver (in the regular sense of this word) with (precisely) \(i\) edges from \(a\) to \(b\), then we represent it by a quiver (in our sense of this word) with an edge from \(a\) to \(b\) labelled by the pair \((i, -i)\).

For the compendium on the cluster algebra and quiver package see [MS2011]

AUTHORS:

- Gregg Musiker
- Christian Stump

See also:

For mutation types of combinatorial quivers, see `QuiverMutationType()`. Cluster seeds are closely related to `ClusterSeed()`.

```
class sage.combinat.cluster_algebra_quiver.quiver.ClusterQuiver(data, frozen=None, user_labels=None)
```

INPUT:
• data – can be any of the following:

- :class:`QuiverMutationType`
- :class:`str` -- a string representing a :class:`QuiverMutationType` or a common quiver type (see Examples)
- :class:`ClusterQuiver`
- :class:`Matrix` -- a skew-symmetrizable matrix
- :class:`DiGraph` -- must be the input data for a quiver
- List of edges -- must be the edge list of a digraph for a quiver

• frozen – (default: None) sets the list of frozen variables if the input type is a :class:`DiGraph`, it is ignored otherwise

• user_labels – (default: None) sets the names of the labels for the vertices of the quiver if the input type is not a :class:`DiGraph`; otherwise it is ignored

EXAMPLES:

From a :class:`QuiverMutationType`:

```python
sage: Q = ClusterQuiver(['A',5]); Q
Quiver on 5 vertices of type ['A', 5]
sage: Q = ClusterQuiver(['B',2]); Q
Quiver on 2 vertices of type ['B', 2]
sage: Q2 = ClusterQuiver(['C',2]); Q2
Quiver on 2 vertices of type ['B', 2]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
True
sage: MT = Q2.mutation_type(); MT.standard_quiver() == Q2
False
sage: Q = ClusterQuiver(['A',[2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: Q = ClusterQuiver(['A', [5,0],1]); Q
Quiver on 5 vertices of type ['D', 5]
sage: Q.is_finite()
True
sage: Q.is_acyclic()
False
sage: Q = ClusterQuiver(['F', 4, [2,1]]); Q
Quiver on 6 vertices of type ['F', 4, [1, 2]]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False
sage: dg = Q.digraph(); Q.mutate([2,1,4,0,5,3])
sage: dg2 = Q.digraph(); dg2.is_isomorphic(dg,edge_labels=True)
False
sage: dg2.is_isomorphic(MT.standard_quiver().digraph(),edge_labels=True)
True
sage: Q = ClusterQuiver(['G',2, (3,1)]); Q
Quiver on 4 vertices of type ['G', 2, [1, 3]]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
```

(continues on next page)
sage: Q = ClusterQuiver(['GR', [3, 6]]); Q
Quiver on 4 vertices of type ['D', 4]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False
sage: Q = ClusterQuiver(['GR', [3, 7]]); Q
Quiver on 6 vertices of type ['E', 6]
sage: Q = ClusterQuiver(['TR', 2]); Q
Quiver on 3 vertices of type ['A', 3]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False
sage: Q.mutate([1, 0]); MT.standard_quiver() == Q
True
sage: Q = ClusterQuiver(['TR', 3]); Q
Quiver on 6 vertices of type ['D', 6]
sage: MT = Q.mutation_type(); MT.standard_quiver() == Q
False

From a \texttt{ClusterQuiver}:

sage: Q = ClusterQuiver(['A', [2, 5], 1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q ); T
Quiver on 7 vertices of type ['A', [2, 5], 1]

From a Matrix:

sage: Q = ClusterQuiver(['A', [2, 5], 1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q._M ); T
Quiver on 7 vertices

sage: Q = ClusterQuiver( matrix([[0, 1, -1], [-1, 0, 1], [1, -1, 0], [1, 2, 3]])); Q
Quiver on 4 vertices with 1 frozen vertex
sage: Q = ClusterQuiver( matrix([])); Q
Quiver without vertices

From a DiGraph:

sage: Q = ClusterQuiver(['A', [2, 5], 1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q._digraph ); T
Quiver on 7 vertices

sage: Q = ClusterQuiver( DiGraph([[1, 2], [2, 3], [3, 4], [4, 1]])); Q
Quiver on 4 vertices
sage: Q = ClusterQuiver( DiGraph([[a', b'], [b', c'], [c', d'], [d', e']]),
frozen=['c']); Q
Quiver on 5 vertices with 1 frozen vertex
sage: Q.mutation_type()
[ ['A', 2], ['A', 2] ]
sage: Q
Quiver on 5 vertices of type [ ['A', 2], ['A', 2] ] with 1 frozen vertex

From a List of edges:

sage: Q = ClusterQuiver(['A',[2,5],1]); Q
Quiver on 7 vertices of type ['A', [2, 5], 1]
sage: T = ClusterQuiver( Q._digraph.edges(sort=True) ); T
Quiver on 7 vertices
sage: Q = ClusterQuiver([[1, 2], [2, 3], [3, 4], [4, 1]]); Q
Quiver on 4 vertices

b_matrix()

Return the b-matrix of self.

EXAMPLES:

sage: ClusterQuiver(['A',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]
sage: ClusterQuiver(['B',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -2 0]
sage: ClusterQuiver(['D',4]).b_matrix()
[ 0 1 0 0]
[-1 0 -1 -1]
[ 0 1 0 0]
[ 0 1 0 0]
sage: ClusterQuiver(QuiverMutationType([[A',2],[B',2]])).b_matrix()
[ 0 1 0 0]
[-1 0 0 0]
[ 0 0 0 1]
[ 0 0 -2 0]

canonical_label(certificate=False)

Return the canonical labelling of self.

See sage.graphs.generic_graph.GenericGraph.canonical_label().

INPUT:

- certificate – boolean (default: False) if True, the dictionary from self.vertices() to the
tvertices of the returned quiver is returned as well.
EXAMPLES:

```python
sage: Q = ClusterQuiver(['A',4]); Q.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: T = Q.canonical_label(); T.digraph().edges(sort=True)
[(0, 3, (1, -1)), (1, 2, (1, -1)), (1, 3, (1, -1))]

sage: T, iso = Q.canonical_label(certificate=True)
sage: T.digraph().edges(sort=True); iso
[(0, 3, (1, -1)), (1, 2, (1, -1)), (1, 3, (1, -1))]
{0: 0, 1: 3, 2: 1, 3: 2}

sage: Q = ClusterQuiver(QuiverMutationType([[B,2],[A,1]])); Q
Quiver on 3 vertices of type [['B', 2], ['A', 1]]

sage: Q.canonical_label()
Quiver on 3 vertices of type [['A', 1], ['B', 2]]

sage: Q.canonical_label(certificate=True)
(Quiver on 3 vertices of type [['A', 1], ['B', 2]], {0: 1, 1: 2, 2: 0})
```

d_vector_fan()

Return the d-vector fan associated with the quiver.

It is the fan whose maximal cones are generated by the d-matrices of the clusters.

This is a complete simplicial fan (and even smooth when the initial quiver is acyclic). It only makes sense for quivers of finite type.

EXAMPLES:

```python
sage: Fd = ClusterQuiver([[1,2]]).d_vector_fan(); Fd
Rational polyhedral fan in 2-d lattice N

sage: Fd.ngenerating_cones()
5

sage: Fd = ClusterQuiver([[1,2],[2,3]]).d_vector_fan(); Fd
Rational polyhedral fan in 3-d lattice N

sage: Fd.ngenerating_cones()
14

sage: Fd.is_smooth()
True

sage: Fd = ClusterQuiver([[1,2],[2,3],[3,1]]).d_vector_fan(); Fd
Rational polyhedral fan in 3-d lattice N

sage: Fd.ngenerating_cones()
14

sage: Fd.is_smooth()
False
```
digraph()

Return the underlying digraph of self.

EXAMPLES:
sage: ClusterQuiver(['A',1]).digraph()
Digraph on 1 vertex
sage: list(ClusterQuiver(['A',1]).digraph())
[0]
sage: ClusterQuiver(['A',1]).digraph().edges(sort=True)
[]

sage: ClusterQuiver(['A',4]).digraph()
Digraph on 4 vertices
sage: ClusterQuiver(['A',4]).digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: ClusterQuiver(['B',4]).digraph()
Digraph on 4 vertices
sage: ClusterQuiver(['A',4]).digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: ClusterQuiver(QuiverMutationType([['A',2],['B',2]])).digraph()
Digraph on 4 vertices
sage: ClusterQuiver(QuiverMutationType([['A',2],['B',2]])).digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 3, (1, -2))]

sage: ClusterQuiver(['C',4], user_labels = ['x', 'y', 'z', 'w']).digraph().edges(sort=True)
[(‘x’, ‘y’, (1, -1)), (‘z’, ‘w’, (2, -1)), (‘z’, ‘y’, (1, -1))]

exchangeable_part()
Return the restriction to the principal part (i.e. exchangeable part) of self, the subquiver obtained by deleting the frozen vertices of self.

EXAMPLES:

sage: Q = ClusterQuiver(['A',4])
sage: T = ClusterQuiver(Q.digraph().edges(sort=True), frozen=[3])
sage: T.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1)), (2, 3, (1, -1))]

sage: T.exchangeable_part().digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 1, (1, -1))]

sage: Q2 = Q.principal_extension()
sage: Q3 = Q2.principal_extension()
sage: Q2.exchangeable_part() == Q3.exchangeable_part()
True

first_sink()
Return the first vertex of self that is a sink.

EXAMPLES:

sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([1,2,4,3,2])

(continues on next page)
Combinatorics, Release 10.1

sage: Q.first_sink()
0

**first_source()**

Return the first vertex of \texttt{self} that is a source

**EXAMPLES:**

```python
sage: Q = ClusterQuiver(['A', 5])
sage: Q.mutate([2, 1, 3, 4, 2])
sage: Q.first_source()
1
```

**free_vertices()**

Return the list of free vertices of \texttt{self}.

**EXAMPLES:**

```python
sage: Q = ClusterQuiver(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']]),
                   frozen=['b', 'd'])
.....
sage: Q.free_vertices()
['a', 'c', 'e']
```

**frozen_vertices()**

Return the list of frozen vertices of \texttt{self}.

**EXAMPLES:**

```python
sage: Q = ClusterQuiver(DiGraph([['a', 'b'], ['c', 'b'], ['c', 'd'], ['e', 'd']]),
                   frozen=['b', 'd'])
.....
sage: sorted(Q.frozen_vertices())
['b', 'd']
```

**g_vector_fan()**

Return the g-vector fan associated with the quiver.

It is the fan whose maximal cones are generated by the g-matrices of the clusters.

This is a complete simplicial fan. It is only supported for quivers of finite type.

**EXAMPLES:**

```python
sage: Fg = ClusterQuiver([[1,2]]).g_vector_fan(); Fg
Rational polyhedral fan in 2-d lattice N
sage: Fg.ngenerating_cones()
5
sage: Fg = ClusterQuiver([[1,2],[2,3]]).g_vector_fan(); Fg
Rational polyhedral fan in 3-d lattice N
sage: Fg.ngenerating_cones()
14
sage: Fg.is_smooth()
True
```
sage: Fg = ClusterQuiver([[1,2],[2,3],[3,1]]).g_vector_fan(); Fg
Rational polyhedral fan in 3-d lattice N
sage: Fg.ngenerating_cones()
14
sage: Fg.is_smooth()
True

interact(fig_size=1, circular=True)
Start an interactive window for cluster quiver mutations.
Only in Jupyter notebook mode.

INPUT:
• fig_size – (default: 1) factor by which the size of the plot is multiplied.
• circular – (default: True) if True, the circular plot is chosen, otherwise >>spring<< is used.

is_acyclic()
Return true if self is acyclic.

EXAMPLES:

sage: ClusterQuiver(['A',4]).is_acyclic()
True
sage: ClusterQuiver(['A',[2,1],[1]]).is_acyclic()
True
sage: ClusterQuiver([[0,1],[1,2],[2,0]]).is_acyclic()
False

is_bipartite(return_bipartition=False)
Return True if self is bipartite.

EXAMPLES:

sage: ClusterQuiver(['A',[3,3]],1).is_bipartite()
True
sage: ClusterQuiver(['A',[4,3]],1).is_bipartite()
False

is_finite()
Return True if self is of finite type.

EXAMPLES:

sage: Q = ClusterQuiver(['A',3])
sage: Q.is_finite()
True
sage: Q = ClusterQuiver(['A',[2,2]],1)
sage: Q.is_finite()
False
sage: Q = ClusterQuiver([[A',3],[B',3]])
is_mutation_finite(nr_of_checks=None, return_path=False)

Uses a non-deterministic method by random mutations in various directions. Can result in a wrong answer.

INPUT:

• nr_of_checks – (default: None) number of mutations applied. Standard is 500*(number of vertices of self).

• return_path – (default: False) if True, in case of self not being mutation finite, a path from self to a quiver with an edge label (a,-b) and a*b > 4 is returned.

ALGORITHM:

A quiver is mutation infinite if and only if every edge label (a,-b) satisfy a*b > 4. Thus, we apply random mutations in random directions.

EXAMPLES:

sage: Q = ClusterQuiver(['A',10])
sage: Q._mutation_type = None
sage: Q.is_mutation_finite()
True

sage: Q = ClusterQuiver([(0,1),(1,2),(2,3),(3,4),(4,5),(5,6),(6,7),(7,8),(2,9)])
sage: Q.is_mutation_finite()
False

m()

Return the number of frozen vertices of self.
EXAMPLES:

```python
sage: Q = ClusterQuiver(['A',4])
sage: Q.m()
0

sage: T = ClusterQuiver(Q.digraph().edges(sort=True), frozen=[3])
sage: T.n()
3
sage: T.m()
1
```

**mutate**(data, inplace=True)

Mutates `self` at a sequence of vertices.

INPUT:

- `sequence` – a vertex of `self`, an iterator of vertices of `self`, a function which takes in the ClusterQuiver and returns a vertex or an iterator of vertices, or a string of the parameter wanting to be called on ClusterQuiver that will return a vertex or an iterator of vertices.
- `inplace` – (default: True) if False, the result is returned, otherwise `self` is modified.

EXAMPLES:

```python
sage: Q = ClusterQuiver(['A',4]); Q.b_matrix()
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

sage: Q.mutate(0); Q.b_matrix()
[ 0 -1 0 0]
[ 1 0 -1 0]
[ 0 1 0 1]
[ 0 0 -1 0]

sage: T = Q.mutate(0, inplace=False); T
Quiver on 4 vertices of type ['A', 4]
sage: Q.mutate(0)
sage: Q == T
True

sage: Q.mutate([0,1,0])
sage: Q.b_matrix()
[ 0 -1 1 0]
[ 1 0 0 0]
[-1 0 0 1]
[ 0 0 -1 0]

sage: Q = ClusterQuiver(QuiverMutationType([['A',1],['A',3]]))
sage: Q.b_matrix()
[ 0 0 0 0]
[ 0 0 1 0]
```

(continues on next page)
Combinatorics, Release 10.1

(continued from previous page)

\[
\begin{bmatrix}
0 & -1 & 0 & -1 \\
0 & 0 & 1 & 0
\end{bmatrix}
\]

```python
sage: T = Q.mutate(0, inplace=False)
sage: Q == T
True
```

```python
sage: Q = ClusterQuiver(["A",3]); Q.b_matrix()
\[
\begin{bmatrix}
0 & 1 & 0 \\
-1 & 0 & -1 \\
0 & 1 & 0
\end{bmatrix}
\]
```

```python
sage: Q.mutate('first_sink'); Q.b_matrix()
\[
\begin{bmatrix}
0 & -1 & 0 \\
1 & 0 & 1 \\
0 & -1 & 0
\end{bmatrix}
\]
```

```python
sage: Q.mutate('first_source'); Q.b_matrix()
\[
\begin{bmatrix}
0 & 1 & 0 \\
-1 & 0 & -1 \\
0 & 1 & 0
\end{bmatrix}
\]
```

```python
dg = DiGraph()
sage: dg.add_vertices(['a','b','c','d','e'])
sage: dg.add_edges([['a','b'],['b','c'],['c','d'],['d','e']])
sage: Q2 = ClusterQuiver(dg, frozen=['c']); Q2.b_matrix()
\[
\begin{bmatrix}
0 & 1 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0 \\
0 & -1 & 1 & 0
\end{bmatrix}
\]
```

```python
sage: Q2.mutate('a'); Q2.b_matrix()
\[
\begin{bmatrix}
0 & -1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0 \\
0 & -1 & 1 & 0
\end{bmatrix}
\]
```

```python
dg = DiGraph([['a','b'], ['b','c'], format='list_of_edges'])
sage: Q = ClusterQuiver(dg); Q
Quiver on 3 vertices
sage: Q.mutate(['a','b'], inplace=False).digraph().edges(sort=True)
[['('a', 'b', (1, -1)), ('c', 'b', (1, -1))]
```

**mutation_class**(depth=+Infinity, show_depth=False, return_paths=False, data_type='quiver', up_to_equivalence=True, sink_source=False)

Return the mutation class of self together with certain constraints.

**INPUT:**

- **depth** – (default: infinity) integer, only seeds with distance at most depth from `self` are returned
- **show_depth** – (default: False) if True, the actual depth of the mutation is shown
- **return_paths** – (default: False) if True, a shortest path of mutation sequences from self to the
given quiver is returned as well

- **data_type** – (default: "quiver") can be one of the following:
  - "quiver" – the quiver is returned
  - "dig6" – the dig6-data is returned
  - "path" – shortest paths of mutation sequences from self are returned

- **sink_source** – (default: False) if True, only mutations at sinks and sources are applied

**EXAMPLES:**

```python
sage: Q = ClusterQuiver(['A',3])
sage: Ts = Q.mutation_class()
sage: for T in Ts: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: Ts = Q.mutation_class(depth=1)
sage: for T in Ts: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: Ts = Q.mutation_class(show_depth=True)
Depth: 0  found: 1  Time: ... s
Depth: 1  found: 3  Time: ... s
Depth: 2  found: 4  Time: ... s

sage: Ts = Q.mutation_class(return_paths=True)
```

(continues on next page)
sage: Ts = Q.mutation_class(return_paths=True, up_to_equivalence=False)
sage: len(Ts)
14
sage: Ts[0]
(Quiver on 3 vertices of type ['A', 3], [])

sage: Ts = Q.mutation_class(show_depth=True)
Depth: 0  found:  1  Time: ... s
Depth: 1  found:  3  Time: ... s
Depth: 2  found:  4  Time: ... s

sage: Ts = Q.mutation_class(show_depth=True, up_to_equivalence=False)
Depth: 0  found:  1  Time: ... s
Depth: 1  found:  4  Time: ... s
Depth: 2  found:  6  Time: ... s
Depth: 3  found: 10  Time: ... s
Depth: 4  found: 14  Time: ... s

**mutation_class_iter**(depth=+Infinity, show_depth=False, return_paths=False, data_type='quiver', up_to_equivalence=True, sink_source=False)

Return an iterator for the mutation class of **self** together with certain constraints.

**INPUT:**

- **depth** – (default: infinity) integer, only quivers with distance at most depth from **self** are returned.
- **show_depth** – (default: False) if True, the actual depth of the mutation is shown.
- **return_paths** – (default: False) if True, a shortest path of mutation sequences from **self** to the given quiver is returned as well.
- **data_type** – (default: “quiver”) can be one of the following:
  - "quiver"
  - "matrix"
  - "digraph"
  - "dig6"
  - "path"

- **up_to_equivalence** – (default: True) if True, only one quiver for each graph-isomorphism class is recorded.
- **sink_source** – (default: False) if True, only mutations at sinks and sources are applied.

**EXAMPLES:**

```
sage: Q = ClusterQuiver(['A',3])
sage: it = Q.mutation_class_iter()
sage: for T in it: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
```
sage: it = Q.mutation_class_iter(depth=1)
sage: for T in it: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: it = Q.mutation_class_iter(show_depth=True)
sage: for T in it: pass
Depth: 0  found: 1  Time: ... s
Depth: 1  found: 3  Time: ... s
Depth: 2  found: 4  Time: ... s

sage: it = Q.mutation_class_iter(return_paths=True)
sage: for T in it: print(T)
(Quiver on 3 vertices of type ['A', 3], [])
(Quiver on 3 vertices of type ['A', 3], [1])
(Quiver on 3 vertices of type ['A', 3], [0])
(Quiver on 3 vertices of type ['A', 3], [0, 1])

sage: it = Q.mutation_class_iter(up_to_equivalence=False)
sage: for T in it: print(T)
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]
Quiver on 3 vertices of type ['A', 3]

sage: it = Q.mutation_class_iter(return_paths=True, up_to_equivalence=False)
sage: mutation_class = list(it)
sage: len(mutation_class)
14
sage: mutation_class[0]
(Quiver on 3 vertices of type ['A', 3], [])

sage: Q = ClusterQuiver(['A',3])
sage: it = Q.mutation_class_iter(data_type='path')
sage: for T in it: print(T)
[]
[1]
[0]
[0, 1]

sage: Q = ClusterQuiver(['A',3])
sage: it = Q.mutation_class_iter(return_paths=True, data_type='matrix')
sage: next(it)
([0 0 1]
[0 0 1]
[-1 -1 0], []
)
sage: dg = DiGraph([['a', 'b'], ['b', 'c']], format='list_of_edges')
sage: S = ClusterQuiver(dg, frozen=['b'])
sage: S.mutation_class()
[Quiver on 3 vertices with 1 frozen vertex,
 Quiver on 3 vertices with 1 frozen vertex,
 Quiver on 3 vertices with 1 frozen vertex]

**mutation_sequence** *(sequence, show_sequence=False, fig_size=1.2)*

Return a list containing the sequence of quivers obtained from self by a sequence of mutations on vertices.

**INPUT:**

- `sequence` – a list or tuple of vertices of self.
- `show_sequence` – (default: False) if True, a png containing the mutation sequence is shown.
- `fig_size` – (default: 1.2) factor by which the size of the sequence is expanded.

**EXAMPLES:**

```sage
sage: Q = ClusterQuiver(['A',4])
sage: seq = Q.mutation_sequence([0,1]); seq
[Quiver on 4 vertices of type ['A', 4],
 Quiver on 4 vertices of type ['A', 4],
 Quiver on 4 vertices of type ['A', 4]]
sage: [T.b_matrix() for T in seq]
[[0 1 0 0] [0 -1 0 0] [0 1 -1 0]
[-1 0 -1 0] [1 0 -1 0] [-1 0 1 0]
[0 1 0 1] [0 1 0 1] [1 -1 0 1]
[0 0 -1 0], [0 0 -1 0], [0 0 -1 0]]
```

**mutation_type()**

Return the mutation type of self.

Return the mutation_type of each connected component of self if it can be determined, otherwise, the mutation type of this component is set to be unknown.

The mutation types of the components are ordered by vertex labels.

If you do many type recognitions, you should consider to save exceptional mutation types using **save_quiver_data()**

**WARNING:**

- All finite types can be detected,
- All affine types can be detected, EXCEPT affine type D (the algorithm is not yet implemented)
• All exceptional types can be detected.

EXAMPLES:

```
sage: ClusterQuiver(['A',4]).mutation_type()
['A', 4]
sage: ClusterQuiver(['A',(3,1),1]).mutation_type()
['A', [1, 3], 1]
sage: ClusterQuiver(['C',2]).mutation_type()
['B', 2]
sage: ClusterQuiver(['B',4,1]).mutation_type()
['BD', 4, 1]
```

finite types:

```
sage: Q = ClusterQuiver(['A',5])
sage: Q._mutation_type = None
sage: Q.mutation_type()
['A', 5]
sage: Q = ClusterQuiver([(0,1),(1,2),(2,3),(3,4)])
sage: Q.mutation_type()
['A', 5]
sage: Q = ClusterQuiver(DiGraph([('A', 'b'), ('c', 'b'), ('c', 'd'), ('e', 'd')]),
  ....:     frozen=['c'])
sage: Q.mutation_type()
[ ['A', 2], ['A', 2] ]
```

affine types:

```
sage: Q = ClusterQuiver(['E',8,[1,1]]); Q
Quiver on 10 vertices of type ['E', 8, [1, 1]]
sage: Q._mutation_type = None; Q
Quiver on 10 vertices
sage: Q.mutation_type() # long time
['E', 8, [1, 1]]
```

the not yet working affine type D (unless user has saved small classical quiver data):

```
sage: Q = ClusterQuiver(['D',4,1])
sage: Q._mutation_type = None
sage: Q.mutation_type() # todo: not implemented
['D', 4, 1]
```

the exceptional types:

```
sage: Q = ClusterQuiver(['X',6])
sage: Q._mutation_type = None
sage: Q.mutation_type() # long time
['X', 6]
```

examples from page 8 of [Ke2008]:

5.1. Comprehensive Module List 245
sage: dg = DiGraph(); dg.add_edges([(9,0),(9,4),(4,6),(6,7),(7,8),(8,3),(3,5),(5,6),(8,1),(2,3)])

sage: ClusterQuiver( dg ).mutation_type() # long time
['E', 8, [1, 1]]

sage: dg = DiGraph( { 0:[3], 1:[0,4], 2:[0,6], 3:[1,2,7], 4:[3,8], 5:[2], 6:[3,5], 7:[4,6], 8:[7] } )
sage: ClusterQuiver( dg ).mutation_type() # long time
['E', 8, 1]

sage: dg = DiGraph( { 0:[3,9], 1:[0,4], 2:[0,6], 3:[1,2,7], 4:[3,8], 5:[2], 6:[3,5], 7:[4,6], 8:[7], 9:[1] } )
sage: ClusterQuiver( dg ).mutation_type() # long time
['E', 8, [1, 1]]

infinite types:

sage: Q = ClusterQuiver([['GR', [4,9]])
sage: Q._mutation_type = None
sage: Q.mutation_type()
'undetermined infinite mutation type'

reducible types:

sage: Q = ClusterQuiver([['A', 3], ['B', 3]])
sage: Q._mutation_type = None
sage: Q.mutation_type()
[ ['A', 3], ['B', 3] ]

sage: Q = ClusterQuiver([['A', 3], ['T', [4,4,4]]])
sage: Q._mutation_type = None
sage: Q.mutation_type()
[ ['A', 3], 'undetermined infinite mutation type' ]

sage: Q = ClusterQuiver([['A', 3], ['B', 3], ['T', [4,4,4]]])
sage: Q._mutation_type = None
sage: Q.mutation_type()
[ ['A', 3], ['B', 3], 'undetermined infinite mutation type' ]

sage: Q = ClusterQuiver([0,1,2],[1,2,2],[2,0,2],[3,4,1],[4,5,1])
sage: Q.mutation_type()
['undetermined finite mutation type', ['A', 3]]

n()  
Return the number of free vertices of self.

EXAMPLES:

sage: ClusterQuiver(['A',4]).n()  
4
sage: ClusterQuiver(['A',(3,1),1]).n()  
4
sage: ClusterQuiver(['B',4]).n()  
4

Combinatorics, Release 10.1

(continued from previous page)

```
sage: ClusterQuiver(['B',4,1]).n()
5
```

**number_of_edges()**

Return the total number of edges on the quiver

Note: This only works with non-valued quivers. If used on a non-valued quiver then the positive value is taken to be the number of edges added

**OUTPUT:**

An integer of the number of edges.

**EXAMPLES:**

```
sage: S = ClusterQuiver(['A',4]); S.number_of_edges()
3
sage: S = ClusterQuiver(['B',4]); S.number_of_edges()
3
```

**plot(circular=True, center=(0,0), directed=True, mark=None, save_pos=False, greens=[])**

Return the plot of the underlying digraph of self.

**INPUT:**

- *circular* – (default: True) if True, the circular plot is chosen, otherwise >>spring<< is used.
- *center* – (default:(0,0)) sets the center of the circular plot, otherwise it is ignored.
- *directed* – (default: True) if True, the directed version is shown, otherwise the undirected.
- *mark* – (default: None) if set to i, the vertex i is highlighted.
- *save_pos* – (default: False) if True, the positions of the vertices are saved.
- *greens* – (default: []) if set to a list, will display the green vertices as green

**EXAMPLES:**

```
sage: Q = ClusterQuiver(['A',5])
sage: Q.plot()
# needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
sage: Q.plot(circular=True)
# needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
sage: Q.plot(circular=True, mark=1)
# needs sage.plot sage.symbolic
Graphics object consisting of 15 graphics primitives
```

**poincare_semistable(theta, d)**

Return the Poincaré polynomial of the moduli space of semi-stable representations of dimension vector \(d\).

**INPUT:**

- *theta* – stability weight, as list or vector of rationals
- *d* – dimension vector, as list or vector of coprime integers
The semi-stability is taken with respect to the slope function

\[ \mu(d) = \theta(d) / \dim(d) \]

where \( d \) is a dimension vector.

This uses the matrix-inversion algorithm from [Rei2002].

EXAMPLES:

```python
sage: Q = ClusterQuiver(['A',2])
sage: Q.poincare_semistable([1,0],[1,0])
1
sage: Q.poincare_semistable([1,0],[1,1])
1
sage: K2 = ClusterQuiver(matrix([[0,2],[-2,0]]))
sage: theta = (1, 0)
sage: K2.poincare_semistable(theta, [1,0])
1
sage: K2.poincare_semistable(theta, [1,1])
v^2 + 1
sage: K2.poincare_semistable(theta, [1,2])
1
sage: K2.poincare_semistable(theta, [1,3])
0
sage: K3 = ClusterQuiver(matrix([[0,3],[-3,0]]))
sage: theta = (1, 0)
sage: K3.poincare_semistable(theta, (2,3))
v^12 + v^10 + 3*v^8 + 3*v^6 + 3*v^4 + v^2 + 1
sage: K3.poincare_semistable(theta, (3,4))(1)
68
```

REFERENCES:

principal_extension

Return the principal extension of \texttt{self}, adding \( n \) frozen vertices to any previously frozen vertices. I.e., the quiver obtained by adding an outgoing edge to every mutable vertex of \texttt{self}.

EXAMPLES:

```python
sage: Q = ClusterQuiver(['A',2]); Q
Quiver on 2 vertices of type ['A', 2]
sage: T = Q.principal_extension(); T
Quiver on 4 vertices of type ['A', 2] with 2 frozen vertices
sage: T2 = T.principal_extension(); T2
Quiver on 6 vertices of type ['A', 2] with 4 frozen vertices
sage: Q.digraph().edges(sort=True)
[(0, 1, (1, -1))]
sage: T.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 0, (1, -1)), (3, 1, (1, -1))]
sage: T2.digraph().edges(sort=True)
[(0, 1, (1, -1)), (2, 0, (1, -1)), (3, 1, (1, -1)), (4, 0, (1, -1)), (5, 1, (1, -1))]
```
qmu_save(filename=None)

Save self in a .qmu file.

This file can then be opened in Bernhard Keller’s Quiver Applet.

See https://webusers.imj-prg.fr/~bernhard.keller/quivermutation/

INPUT:

• filename – the filename the image is saved to.

If a filename is not specified, the default name is from_sage.qmu in the current sage directory.

EXAMPLES:

```python
def qmu_save(filename=None):
    save(self, filename=filename, extension='qmu')
```

Make sure we can save quivers with $m! = n$ frozen variables, see github issue #14851:

```python
def qmu_save(filename=None):
    save(self, filename=filename, extension='qmu')
```

relabel(relabelling, inplace=True)

Return the quiver after doing a relabelling

Will relabel the vertices of the quiver

INPUT:

• relabelling – Dictionary of labels to move around

• inplace – (default:True) if True, will return a duplicate of the quiver

EXAMPLES:

```python
def relabel(relabelling, inplace=True):
    quiver = self.copy()
    for old, new in relabelling.items():
        for i in range(len(quiver.labels())):
            if quiver.labels()[i] == old:
                quiver.set_label(i, new)
    return quiver if inplace else quiver.copy()
```

reorient(data)

Reorient self with respect to the given total order, or with respect to an iterator of edges in self to be reverted.

**Warning:** This operation might change the mutation type of self.

INPUT:

• data – an iterator defining a total order on self.vertices(), or an iterator of edges in self to be reoriented.

EXAMPLES:
sage: Q = ClusterQuiver(['A', (2, 3), 1])
sage: Q.mutation_type()
['A', [2, 3], 1]
sage: Q.reorient([(0, 1), (1, 2), (2, 3), (3, 4)])
sage: Q.mutation_type()
['D', 5]
sage: Q.reorient([0, 1, 2, 3, 4])
sage: Q.mutation_type()
['A', [1, 4], 1]

save_image(filename, circular=False)
Save the plot of the underlying digraph of self.

INPUT:

• filename – the filename the image is saved to.
• circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.

EXAMPLES:

sage: Q = ClusterQuiver(['F', 4, [1, 2]])
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix='.png') as f:
    # needs sage.plot sage.symbolic
    ....:    Q.save_image(f.name)

show(fig_size=1, circular=False, directed=True, mark=None, save_pos=False, greens=[])
Show the plot of the underlying digraph of self.

INPUT:

• fig_size – (default: 1) factor by which the size of the plot is multiplied.
• circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
• directed – (default: True) if True, the directed version is shown, otherwise the undirected.
• mark – (default: None) if set to i, the vertex i is highlighted.
• save_pos – (default:None) if True, the positions of the vertices are saved.
• greens – (default:[]) if set to a list, will display the green vertices as green

sinks()
Return all vertices of self that are sinks.

EXAMPLES:

sage: Q = ClusterQuiver(['A', 5])
sage: Q.mutate([1, 2, 4, 3, 2])
sage: Q.sinks()
[0, 2]
sage: Q = ClusterQuiver(['A', 5])
sage: Q.mutate([2, 1, 3, 4, 2])
(continues on next page)
Return all vertices of self that are sources.

EXAMPLES:

```python
sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([1,2,4,3,2])
sage: Q.sources()
[]
sage: Q = ClusterQuiver(['A',5])
sage: Q.mutate([2,1,3,4,2])
sage: Q.sources()
[1]
```

5.1.22 Quiver mutation types

AUTHORS:

- Gregg Musiker (2012, initial version)
- Christian Stump (2012, initial version)
- Hugh Thomas (2012, initial version)

```python
sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType(*args)
```

*Quiver mutation types* can be seen as a slight generalization of generalized Cartan types.

Background on generalized Cartan types can be found at

For the compendium on the cluster algebra and quiver package in Sage see [MS2011]

A $B$-matrix is a skew-symmetrizable ($n \times n$)-matrix $M$. I.e., there exists an invertible diagonal matrix $D$ such that $DM$ is skew-symmetric. $M$ can be encoded as a quiver by having a directed edge from vertex $i$ to vertex $j$ with label $(a, b)$ if $a = M_{i,j} > 0$ and $b = M_{j,i} < 0$. We consider quivers up to *mutation equivalence*.

To a quiver mutation type we can associate a *generalized Cartan type* by sending $M$ to the generalized Cartan matrix $C(M)$ obtained by replacing all positive entries by their negatives and adding 2’s on the main diagonal.

*QuiverMutationType* constructs a quiver mutation type object. For more detail on the possible different types, please see the compendium.

**INPUT:**

The input consists either of a quiver mutation type, or of a *letter* (a string), a *rank* (one integer or a list/tuple of integers), and an optional *twist* (an integer or a list of integers). There are several different naming conventions for quiver mutation types.

- Finite type – *letter* is a Dynkin type (A-G), and *rank* is the rank.
- Affine type – there is more than one convention for naming affine types.
Kac’s notation: letter is a Dynkin type, rank is the rank of the associated finite Dynkin diagram, and twist is the twist, which could be 1, 2, or 3. In the special case of affine type A, there is more than one quiver mutation type associated to the Cartan type. In this case only, rank is a pair of integers (i,j), giving the number of edges pointing clockwise and the number of edges pointing counter-clockwise. The total number of vertices is given by i+j in this case.

Naive notation: letter is one of ‘BB’, ‘BC’, ‘BD’, ‘CC’, ‘CD’. The name specifies the two ends of the diagram, which are joined by a path. The total number of vertices is given by rank +1 (to match the indexing people expect because these are affine types). In general, rank must be large enough for the picture to make sense, but we accept letter is BC and rank=1.

Macdonald notation: for the dual of an untwisted affine type (such as [‘C’, 6, 1]), we accept a twist of -1 (i.e., [‘C’,6,-1]).

Elliptic type – letter is a Dynkin type, rank is the rank of the finite Dynkin diagram, and twist is a tuple of two integers. We follow Saito’s notation.

Other shapes:
- Rank 2: letter is ‘R2’, and rank is a pair of integers specifying the label on the unique edge.
- Triangle: letter is TR, and rank is the number of vertices along a side.
- T: This defines a quiver shaped like a T. letter is ‘T’, and the rank is a triple, whose entries specify the number of vertices along each path from the branch point (counting the branch point).
- Grassmannian: This defines the cluster algebra (without coefficients) corresponding to the cluster algebra with coefficients which is the coordinate ring of a Grassmannian. letter is ‘GR’. rank is a pair of integers (k, n) with ‘k’ < ‘n’ specifying the Grassmannian of k-planes in n-space. This defines a quiver given by a (k-1) x (n-k-1) grid where each square is cyclically oriented.
- Exceptional mutation finite quivers: The two exceptional mutation finite quivers, found by Derksen-Owen, have letter as ‘X’ and rank 6 or 7, equal to the number of vertices.
- AE, BE, CE, DE: Quivers are built of one end which looks like type (affine A), B, C, or D, and the other end which looks like type E (i.e., it consists of two antennae, one of length one, and one of length two). letter is ‘AE’, ‘BE’, ‘CE’, or ‘DE’, and rank is the total number of vertices. Note that ‘AE’ is of a slightly different form and requires rank to be a pair of integers (i,j) just as in the case of affine type A. See Exercise 4.3 in Kac’s book Infinite Dimensional Lie Algebras for more details.
- Infinite type E: It is also possible to obtain infinite-type E quivers by specifying letter as ‘E’ and rank as the number of vertices.

REFERENCES:
- A good reference for finite and affine Dynkin diagrams, including Kac’s notation, is the Wikipedia article Dynkin diagram.
- A good reference for the skew-symmetrizable elliptic diagrams is “Cluster algebras of finite mutation type via unfolding” by A. Felikson, M. Shapiro, and P. Tumarkin, [FST2012].

EXAMPLES:

Finite types:

```python
sage: QuiverMutationType('A', 1)
['A', 1]
sage: QuiverMutationType('A',5)
['A', 5]
sage: QuiverMutationType('B', 2)
```

(continues on next page)
['B', 2]
sage: QuiverMutationType('B', 5)
['B', 5]

sage: QuiverMutationType('C', 2)
['B', 2]
sage: QuiverMutationType('C', 5)
['C', 5]

sage: QuiverMutationType('D', 2)
['A', 1], ['A', 1]
sage: QuiverMutationType('D', 3)
['A', 3]
sage: QuiverMutationType('D', 4)
['D', 4]

sage: QuiverMutationType('E', 6)
['E', 6]

sage: QuiverMutationType('G', 2)
['G', 2]

sage: QuiverMutationType('A', (1, 0), 1)
['A', 1]

sage: QuiverMutationType('A', (2, 4), 1)
['A', [2, 4], 1]

sage: QuiverMutationType('B', 2, 1)
['B', 2, 1]
sage: QuiverMutationType('B', 4, 1)
['B', 4, 1]

sage: QuiverMutationType('C', 2, 1)
['C', 2, 1]

sage: QuiverMutationType('C', 4, 1)
['C', 4, 1]

sage: QuiverMutationType('B', 1, 1)
['B', 1, 1]
sage: QuiverMutationType('B', 5, 1)
['B', 5, 1]

Affine types:

sage: QuiverMutationType('A', (1, 1), 1)
['A', [1, 1], 1]
sage: QuiverMutationType('A', (2, 4), 1)
['A', [2, 4], 1]

sage: QuiverMutationType('BB', 2, 1)
['BB', 2, 1]
sage: QuiverMutationType('BB', 4, 1)
['BB', 4, 1]

sage: QuiverMutationType('CC', 2, 1)
['CC', 2, 1]

sage: QuiverMutationType('CC', 4, 1)
['CC', 4, 1]

sage: QuiverMutationType('BC', 1, 1)
['BC', 1, 1]

sage: QuiverMutationType('BC', 5, 1)
['BC', 5, 1]
sage: QuiverMutationType('BD',3, 1)
['BD', 3, 1]
sage: QuiverMutationType('BD',5, 1)
['BD', 5, 1]
sage: QuiverMutationType('CD',3, 1)
['CD', 3, 1]
sage: QuiverMutationType('CD',5, 1)
['CD', 5, 1]
sage: QuiverMutationType('D',4, 1)
['D', 4, 1]
sage: QuiverMutationType('D',6, 1)
['D', 6, 1]
sage: QuiverMutationType('E',6, 1)
['E', 6, 1]
sage: QuiverMutationType('E',7, 1)
['E', 7, 1]
sage: QuiverMutationType('E',8, 1)
['E', 8, 1]
sage: QuiverMutationType('F',4, 1)
['F', 4, 1]
sage: QuiverMutationType('F',4,-1)
['F', 4, -1]
sage: QuiverMutationType('G',2, 1)
['G', 2, 1]
sage: QuiverMutationType('G',2,-1)
['G', 2, -1]
sage: QuiverMutationType('A',3, 2) == QuiverMutationType('D',3, 2)
True

Affine types using Kac’s Notation:

sage: QuiverMutationType('A', 1, 1)
['A', [1, 1], 1]
sage: QuiverMutationType('B',5, 1)
['BD', 5, 1]
sage: QuiverMutationType('C',5, 1)
['CC', 5, 1]
sage: QuiverMutationType('A',2, 2)
['BC', 1, 1]
sage: QuiverMutationType('A',7, 2)
['CD', 4, 1]
sage: QuiverMutationType('A',8, 2)
['BC', 4, 1]
sage: QuiverMutationType('D',6, 2)
['BB', 5, 1]
sage: QuiverMutationType('E',6, 2)
Elliptic types:

| sage: QuiverMutationType('E', 6, [1, 1]) |
| ['E', 6, [1, 1]] |
| sage: QuiverMutationType('F', 4, [2, 1]) |
| ['F', 4, [2, 1]] |
| sage: QuiverMutationType('G', 2, [3, 3]) |
| ['G', 2, [3, 3]] |

Mutation finite types:

Rank 2 cases:

| sage: QuiverMutationType('R2', (1, 1)) |
| ['A', 2] |
| sage: QuiverMutationType('R2', (1, 2)) |
| ['B', 2] |
| sage: QuiverMutationType('R2', (1, 3)) |
| ['G', 2] |
| sage: QuiverMutationType('R2', (1, 4)) |
| ['BC', 1, 1] |
| sage: QuiverMutationType('R2', (1, 5)) |
| ['R2', [1, 5]] |
| sage: QuiverMutationType('R2', (2, 2)) |
| ['A', [1, 1], 1] |
| sage: QuiverMutationType('R2', (3, 5)) |
| ['R2', [3, 5]] |

Exceptional Derksen-Owen quivers:

| sage: QuiverMutationType('X', 6) |
| ['X', 6] |

(Mainly) mutation infinite types:

Infinite type E:

| sage: QuiverMutationType('E', 9) |
| ['E', 8, 1] |
| sage: QuiverMutationType('E', 10) |
| ['E', 10] |
| sage: QuiverMutationType('E', 12) |
| ['E', 12] |
| sage: QuiverMutationType('AE', (2, 3)) |
| ['AE', [2, 3]] |
| sage: QuiverMutationType('BE', 5) |
| ['BE', 5] |
| sage: QuiverMutationType('CE', 5) |
| ['CE', 5] |
Grassmannian types:

```
sage: QuiverMutationType('GR', (2, 4))
['A', 1]
sage: QuiverMutationType('GR', (2, 6))
['A', 3]
sage: QuiverMutationType('GR', (3, 6))
['D', 4]
sage: QuiverMutationType('GR', (3, 7))
['E', 6]
sage: QuiverMutationType('GR', (3, 8))
['E', 8]
sage: QuiverMutationType('GR', (3, 10))
['GR', [3, 10]]
```

Triangular types:

```
sage: QuiverMutationType('TR', 2)
['A', 3]
sage: QuiverMutationType('TR', 3)
['D', 6]
sage: QuiverMutationType('TR', 4)
['E', 8, [1, 1]]
sage: QuiverMutationType('TR', 5)
['TR', 5]
```

T types:

```
sage: QuiverMutationType('T', (1, 1, 1))
['A', 1]
sage: QuiverMutationType('T', (1, 1, 4))
['A', 4]
sage: QuiverMutationType('T', (1, 4, 4))
['A', 7]
sage: QuiverMutationType('T', (2, 2, 2))
['D', 4]
sage: QuiverMutationType('T', (2, 2, 4))
['D', 6]
sage: QuiverMutationType('T', (2, 3, 3))
['E', 6]
sage: QuiverMutationType('T', (2, 3, 4))
['E', 7]
sage: QuiverMutationType('T', (2, 3, 5))
['E', 8]
sage: QuiverMutationType('T', (2, 3, 6))
['E', 8, 1]
sage: QuiverMutationType('T', (2, 3, 7))
['E', 10]
sage: QuiverMutationType('T', (3, 3, 3))
['E', 6, 1]
```
sage: QuiverMutationType('T', (3, 3, 4))
['T', [3, 3, 4]]

Reducible types:

sage: QuiverMutationType(['A', 3], ['B', 4])
[[['A', 3], ['B', 4]]]

class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationTypeFactory
Bases: SageObject

samples(finite=None, affine=None, elliptic=None, mutation_finite=None)

Return a sample of the available quiver mutations types.

INPUT:

- finite
- affine
- elliptic
- mutation_finite

All four input keywords default values are None. If set to True or False, only these samples are returned.

EXAMPLES:

sage: QuiverMutationType.samples()
[[['A', 1], ['A', 5], ['B', 2], ['B', 5], ['C', 3],
  ['C', 5], [ ['A', 1], ['A', 1] ], ['D', 5], ['E', 6],
  ['E', 7], ['E', 8], ['F', 4], ['G', 2],
  ['A', [1, 1], 1], ['A', [4, 5], 1], ['D', 4, 1],
  ['BB', 5, 1], ['E', 6, [1, 1]], ['E', 7, [1, 1]],
  ['R2', [1, 5]], ['R2', [3, 5]], ['E', 10], ['BE', 5],
  ['GR', [3, 10]], ['T', [3, 3, 4]]]

sage: QuiverMutationType.samples(finite=True)
[[['A', 1], ['A', 5], ['B', 2], ['B', 5], ['C', 3],
  ['C', 5], [ ['A', 1], ['A', 1] ], ['D', 5], ['E', 6],
  ['E', 7], ['E', 8], ['F', 4], ['G', 2]]

sage: QuiverMutationType.samples(affine=True)
[[['A', [1, 1], 1], ['A', [4, 5], 1], ['D', 4, 1], ['BB', 5, 1]]

sage: QuiverMutationType.samples(elliptic=True)
[[['E', 6, [1, 1]], ['E', 7, [1, 1]]]

sage: QuiverMutationType.samples(mutation_finite=False)
[[['R2', [1, 5]], ['R2', [3, 5]], ['E', 10], ['BE', 5],
  ['GR', [3, 10]], ['T', [3, 3, 4]]]

class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType_Irreducible(letter, rank, twist=None)
Bases: QuiverMutationType_abstract

5.1. Comprehensive Module List
The mutation type for a cluster algebra or a quiver. Should not be called directly, but through `QuiverMutationType`.

**class_size()**

If it is known, the size of the mutation class of all quivers which are mutation equivalent to the standard quiver of `self` (up to isomorphism) is returned.

Otherwise, `NotImplemented` is returned.

Formula for finite type A is taken from Torkildsen - Counting cluster-tilted algebras of type $A_n$. Formulas for affine type A and finite type D are taken from Bastian, Prellberg, Rubey, Stump - Counting the number of elements in the mutation classes of $\tilde{A}_n$ quivers. Formulas for finite and affine types B and C are proven but not yet published. Conjectural formulas for several other non-simply-laced affine types are implemented. Exceptional Types (finite, affine, and elliptic) E, F, G, and X are hardcoded.

**EXAMPLES:**

```sage
sage: mut_type = QuiverMutationType(["A",5]); mut_type
["A", 5]
sage: mut_type.class_size()
19
sage: mut_type = QuiverMutationType(["A",[10,3], 1]); mut_type
["A", [3, 10], 1]
sage: mut_type.class_size()
142120
sage: mut_type = QuiverMutationType(["B",6 ]); mut_type
["B", 6]
sage: mut_type.class_size()
132
sage: mut_type = QuiverMutationType(["BD",6, 1]); mut_type
["BD", 6, 1]
sage: mut_type.class_size()
Warning: This method uses a formula which has not been proved correct.
504
```

Check that github issue #14048 is fixed:

```sage
sage: mut_type = QuiverMutationType(["F",4,(2, 1)] )
sage: mut_type.class_size()
90
```

**dual()**

Return the `QuiverMutationType` which is dual to `self`.

**EXAMPLES:**

```sage
sage: mut_type = QuiverMutationType('A',5); mut_type
["A", 5]
sage: mut_type.dual()
["A", 5]
sage: mut_type = QuiverMutationType('B',5); mut_type
["B", 5]
```
\begin{verbatim}
sage: mut_type.dual()
["C", 5]
sage: mut_type.dual().dual()
["B", 5]
sage: mut_type.dual().dual() == mut_type
True
\end{verbatim}

**irreducible_components()**

Return a list of all irreducible components of `self`.

**Examples:**

\begin{verbatim}
sage: mut_type = QuiverMutationType(['A',3]); mut_type
['A', 3]
sage: mut_type.irreducible_components()
(['A', 3],)
\end{verbatim}

**class**

\begin{verbatim}
class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType_Reducible(*args)
Bases: QuiverMutationType_abstract

The mutation type for a cluster algebra or a quiver. Should not be called directly, but through
QuiverMutationType. Inherits from QuiverMutationType_abstract.

**class_size()**

If it is known, the size of the mutation class of all quivers which are mutation equivalent to the standard
quiver of `self` (up to isomorphism) is returned.

Otherwise, `NotImplemented` is returned.

**Examples:**

\begin{verbatim}
sage: mut_type = QuiverMutationType(['A',3],["B",3]); mut_type
[['A', 3], ['B', 3]]
sage: mut_type.class_size()
20
sage: mut_type = QuiverMutationType(['A',3],["B",3],["X",6])
sage: mut_type
[['A', 3], ['B', 3], ['X', 6]]
sage: mut_type.class_size()
100
\end{verbatim}

**dual()**

Return the `QuiverMutationType` which is dual to `self`.

**Examples:**

\begin{verbatim}
sage: mut_type = QuiverMutationType(['A',5],["B",6],["C",5],["D",4]); mut_type
[['A', 5], ['B', 6], ['C', 5], ['D', 4]]
sage: mut_type.dual()
[['A', 5], ['C', 6], ['B', 5], ['D', 4]]
\end{verbatim}

**irreducible_components()**

Return a list of all irreducible components of `self`.

**Examples:**

**5.1. Comprehensive Module List**

259
sage: mut_type = QuiverMutationType('A',3); mut_type
['A', 3]
sage: mut_type.irreducible_components()
([['A', 3],])

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[['A', 3], ['B', 3]]
sage: mut_type.irreducible_components()
([['A', 3], ['B', 3]])

sage: mut_type = QuiverMutationType(['A',3],['B',3],['X',6])

sage: mut_type.irreducible_components()
([['A', 3], ['B', 3], ['X', 6]])

class sage.combinat.cluster_algebra_quiver.quiver_mutation_type.QuiverMutationType_abstract
    Bases: UniqueRepresentation, SageObject

    EXAMPLES:

sage: mut_type1 = QuiverMutationType('A',5)
sage: mut_type2 = QuiverMutationType('A',5)
sage: mut_type3 = QuiverMutationType('A',6)
sage: mut_type1 == mut_type2
True
sage: mut_type1 == mut_type3
False

b_matrix()

    Return the B-matrix of the standard quiver of self.

    The conventions for B-matrices agree with Fomin-Zelevinsky (up to a reordering of the simple roots).

    EXAMPLES:

sage: mut_type = QuiverMutationType(['A',5]); mut_type
['A', 5]
sage: mut_type.b_matrix()  # needs sage.modules
[ 0 1 0 0 0]
[-1 0 -1 0 0]
[ 0 1 0 1 0]
[ 0 0 -1 0 -1]
[ 0 0 0 1 0]

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[['A', 3], ['B', 3]]
sage: mut_type.b_matrix()  # needs sage.modules
[ 0 1 0 0 0 0]
[-1 0 -1 0 0 0]
[ 0 1 0 1 0 0]
[ 0 0 -1 0 -1 0]
[ 0 0 0 1 0 0]
cartan_matrix()

Return the Cartan matrix of self.

Note that (up to a reordering of the simple roots) the convention for the definition of Cartan matrix, used here and elsewhere in Sage, agrees with the conventions of Kac, Fulton-Harris, and Fomin-Zelevinsky, but disagrees with the convention of Bourbaki. The \((i, j)\) entry is \(2(\alpha_i, \alpha_j)/(\alpha_i, \alpha_i)\).

EXAMPLES:

\begin{verbatim}
sage: mut_type = QuiverMutationType(['A',5]); mut_type ['A', 5]
sage: mut_type.cartan_matrix() # needs sage.modules
[ 2 -1  0  0  0]
[-1  2 -1  0  0]
[ 0  0 -1  2 -1]
[ 0  0  0 -1  2]
[ 0  0 0 0 -1]
\end{verbatim}

\begin{verbatim}
sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type [['A', 3], ['B', 3]]
sage: mut_type.cartan_matrix() # needs sage.modules
[ 2 -1  0  0  0  0]
[-1  2 -1  0  0  0]
[ 0 -1  2  0  0  0]
[ 0  0  0  2 -1  0]
[ 0  0  0 -1  2 -1]
[ 0  0 0 0 -2  2]
\end{verbatim}

is_affine()

Return True if self is of affine type.

EXAMPLES:

\begin{verbatim}
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_affine()
False

sage: mt = QuiverMutationType(['A', [4, 2], 1])
sage: mt.is_affine()
True
\end{verbatim}

is_elliptic()

Return True if self is of elliptic type.

EXAMPLES:

\begin{verbatim}
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_elliptic()
\end{verbatim}
Combinatorics, Release 10.1

False

```
sage: mt = QuiverMutationType(['E', 6, [1, 1]])
sage: mt.is_elliptic()
True
```

**is_finite()**

Return True if self is of finite type.

This means that the cluster algebra associated to self has only a finite number of cluster variables.

**EXAMPLES:**

```
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_finite()
True
sage: mt = QuiverMutationType(['A', [4, 2], 1])
sage: mt.is_finite()
False
```

**is_irreducible()**

Return True if self is irreducible.

**EXAMPLES:**

```
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_irreducible()
True
```

**is_mutation_finite()**

Return True if self is of finite mutation type.

This means that its mutation class has only finitely many different B-matrices.

**EXAMPLES:**

```
sage: mt = QuiverMutationType(['D', 5, 1])
sage: mt.is_mutation_finite()
True
```

**is_simply_laced()**

Return True if self is simply laced.

This means that the only arrows that appear in the quiver of self are single unlabelled arrows.

**EXAMPLES:**

```
sage: mt = QuiverMutationType(['A', 2])
sage: mt.is_simply_laced()
True
sage: mt = QuiverMutationType(['B', 2])
sage: mt.is_simply_laced()
False
```
mt = QuiverMutationType(['A', (1, 1), 1])
mt.is_simply_laced()
False

is_skew_symmetric()
Return True if the B-matrix of self is skew-symmetric.
EXAMPLES:

mt = QuiverMutationType(['A', 2])
mt.is_skew_symmetric()
True

mt = QuiverMutationType(['B', 2])
mt.is_skew_symmetric()
False

mt = QuiverMutationType(['A', (1, 1), 1])
mt.is_skew_symmetric()
True

letter()
Return the classification letter of self.
EXAMPLES:

mut_type = QuiverMutationType(['A', 5]); mut_type
['A', 5]
mut_type.letter()
'A'

mut_type = QuiverMutationType(['BC', 5, 1]); mut_type
['BC', 5, 1]
mut_type.letter()
'BC'

mut_type = QuiverMutationType(['A', 3], ['B', 3]); mut_type
[['A', 3], ['B', 3]]
mut_type.letter()
'A x B'

mut_type = QuiverMutationType(['A', 3], ['B', 3], ['X', 6]); mut_type
[['A', 3], ['B', 3], ['X', 6]]
mut_type.letter()
'A x B x X'

plot(circular=False, directed=True)
Return the plot of the underlying graph or digraph of self.

INPUT:
- circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
- directed – (default: True) if True, the directed version is shown, otherwise the undirected.
EXAMPLES:

```
sage: QMT = QuiverMutationType(['A',5])
sage: pl = QMT.plot()  # needs sage.plot sage.symbolic
sage: pl = QMT.plot(circular=True)  # needs sage.plot sage.symbolic
```

`properties()`

Print a scheme of all properties of `self`.

Most properties have natural definitions for either irreducible or reducible types. `affine` and `elliptic` are only defined for irreducible types.

EXAMPLES:

```
sage: mut_type = QuiverMutationType(['A',3]); mut_type
['A', 3]
sage: mut_type.properties()
['A', 3] has rank 3 and the following properties:
- irreducible: True
- mutation finite: True
- simply-laced: True
- skew-symmetric: True
- finite: True
- affine: False
- elliptic: False

sage: mut_type = QuiverMutationType(['B',3]); mut_type
['B', 3]
sage: mut_type.properties()
['B', 3] has rank 3 and the following properties:
- irreducible: True
- mutation finite: True
- simply-laced: False
- skew-symmetric: False
- finite: True
- affine: False
- elliptic: False

sage: mut_type = QuiverMutationType(['B',3,1]); mut_type
['BD', 3, 1]
sage: mut_type.properties()
['BD', 3, 1] has rank 4 and the following properties:
- irreducible: True
- mutation finite: True
- simply-laced: False
- skew-symmetric: False
- finite: False
- affine: True
- elliptic: False

sage: mut_type = QuiverMutationType(['E',6,[1, 1]]); mut_type
['E', 6, [1, 1]]
```
sage: mut_type.properties()
['E', 6, [1, 1]] has rank 8 and the following properties:
- irreducible: True
- mutation finite: True
- simply-laced: False
- skew-symmetric: True
- finite: False
- affine: False
- elliptic: True

sage: mut_type = QuiverMutationType(['A',3],['B',3]); mut_type
[ ['A', 3], ['B', 3] ]
sage: mut_type.properties()
[ ['A', 3], ['B', 3] ] has rank 6 and the following properties:
- irreducible: False
- mutation finite: True
- simply-laced: False
- skew-symmetric: False
- finite: True

sage: mut_type = QuiverMutationType('GR',[4,9]); mut_type
['GR', [4, 9]]
sage: mut_type.properties()
['GR', [4, 9]] has rank 12 and the following properties:
- irreducible: True
- mutation finite: False
- simply-laced: True
- skew-symmetric: True
- finite: False
- affine: False
- elliptic: False

rank()

Return the rank in the standard quiver of self.

The rank is the number of vertices.

EXAMPLES:

sage: mut_type = QuiverMutationType( ['A',5] ); mut_type
['A', 5]
sage: mut_type.rank()
5

sage: mut_type = QuiverMutationType( ['A',[4,5], 1] ); mut_type
['A', [4, 5], 1]
sage: mut_type.rank()
9

sage: mut_type = QuiverMutationType( ['BC',5, 1] ); mut_type
['BC', 5, 1]
sage: mut_type.rank()
6
sage: mut_type = QuiverMutationType([['A',3],['B',3]]); mut_type
[[['A', 3], ['B', 3]]]
sage: mut_type.rank()
6

sage: mut_type = QuiverMutationType([['A',3],['B',3],['X',6]]); mut_type
[[['A', 3], ['B', 3], ['X', 6]]]
sage: mut_type.rank()
12

show(circular=False, directed=True)
Show the plot of the underlying digraph of self.

INPUT:
  • circular – (default: False) if True, the circular plot is chosen, otherwise >>spring<< is used.
  • directed – (default: True) if True, the directed version is shown, otherwise the undirected.

standard_quiver()
Return the standard quiver of self.

EXAMPLES:

sage: mut_type = QuiverMutationType([['A',5]]); mut_type
[['A', 5]]
sage: mut_type.standard_quiver()
Quiver on 5 vertices of type ['A', 5]

sage: mut_type = QuiverMutationType([['A',[5,3],1]]); mut_type
[['A', [3, 5], 1]]
sage: mut_type.standard_quiver()
Quiver on 8 vertices of type ['A', [3, 5], 1]

sage: mut_type = QuiverMutationType([['A',3],[['B',3]]]; mut_type
[[['A', 3], ['B', 3]]]
sage: mut_type.standard_quiver()
Quiver on 6 vertices of type [['A', 3], ['B', 3]]

sage: mut_type = QuiverMutationType([['A',3],[['B',3],[['X',6]]]; mut_type
[[['A', 3], ['B', 3], ['X', 6]]]
sage: mut_type.standard_quiver()
Quiver on 12 vertices of type [['A', 3], ['B', 3], ['X', 6]]

sage.combinat.cluster_algebra_quiver.quiver_mutation_type.save_quiver_data(n, up_to=True, types='ClassicalExceptional', verbose=True)

Save mutation classes of certain quivers of ranks up to and equal to n or equal to n to DOT_SAGE/cluster_algebra_quiver/mutation_classes_n.dig6.

This data will then be used to determine quiver mutation types.

INPUT:
  • n – the rank (or the upper limit on the rank) of the mutation classes that are being saved.
• **up_to** – (default: True) if True, saves data for ranks smaller than or equal to \( n \). If False, saves data for rank exactly \( n \).
• **types** – (default: ‘ClassicalExceptional’) if all, saves data for both exceptional mutation-finite quivers and for classical quiver. The input ‘Exceptional’ or ‘Classical’ is also allowed to save only part of this data.

### 5.1.23 Cluster complex (or generalized dual associahedron)

**EXAMPLES:**

A first example of a cluster complex:

```python
sage: C = ClusterComplex(['A', 2]); C
Cluster complex of type ['A', 2] with 5 vertices and 5 facets
```

Its vertices, facets, and minimal non-faces:

```python
sage: C.vertices()
(0, 1, 2, 3, 4)
sage: C.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
sage: for F in C.facets(): F.cluster()
[(-1, 0), (0, -1)]
[(-1, 0), (0, 1)]
[(0, -1), (1, 0)]
[(1, 0), (1, 1)]
[(1, 1), (0, 1)]
sage: C.minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

We can do everything we can do on simplicial complexes, e.g. computing its homology:

```python
sage: C.homology()
{0: 0, 1: \ZZ}
```

**AUTHORS:**

- Christian Stump (2011) Initial version

```python
class sage.combinat.cluster_complex.ClusterComplex(W, k, coxeter_element, algorithm)

Bases: SubwordComplex

A cluster complex (or generalized dual associahedron).

The cluster complex (or generalized dual associahedron) is a simplicial complex constructed from a cluster algebra. Its vertices are the cluster variables and its facets are the clusters, i.e., maximal subsets of compatible cluster variables.

The cluster complex of type \( A_n \) is the simplicial complex with vertices being (proper) diagonals in a convex \((n+3)\)-gon and with facets being triangulations.

The implementation of the cluster complex depends on its connection to subword complexes, see [CLS2014]. Let \( c \) be a Coxeter element with reduced word \( c \) in a finite Coxeter group \( W \), and let \( w_o \) be the \( c \)-sorting word for the longest element \( w_o \in W \).
```
The multi-cluster complex $\Delta(W,k)$ has vertices in one-to-one correspondence with letters in the word $Q = c^k w_o$ and with facets being complements in $Q$ of reduced expressions for $w_o$.

For $k = 1$, the multi-cluster complex is isomorphic to the cluster complex as defined above.

EXAMPLES:

A first example of a cluster complex:

```
sage: C = ClusterComplex(['A', 2]); C
Cluster complex of type ['A', 2] with 5 vertices and 5 facets
```

Its vertices, facets, and minimal non-faces:

```
sage: C.vertices()
(0, 1, 2, 3, 4)
sage: C.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
sage: C.minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

We can do everything we can do on simplicial complexes, e.g. computing its homology:

```
sage: C.homology()
{0: 0, 1: Z}
```

We can also create a multi-cluster complex:

```
sage: ClusterComplex(['A', 2], k=2)
Multi-cluster complex of type ['A', 2] with 7 vertices and 14 facets
```

REFERENCES:

- [CLS2014]

Element

alias of `ClusterComplexFacet`

cyclic_rotation()

Return the operation on the facets of self obtained by the cyclic rotation as defined in [CLS2014].

EXAMPLES:

```
sage: ClusterComplex(['A', 2]).cyclic_rotation()
<function ...act at ...>
```

k()

Return the index $k$ of self.

EXAMPLES:

```
sage: ClusterComplex(['A', 2]).k()
1
```
**minimal_nonfaces()**
Return the minimal non-faces of self.

**EXAMPLES:**
```sage
ClusterComplex(['A', 2]).minimal_nonfaces()
[[0, 2], [0, 3], [1, 3], [1, 4], [2, 4]]
```

**class** `sage.combinat.cluster_complex.ClusterComplexFacet(parent, positions, facet_test=True)`
**Bases:** `SubwordComplexFacet`
A cluster (i.e., a facet) of a cluster complex.

**cluster()**
Return this cluster as a set of almost positive roots.

**EXAMPLES:**
```sage
C = ClusterComplex(['A', 2])
F = C((0, 1))
F.cluster()
[(-1, 0), (0, -1)]
```

**product_of_upper_cluster()**
Return the product of the upper cluster in reversed order.

**EXAMPLES:**
```sage
C = ClusterComplex(['A', 2])
for F in C: F.product_of_upper_cluster().reduced_word()
[]
[2]
[1]
[1, 2]
[1, 2]
```

**upper_cluster()**
Return the part of the cluster that contains positive roots

**EXAMPLES:**
```sage
C = ClusterComplex(['A', 2])
F = C((0, 1))
F.upper_cluster()
[]
```

### 5.1.24 Colored Permutations

**Todo:** Much of the colored permutations (and element) class can be generalized to $G \wr S_n$

**class** `sage.combinat.colored_permutations.ColoredPermutation(parent, colors, perm)`
**Bases:** `MultiplicativeGroupElement`
A colored permutation.
colors()

Return the colors of self.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: s1, s2, t = C.gens()
sage: x = s1*s2*t
sage: x.colors()
[1, 0, 0]
```

has_left_descent(i)

Return True if i is a left descent of self.

Let \( p = (s_1, \ldots, s_n, \sigma) \) be a colored permutation. We say \( p \) has a left \( n \)-descent if \( s_n > 0 \). If \( i < n \), then we say \( p \) has a left \( i \)-descent if either

- \( s_i \neq 0, s_{i+1} = 0 \) and \( \sigma_i < \sigma_{i+1} \) or
- \( s_i = s_{i+1} \) and \( \sigma_i > \sigma_{i+1} \).

This notion of a left \( i \)-descent is done in order to recursively construct \( w(p) = \sigma_i w(\sigma_i^{-1} p) \), where \( w(p) \) denotes a reduced word of \( p \).

EXAMPLES:

```
sage: C = ColoredPermutations(2, 4)
sage: s1, s2, s3, s4 = C.gens()
sage: x = s4*s1*s2*s3*s4
sage: [x.has_left_descent(i) for i in C.index_set()]
[True, False, False, True]
sage: C = ColoredPermutations(1, 5)
sage: s1, s2, s3, s4 = C.gens()
sage: x = s4*s1*s2*s3*s4
sage: [x.has_left_descent(i) for i in C.index_set()]
[True, False, False, True]
sage: C = ColoredPermutations(3, 3)
sage: x = C([[2, 1, 0], [3, 1, 2]])
sage: [x.has_left_descent(i) for i in C.index_set()]
[False, True, False]
sage: C = ColoredPermutations(4, 4)
sage: x = C([[2, 1, 0, 1], [3, 2, 4, 1]])
sage: [x.has_left_descent(i) for i in C.index_set()]
[False, True, False, True]
```

length()

Return the length of self in generating reflections.

This is the minimal numbers of generating reflections needed to obtain self.

EXAMPLES:

```
sage: C = ColoredPermutations(3, 3)
sage: x = C([[2, 1, 0], [3, 1, 2]])
```

(continues on next page)
sage: x.length()
7

sage: C = ColoredPermutations(4, 4)
sage: x = C([[2,1,0,1],[3,2,4,1]])
sage: x.length()
12

**one_line_form()**

Return the one line form of self.

**EXAMPLES:**

sage: C = ColoredPermutations(4, 3)
sage: s1,s2,t = C.gens()
sage: x = s1*s2*t
sage: x
[[1, 0, 0], [3, 1, 2]]
sage: x.one_line_form()
[(1, 3), (0, 1), (0, 2)]

**permutation()**

Return the permutation of self.

This is obtained by forgetting the colors.

**EXAMPLES:**

sage: C = ColoredPermutations(4, 3)
sage: s1,s2,t = C.gens()
sage: x = s1*s2*t
sage: x.permutation()
[3, 1, 2]

**reduced_word()**

Return a word in the simple reflections to obtain self.

**EXAMPLES:**

sage: C = ColoredPermutations(3, 3)
sage: x = C([[2,1,0],[3,1,2]])
sage: x.reduced_word()
[2, 1, 3, 2, 1, 3, 3]
sage: C = ColoredPermutations(4, 4)
sage: x = C([[2,1,0,1],[3,2,4,1]])
sage: x.reduced_word()
[2, 1, 4, 3, 2, 1, 4, 3, 2, 4, 4, 3]

**to_matrix()**

Return a matrix of self.

The colors are mapped to roots of unity.

**EXAMPLES:**
sage: C = ColoredPermutations(4, 3)
sage: s1, s2, t = C.gens()
sage: x = s1*s2*t*s2; x.one_line_form()
[(1, 2), (0, 1), (0, 3)]
sage: M = x.to_matrix(); M
[ 0 1 0]
[1, 3, 2]
[ 0 0 1]

The matrix multiplication is in the opposite order:
sage: M == s2.to_matrix()*t.to_matrix()*s2.to_matrix()*s1.to_matrix()
True

class sage.combinat.colored_permutations.ColoredPermutations(m, n)
Bases: Parent, UniqueRepresentation

The group of \( m \)-colored permutations on \( \{1, 2, \ldots, n\} \).

Let \( S_n \) be the symmetric group on \( n \) letters and \( C_m \) be the cyclic group of order \( m \). The \( m \)-colored permutation group on \( n \) letters is given by \( P_m^n = C_m \rtimes S_n \). This is also the complex reflection group \( G(m, 1, n) \).

We define our multiplication by
\[
((s_1, \ldots, s_n), \sigma) \cdot ((t_1, \ldots, t_n), \tau) = ((s_1 t_{\sigma(1)}, \ldots, s_n t_{\sigma(n)}), \tau \sigma).
\]

EXAMPLES:
sage: C = ColoredPermutations(4, 3); C
4-colored permutations of size 3
sage: s1, s2, t = C.gens()
sage: (s1, s2, t)
(([[0, 0, 0], [1, 2, 3]], [[0, 0, 0], [1, 3, 2]], [[0, 0, 1], [1, 2, 3]]),
[[0, 0, 0], [1, 2, 3]],
[[0, 0, 1], [1, 2, 3]])
sage: s1*s2
[[0, 0, 0], [3, 1, 2]]
sage: s1*s2*s1 == s2*s1*s2
True
sage: t^4 == C.one()
True
sage: s2*t*s2
[[0, 1, 0], [1, 2, 3]]

We can also create a colored permutation by passing an iterable consisting of tuples consisting of (color, element):
sage: x = C(((2,1), (3,3), (3,2))); x
[[2, 3, 3], [1, 3, 2]]

or a list of colors and a permutation:
sage: C([[3,3,1], [1,3,2]])
[[3, 3, 1], [1, 3, 2]]
sage: C([[3,3,1], [1,3,2]])
[[3, 3, 1], [1, 3, 2]]

There is also the natural lift from permutations:
Combinatorics, Release 10.1

```
sage: P = Permutations(3)
sage: C(P.an_element())
[[0, 0, 0], [3, 1, 2]]
```

A colored permutation:

```
sage: C(C.an_element()) == C.an_element()
True
```

REFERENCES:

- Wikipedia article Generalized_symmetric_group
- Wikipedia article Complex_reflection_group

Element

- alias of ColoredPermutation

as_permutation_group()

- Return the permutation group corresponding to self.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: C.as_permutation_group()
Complex reflection group G(4, 1, 3) as a permutation group
```

cardinality()

- Return the cardinality of self.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: C.cardinality()
384
sage: C.cardinality() == 4**3 * factorial(3)
True
```

codegrees()

- Return the codegrees of self.

Let $G$ be a complex reflection group. The codegrees $d_1 \leq d_2 \leq \cdots \leq d_{\ell}$ of $G$ can be defined by:

$$
\prod_{i=1}^{\ell}(q - d_i^*) - 1 = \sum_{g \in G} \det(g)q^{\dim(V^g)},
$$

where $V$ is the natural complex vector space that $G$ acts on and $\ell$ is the rank().

If $m = 1$, then we are in the special case of the symmetric group and the codegrees are $(n-2, n-3, \ldots, 1, 0)$. Otherwise the degrees are $(m - 1)m, (n - 2)m, \ldots, m, 0$.

EXAMPLES:

```
sage: C = ColoredPermutations(4, 3)
sage: C.codegrees()
(8, 4, 0)
sage: S = ColoredPermutations(1, 3)
```

sage: S.codegrees()
(1, 0)

**coxeter_matrix()**

Return the Coxeter matrix of `self`.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(3, 4)
sage: C.coxeter_matrix()
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: C = ColoredPermutations(1, 4)
sage: C.coxeter_matrix()
[1 3 2]
[3 1 3]
[2 3 1]
```

**degrees()**

Return the degrees of `self`.

The degrees of a complex reflection group are the degrees of the fundamental invariants of the ring of polynomial invariants.

If \( m = 1 \), then we are in the special case of the symmetric group and the degrees are \((2, 3, \ldots, n, n+1)\). Otherwise the degrees are \((m, 2m, \ldots, nm)\).

**EXAMPLES:**

```python
sage: C = ColoredPermutations(4, 3)
sage: C.degrees()
(4, 8, 12)
sage: S = ColoredPermutations(1, 3)
sage: S.degrees()
(2, 3)
```

We now check that the product of the degrees is equal to the cardinality of `self`:

```python
sage: prod(C.degrees()) == C.cardinality()
True
sage: prod(S.degrees()) == S.cardinality()
True
```

**fixed_point_polynomial**

The fixed point polynomial of `self`.

The fixed point polynomial \( f_G \) of a complex reflection group \( G \) is counting the dimensions of fixed points subspaces:

\[
f_G(q) = \sum_{w \in W} q^{\dim V^w}.
\]
Furthermore, let $d_1, d_2, \ldots, d_\ell$ be the degrees of $G$, where $\ell$ is the rank(). Then the fixed point polynomial is given by

$$f_G(q) = \prod_{i=1}^{\ell} (q + d_i - 1).$$

**INPUT:**

- $q$ – (default: the generator of $\mathbb{Z}[\text{ }q\text{ }]$) the parameter $q$

**EXAMPLES:**

```python
sage: C = ColoredPermutations(4, 3)
sage: C.fixed_point_polynomial()
sage: C.gens()
sage: C.index_set()
sage: C.is_well_generated()
```

**gens()**

Return the generators of self.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(4, 3)
sage: C.gens()
```

**index_set()**

Return the index set of self.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(3, 4)
sage: C.index_set()
```

**is_well_generated()**

Return if self is a well-generated complex reflection group.

A complex reflection group $G$ is well-generated if it is generated by $\ell$ reflections. Equivalently, $G$ is well-generated if $d_i + d^*_i = d_\ell$ for all $1 \leq i \leq \ell$.

**EXAMPLES:**
sage: C = ColoredPermutations(4, 3)
sage: C.is_well_generated()
True
sage: C = ColoredPermutations(2, 8)
sage: C.is_well_generated()
True
sage: C = ColoredPermutations(1, 4)
sage: C.is_well_generated()
True

matrix_group()
Return the matrix group corresponding to self.

EXAMPLES:

sage: C = ColoredPermutations(4, 3)
sage: C.matrix_group()
Matrix group over Cyclotomic Field of order 4 and degree 2 with 3 generators ( 
[0 1 0] [1 0 0] [ 1 0 0]
[1 0 0] [0 0 1] [ 0 1 0]
[0 0 1], [0 1 0], [ 0 0 zeta4] )

number_of_reflection_hyperplanes()
Return the number of reflection hyperplanes of self.
The number of reflection hyperplanes of a complex reflection group is equal to the sum of the codegrees plus the rank.

EXAMPLES:

sage: C = ColoredPermutations(1, 2)
sage: C.number_of_reflection_hyperplanes()
1
sage: C = ColoredPermutations(1, 3)
sage: C.number_of_reflection_hyperplanes()
3
sage: C = ColoredPermutations(4, 12)
sage: C.number_of_reflection_hyperplanes()
276

one()
Return the identity element of self.

EXAMPLES:

sage: C = ColoredPermutations(4, 3)
sage: C.one()
[[0, 0, 0], [1, 2, 3]]

order()
Return the cardinality of self.

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: C = ColoredPermutations(4, 3)
sage: C.cardinality()
384
sage: C.cardinality() == 4**3 * factorial(3)
True
```

**rank()**

Return the rank of self.

The rank of a complex reflection group is equal to the dimension of the complex vector space the group acts on.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(4, 12)
sage: C.rank()
12
sage: C = ColoredPermutations(7, 4)
sage: C.rank()
4
sage: C = ColoredPermutations(1, 4)
sage: C.rank()
3
```

**simple_reflection(i)**

Return the i-th simple reflection of self.

**EXAMPLES:**

```python
sage: C = ColoredPermutations(4, 3)
sage: C.gens()
([0, 0, 0], [2, 1, 3]), ([0, 0, 0], [1, 3, 2]), ([0, 0, 1], [1, 2, 3])
sage: C.simple_reflection(2)
([0, 0, 0], [1, 3, 2])
sage: C.simple_reflection(3)
([0, 0, 1], [1, 2, 3])
sage: S = SignedPermutations(4)
sage: S.simple_reflection(1)
[2, 1, 3, -4]
sage: S.simple_reflection(4)
[1, 2, 3, -4]
```

**class** `sage.combinat.colored_permutations.SignedPermutation(parent, colors, perm)`

Bases: `ColoredPermutation`

A signed permutation.

**has_left_descent(i)**

Return True if i is a left descent of self.

**EXAMPLES:**

```python
sage: S = SignedPermutations(4)
sage: s1,s2,s3,s4 = S.gens()
```
sage: x = s4*s1*s2*s3*s4

sage: [x.has_left_descent(i) for i in S.index_set()]
[True, False, False, True]

order()

Return the multiplicative order of the signed permutation.

EXAMPLES:

sage: pi = SignedPermutations(7)([2,-1,4,-6,-5,-3,7])

sage: pi.to_cycles(singletons=False)
[[1, 2, -1, -2), (3, 4, -6), (5, -5)]

sage: pi.order()
12

to_cycles(singletons=True, use_min=True, negative_singletons=True)

Return the signed permutation self as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest positive element. We do not include the corresponding negative cycles.

INPUT:

• singletons – (default: True) whether to include singleton cycles or not

• use_min – (default: True) if False, the cycles are returned in the order of increasing largest (not smallest) elements, and each cycle starts with its largest element

EXAMPLES:

sage: pi = SignedPermutations(7)([2,-1,4,-6,-5,-3,7])

sage: pi.to_cycles()
[(1, 2, -1, -2), (3, 4, -6), (5, -5), (7,)]

sage: pi.to_cycles(singletons=False)
[(1, 2, -1, -2), (3, 4, -6), (5, -5)]

sage: pi.to_cycles(use_min=False)
[(7,), (6, -3, -4), (5, -5), (2, -1, -2, 1)]

sage: pi.to_cycles(singletons=False, use_min=False)
[(6, -3, -4), (5, -5), (2, -1, -2, 1)]

to_matrix()

Return a matrix of self.

EXAMPLES:

sage: S = SignedPermutations(4)

sage: s1,s2,s3,s4 = S.gens()

sage: x = s4*s1*s2*s3*s4

sage: M = x.to_matrix(); M

[0 1 0 0]
[0 0 1 0]
[0 0 0 -1]
[-1 0 0 0]

The matrix multiplication is in the opposite order:
Combinatorics, Release 10.1

```python
sage: m1, m2, m3, m4 = [g.to_matrix() for g in S.gens()]
sage: M == m4 * m3 * m2 * m1 * m4
True
```

class sage.combinat.colored_permutations.SignedPermutations(n)

Bases: ColoredPermutations

Group of signed permutations.

The group of signed permutations is also known as the hyperoctahedral group, the Coxeter group of type \( B_n \), and the 2-colored permutation group. Thus it can be constructed as the wreath product \( S_2 \wr S_n \).

EXAMPLES:

```python
sage: S = SignedPermutations(4)
sage: s1, s2, s3, s4 = S.group_generators()
sage: x = s4 * s1 * s2 * s3 * s4; x
[-4, 1, 2, -3]
sage: x^4 == S.one()
True
```

This is a finite Coxeter group of type \( B_n \):

```python
sage: S.canonical_representation()
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 2 with a \rightarrow 1.414213562373095? with Coxeter matrix:
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]
sage: S.long_element()
[-1, -2, -3, -4]
sage: S.long_element().reduced_word()
[1, 2, 1, 3, 2, 1, 4, 3, 2, 1, 4, 3, 2, 4, 3, 4]
```

We can also go between the 2-colored permutation group:

```python
sage: C = ColoredPermutations(2, 3)
sage: S = SignedPermutations(3)
sage: x = S(C.an_element()); x
[-3, 1, 2]
sage: x.parent()
Signed permutations of 3
```

There is also the natural lift from permutations:

```python
sage: P = Permutations(3)
sage: x = S(P.an_element()); x
[3, 1, 2]
sage: x.parent()
Signed permutations of 3
```
REFERENCES:

• Wikipedia article Hyperoctahedral_group

Element
alias of SignedPermutation

long_element(index_set=None)

Return the longest element of self, or of the parabolic subgroup corresponding to the given index_set.

INPUT:

• index_set – (optional) a subset (as a list or iterable) of the nodes of the indexing set

EXAMPLES:

```
sage: S = SignedPermutations(4)
sage: S.long_element()
[-1, -2, -3, -4]
```

one()

Return the identity element of self.

EXAMPLES:

```
sage: S = SignedPermutations(4)
sage: S.one()
[1, 2, 3, 4]
```

simple_reflection(i)

Return the i-th simple reflection of self.

EXAMPLES:

```
sage: S = SignedPermutations(4)
sage: S.simple_reflection(1)
[2, 1, 3, 4]
sage: S.simple_reflection(4)
[1, 2, 3, -4]
```

5.1.25 Combinatorial Functions

This module implements some combinatorial functions, as listed below. For a more detailed description, see the relevant docstrings.

Sequences:

• Bell numbers, bell_number()
• Catalan numbers, catalan_number() (not to be confused with the Catalan constant)
• Narayana numbers, narayana_number()
• Euler numbers, euler_number() (Maxima)
• Eulerian numbers, eulerian_number()
• Eulerian polynomial, eulerian_polynomial()
• Fibonacci numbers, fibonacci() (PARI) and fibonacci_number() (GAP) The PARI version is better.
• Lucas numbers, `lucas_number1()`, `lucas_number2()`.
• Stirling numbers, `stirling_number1()`, `stirling_number2()`.
• Polygonal numbers, `polygonal_number()`

Set-theoretic constructions:

• Derangements of a multiset, `derangements()` and `number_of_derangements()`.
• Tuples of a multiset, `tuples()` and `number_of_tuples()`. An ordered tuple of length k of set S is a ordered selection with repetitions of S and is represented by a sorted list of length k containing elements from S.
• Unordered tuples of a set, `unordered_tuples()` and `number_of_unordered_tuples()`. An unordered tuple of length k of set S is an unordered selection with repetitions of S and is represented by a sorted list of length k containing elements from S.

Warning: The following function is deprecated and will soon be removed.

• Permutations of a multiset, `permutations()`, `permutations_iterator()`, `number_of_permutations()`. A permutation is a list that contains exactly the same elements but possibly in different order.

Related functions:

• Bernoulli polynomials, `bernoulli_polynomial()`

Implemented in other modules (listed for completeness):

The package `sage.arith` contains the following combinatorial functions:

• `binomial()` the binomial coefficient (wrapped from PARI)
• `factorial()` (wrapped from PARI)
• `falling_factorial()` Definition: for integer \( a \geq 0 \) we have \( x(x-1) \cdots (x-a+1) \). In all other cases we use the GAMMA-function: \( \frac{\Gamma(x+1)}{\Gamma(x-a+1)} \).
• `rising_factorial()` Definition: for integer \( a \geq 0 \) we have \( x(x+1) \cdots (x+a-1) \). In all other cases we use the GAMMA-function: \( \frac{\Gamma(x+a)}{\Gamma(x)} \).

From other modules:

• `number_of_partitions()` (wrapped from PARI) the number of partitions:
• `sage.combinat.q_analogues.gaussian_binomial()` the Gaussian binomial

\[
\binom{n}{k}_q = \frac{(1-q^m)(1-q^{m-1}) \cdots (1-q^{m-r+1})}{(1-q)(1-q^2) \cdots (1-q^r)}.
\]

The `sage.groups.perm_gps.permgroup_elements` contains the following combinatorial functions:

• matrix method of PermutationGroupElement yielding the permutation matrix of the group element.

Todo:

GUAVA commands:

• VandermondeMat
• GrayMat returns a list of all different vectors of length n over the field F, using Gray ordering.

Not in GAP:
• Rencontres numbers (Wikipedia article Rencontres_number)

• Punarbasu Purkayastha (2012-12): deprecate arrangements, combinations, combinations_iterator, and clean up very old deprecated methods.

Functions and classes

class sage.combinat.combinat.CombinatorialClass(category=None)
    Bases: Parent
    This class is deprecated, and will disappear as soon as all derived classes in Sage’s library will have been fixed. Please derive directly from Parent and use the category EnumeratedSets, FiniteEnumeratedSets, or InfiniteEnumeratedSets, as appropriate.
    For examples, see:

    sage: FiniteEnumeratedSets().example()
    An example of a finite enumerated set: {1,2,3}
    sage: InfiniteEnumeratedSets().example()
    An example of an infinite enumerated set: the non negative integers

Element
    alias of CombinatorialObject

cardinality()

    Default implementation of cardinality which just goes through the iterator of the combinatorial class to count the number of objects.
    EXAMPLES:

    sage: class C(CombinatorialClass):
    .....    def __iter__(self):
    .....        return iter([1,2,3])
    sage: C().cardinality() # indirect doctest
    3

element_class()
This function is a temporary helper so that a CombinatorialClass behaves as a parent for creating elements. This will disappear when combinatorial classes will be turned into actual parents (in the category EnumeratedSets).

filter(f, name=None)
Return the combinatorial subclass of f which consists of the elements x of self such that f(x) is True.

EXAMPLES:

```python
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).filter(lambda x: x.avoids([1,2]))
```

first()
Default implementation for first which uses iterator.

EXAMPLES:

```python
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.first() # indirect doctest
1
```

is_finite()
Return whether self is finite or not.

EXAMPLES:

```python
sage: Partitions(5).is_finite() # optional - sage.combinat
True
sage: Permutations().is_finite()
False
```

last()
Default implementation for first which uses iterator.

EXAMPLES:

```python
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.last() # indirect doctest
3
```

list()
The default implementation of list which builds the list from the iterator.

EXAMPLES:

```python
sage: class C(CombinatorialClass):
....:     def __iter__(self):
....:         return iter([1,2,3])
sage: C().list() # indirect doctest
[1, 2, 3]
```
map\((f, name, is\_injective=None)\)

Return the image \(\{f(x)|x \in \text{self}\}\) of this combinatorial class by \(f\), as a combinatorial class.

INPUT:

- **is\_injective** – boolean (default: True) whether to assume that \(f\) is injective.

EXAMPLES:

```python
sage: R = Permutations(3).map(attrcall('reduced_word')); R
Image of Standard permutations of 3 by
The map *.reduced_word() from Standard permutations of 3
sage: R.cardinality()
6
sage: R.list()
[[], [2], [1], [1, 2], [2, 1], [2, 1, 2]]
sage: [ r for r in R]
[[], [2], [1], [1, 2], [2, 1], [2, 1, 2]]
```

If the function is not injective, then there may be repeated elements:

```python
sage: P = Partitions(4)    # optional - sage.combinat
sage: P.list()            # optional - sage.combinat
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: P.map(len).list()   # optional - sage.combinat
[1, 2, 2, 3, 4]
sage: P.map(len, is\_injective=False).list()   # optional - sage.combinat
[1, 2, 3, 4]
```

next\((obj)\)

Default implementation for next which uses iterator.

EXAMPLES:

```python
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.next(2) # indirect doctest
3
```

previous\((obj)\)

Default implementation for next which uses iterator.

EXAMPLES:

```python
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.previous(2) # indirect doctest
1
```
random_element()  
Default implementation of random which uses unrank.

EXAMPLES:
```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.random_element()   # random   # indirect doctest
1
```

rank(\textit{obj})  
Default implementation of rank which uses iterator.

EXAMPLES:
```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.rank(3)   # indirect doctest
2
```

union(\textit{right_cc}, name=None)  
Return the combinatorial class representing the union of \textit{self} and \textit{right_cc}.

EXAMPLES:
```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(2).union(Permutations_CC(1))
sage: P.list()  
[[1, 2], [2, 1], [1]]
```

unrank(r)  
Default implementation of unrank which goes through the iterator.

EXAMPLES:
```
sage: C = CombinatorialClass()
sage: C.list = lambda: [1,2,3]
sage: C.unrank(1)   # indirect doctest
2
```

class \texttt{sage.combinat.combinat.CombinatorialElement}({\textit{parent}}, *\textit{args}, **\textit{kwds})

\texttt{CombinatorialElement} is both a \texttt{CombinatorialObject} and an \texttt{Element}. So it represents a list which is an element of some parent.

A \texttt{CombinatorialElement} subclass also automatically supports the \_\_\texttt{classcall\_\_} mechanism.

\textbf{Warning:} This class is slowly being deprecated. Use \texttt{ClonableList} instead.

INPUT:
- \texttt{parent} – the \texttt{Parent} class for this element.
- \texttt{lst} – a list or any object that can be converted to a list by calling \texttt{list()}.

EXAMPLES:
sage: from sage.combinat.combinat import CombinatorialElement
sage: e = CombinatorialElement(Partitions(6), [3,2,1])  # Optional - sage.combinat
sage: e == loads(dumps(e))  # Optional - sage.combinat
True
sage: parent(e)  # Optional - sage.combinat
Partitions of the integer 6
sage: list(e)  # Optional - sage.combinat
[3, 2, 1]

Check classcalls:

sage: class Foo(CombinatorialElement):
    ....: @staticmethod
    ....: def __classcall__(cls, x):
    ....:     return x
sage: Foo(17)
17

class sage.combinat.combinat.CombinatorialObject(l, copy=True)

Bases: SageObject

CombinatorialObject provides a thin wrapper around a list. The main differences are that __setitem__ is disabled so that CombinatorialObjects are shallowly immutable, and the intention is that they are semantically immutable.

Because of this, CombinatorialObjects provide a __hash__ function which computes the hash of the string representation of a list and the hash of its parent’s class. Thus, each CombinatorialObject should have a unique string representation.

See also:

CombinatorialElement if you want a combinatorial object which is an element of a parent.

Warning: This class is slowly being deprecated. Use ClonableList instead.

INPUT:

- l – a list or any object that can be converted to a list by calling list().
- copy – (boolean, default True) if False, then l must be a list, which is assigned to self._list without copying.

EXAMPLES:

sage: c = CombinatorialObject([1,2,3])
sage: c == loads(dumps(c))
True
sage: c._list
[1, 2, 3]
sage: c._hash is None
True

For efficiency, you can specify copy=False if you know what you are doing:
sage: from sage.combinat.combinat import CombinatorialObject
sage: x = [3, 2, 1]
sage: C = CombinatorialObject(x, copy=False)
sage: C
[3, 2, 1]
sage: x[0] = 5
sage: C
[5, 2, 1]

index(key)
EXAMPLES:

sage: c = CombinatorialObject([1,2,3])
sage: c.index(1)
0
sage: c.index(3)
2

class sage.combinat.combinat.FilteredCombinatorialClass(combinatorial_class, f, name=None)

Bases: CombinatorialClass

A filtered combinatorial class F is a subset of another combinatorial class C specified by a function f that takes
in an element c of C and returns True if and only if c is in F.

cardinality()
EXAMPLES:

sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).filter(lambda x: x.avoids([1,2]))
sage: P.cardinality()                 # optional - sage.combinat
1

class sage.combinat.combinat.InfiniteAbstractCombinatorialClass(category=None)

Bases: CombinatorialClass

This is an internal class that should not be used directly. A class which inherits from InfiniteAbstractCombinatorialClass inherits the standard methods list and count.

If self._infinite_cclass_slice exists then self.__iter__ returns an iterator for self, otherwise raise NotImplement-edError. The method self._infinite_cclass_slice is supposed to accept any integer as an argument and return something which is iterable.

cardinality()
Count the elements of the combinatorial class.

EXAMPLES:

sage: R = InfiniteAbstractCombinatorialClass()
doctest:warning...
DeprecationWarning: this class is deprecated, do not use
See https://github.com/sagemath/sage/issues/31545 for details.

sage: R.cardinality()
+Infinity
list()
    Return an error since self is an infinite combinatorial class.

    EXAMPLES:
    
    sage: R = InfiniteAbstractCombinatorialClass()
    sage: R.list()
    Traceback (most recent call last):
    ...     NotImplementedError: infinite list

class sage.combinat.combinat.MapCombinatorialClass(cc, f, name=None, *, is_injective=True)
    Bases: ImageSubobject, CombinatorialClass
    The image of a combinatorial class through a function.

    INPUT:
    
    • is_injective – boolean (default: True) whether to assume that f is injective.

    See CombinatorialClass.map() for examples

    EXAMPLES:

    sage: R = SymmetricGroup(10).map(attrcall('reduced_word'))
    # optional - sage.groups
    sage: R.an_element()  # optional - sage.groups
    [9, 8, 7, 6, 5, 4, 3, 2]
    sage: R.cardinality()  # optional - sage.groups
    3628800
    sage: i = iter(R)  # optional - sage.groups
    sage: next(i), next(i), next(i)  # optional - sage.groups
    ([], [1, 2, 3, 4, 5, 6, 7, 8, 9], [1])

class sage.combinat.combinat.Permutations_CC(n)
    Bases: CombinatorialClass
    A testing class for CombinatorialClass since Permutations no longer inherits from CombinatorialClass
    in github issue #14772.

class sage.combinat.combinat.UnionCombinatorialClass(left_cc, right_cc, name=None)
    Bases: CombinatorialClass
    A UnionCombinatorialClass is a union of two other combinatorial classes.

cardinality()

    EXAMPLES:

    sage: from sage.combinat.combinat import Permutations_CC
    sage: P = Permutations_CC(3).union(Permutations_CC(2))
    sage: P.cardinality()
    8
first()
EXAMPLES:
```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.first()
[1, 2, 3]
```
last()
EXAMPLES:
```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.last()
[2, 1]
```
list()
EXAMPLES:
```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.list()
[[1, 2, 3],
 [1, 3, 2],
 [2, 1, 3],
 [2, 3, 1],
 [3, 1, 2],
 [3, 2, 1],
 [1, 2],
 [2, 1]]
```
rank(x)
EXAMPLES:
```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.rank(Permutation([2,1]))
7
sage: P.rank(Permutation([1,2,3]))
0
```
unrank(x)
EXAMPLES:
```
sage: from sage.combinat.combinat import Permutations_CC
sage: P = Permutations_CC(3).union(Permutations_CC(2))
sage: P.unrank(7)
[2, 1]
sage: P.unrank(0)
[1, 2, 3]
```
sage.combinat.combinat.bell_number(n, algorithm='flint', **options)
Return the $n$-th Bell number.

5.1. Comprehensive Module List
This is the number of ways to partition a set of \( n \) elements into pairwise disjoint nonempty subsets.

**INPUT:**

- \( n \) – a positive integer
- **algorithm** – (Default: 'flint') any one of the following:
  - 'dobinski' – Use Dobinski’s formula implemented in Sage
  - 'flint' – Wrap FLINT’s arith_bell_number
  - 'gap' – Wrap GAP’s Bell
  - 'mpmath' – Wrap mpmath’s bell

**Warning:** When using the mpmath algorithm to compute Bell numbers and you specify \( \text{prec} \), it can return incorrect results due to low precision. See the examples section.

Let \( B_n \) denote the \( n \)-th Bell number. Dobinski’s formula is:

\[
B_n = e^{-1} \sum_{k=0}^{\infty} \frac{k^n}{k!}.
\]

To show our implementation of Dobinski’s method works, suppose that \( n \geq 5 \) and let \( k_0 \) be the smallest positive integer such that \( \frac{k_0^n}{k_0!} < 1 \). Note that \( k_0 > n \) and \( k_0 \leq 2n \) because we can prove that \( \frac{(2n)^n}{(2n)!} < 1 \) by Stirling.

If \( k > k_0 \), then we have \( \frac{k^n}{k!} < \frac{1}{2^{k-k_0}} \). We show this by induction: let \( c_k = \frac{k^n}{k!} \), if \( k > n \) then

\[
\frac{c_{k+1}}{c_k} = \frac{(1+k^{-1})^n}{1+k} < \frac{(1+n^{-1})^n}{n} < \frac{1}{2}.
\]

The last inequality can easily be checked numerically for \( n \geq 5 \).

Using this, we can see that \( \frac{c_k}{c_{k_0}} < \frac{1}{2^{k-k_0}} \) for \( k > k_0 > n \). So summing this it gives that \( \sum_{k=k_0+1}^{\infty} \frac{k^n}{k!} < 1 \), and hence

\[
B_n = e^{-1} \left( \sum_{k=0}^{k_0} \frac{k^n}{k!} + E_3 \right) = e^{-1} \sum_{k=0}^{k_0} \frac{k^n}{k!} + E_2,
\]

where \( 0 < E_1 < 1 \) and \( 0 < E_2 < e^{-1} \). Next we have for any \( q > 0 \)

\[
\sum_{k=0}^{k_0} \frac{k^n}{k!} = \frac{1}{q} \sum_{k=0}^{k_0} \left\lfloor \frac{q k^n}{k!} \right\rfloor + \frac{E_3}{q}
\]

where \( 0 \leq E_4 \leq k_0 + 1 \leq 2n + 1 \). Let \( E_4 = \frac{E_3}{q} \) and let \( q = 2n + 1 \). We find \( 0 \leq E_4 \leq 1 \). These two bounds give:

\[
B_n = e^{-1} \sum_{k=0}^{q_0} \left\lfloor \frac{q k^n}{k!} \right\rfloor + e^{-1} E_4 + E_2
\]

\[
= e^{-1} \sum_{k=0}^{q_0} \left\lfloor \frac{q k^n}{k!} \right\rfloor + E_5
\]

where

\[
0 < E_5 = e^{-1} E_4 + E_2 \leq e^{-1} + e^{-1} < \frac{3}{4}.
\]
It follows that

\[
B_n = \left\lceil \frac{e^{-1}}{q} \sum_{k=0}^{k_0} \frac{q^k n^k}{k!} \right\rceil.
\]

Now define

\[
b = \sum_{k=0}^{k_0} \left\lfloor \frac{q^k n^k}{k!} \right\rfloor.
\]

This \(b\) can be computed exactly using integer arithmetic. To avoid the costly integer division by \(k!\), we collect more terms and do only one division, for example with 3 terms:

\[
\frac{k^n}{k!} + \frac{(k + 1)^n}{(k + 1)!} + \frac{(k + 2)^n}{(k + 2)!} = \frac{k^n(k + 1)(k + 2) + (k + 1)^n(k + 2) + (k + 2)^n}{(k + 2)!}
\]

In the implementation, we collect \(\sqrt{n}/2\) terms.

To actually compute \(B_n\) from \(b\), we let \(p = \lceil \log_2(b) \rceil + 1\) such that \(b < 2^p\) and we compute with \(p\) bits of precision. This implies that \(b\) (and \(q < b\)) can be represented exactly.

We compute \(\frac{e^{-1}}{q} b\), rounding down, and we must have an absolute error of at most \(1/4\) (given that \(E_5 < 3/4\)). This means that we need a relative error of at most

\[
\frac{eq}{4b} > \frac{(eq)/4}{2^p} > \frac{7}{2^p}
\]

(assuming \(n \geq 5\)). With a precision of \(p\) bits and rounding down, every rounding has a relative error of at most \(2^{1-p} = 2/2^p\). Since we do 3 roundings (\(b\) and \(q\) do not require rounding), we get a relative error of at most \(6/2^p\). All this implies that the precision of \(p\) bits is sufficient.

EXAMPLES:

```
sage: bell_number(10)                       # optional - sage.libs.flint
115975
sage: bell_number(2)                        # optional - sage.libs.flint
2
sage: bell_number(-10)                       # optional - sage.libs.flint
Traceback (most recent call last):
  ... ArithmeticError: Bell numbers not defined for negative indices
sage: bell_number(1)                         # optional - sage.libs.flint
1
sage: bell_number(1/3)                       # optional - sage.libs.flint
Traceback (most recent call last):
  ... TypeError: no conversion of this rational to integer
```

When using the mpmath algorithm, we are required have mpmath’s precision set to at least \(\log_2(B_n)\) bits. If upon computing the Bell number the first time, we deem the precision too low, we use our guess to (temporarily) raise mpmath’s precision and the Bell number is recomputed.
If you know what precision is necessary before computing the Bell number, you can use the `prec` option:

```sage
sage: k2 = bell_number(30, 'mpmath', prec=30); k2
#optional - mpmath
846749014511809388871680
sage: k == k2
#optional - mpmath sage.libs.flint
True
```

**Warning:** Running `mpmath` with the precision set too low can result in incorrect results:

```sage
sage: k = bell_number(30, 'mpmath', prec=15); k
#optional - mpmath
846749014511809332450147
sage: k == bell_number(30)
#optional - mpmath sage.libs.flint
False
```

**AUTHORS:**

**REFERENCES:**

- Wikipedia article Bell_number

```sage
sage.combinat.combinat.bell_polynomial(n, k)
```

Return the Bell Polynomial

\[
B_{n,k}(x_0, x_1, \ldots, x_{n-k}) = \sum_{j_0+j_1+\cdots+j_{n-k} = n} \frac{n!}{j_0! j_1! \cdots j_{n-k}!} \left( \begin{array}{c} x_0 \\ 0+1 \end{array} \right)^{j_0} \left( \begin{array}{c} x_1 \\ 1+1 \end{array} \right)^{j_1} \cdots \left( \begin{array}{c} x_{n-k} \\ n-k+1 \end{array} \right)^{j_{n-k}}.
\]

**INPUT:**

- `n` – integer
- `k` – integer

**OUTPUT:**

- a polynomial in `n - k + 1` variables over \( \mathbb{Z} \)

**EXAMPLES:**
Combinatorics, Release 10.1

```
sage: bell_polynomial(6,2)  #→
10*x2^2 + 15*x1*x3 + 6*x0^3*x4
sage: bell_polynomial(6,3)  #→
15*x1^3 + 60*x0*x1*x2 + 15*x0^2*x3
```

REFERENCES:

• [Bel1927]

AUTHORS:

• Blair Sutton (2009-01-26)
• Thierry Monteil (2015-09-29): the result must always be a polynomial.

```
sage.combinat.combinat.bell_polynomial(x, n)
```

Return the n-th Bell polynomial evaluated at x.

The generating function for the Bell polynomials is

\[
\frac{te^x}{e^t - 1} = \sum_{n=0}^{\infty} B_n(x) \frac{t^n}{n!},
\]

and they are given directly by

\[
B_n(x) = \sum_{i=0}^{n} \binom{n}{i} B_{n-i}x^i.
\]

One has \(B_n(x) = -n\zeta(1 - n, x)\), where \(\zeta(s, x)\) is the Hurwitz zeta function. Thus, in a certain sense, the Hurwitz zeta function generalizes the Bernoulli polynomials to non-integer values of n.

EXAMPLES:

```
sage: y = QQ['y'].0
sage: bernoulli_polynomial(y, 5)  #→
y^5 - 5/2*y^4 + 5/3*y^3 - 1/6*y
sage: bernoulli_polynomial(y, 5)(12)  #→
199870
sage: bernoulli_polynomial(y^2 + 1, 5)  #→
y^10 + 5/2*y^8 + 5/3*y^6 - 1/6*y^2
```

We verify an instance of the formula which is the origin of the Bernoulli polynomials (and numbers):
sage: power_sum = sum(k^4 for k in range(10))
sage: 5*power_sum == bernoulli_polynomial(10, 5) - bernoulli(5) # optional - sage.libs.flint
True

REFERENCES:

• Wikipedia article Bernoulli_polynomials

sage.combinat.combinat.catalan_number(n)

Return the $n$-th Catalan number.

The $n$-th Catalan number is given directly in terms of binomial coefficients by

$$C_n = \frac{1}{n+1} \binom{2n}{n} = \frac{(2n)!}{(n+1)!n!}$$

for $n \geq 0$.

Consider the set $S = \{1, ..., n\}$. A noncrossing partition of $S$ is a partition in which no two blocks “cross” each other, i.e., if $a$ and $b$ belong to one block and $x$ and $y$ to another, they are not arranged in the order $axby$. $C_n$ is the number of noncrossing partitions of the set $S$. There are many other interpretations (see REFERENCES).

When $n = -1$, this function returns the limit value $-1/2$. For other $n < 0$ it returns 0.

INPUT:

• $n$ – integer

OUTPUT:

type: integer

EXAMPLES:

sage: [catalan_number(i) for i in range(7)]
[1, 1, 2, 5, 14, 42, 132]

sage: x = (QQ[['x']].0).O(8)
sage: (-1/2)*sqrt(1 - 4*x)
-1/2 + x + x^2 + 2*x^3 + 5*x^4 + 14*x^5 + 42*x^6 + 132*x^7 + O(x^8)

sage: [catalan_number(i) for i in range(-7,7)]
[0, 0, 0, 0, 0, 0, -1/2, 1, 1, 2, 5, 14, 42, 132]

sage: [catalan_number(n).mod(2) for n in range(16)]
[1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 1]

REFERENCES:

• Wikipedia article Catalan_number

• http://www-history.mcs.st-andrews.ac.uk/~history/Miscellaneous/CatalanNumbers/catalan.html

sage.combinat.combinat.euler_number(n, algorithm='flint')

Return the $n$-th Euler number.

INPUT:

• $n$ – a positive integer

• algorithm – (Default: 'flint') any one of the following:
  - 'maxima' – Wraps Maxima's euler.
  - 'flint' – Wrap FLINT's arith_euler_number

EXAMPLES:
```python
sage: [euler_number(i) for i in range(10)]  # optional - sage.libs.flint
[1, 0, -1, 0, 5, 0, -61, 0, 1385, 0]
sage: x = PowerSeriesRing(QQ, 'x').gen().O(10)
sage: 2/(exp(x)+exp(-x))  # optional - sage.symbolic
1 - 1/2*x^2 + 5/24*x^4 - 61/720*x^6 + 277/8064*x^8 + O(x^10)
sage: [euler_number(i)/factorial(i) for i in range(11)]  # optional - sage.libs.flint
[1, 0, -1/2, 0, 5/24, 0, -61/720, 0, 277/8064, 0, -50521/3628800]
sage: euler_number(-1)
Traceback (most recent call last):
  ... ValueError: n (=1) must be a nonnegative integer
```

REFERENCES:

- Wikipedia article Euler_number

```
sage.combinat.combinat.eulerian_number(k, algorithm='recursive')
```

Return the Eulerian number of index \((n, k)\).

This is the coefficient of \(t^k\) in the Eulerian polynomial \(A_n(t)\).

INPUT:

- \(n\) – integer
- \(k\) – integer between 0 and \(n - 1\)
- \(algorithm\) – "recursive" (default) or "formula"

OUTPUT:

an integer

See also:

eulerian_polynomial()

EXAMPLES:

```python
sage: from sage.combinat.combinat import eulerian_number
sage: [eulerian_number(5,i) for i in range(5)]
[1, 26, 66, 26, 1]
```

```
sage.combinat.combinat.eulerian_polynomial(algorithm='derivative')
```

Return the Eulerian polynomial of index \(n\).

This is the generating polynomial counting permutations in the symmetric group \(S_n\) according to their number of descents.

INPUT:

- \(n\) – an integer
- \(algorithm\) – "derivative" (default) or "coeffs"

OUTPUT:

polynomial in one variable \(t\)
See also:

eulerian_number()

EXAMPLES:

```python
sage: from sage.combinat.combinat import eulerian_polynomial
sage: eulerian_polynomial(5)
t^4 + 26*t^3 + 66*t^2 + 26*t + 1
```

REFERENCES:

- Wikipedia article Eulerian_number

sage.combinat.combinat.fibonacci(n, algorithm='pari')

Return the \( n \)-th Fibonacci number.

The Fibonacci sequence \( F_n \) is defined by the initial conditions \( F_1 = F_2 = 1 \) and the recurrence relation \( F_{n+2} = F_{n+1} + F_n \). For negative \( n \) we define \( F_n = (-1)^{n+1}F_{-n} \), which is consistent with the recurrence relation.

INPUT:

- algorithm – a string:
  - "pari" - (default) use the PARI C library’s pari:fibo function
  - "gap" - use GAP’s Fibonacci function

Note: PARI is tens to hundreds of times faster than GAP here. Moreover, PARI works for every large input whereas GAP does not.

EXAMPLES:

```python
sage: fibonacci(10)  # optional - sage.libs.pari
55
sage: fibonacci(10, algorithm='gap')  # optional - sage.libs.gap
55
```

```python
sage: fibonacci(-100)  # optional - sage.libs.pari
-354224848179261915075
sage: fibonacci(100)  # optional - sage.libs.pari
354224848179261915075
```

```python
sage: fibonacci(0)  # optional - sage.libs.pari
0
```

```
sage: fibonacci(1/2)
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```
sage.combinat.combinat.fibonacci_sequence(start, stop=None, algorithm=None)

Return an iterator over the Fibonacci sequence, for all fibonacci numbers \( f_n \) from \( n = \text{start} \) up to (but not including) \( n = \text{stop} \).

INPUT:

- `start` – starting value
- `stop` – stopping value
- `algorithm` – (default: None) passed on to fibonacci function (or not passed on if None, i.e., use the default)

EXAMPLES:

```
sage: fibs = [i for i in fibonacci_sequence(10, 20)]; fibs
       # optional - sage.libs.pari
[55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181]
```

```
sage: sum([i for i in fibonacci_sequence(100, 110)])
       # optional - sage.libs.pari
69919376923075308730013
```

See also:

`fibonacci_xrange()`

AUTHORS:

- Bobby Moretti

sage.combinat.combinat.fibonacci_xrange(start, stop=None, algorithm='pari')

Return an iterator over all of the Fibonacci numbers in the given range, including \( f_n = \text{start} \) up to, but not including, \( f_n = \text{stop} \).

EXAMPLES:

```
sage: fibs_in_some_range = [i for i in fibonacci_xrange(10^7, 10^8)]; fibs_in_some_range
       # optional - sage.libs.pari
[14930352, 24157817, 39088169, 63245986]
sage: len(fibs_in_some_range)
       # optional - sage.libs.pari
4
```

```
sage: fibs = [i for i in fibonacci_xrange(10, 100)]; fibs
       # optional - sage.libs.pari
[13, 21, 34, 55, 89]
sage: list(fibonacci_xrange(13, 34))
       # optional - sage.libs.pari
[13, 21]
```

A solution to the second Project Euler problem:

```
sage: sum([i for i in fibonacci_xrange(10^6) if is_even(i)])
       # optional - sage.libs.pari
1089154
```
See also:

*fibonacci_sequence()*

AUTHORS:

• Bobby Moretti

`sage.combinat.combinat.lucas_number1(n, P, Q)`

Return the \( n \)-th Lucas number “of the first kind” (this is not standard terminology). The Lucas sequence \( L_n^{(1)} \) is defined by the initial conditions \( L_1^{(1)} = 0, L_2^{(1)} = 1 \) and the recurrence relation \( L_{n+2}^{(1)} = P \cdot L_{n+1}^{(1)} - Q \cdot L_n^{(1)} \).

Wraps GAP’s `Lucas(...)`.\(^1\)

\( P = 1, Q = -1 \) gives the Fibonacci sequence.

INPUT:

• \( n \) – integer
• \( P, Q \) – integer or rational numbers

OUTPUT: integer or rational number

EXAMPLES:

```
sage: lucas_number1(5,1,-1)       # optional - sage.libs.gap
5
sage: lucas_number1(6,1,-1)       # optional - sage.libs.gap
8
sage: lucas_number1(7,1,-1)       # optional - sage.libs.gap
13
sage: lucas_number1(7,1,-2)       # optional - sage.libs.gap
43
sage: lucas_number1(5,2,3/5)      # optional - sage.libs.gap
229/25
sage: lucas_number1(5,2,1.5)      # optional - sage.libs.gap
1/4
```

There was a conjecture that the sequence \( L_n \) defined by \( L_{n+2} = L_{n+1} + L_n, L_1 = 1, L_2 = 3, \) has the property that \( n \) prime implies that \( L_n \) is prime.

```
sage: def lucas(n):
    ....:    return Integer((5/2)^lucas_number1(n,1,-1) + (1/2)^lucas_number2(n,1,-1))
sage: [[lucas(n), is_prime(lucas(n)), n+1, is_prime(n+1)] for n in range(15)] # optional - sage.libs.gap
[[1, False, 1, False],
 [3, True, 2, True],
 [4, False, 3, True],
 [7, True, 4, False],
 [11, True, 5, True],
 [18, False, 6, False],
]
```

(continues on next page)
Can you use Sage to find a counterexample to the conjecture?

```
sage.combinat.combinat.lucas_number2(n, P, Q)
```

Return the \(n\)-th Lucas number “of the second kind” (this is not standard terminology). The Lucas sequence \(L_n^{(2)}\) is defined by the initial conditions \(L_1^{(2)} = 2, L_2^{(2)} = P\) and the recurrence relation \(L_{n+2}^{(2)} = P \cdot L_{n+1}^{(2)} - Q \cdot L_n^{(2)}\).

Wraps GAP’s Lucas(...)[2].

**INPUT:**
- \(n\) - integer
- \(P, Q\) - integer or rational numbers

**OUTPUT:** integer or rational number

**EXAMPLES:**

```
sage: [lucas_number2(i,1,-1) for i in range(10)] #← optional - sage.libs.gap
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
sage: [fibonacci(i-1)+fibonacci(i+1) for i in range(10)] #← optional - sage.libs.pari
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
sage: n = lucas_number2(5,2,3); n #← optional - sage.libs.gap
2
sage: type(n) #← optional - sage.libs.gap
<class 'sage.rings.integer.Integer'>
sage: n = lucas_number2(5,2,-3/9); n #← optional - sage.libs.gap
418/9
sage: type(n) #← optional - sage.libs.gap
<class 'sage.rings.rational.Rational'>
```

The case \(P = 1, Q = -1\) is the Lucas sequence in Brualdi’s Introductory Combinatorics, 4th ed., Prentice-Hall, 2004:

```
sage: [lucas_number2(n,1,-1) for n in range(10)] #← optional - sage.libs.gap
[2, 1, 3, 4, 7, 11, 18, 29, 47, 76]
```
sage.combinat.combinat.narayana_number(n, k)

Return the Narayana number of index \((n, k)\).

For every integer \(n \geq 1\), the sum of Narayana numbers \(\sum_{k} N_{n,k}\) is the Catalan number \(C_n\).

**INPUT:**
- \(n\) – an integer
- \(k\) – an integer between \(0\) and \(n - 1\)

**OUTPUT:**
an integer

**EXAMPLES:**

```python
sage: from sage.combinat.combinat import narayana_number
sage: [narayana_number(3, i) for i in range(3)]
[1, 3, 1]
sage: sum(narayana_number(7,i) for i in range(7)) == catalan_number(7)
True
```

**REFERENCES:**
- Wikipedia article Narayana_number

sage.combinat.combinat.number_of_tuples(S, k, algorithm='naive')

Return the size of tuples \((S, k)\) when \(S\) is a set. More generally, return the size of tuples(set(S), k). (So, unlike tuples(), this method removes redundant entries from \(S\).)

**INPUT:**
- \(S\) – the base set
- \(k\) – the length of the tuples
- **algorithm** – can be one of the following:
  - 'naive' - (default) use the naive counting \(|S|^k\)
  - 'gap' - wraps GAP's NrTuples

**Warning:** When using algorithm='gap', \(S\) must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If \(S\) consists of at all complicated Sage objects, this function might not do what you expect.

**EXAMPLES:**

```python
sage: S = [1,2,3,4,5]
sage: number_of_tuples(S,2)
25
sage: number_of_tuples(S,2, algorithm="gap")
# optional - sage.libs.gap
25
sage: S = [1,1,2,3,4,5]
sage: number_of_tuples(S,2)
25
sage: number_of_tuples(S,2, algorithm="gap")
# optional - sage.libs.gap
(continues on next page)
```
sage.combinat.combinat.number_of_unordered_tuples(S, k, algorithm='naive')

Return the size of unordered_tuples(S, k) when S is a set.

INPUT:

• S – the base set
• k – the length of the tuples
• algorithm – can be one of the following:
  – 'naive' - (default) use the naive counting \( \binom{|S|+k-1}{k} \)
  – 'gap' - wraps GAP's NrUnorderedTuples

Warning: When using algorithm='gap', S must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If S consists of at all complicated Sage objects, this function might not do what you expect.

EXAMPLES:

```
sage: S = [1,2,3,4,5]
sage: number_of_unordered_tuples(S,2)
15
sage: number_of_unordered_tuples(S,2, algorithm="gap")
15
  optional - sage.libs.gap
sage: S = [1,1,2,3,4,5]
sage: number_of_unordered_tuples(S,2)
15
sage: number_of_unordered_tuples(S,2, algorithm="gap")
15
  optional - sage.libs.gap
sage: number_of_unordered_tuples(S,0)
1
sage: number_of_unordered_tuples(S,0, algorithm="gap")
1
  optional - sage.libs.gap
```

sage.combinat.combinat.polygonal_number(s, n)

Return the n-th s-gonal number.

Polygonal sequences are represented by dots forming a regular polygon. Two famous sequences are the triangular numbers (3rd column of Pascal’s Triangle) and the square numbers. The n-th term in a polygonal sequence is defined by

\[ P(s, n) = \frac{n^2(s-2) - n(s-4)}{2}, \]
where $s$ is the number of sides of the polygon.

INPUT:

- $s$ – integer greater than 1; the number of sides of the polygon
- $n$ – integer; the index of the returned $s$-gonal number

OUTPUT: an integer

EXAMPLES:

The triangular numbers:

```
sage: [polygonal_number(3, n) for n in range(10)]
[0, 1, 3, 6, 10, 15, 21, 28, 36, 45]
sage: [polygonal_number(3, n) for n in range(-10, 0)]
[45, 36, 28, 21, 15, 10, 6, 3, 1, 0]
```

The square numbers:

```
sage: [polygonal_number(4, n) for n in range(10)]
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

The pentagonal numbers:

```
sage: [polygonal_number(5, n) for n in range(10)]
[0, 1, 5, 12, 22, 35, 51, 70, 92, 117]
```

The hexagonal numbers:

```
sage: [polygonal_number(6, n) for n in range(10)]
[0, 1, 6, 15, 28, 45, 66, 91, 120, 153]
```

The input is converted into an integer:

```
sage: polygonal_number(3.0, 2.0)
3
```

A non-integer input returns an error:

```
sage: polygonal_number(3.5, 1)
Traceback (most recent call last):
...
TypeError: Attempt to coerce non-integral RealNumber to Integer
```

$s$ must be greater than 1:

```
sage: polygonal_number(1, 4)
Traceback (most recent call last):
...
ValueError: s (=1) must be greater than 1
```

REFERENCES:

- Wikipedia article Polygonal_number
sage.combinat.combinat.stirling_number1(n, k, algorithm='gap')

Return the $n$-th Stirling number $S_1(n, k)$ of the first kind.

This is the number of permutations of $n$ points with $k$ cycles.

See Wikipedia article Stirling_numbers_of_the_first_kind.

INPUT:

• $n$ – nonnegative machine-size integer
• $k$ – nonnegative machine-size integer
• algorithm:
  – "gap" (default) – use GAP’s Stirling1 function
  – "flint" – use flint’s arith_stirling_number_1u function

EXAMPLES:

```
sage: stirling_number1(3, 2)  
# optional - sage.libs.gap
3
sage: stirling_number1(5, 2)  
# optional - sage.libs.gap
50
sage: 9*stirling_number1(9, 5) + stirling_number1(9, 4)  
# optional - sage.libs.gap
269325
sage: stirling_number1(10, 5)  
# optional - sage.libs.gap
269325
```

Indeed, $S_1(n, k) = S_1(n - 1, k - 1) + (n - 1)S_1(n - 1, k)$.

sage.combinat.combinat.stirling_number2(n, k, algorithm=None)

Return the $n$-th Stirling number $S_2(n, k)$ of the second kind.

This is the number of ways to partition a set of $n$ elements into $k$ pairwise disjoint nonempty subsets. The $n$-th Bell number is the sum of the $S_2(n, k)$’s, $k = 0, ..., n$.

See Wikipedia article Stirling_numbers_of_the_second_kind.

INPUT:

• $n$ – nonnegative machine-size integer
• $k$ – nonnegative machine-size integer
• algorithm:
  – None (default) – use native implementation
  – "flint" – use flint’s arith_stirling_number_2 function
  – "gap" – use GAP’s Stirling2 function
  – "maxima" – use Maxima’s stirling2 function

EXAMPLES:

Print a table of the first several Stirling numbers of the second kind:
Combinatorics, Release 10.1

```python
sage: for n in range(10):
    ...:     for k in range(10):
    ...:         print(str(stirling_number2(n,k)).rjust(k and 6))
1 0 0 0 0 0 0 0 0 0
0 1 0 0 0 0 0 0 0 0
0 1 1 0 0 0 0 0 0 0
0 1 3 1 0 0 0 0 0 0
0 1 7 6 1 0 0 0 0 0
0 1 15 25 10 1 0 0 0 0
0 1 31 90 65 15 1 0 0 0
0 1 63 301 350 140 21 1 0 0
0 1 127 966 1701 1050 266 28 1 0
```

Stirling numbers satisfy $S_2(n,k) = S_2(n-1,k-1) + kS_2(n-1,k)$:

```python
sage: 5*stirling_number2(9,5) + stirling_number2(9,4)
42525
sage: stirling_number2(10,5)
42525
```

```python
sage.combinat.combinat.tuples(S, k, algorithm='itertools')
```

Return a list of all $k$-tuples of elements of a given set $S$. This function accepts the set $S$ in the form of any iterable (list, tuple or iterator), and returns a list of $k$-tuples. If $S$ contains duplicate entries, then you should expect the method to return tuples multiple times!

Recall that $k$-tuples are ordered (in the sense that two $k$-tuples differing in the order of their entries count as different) and can have repeated entries (even if $S$ is a list with no repetition).

**INPUT:**

- $S$ – the base set
- $k$ – the length of the tuples
- `algorithm` – can be one of the following:
  - `'itertools'` - (default) use python's itertools
  - `'native'` - use a native Sage implementation

**Note:** The ordering of the list of tuples depends on the algorithm.

**EXAMPLES:**

```python
sage: S = [1,2]
sage: tuples(S,3)
[(1, 1, 1), (1, 1, 2), (1, 2, 1), (1, 2, 2), (2, 1, 1), (2, 1, 2), (2, 2, 1), (2, 2, 2)]
sage: mset = ['s','t','e','i','n']
sage: tuples(mset, 2)
[('s', 's'), ('s', 't'), ('s', 'e'), ('s', 'i'), ('s', 'n'), ('t', 's'), ('t', 't'), ('t', 'e'), ('t', 'i'), ('t', 'n'), ('e', 's'), ('e', 't'), ('e', 'e'), ('e', 'i'), ('e', 'n'),
('i', 's'), ('i', 't'), ('i', 'e'), ('i', 'i'), ('i', 'n'), ('n', 's'), ('n', 't'), ('n', 'e'), ('n', 'i'), ('n', 'n'),]
```

(continues on next page)
('i', 's'), ('i', 't'), ('i', 'e'), ('i', 'i'), ('i', 'n'),
('n', 's'), ('n', 't'), ('n', 'e'), ('n', 'i'), ('n', 'n')]

We check that the implementations agree (up to ordering):

```python
sage: tuples(S, 3, 'native')
[(1, 1, 1), (2, 1, 1), (1, 2, 1), (2, 2, 1),
 (1, 1, 2), (2, 1, 2), (1, 2, 2), (2, 2, 2)]
```

Lastly we check on a multiset:

```python
sage: S = [1,1,2]
sage: sorted(tuples(S, 3)) == sorted(tuples(S, 3, 'native'))
True
```

AUTHORS:

- Jon Hanke (2006-08)

sage.combinat.combinat.unordered_tuples(S, k, algorithm='itertools')

Return a list of all unordered tuples of length k of the set S.

An unordered tuple of length k of set S is a unordered selection with repetitions of S and is represented by a sorted list of length k containing elements from S.

Unlike tuples(), the result of this method does not depend on how often an element appears in S: only the set S is being used. For example, unordered_tuples([1, 1, 1], 2) will return [(1, 1)]. If you want it to return [(1, 1), (1, 1), (1, 1)], use Python’s itertools.combinations_with_replacement instead.

INPUT:

- S – the base set
- k – the length of the tuples
- algorithm – can be one of the following:
  - 'itertools' - (default) use python’s itertools
  - 'gap' - wraps GAP’s UnorderedTuples

**Warning:** When using algorithm='gap', S must be a list of objects that have string representations that can be interpreted by the GAP interpreter. If S consists of at all complicated Sage objects, this function might not do what you expect.

EXAMPLES:
```python
sage: S = [1,2]
sage: unordered_tuples(S, 3)
[(1, 1, 1), (1, 1, 2), (1, 2, 2), (2, 2, 2)]
We check that this agrees with GAP:
```
5.1. Comprehensive Module List

5.1.26 Fast computation of combinatorial functions (Cython + mpz)

Currently implemented:

- Stirling numbers of the second kind
- Iterators for set partitions
- Iterator for Lyndon words
- Iterator for perfect matchings
- Conjugate of partitions

AUTHORS:

- Fredrik Johansson (2010-10): Stirling numbers of second kind
- Martin Rubey and Travis Scrimshaw (2018): iterators for set partitions, Lyndon words, and perfect matchings

`sage.combinat.combinat_cython.conjugate(p)`

Return the conjugate partition associated to the partition `p` as a list.

EXAMPLES:

```python
sage: from sage.combinat.combinat_cython import conjugate
sage: conjugate([2,2])
[2, 2]
sage: conjugate([6,3,1])
[3, 2, 2, 1, 1, 1]
```

`sage.combinat.combinat_cython.lyndon_word_iterator(n, k)`

Generate the Lyndon words of fixed length `k` with `n` letters.

The resulting Lyndon words will be words represented as lists whose alphabet is `range(n)` (= `{0, 1, ..., n-1}`).

ALGORITHM:

The iterative FKM Algorithm 7.2 from [Rus2003].

EXAMPLES:

```python
sage: from sage.combinat.combinat_cython import lyndon_word_iterator
sage: list(lyndon_word_iterator(4, 2))
[[[0, 1], [0, 2], [0, 3], [1, 2], [1, 3], [2, 3]]
sage: list(lyndon_word_iterator(2, 4))
[[[0, 0, 0, 1], [0, 0, 1, 1], [0, 1, 1, 1]]
```

`sage.combinat.combinat_cython.perfect_matchings_iterator(n)`

Iterate over all perfect matchings with `n` parts.

This iterates over all perfect matchings of `{0, 1, ..., 2n - 1}` using a Gray code for fixed-point-free involutions due to Walsh [Wal2001].
EXAMPLES:

```
sage: from sage.combinat.combinat_cython import perfect_matchings_iterator
sage: list(perfect_matchings_iterator(1))
[[0, 1]]
sage: list(perfect_matchings_iterator(2))
[[0, 1], [2, 3], [(0, 2), (1, 3)], [(0, 3), (1, 2)]
sage: list(perfect_matchings_iterator(0))
[]
```

REFERENCES:

• [Wal2001]

```
sage.combinat.combinat_cython.set_partition_composition(sp1, sp2)
```

Return a tuple consisting of the composition of the set partitions sp1 and sp2 and the number of components removed from the middle rows of the graph.

EXAMPLES:

```
sage: from sage.combinat.combinat_cython import set_partition_composition
sage: sp1 = ((1,-2),(2,-1))
sage: sp2 = ((1,-2),(2,-1))
sage: p, c = set_partition_composition(sp1, sp2)
sage: (SetPartition(p), c) == (SetPartition([[1,-1],[2,-2]]), 0) # optional - sage.combinat
True
```

5.1.27 Combinations

AUTHORS:

• Mike Hansen (2007): initial implementation
• Vincent Delecroix (2011): cleaning, bug corrections, doctests
• Antoine Genitrini (2020): new implementation of the lexicographic unranking of combinations

```
class sage.combinat.combination.ChoseNK(mset, k)
    Bases: Combinations_setk
```

```
sage.combinat.combination.Combinations(mset, k= None)
    Return the combinatorial class of combinations of the multiset mset. If k is specified, then it returns the combinatorial class of combinations of mset of size k.
```

A combination of a multiset \(M\) is an unordered selection of \(k\) objects of \(M\), where every object can appear at most as many times as it appears in \(M\).

The combinatorial classes correctly handle the cases where mset has duplicate elements.

EXAMPLES:

```
sage: C = Combinations(range(4)); C
Combinations of [0, 1, 2, 3]
sage: C.list()
[]
```

(continues on next page)
sage: C = Combinations(range(4),2); C
Combinations of [0, 1, 2, 3] of length 2
sage: C.list()
[[0, 1], [0, 2], [0, 3], [1, 2], [1, 3], [2, 3], [0, 1, 2], [0, 1, 3], [0, 2, 3], [1, 2, 3], [0, 1, 2, 3]]
sage: C.cardinality()
16

sage: C2 = Combinations(range(4),2); C2
Combinations of [0, 1, 2, 3] of length 2
sage: C2.list()
[[0, 1], [0, 2], [0, 3], [1, 2], [1, 3], [2, 3], [0, 1, 2], [0, 1, 3], [0, 2, 3], [1, 2, 3], [0, 1, 2, 3]]
sage: C2.cardinality()
6

sage: C3 = Combinations([1,2,2,3], 2).list()

sage: mset = [1,1,2,3,4,4,5]
sage: Combinations(mset, 2).list()
It is possible to take combinations of Sage objects:

```
sage: Combinations([vector([1,1]), vector([2,2]), vector([3,3])], 2).list()  # optional - sage.modules
[[[1, 1), (2, 2)], [[1, 1), (3, 3)], [(2, 2), (3, 3)]
```

class `sage.combinat.combination.Combinations_mset(mset)`

Bases: `Parent`

`cardinality()`

class `sage.combinat.combination.Combinations_msetk(mset, k)`

Bases: `Parent`

`cardinality()`

Return the size of combinations(mset, k).

IMPLEMENTATION: Wraps GAP’s NrCombinations.

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: Combinations(mset,2).cardinality()  # optional - sage.libs.gap
12
```
class sage.combinat.combination.Combinations_set(mset)
    Bases: Combinations_mset

cardinality()
    Return the size of Combinations(set).

    EXAMPLES:
    sage: Combinations(range(16000)).cardinality() == 2^16000
    True

rank(x)
    EXAMPLES:
    sage: c = Combinations([1,2,3])
    sage: list(range(c.cardinality())) == list(map(c.rank, c))
    True

unrank(r)
    EXAMPLES:
    sage: c = Combinations([1,2,3])
    sage: c.list() == list(map(c.unrank, range(c.cardinality())))
    True

class sage.combinat.combination.Combinations_setk(mset, k)
    Bases: Combinations_msetk

cardinality()
    Return the size of combinations(set, k).

    EXAMPLES:
    sage: Combinations(range(16000), 5).cardinality()
    8732673194560003200

list()
    EXAMPLES:
    sage: Combinations([1,2,3,4,5], 3).list()
    [[1, 2, 3],
     [1, 2, 4],
     [1, 2, 5],
     [1, 3, 4],
     [1, 3, 5],
     [1, 4, 5],
     [2, 3, 4],
     [2, 3, 5],
     [2, 4, 5],
     [3, 4, 5]]

rank(x)
    EXAMPLES:
Combinatorics, Release 10.1

```python
sage: c = Combinations([1,2,3], 2)
sage: list(range(c.cardinality())) == list(map(c.rank, c.list()))
True
```

**unrank**(*r*)

EXAMPLES:

```python
sage: c = Combinations([1,2,3], 2)
sage: c.list() == list(map(c.unrank, range(c.cardinality())))
True
```

```python
sage.combinat.combination.from_rank(*r*, *n*, *k*)
```

Return the combination of rank *r* in the subsets of `range(n)` of size *k* when listed in lexicographic order.

The algorithm used is based on factoradics and presented in [DGH2020]. It is there compared to the other from the literature.

EXAMPLES:

```python
sage: import sage.combinat.combination as combination
sage: combination.from_rank(0,3,0)
()
sage: combination.from_rank(0,3,1)
(0,)
sage: combination.from_rank(1,3,1)
(1,)
sage: combination.from_rank(2,3,1)
(2,)
sage: combination.from_rank(0,3,2)
(0, 1)
sage: combination.from_rank(1,3,2)
(0, 2)
sage: combination.from_rank(2,3,2)
(1, 2)
sage: combination.from_rank(0,3,3)
(0, 1, 2)
```

```python
sage.combinat.combination.rank(*comb*, *n*, *check=True*)
```

Return the rank of *comb* in the subsets of `range(n)` of size *k* where *k* is the length of *comb*.

The algorithm used is based on combinadics and James McCaffrey’s MSDN article. See: [Wikipedia article on Combinadic](https://en.wikipedia.org/wiki/Combinadic).

EXAMPLES:

```python
sage: import sage.combinat.combination as combination
sage: combination.rank((), 3)
0
sage: combination.rank((0,), 3)
0
sage: combination.rank((1,), 3)
1
sage: combination.rank((2,), 3)
2
sage: combination.rank((0,1), 3)
(continues on next page)
```
5.1.28 Combinatorial maps

This module provides a decorator that can be used to add semantic to a Python method by marking it as implementing a combinatorial map, that is a map between two enumerated sets:

```python
sage: from sage.combinat.combinatorial_map import combinatorial_map
sage: class MyPermutation:
    ...: @combinatorial_map()
    ...: def reverse(self):
    ...:     '''Reverse the permutation
    ...:     '''
    ...:     # ... code ...
```

By default, this decorator is a no-op: it returns the decorated method as is:

```python
sage: MyPermutation.reverse
<function MyPermutation.reverse at ...>
```

See `combinatorial_map_wrapper()` for the various options this decorator can take.

Projects built on top of Sage are welcome to customize locally this hook to instrument the Sage code and exploit this semantic information. Typically, the decorator could be used to populate a database of maps. For a real-life application, see the project [FindStat](http://findstat.org/). As a basic example, a variant of the decorator is provided as `combinatorial_map_decorator();` it wraps the decorated method, so that one can later use `combinatorial_maps_in_class()` to query an object, or class thereof, for all the combinatorial maps that apply to it.

**Note:** Since decorators are evaluated upon loading Python modules, customizing combinatorial map needs to be done before the modules using it are loaded. In the examples below, where we illustrate the customized context...
combinatorial_map decorator on the \texttt{sage.combinat.permutation} module, we resort to force a reload of this module after dynamically changing \texttt{sage.combinat.combinatorial_map.combinatorial_map}. This is good enough for those doctests, but remains fragile.

For real use cases, it is probably best to just edit this source file statically (see below).

```python
class \texttt{sage.combinat.combinatorial_map.CombinatorialMap}(f, order=None, name=None)
    Bases: object
    
    This is a wrapper class for methods that are \textit{combinatorial maps}. 
    For further details and doctests, see \texttt{Combinatorial maps} and \texttt{combinatorial_map_wrapper()}. 

    \texttt{name()}
    Returns the name of a combinatorial map. This is used for the string representation of self. 

    EXAMPLES:

    \begin{verbatim}
    sage: from sage.combinat.combinatorial_map import combinatorial_map
    sage: class CombinatorialClass:
    ....:     @combinatorial_map(name='map1')
    ....:     def to_self_1(): pass
    ....:     @combinatorial_map()
    ....:     def to_self_2(): pass
    sage: CombinatorialClass.to_self_1.name()
    'map1'
    sage: CombinatorialClass.to_self_2.name()
    'to_self_2'
    \end{verbatim}

    \texttt{order()}
    Returns the order of self, or \texttt{None} if the order is not known. 

    EXAMPLES:

    \begin{verbatim}
    sage: from sage.combinat.combinatorial_map import combinatorial_map
    sage: class CombinatorialClass:
    ....:     @combinatorial_map(order=2)
    ....:     def to_self_1(): pass
    ....:     @combinatorial_map()
    ....:     def to_self_2(): pass
    sage: CombinatorialClass.to_self_1.order()
    2
    sage: CombinatorialClass.to_self_2.order() is None
    True
    \end{verbatim}

    \texttt{unbounded_map()}
    Return the unbounded version of self. 
    You can use this method to return a function which takes as input an element in the domain of the combinatorial map. See the example below. 

    EXAMPLES:

    \begin{verbatim}
    sage: sage.combinat.combinatorial_map.combinatorial_map = sage.combinat.
    \text{combinatorial_map.combinatorial_map_wrapper}
    sage: from importlib import reload
    \end{verbatim}
```
sage: _ = reload(sage.combinat.permutation)
sage: from sage.combinat.permutation import Permutation
sage: pi = Permutation([1,3,2])
sage: f = pi.reverse
sage: F = f.unbounded_map()
sage: F(pi)
[2, 3, 1]

sage.combinat.combinatorial_map.combinatorial_map(f=None, order=None, name=None)

Combinatorial map decorator

See `Combinatorial maps` for a description of this decorator and its purpose. This default implementation does nothing.

INPUT:

- \( f \) – (default: None, if `combinatorial_map` is used as a decorator) a function
- \( \text{name} \) – (default: None) the name for nicer outputs on combinatorial maps
- \( \text{order} \) – (default: None) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

OUTPUT:

- \( f \) unchanged

EXAMPLES:

```python
sage: from sage.combinat.combinatorial_map import combinatorial_map_trivial as _

sage: class MyPermutation():
    ....:     @combinatorial_map
    ....:     def reverse(self):
    ....:         '''Reverse the permutation'''
    ....:         # ... code ...
    ....:         @combinatorial_map(name='descent set of permutation')
    ....:         def descent_set(self):
    ....:             '''The descent set of the permutation'''
    ....:             # ... code ...

sage: MyPermutation.reverse
<function MyPermutation.reverse at ...>

sage: MyPermutation.descent_set
<function MyPermutation.descent_set at ...>
```

sage.combinat.combinatorial_map.combinatorial_map_trivial(f=None, order=None, name=None)

Combinatorial map decorator

See `Combinatorial maps` for a description of this decorator and its purpose. This default implementation does nothing.

INPUT:
Combinatorics, Release 10.1

• $f$ – (default: None, if combinatorial_map is used as a decorator) a function

• name – (default: None) the name for nicer outputs on combinatorial maps

• order – (default: None) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

OUTPUT:

• $f$ unchanged

EXAMPLES:

```python
sage: from sage.combinat.combinatorial_map import combinatorial_map_trivial as combinatorial_map
sage: class MyPermutation:
    ....:     @combinatorial_map
    ....:     def reverse(self):
    ....:         '''Reverse the permutation''''
    ....:     # ... code ...
    ....:     @combinatorial_map(name='descent set of permutation')
    ....:     def descent_set(self):
    ....:         '''The descent set of the permutation''''
    ....:     # ... code ...

sage: MyPermutation.reverse
<function MyPermutation.reverse at ...>

sage: MyPermutation.descent_set
<function MyPermutation.descent_set at ...>
```

sage.combinat.combinatorial_map.combinatorial_map_wrapper($f=None, order=None, name=None$)

Combinatorial map decorator (basic example).

See Combinatorial maps for a description of the combinatorial_map decorator and its purpose. This implementation, together with combinatorial_maps_in_class() illustrates how to use this decorator as a hook to instrument the Sage code.

INPUT:

• $f$ – (default: None, if combinatorial_map is used as a decorator) a function

• name – (default: None) the name for nicer outputs on combinatorial maps

• order – (default: None) the order of the combinatorial map, if it is known. Is not used, but might be helpful later

OUTPUT:

• A combinatorial map. This is an instance of the CombinatorialMap.

EXAMPLES:

We define a class illustrating the use of this implementation of the combinatorial_map decorator with its various arguments:
sage: from sage.combinat.combinatorial_map import combinatorial_map
sage: class MyPermutation():
    ....:     @combinatorial_map()
    ....:     def reverse(self):
    ....:         """
    ....:         Reverse the permutation
    ....:         """
    ....:         pass
    ....:     @combinatorial_map(order=2)
    ....:     def inverse(self):
    ....:         """
    ....:         The inverse of the permutation
    ....:         """
    ....:         pass
    ....:     @combinatorial_map(name='descent set of permutation')
    ....:     def descent_set(self):
    ....:         """
    ....:         The descent set of the permutation
    ....:         """
    ....:         pass
    ....:     def major_index(self):
    ....:         """
    ....:         The major index of the permutation
    ....:         """
    ....:         pass
sage: MyPermutation.reverse
Combinatorial map: reverse
sage: MyPermutation.descent_set
Combinatorial map: descent set of permutation
sage: MyPermutation.inverse
Combinatorial map: inverse

One can now determine all the combinatorial maps associated with a given object as follows:

sage: from sage.combinat.combinatorial_map import combinatorial_maps_in_class
sage: X = combinatorial_maps_in_class(MyPermutation); X
[Combinatorial map: reverse,
 Combinatorial map: descent set of permutation,
 Combinatorial map: inverse]

The method major_index defined about is not a combinatorial map:

sage: MyPermutation.major_index
<function MyPermutation.major_index at ...

But one can define a function that turns major_index into a combinatorial map:

sage: def major_index(p):
    ....:     return p.major_index()

5.1. Comprehensive Module List
sage.combinat.combinatorial_map.combinatorial_maps_in_class(cls)

Return the combinatorial maps of the class as a list of combinatorial maps.

For further details and doctests, see *Combinatorial maps* and *combinatorial_map_wrapper()*.

**EXAMPLES:**

```python
sage: sage.combinat.combinatorial_map.combinatorial_map = sage.combinat.combinatorial_map.combinatorial_map_wrapper
sage: from importlib import reload
sage: _ = reload(sage.combinat.permutation)
sage: from sage.combinat.combinatorial_map import combinatorial_maps_in_class
sage: p = Permutation([1,3,2,4])
sage: cmaps = combinatorial_maps_in_class(p)
sage: cmaps
# random
[Combinatorial map: Robinson-Schensted insertion tableau,
 Combinatorial map: Robinson-Schensted recording tableau,
 Combinatorial map: Robinson-Schensted tableau shape,
 Combinatorial map: complement,
 Combinatorial map: descent composition,
 Combinatorial map: inverse, ...]
sage: p.left_tableau in cmaps
True
sage: p.right_tableau in cmaps
True
sage: p.complement in cmaps
True
```

### 5.1.29 Integer compositions

A composition $c$ of a nonnegative integer $n$ is a list of positive integers (the *parts* of the composition) with total sum $n$.

This module provides tools for manipulating compositions and enumerated sets of compositions.

**EXAMPLES:**

```python
sage: Composition([5, 3, 1, 3])
[5, 3, 1, 3]
sage: list(Compositions(4))
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

**AUTHORS:**

- Mike Hansen, Nicolas M. Thiéry
- MuPAD-Combinat developers (algorithms and design inspiration)
- Travis Scrimshaw (2013-02-03): Removed CombinatorialClass

```python
class sage.combinat.composition.Composition(parent, *args, **kwds)
    Bases: CombinatorialElement

    Integer compositions

    A composition of a nonnegative integer $n$ is a list $(i_1, \ldots, i_k)$ of positive integers with total sum $n$.

    **EXAMPLES:**

    The simplest way to create a composition is by specifying its entries as a list, tuple (or other iterable):
```
You can also create a composition from its code. The code of a composition \((i_1, i_2, \ldots, i_k)\) of \(n\) is a list of length \(n\) that consists of a 1 followed by \(i_1 - 1\) zeros, then a 1 followed by \(i_2 - 1\) zeros, and so on.

```python
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Composition(code=_)
[4, 1, 2, 3, 5]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Composition(code=_)
[3, 1, 2, 3, 5]
```

You can also create the composition of \(n\) corresponding to a subset of \(\{1, 2, \ldots, n - 1\}\) under the bijection that maps the composition \((i_1, i_2, \ldots, i_k)\) of \(n\) to the subset \(\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + \cdots + i_k - 1\}\) (see `to_subset()`):

```python
sage: Composition(from_subset={(1, 2, 4), 5})
[1, 1, 2, 1]
sage: Composition([1, 1, 2, 1]).to_subset()
{1, 2, 4}
```

The following notation equivalently specifies the composition from the set \(\{i_1 - 1, i_1 + i_2 - 1, i_1 + i_2 + i_3 - 1, \ldots, i_1 + \cdots + i_k - 1 - n - 1\}\) or \(\{i_1 - 1, i_1 + i_2 - 1, i_1 + i_2 + i_3 - 1, \ldots, i_1 + \cdots + i_k - 1\}\) and \(n\). This provides compatibility with Python’s 0-indexing.

```python
sage: Composition(descents=[1,1,3,4,3])
[1, 1, 3, 4, 3]
sage: Composition(descents=(1,1,3,4))
[1, 1, 3, 4]
sage: Composition(descents=(1,1,3,5))
[1, 1, 3, 5]
sage: Composition(descents=(1,1,3,5))
[1, 1, 3, 5]
```

An integer composition may be regarded as a sequence. Thus it is an instance of the Python abstract base class `Sequence` allows us to check if objects behave “like” sequences based on implemented methods. Note that `collections.abc.Sequence` is not the same as `sage.structure.sequence.Sequence`:

```python
sage: import collections.abc
dsage: C = Composition([3,2,3])
sage: isinstance(C, collections.abc.Sequence)
True
sage: issubclass(C.__class__, collections.abc.Sequence)
True
```

Typically, instances of `collections.abc.Sequence` have a `.count` method. `Composition.count` counts the number of parts of a specified size:
Combinatorics, Release 10.1

```python
sage: C.count(3)
2
```

**EXAMPLES:**

```python
sage: C = Composition([3,1,2])
sage: TestSuite(C).run()

```

**complement()**

Return the complement of the composition `self`.

The complement of a composition `I` is defined as follows:

If `I` is the empty composition, then the complement is the empty composition as well. Otherwise, let `S` be the descent set of `I` (that is, the subset `{i_1, i_1 + i_2, ..., i_1 + i_2 + ... + i_k-1}` of `{1, 2, ..., |I| - 1}`, where `I` is written as `(i_1, i_2, ..., i_k)`). Then, the complement of `I` is defined as the composition of size `|I|` whose descent set is `{1, 2, ..., |I| - 1} \ S`.

The complement of a composition `I` also is the reverse composition (`reversed()`) of the conjugate (`conjugate()`) of `I`.

**EXAMPLES:**

```python
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
sage: Composition([1, 1, 3, 1, 2, 1, 3]).complement()
[3, 1, 3, 3, 1, 1]
```

**conjugate()**

Return the conjugate of the composition `self`.

The conjugate of a composition `I` is defined as the complement (see `complement()`) of the reverse composition (see `reversed()`) of `I`.

An equivalent definition of the conjugate goes by saying that the ribbon shape of the conjugate of a composition `I` is the conjugate of the ribbon shape of `I`. (The ribbon shape of a composition is returned by `to_skew_partition()`.)

This implementation uses the algorithm from mupad-combinat.

**EXAMPLES:**

```python
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
```

The ribbon shape of the conjugate of `I` is the conjugate of the ribbon shape of `I`:

```python
sage: all( I.conjugate().to_skew_partition() == I.to_skew_partition().conjugate() for I in Compositions(4) )
True
```

**count**(n)

Return the number of parts of size `n`.

**EXAMPLES:**
sage: C = Composition([3,2,3])
sage: C.count(3)
2
sage: C.count(2)
1
sage: C.count(1)
0

descents(final_descent=False)

This gives one fewer than the partial sums of the composition.
This is here to maintain some sort of backward compatibility, even through the original implementation
was broken (it gave the wrong answer). The same information can be found in `partial_sums()`.

See also:
`partial_sums()`

INPUT:
- final_descent – (Default: False) a boolean integer

OUTPUT:
- the list of partial sums of self with each part decremented by 1. This includes the sum of all entries
  when final_descent is True.

EXAMPLES:

sage: c = Composition([2,1,3,2])
sage: c.descents()
[1, 2, 5]
sage: c.descents(final_descent=True)
[1, 2, 5, 7]

fatten(grouping)

Return the composition fatter than self, obtained by grouping together consecutive parts according to
`grouping`.

INPUT:
- grouping – a composition whose sum is the length of self

EXAMPLES:

Let us start with the composition:

sage: c = Composition([4,5,2,7,1])

With grouping equal to (1,...,1), c is left unchanged:

sage: c.fatten(Composition([1,1,1,1,1]))
[4, 5, 2, 7, 1]

With grouping equal to \((\ell)\) where \(\ell\) is the length of c, this yields the coarsest composition above c:

sage: c.fatten(Composition([5]))
[19]

Other values for grouping yield (all the) other compositions coarser than c:
fatten()

Return the set of compositions which are fatter than self.

Complexity for generation: \( O(|c|) \) memory, \( O(|r|) \) time where \(|c|\) is the size of self and \( r \) is the result.

**EXAMPLES:**

```
sage: C = Composition([4,5,2]).fatter()
sage: C.cardinality()
4
sage: list(C)
[[4, 5, 2], [4, 7], [9, 2], [11]]
```

Some extreme cases:

```
sage: list(Composition([5]).fatter())
[[5]]
sage: list(Composition([]).fatter())
[[]]
sage: list(Composition([1,1,1,1]).fatter()) == list(Compositions(4))
True
```

finer()

Return the set of compositions which are finer than self.

**EXAMPLES:**

```
sage: C = Composition([3,2]).finer()
sage: C.cardinality()
8
sage: C.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 2, 1, 1], [1, 2, 2], [2, 1, 1, 1], [2, 1, 2],
 [3, 1, 1], [3, 2]]
sage: Composition([]).finer()
[]
```

inf(other, check=True)

Return the meet of self with a composition other of the same size.

The meet of two compositions \( I \) and \( J \) of size \( n \) is the finest composition of \( n \) which is coarser than each of \( I \) and \( J \). It can be described as the composition whose descent set is the intersection of the descent sets of \( I \) and \( J \).

**INPUT:**

- **other** – composition of same size as self
- **check** – (default: True) a Boolean determining whether to check the input compositions for having the same size

**OUTPUT:**
• the meet of the compositions self and other

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).meet([4, 3, 2])
[4, 5]
sage: Composition([9, 6]).meet([1, 3, 6, 3, 2])
[15]
sage: Composition([9, 6]).meet([1, 3, 5, 1, 3, 2])
[9, 6]
sage: Composition([1, 1, 1, 1, 1]).meet([3, 2])
[3, 2]
sage: Composition([4, 2]).meet([3, 3])
[6]
sage: Composition([]).meet([])
[]
sage: Composition([1]).meet([1])
[1]
```

Let us verify on small examples that the meet of \( I \) and \( J \) is coarser than both of \( I \) and \( J \):

```
sage: all( all( I.is_finer(I.meet(J)) and
....: J.is_finer(I.meet(J))
....: for J in Compositions(4) )
....: for I in Compositions(4) )
True
```

and is the finest composition to do so:

```
sage: all( all( I.meet(J).is_finer(K)
....: for K in I.fatter() 
....: if J.is_finer(K) )
....: for J in Compositions(3) )
....: for I in Compositions(3) )
True
```

The descent set of the meet of \( I \) and \( J \) is the intersection of the descent sets of \( I \) and \( J \):

```
sage: def test_meet(n):
....:     return all( all( I.to_subset().intersection(J.to_subset())
....: == I.meet(J).to_subset()
....: for J in Compositions(n) )
....: for I in Compositions(n) )
sage: all( test_meet(n) for n in range(1, 5) )
True
```

See also:

`join()`

AUTHORS:

• Darij Grinberg (2013-09-05)

`is_finer(co2)`

Return True if the composition self is finer than the composition co2; otherwise, return False.

EXAMPLES:
sage: Composition([4,1,2]).is_finer([3,1,3])
False
sage: Composition([3,1,3]).is_finer([4,1,2])
False
sage: Composition([1,2,2,1,1,2]).is_finer([5,1,3])
True
sage: Composition([2,2,2]).is_finer([4,2])
True

join(other, check=True)

Return the join of self with a composition other of the same size.

The join of two compositions \( I \) and \( J \) of size \( n \) is the coarsest composition of \( n \) which refines each of \( I \) and \( J \). It can be described as the composition whose descent set is the union of the descent sets of \( I \) and \( J \). It is also the concatenation of \( I_1, I_2, \ldots, I_m \), where \( I = I_1 \circ I_2 \circ \ldots \circ I_m \) is the ribbon decomposition of \( I \) with respect to \( J \) (see \texttt{ribbon_decomposition()}).

INPUT:

- \( \text{other} \) – composition of same size as \( \text{self} \)
- \( \text{check} \) – (default: \text{True}) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

- the join of the compositions \( \text{self} \) and \( \text{other} \)

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).join([4, 3, 2])
[3, 1, 1, 2, 1, 1]
sage: Composition([9, 6]).join([1, 3, 6, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([9, 6]).join([1, 3, 5, 1, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([1, 1, 1, 1, 1]).join([3, 2])
[1, 1, 1, 1, 1]
sage: Composition([4, 2]).join([3, 3])
[3, 1, 2]
sage: Composition([]).join([])
[]
```

Let us verify on small examples that the join of \( I \) and \( J \) refines both of \( I \) and \( J \):

```
sage: all( all( I.join(J).is_finer(I) and
.....: I.join(J).is_finer(J)
.....: for J in Compositions(4) )
.....: for I in Compositions(4) )
True
```

and is the coarsest composition to do so:

```
sage: all( all( K.is_finer(I.join(J))
.....: for K in I.finer()
.....: if K.is_finer(J) )
```

(continues on next page)
Let us check that the join of $I$ and $J$ is indeed the concatenation of $I_1, I_2, \cdots, I_m$, where $I = I_1 \cdot I_2 \cdot \cdots \cdot I_m$
is the ribbon decomposition of $I$ with respect to $J$:

```sage
sage: all( all( Composition.sum(I.ribbon_decomposition(J)[0])
........: == I.join(J) for J in Compositions(4) )
........: for I in Compositions(4) )
True
```

Also, the descent set of the join of $I$ and $J$ is the union of the descent sets of $I$ and $J$:

```sage
sage: all( all( I.to_subset().union(J.to_subset())
........: == I.join(J).to_subset() 
........: for J in Compositions(4) )
........: for I in Compositions(4) )
True
```

See also:

`meet()`, `ribbon_decomposition()`

AUTHORS:

• Darij Grinberg (2013-09-05)

```python
major_index()
```

Return the major index of `self`. The major index is defined as the sum of the descents.

EXAMPLES:

```sage
sage: Composition([1, 1, 3, 1, 2, 1, 3]).major_index()
31
```

```python
meet(other, check=True)
```

Return the meet of `self` with a composition `other` of the same size.

The meet of two compositions $I$ and $J$ of size $n$ is the finest composition of $n$ which is coarser than each of $I$ and $J$. It can be described as the composition whose descent set is the intersection of the descent sets of $I$ and $J$.

INPUT:

• `other` – composition of same size as `self`

• `check` – (default: True) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

• the meet of the compositions `self` and `other`

EXAMPLES:

```sage
sage: Composition([3, 1, 1, 3, 1]).meet([4, 3, 2])
[4, 5]
```
Let us verify on small examples that the meet of $I$ and $J$ is coarser than both of $I$ and $J$:

```python
sage: all( all( I.is_finer(I.meet(J)) and 
........: J.is_finer(I.meet(J)) 
........: for J in Compositions(4) ) 
........: for I in Compositions(4) )
True
```

and is the finest composition to do so:

```python
sage: all( all( I.meet(J).is_finer(K) 
........: for K in I.fatter() 
........: if J.is_finer(K) ) 
........: for J in Compositions(3) ) 
........: for I in Compositions(3) )
True
```

The descent set of the meet of $I$ and $J$ is the intersection of the descent sets of $I$ and $J$:

```python
sage: def test_meet(n):
........: return all( all( I.to_subset().intersection(J.to_subset()) 
........: == I.meet(J).to_subset() 
........: for J in Compositions(n) ) 
........: for I in Compositions(n) )
sage: all( test_meet(n) for n in range(1, 5) )
True
```

See also:

`join()`

AUTHORS:

• Darij Grinberg (2013-09-05)

`near_concatenation(other)`

Return the near-concatenation of two nonempty compositions `self` and `other`.

The near-concatenation $I \odot J$ of two nonempty compositions $I$ and $J$ is defined as the composition $(i_1, i_2, \ldots, i_{n-1}, i_n + j_1, j_2, j_3, \ldots, j_m)$, where $(i_1, i_2, \ldots, i_n) = I$ and $(j_1, j_2, \ldots, j_m) = J$.

This method returns `None` if one of the two input compositions is empty.

EXAMPLES:
sage: Composition([1, 1, 3]).near_concatenation(Composition([4, 1, 2]))
[1, 1, 7, 1, 2]
sage: Composition([6]).near_concatenation(Composition([1, 5]))
[7, 5]
sage: Composition([1, 5]).near_concatenation(Composition([6]))
[1, 11]

**partial_sums** *(final=True)*

The partial sums of the sequence defined by the entries of the composition.

If \( I = (i_1, \ldots, i_m) \) is a composition, then the partial sums of the entries of the composition are \([i_1, i_1 + i_2, \ldots, i_1 + i_2 + \cdots + i_m] \).

**INPUT:**

- **final** – (default: True) whether or not to include the final partial sum, which is always the size of the composition.

**See also:**

to_subset()

**EXAMPLES:**

sage: Composition([1,1,3,1,2,1,3]).partial_sums()
[1, 2, 5, 6, 8, 9, 12]

With final = False, the last partial sum is not included:

sage: Composition([1,1,3,1,2,1,3]).partial_sums(final=False)
[1, 2, 5, 6, 8, 9]

**peaks**

Return a list of the peaks of the composition self.

The peaks of a composition are the descents which do not immediately follow another descent.

**EXAMPLES:**

sage: Composition([1, 1, 3, 1, 2, 1, 3]).peaks()
[4, 7]

**refinement_splitting** *(J)*

Return the refinement splitting of self according to J.

**INPUT:**

- **J** – A composition such that self is finer than J

**OUTPUT:**

- the unique list of compositions \((I^{(p)})_{p=1,\ldots,m}\) obtained by splitting \(I\), such that \(|I^{(p)}| = J_p\) for all \(p = 1, \ldots, m\).

**See also:**

refinement_splitting_lengths()

**EXAMPLES:**
refinement_splitting_lengths(J)
Return the lengths of the compositions in the refinement splitting of \( \text{self} \) according to \( \text{J} \).

See also:

refinement_splitting() for the definition of refinement splitting

EXAMPLES:

```python
sage: Composition([1, 2, 2, 1, 1, 2]).refinement_splitting_lengths([5, 1, 3])
[3, 1, 2]
```

```python
sage: Composition([]).refinement_splitting_lengths([])
[]
```

```python
sage: Composition([3]).refinement_splitting_lengths([2])
Traceback (most recent call last):
...
ValueError: compositions \( \text{self} (= [3]) \) and \( \text{J} (= [2]) \) must be of the same size
```

```python
sage: Composition([2, 1]).refinement_splitting_lengths([1, 2])
Traceback (most recent call last):
...
ValueError: composition \( \text{J} (= [2, 1]) \) does not refine \( \text{self} (= [1, 2]) \)
```

reversed()
Return the reverse composition of \( \text{self} \).

The reverse composition of a composition \((i_1, i_2, \ldots, i_k)\) is defined as the composition \((i_k, i_{k-1}, \ldots, i_1)\).

EXAMPLES:

```python
sage: Composition([1, 1, 3, 1, 2, 1, 3]).reversed()
[3, 1, 2, 1, 3, 1, 1]
```

ribbon_decomposition(other, check=True)
Return a pair describing the ribbon decomposition of a composition \( \text{self} \) with respect to a composition \( \text{other} \) of the same size.

If \( I \) and \( J \) are two compositions of the same nonzero size, then the ribbon decomposition of \( I \) with respect to \( J \) is defined as follows: Write \( I \) and \( J \) as \( I = (i_1, i_2, \ldots, i_n) \) and \( J = (j_1, j_2, \ldots, j_m) \). Then, the equality \( I = I_1 \circ I_2 \circ \ldots \circ I_m \) holds for a unique \( m \)-tuple \((I_1, I_2, \ldots, I_m)\) of compositions such that each \( I_k \) has size \( j_k \) and for a unique choice of \( m - 1 \) signs \( \circ \) each of which is either the concatenation sign \( \cdot \) or the near-concatenation sign \( \circ \) (see \_add\_() and near_concatenation() for the definitions of these two signs). This \( m \)-tuple and this choice of signs together are said to form the ribbon decomposition of \( I \).
with respect to \( J \). If \( I \) and \( J \) are empty, then the same definition applies, except that there are 0 rather than \( m - 1 \) signs.

See Section 4.8 of [NCSF1].

INPUT:

- \( \text{other} \) – composition of same size as self
- \( \text{check} \) – (default: True) a Boolean determining whether to check the input compositions for having the same size

OUTPUT:

- a pair \((u, v)\), where \( u \) is a tuple of compositions (corresponding to the \( m \)-tuple \((I_1, I_2, \ldots, I_m)\) in the above definition), and \( v \) is a tuple of \( 0 \)'s and \( 1 \)'s (encoding the choice of signs \( \bullet \) in the above definition, with a 0 standing for \( \cdot \) and a 1 standing for \( \circ \)).

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).ribbon_decomposition([4, 3, 2])
(([3, 1], [1, 2], [1, 1]), (0, 1))
sage: Composition([9, 6]).ribbon_decomposition([1, 3, 6, 3, 2])
(([1], [3], [5, 1], [3], [2]), (1, 1, 1, 1))
sage: Composition([9, 6]).ribbon_decomposition([1, 3, 5, 1, 3, 2])
(([1], [3], [5], [1], [3], [2]), (1, 1, 0, 1, 1))
sage: Composition([1, 1, 1, 1, 1]).ribbon_decomposition([3, 2])
(([1, 1, 1], [1, 1]), (0,))
sage: Composition([4, 2]).ribbon_decomposition([6])
(([4, 2],), ())
```

Let us check that the defining property \( I = I_1 \bullet I_2 \bullet \ldots \bullet I_m \) is satisfied:

```
sage: def compose_back(u, v):
    ...:     comp = u[0]
    ...:     r = len(v)
    ...:     if len(u) != r + 1:
    ...:         raise ValueError("something is wrong")
    ...:     for i in range(r):
    ...:         if v[i] == 0:
    ...:             comp += u[i + 1]
    ...:     else:
    ...:         comp = comp.near_concatenation(u[i + 1])
    ...:     return comp
sage: all( all( all( compose_back(*I.ribbon_decomposition(J))) == I
    ...:             for J in Compositions(n) )
    ...:         for I in Compositions(n) )
    ...:     for n in range(1, 5) )
True
```

AUTHORS:

- Darij Grinberg (2013-08-29)

\( \text{shuffle_product} \) (other, overlap=False)

The (overlapping) shuffles of self and other.
Suppose $I = (i_1, \ldots, i_k)$ and $J = (j_1, \ldots, j_l)$ are two compositions. A *shuffle* of $I$ and $J$ is a composition of length $k + l$ that contains both $I$ and $J$ as subsequences.

More generally, an *overlapping shuffle* of $I$ and $J$ is obtained by distributing the elements of $I$ and $J$ (preserving the relative ordering of these elements) among the positions of an empty list; an element of $I$ and an element of $J$ are permitted to share the same position, in which case they are replaced by their sum. In particular, a shuffle of $I$ and $J$ is an overlapping shuffle of $I$ and $J$.

**INPUT:**

- *other* – composition
- *overlap* – boolean (default: False); if True, the overlapping shuffle product is returned.

**OUTPUT:**

An enumerated set (allowing for multiplicities)

**EXAMPLES:**

The shuffle product of $[2, 2]$ and $[1, 1, 3]$:

```
sage: alph = Composition([2,2])
sage: beta = Composition([1,1,3])
sage: S = alph.shuffle_product(beta); S
Shuffle product of [2, 2] and [1, 1, 3]
sage: S.list()
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2], [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3], [1, 1, 2, 3, 2], [1, 1, 3, 2, 2]]
```

The overlapping shuffle product of $[2, 2]$ and $[1, 1, 3]$:

```
sage: alph = Composition([2,2])
sage: beta = Composition([1,1,3])
sage: O = alph.shuffle_product(beta, overlap=True); O
Overlapping shuffle product of [2, 2] and [1, 1, 3]
sage: O.list()
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2], [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3], [1, 1, 2, 3, 2], [1, 1, 3, 2, 2], [3, 2, 1, 3], [2, 3, 1, 3], [3, 1, 2, 3], [2, 1, 3, 3], [3, 1, 3, 2], [2, 1, 1, 5], [1, 3, 2, 3], [1, 2, 3, 3], [1, 3, 3, 2], [1, 1, 5, 2], [1, 1, 2, 5], [3, 3, 3], [3, 1, 5], [1, 3, 5]]
```

Note that the shuffle product of two compositions can include the same composition more than once since a composition can be a shuffle of two compositions in several ways. For example:

```
sage: w1 = Composition([1])
sage: S = w1.shuffle_product(w1); S
Shuffle product of [1] and [1]
sage: S.list()
```

(continues on next page)
size()

Return the size of self, that is the sum of its parts.

EXAMPLES:

```python
sage: Composition([7,1,3]).size()
11
```

specht_module(base_ring=None)

Return the Specht module corresponding to self.

EXAMPLES:

```python
sage: SM = Composition([1,2,2]).specht_module(QQ); SM
Specht module of [(0, 0), (1, 0), (1, 1), (2, 0), (2, 1)] over Rational Field
```

```python
sage: s = SymmetricFunctions(QQ).s()
```

```python
s[SM.frobenius_image()]
```

specht_module_dimension(base_ring=None)

Return the dimension of the Specht module corresponding to self.

INPUT:

- base_ring – (default: Q) the base ring

EXAMPLES:

```python
sage: Composition([1,2,2]).specht_module_dimension()
5
sage: Composition([1,2,2]).specht_module_dimension(GF(2))
5
```

static sum(compositions)

Return the concatenation of the given compositions.

INPUT:

- compositions – a list (or iterable) of compositions

EXAMPLES:
Any iterable can be provided as input:

```python
sage: Composition.sum([Composition([1, 1, 3]), Composition([4, 1, 2]), Composition([3, 1])])
[1, 1, 3, 4, 1, 2, 3, 1]
```

Empty inputs are handled gracefully:

```python
sage: Composition.sum([]) == Composition([])
True
```

\[ \operatorname{sup}(other, \text{check}=\text{True}) \]

Return the join of \( \text{self} \) with a composition \text{other} of the same size.

The join of two compositions \( I \) and \( J \) of size \( n \) is the coarsest composition of \( n \) which refines each of \( I \) and \( J \). It can be described as the composition whose descent set is the union of the descent sets of \( I \) and \( J \). It is also the concatenation of \( I_1, I_2, \ldots, I_m \), where \( I = I_1 \bullet I_2 \bullet \ldots \bullet I_m \) is the ribbon decomposition of \( I \) with respect to \( J \) (see \text{ribbon_decomposition}()).

**INPUT:**

- \text{other} – composition of same size as \text{self}
- \text{check} – (default: True) a Boolean determining whether to check the input compositions for having the same size

**OUTPUT:**

- the join of the compositions \text{self} and \text{other}

**EXAMPLES:**

```python
sage: Composition([3, 1, 1, 3, 1]).join([4, 3, 2])
[3, 1, 1, 2, 1, 1]
sage: Composition([9, 6]).join([1, 3, 6, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([9, 6]).join([1, 3, 5, 1, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([1, 1, 1, 1, 1]).join([3, 2])
[1, 1, 1, 1, 1]
sage: Composition([4, 2]).join([3, 3])
[3, 1, 2]
sage: Composition([]).join([])
[]
```

Let us verify on small examples that the join of \( I \) and \( J \) refines both of \( I \) and \( J \):

```python
sage: all( all( I.join(J).is_finer(I) and I.join(J).is_finer(J) and for J in Compositions(4) ) for I in Compositions(4) )
True
```

and is the coarsest composition to do so:
(K is finer(J))
....:     for J in Compositions(3) )
....:     for I in Compositions(3) )
True

Let us check that the join of $I$ and $J$ is indeed the concatenation of $I_1, I_2, \cdots, I_m$, where $I = I_1 \cdot I_2 \cdot \cdots \cdot I_m$ is the ribbon decomposition of $I$ with respect to $J$:

```
sage: all( all( Composition.sum(I.ribbon_decomposition(J)[0])
       == I.join(J) for J in Compositions(4) )
    for I in Compositions(4) )
True
```

Also, the descent set of the join of $I$ and $J$ is the union of the descent sets of $I$ and $J$:

```
sage: all( all( I.to_subset().union(J.to_subset())
       == I.join(J).to_subset() for J in Compositions(4) )
    for I in Compositions(4) )
True
```

See also:

meet(), ribbon_decomposition()

AUTHORS:

• Darij Grinberg (2013-09-05)

to_code()

Return the code of the composition self.

The code of a composition $I$ is a list of length $size(I)$ of 1s and 0s such that there is a 1 wherever a new part starts. (Exceptional case: When the composition is empty, the code is [0].)

EXAMPLES:

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
```

to_partition()

Return the partition obtained by sorting self into decreasing order.

EXAMPLES:

```
sage: Composition([2,1,3]).to_partition()       # optional - sage.combinat
[3, 2, 1]
sage: Composition([4,2,2]).to_partition()      # optional - sage.combinat
[4, 2, 2]
sage: Composition([]).to_partition()          # optional - sage.combinat
[]
```
**to_skew_partition**(*overlap=1*)

Return the skew partition obtained from *self*.

This is a skew partition whose rows have the entries of *self* as their length, taken in reverse order (so the first entry of *self* is the length of the lowermost row, etc.). The parameter *overlap* indicates the number of cells on each row that are directly below cells of the previous row. When it is set to 1 (its default value), the result is the ribbon shape of *self*.

**EXAMPLES:**

```python
sage: Composition([3,4,1]).to_skew_partition()
          # optional - sage.combinat
[6, 6, 3] / [5, 2]
sage: Composition([3,4,1]).to_skew_partition(overlap=0)
          # optional - sage.combinat
[8, 7, 3] / [7, 3]
sage: Composition([]).to_skew_partition()
          # optional - sage.combinat
[] / []
sage: Composition([1,2]).to_skew_partition()
          # optional - sage.combinat
[2, 1] / []
sage: Composition([2,1]).to_skew_partition()
          # optional - sage.combinat
[2, 2] / [1]
```

**to_subset**(*final=False*)

The subset corresponding to *self* under the bijection (see below) between compositions of *n* and subsets of \{1, 2, \ldots, n-1\}.

The bijection maps a composition \((i_1, \ldots, i_k)\) of *n* to \{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + \cdots + i_{k-1}\}.

**INPUT:**

- *final* – (default: False) whether or not to include the final partial sum, which is always the size of the composition.

**See also:**

*partial_sums()*

**EXAMPLES:**

```python
sage: Composition([1,1,3,1,2,1,3]).to_subset()
{1, 2, 5, 6, 8, 9}
sage: for I in Compositions(3): print(I.to_subset())
{1, 2}
{1}
{2}
{}
```

With *final=True*, the sum of all the elements of the composition is included in the subset:

```python
sage: Composition([1,1,3,1,2,1,3]).to_subset(final=True)
{1, 2, 5, 6, 8, 9, 12}
```
wll_gt(co2)

Return True if the composition self is greater than the composition co2 with respect to the wll-ordering; otherwise, return False.

The wll-ordering is a total order on the set of all compositions defined as follows: A composition $I$ is greater than a composition $J$ if and only if one of the following conditions holds:

- The size of $I$ is greater than the size of $J$.
- The size of $I$ equals the size of $J$, but the length of $I$ is greater than the length of $J$.
- The size of $I$ equals the size of $J$, and the length of $I$ equals the length of $J$, but $I$ is lexicographically greater than $J$.

(“wll-ordering” is short for “weight, length, lexicographic ordering”.)

EXAMPLES:

```
sage: Composition([4,1,2]).wll_gt([3,1,3])
True
sage: Composition([7]).wll_gt([4,1,2])
False
sage: Composition([8]).wll_gt([4,1,2])
True
sage: Composition([3,2,2,2]).wll_gt([5,2])
True
sage: Composition([]).wll_gt([3])
False
sage: Composition([2,1]).wll_gt([2,1])
False
sage: Composition([2,2,2]).wll_gt([4,2])
True
sage: Composition([4,2]).wll_gt([2,2,2])
False
sage: Composition([1,1,2]).wll_gt([2,2])
True
sage: Composition([2,2]).wll_gt([1,3])
True
sage: Composition([2,1,2]).wll_gt([])
True
```
sage: Compositions(4).cardinality()
8

Here is the list of them:

sage: Compositions(4).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]

You can use the .first() method to get the ‘first’ composition of a number:

sage: Compositions(4).first()
[1, 1, 1, 1]

You can also calculate the ‘next’ composition given the current one:

sage: Compositions(4).next([1,1,2])
[1, 2, 1]

If \( n \) is not specified, this returns the combinatorial class of all (non-negative) integer compositions:

sage: Compositions()
Compositions of non-negative integers
sage: [] in Compositions()
True
sage: [2,3,1] in Compositions()
True
sage: [-2,3,1] in Compositions()
False

If \( n \) is specified, it returns the class of compositions of \( n \):

sage: Compositions(3)
Compositions of 3
sage: list(Compositions(3))
[[1, 1, 1], [1, 2], [2, 1], [3]]

sage: Compositions(3).cardinality()
4

The following examples show how to test whether or not an object is a composition:

sage: [3,4] in Compositions()
True
sage: [3,4] in Compositions(7)
True
sage: [3,4] in Compositions(5)
False

Similarly, one can check whether or not an object is a composition which satisfies further constraints:

sage: [4,2] in Compositions(6, inner=[2,2])
True
sage: [4,2] in Compositions(6, inner=[2,3])
False
sage: [4,1] in Compositions(5, inner=[2,1], max_slope = 0)
True
An example with incompatible constraints:

```
sage: [4,2] in Compositions(6, inner=[2,2], min_part=3)
False
```

The options `length`, `min_length`, and `max_length` can be used to set length constraints on the compositions. For example, the compositions of 4 of length equal to, at least, and at most 2 are given by:

```
sage: Compositions(4, length=2).list()
[[3, 1], [2, 2], [1, 3]]
sage: Compositions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
sage: Compositions(4, max_length=2).list()
[[4], [3, 1], [2, 2], [1, 3]]
```

Setting both `min_length` and `max_length` to the same value is equivalent to setting `length` to this value:

```
sage: Compositions(4, min_length=2, max_length=2).list()
[[3, 1], [2, 2], [1, 3]]
```

The options `inner` and `outer` can be used to set part-by-part containment constraints. The list of compositions of 4 bounded above by [3,1,2] is given by:

```
sage: list(Compositions(4, outer=[3,1,2]))
[[3, 1], [2, 1, 1], [1, 1, 2]]
```

`outer` sets `max_length` to the length of its argument. Moreover, the parts of `outer` may be infinite to clear the constraint on specific parts. This is the list of compositions of 4 of length at most 3 such that the first and third parts are at most 1:

```
sage: Compositions(4, outer=[1,oo,1]).list()
[[1, 3], [1, 2, 1]]
```

This is the list of compositions of 4 bounded below by [1,1,1]:

```
sage: Compositions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

The options `min_slope` and `max_slope` can be used to set constraints on the slope, that is the difference \( p[i+1] - p[i] \) of two consecutive parts. The following is the list of weakly increasing compositions of 4:

```
sage: Compositions(4, min_slope=0).list()
[[4], [2, 2], [1, 3], [1, 1, 2], [1, 1, 1, 1]]
```

Here are the weakly decreasing ones:

```
sage: Compositions(4, max_slope=0).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The following is the list of compositions of 4 such that two consecutive parts differ by at most one:

```
sage: Compositions(4, min_slope=-1, max_slope=1).list()
[[4], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

The constraints can be combined together in all reasonable ways. This is the list of compositions of 5 of length between 2 and 4 such that the difference between consecutive parts is between -2 and 1:
We can do the same thing with an outer constraint:

```python
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4, outer=[2, 5, 2]).list()
[[2, 3], [2, 2, 1], [2, 1, 2], [1, 2, 2]]
```

However, providing incoherent constraints may yield strange results. It is up to the user to ensure that the inner and outer compositions themselves satisfy the parts and slope constraints.

Note that setting \( \text{min\_part}=0 \) is not allowed:

```python
sage: Compositions(2, length=3, min_part=0)
Traceback (most recent call last):
... ValueError: setting min\_part=0 is not allowed for Compositions
```

Instead you must use \texttt{IntegerVectors}:

```python
sage: list(IntegerVectors(2, 3))
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

The generation algorithm is constant amortized time, and handled by the generic tool \textit{IntegerListsLex}.

### Element

\texttt{alias of Composition}

#### from\_code(code)

Return the composition from its code. The code of a composition \( I \) is a list of length \( \text{size}(I) \) consisting of 1s and 0s such that there is a 1 wherever a new part starts. (Exceptional case: When the composition is empty, the code is \([0]\).)

**EXAMPLES:**

```python
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Compositions().from_code(_)[[4, 1, 2, 3, 5]]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Compositions().from_code(_)[[3, 1, 2, 3, 5]]
```

#### from\_descents(descents, nps=None)

Return a composition from the list of descents.

**INPUT:**

- \( \text{descents} \) – an iterable
- \( \text{nps} \) – (default: \text{None}) an integer or \text{None}

**OUTPUT:**
• The composition of \(nps\) whose descents are listed in \(descents\), assuming that \(nps\) is not \(None\) (otherwise, the last element of \(descents\) is removed from \(descents\), and \(nps\) is set to be this last element plus 1).

**EXAMPLES:**

```sage
sage: [x-1 for x in Composition([1, 1, 3, 4, 3]).to_subset()]
[0, 1, 4, 8]
sage: Compositions().from_descents([1,0,4,8],12)
[1, 1, 3, 4, 3]
sage: Compositions().from_descents([1,0,4,8,11])
[1, 1, 3, 4, 3]
```

**from_subset** \((S, n)\)

The composition of \(n\) corresponding to the subset \(S\) of \(\{1, 2, \ldots, n-1\}\) under the bijection that maps the composition \((i_1, i_2, \ldots, i_k)\) of \(n\) to the subset \(\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + \cdots + i_{k-1}\}\) (see `Composition.to_subset()`).

**INPUT:**

- \(S\) – an iterable, a subset of \(\{1, 2, \ldots, n-1\}\)
- \(n\) – an integer

**EXAMPLES:**

```sage
sage: Compositions().from_subset([2,1,5,9], 12)
[1, 1, 3, 4, 3]
sage: Compositions().from_subset({2,1,5,9}, 12)
[1, 1, 3, 4, 3]
sage: Compositions().from_subset([], 12)
[12]
sage: Compositions().from_subset([], 0)
[]
```

**class** `sage.combinat.composition.Compositions_all`

**Bases:** `Compositions`

Class of all compositions.

**subset** (\(size=None\))

Return the set of compositions of the given size.

**EXAMPLES:**

```sage
sage: C = Compositions()
sage: C.subset(4)
Compositions of 4
sage: C.subset(size=3)
Compositions of 3
```

**zero()**

Return the zero of the additive monoid.

This is the empty composition.

**EXAMPLES:**
class sage.combinat.composition.Compositions_constraints(*args, **kwds)
    Bases: IntegerListsLex

class sage.combinat.composition.Compositions_n(n)
    Bases: Compositions
    Class of compositions of a fixed \( n \).

    cardinality()
        Return the number of compositions of \( n \).

    random_element()
        Return a random Composition with uniform probability.
        This method generates a random binary word starting with a 1 and then uses the bijection between compositions and their code.

        EXAMPLES:
        
        sage: Compositions(5).random_element()  # random
        [2, 1, 1, 1]
        sage: Compositions(0).random_element()
        []
        sage: Compositions(1).random_element()
        [1]

sage.combinat.composition.composition_iterator_fast(n)
Iterator over compositions of \( n \) yielded as lists.

5.1.30 Signed Compositions

class sage.combinat.composition_signed.SignedCompositions(n)
    Bases: Compositions_n
    The class of signed compositions of \( n \).

    EXAMPLES:

    sage: SC3 = SignedCompositions(3); SC3
    Signed compositions of 3
    sage: SC3.cardinality()
    18
    sage: len(SC3.list())
    18
    sage: SC3.first()
    [1, 1, 1]
    sage: SC3.last()
    [-3]
    sage: SC3.random_element()  # random
    [1, -1, 1]
    sage: SC3.list()

(continues on next page)
[[1, 1, 1],
[1, 1, -1],
[1, -1, 1],
[1, -1, -1],
[-1, 1, 1],
[-1, 1, -1],
[-1, -1, 1],
[-1, -1, -1],
[1, 2],
[1, -2],
[-1, 2],
[-1, -2],
[2, 1],
[2, -1],
[-2, 1],
[-2, -1],
[3],
[-3]]

cardinality()

Return the number of elements in self.

The number of signed compositions of \( n \) is equal to

\[
\sum_{i=1}^{n+1} \binom{n-1}{i-1} 2^i
\]

EXAMPLES:

```sage
sage: SC4 = SignedCompositions(4)
sage: SC4.cardinality() == len(SC4.list())
True
sage: SignedCompositions(3).cardinality()
18
```

### 5.1.31 Composition Tableaux

AUTHORS:

- Chris Berg, Jeff Ferreira (2012-9): Initial version

**class** `sage.combinat.composition_tableau.CompositionTableau(parent, t)`

Bases: `CombinatorialElement`

A composition tableau.

A composition tableau \( t \) of shape \( I = (I_1, \ldots, I_\ell) \) is an array of boxes in rows, \( I_i \) boxes in row \( i \), filled with positive integers such that:

1) the entries in the rows of \( t \) weakly decrease from left to right,

2) the left-most column of \( t \) strictly increase from top to bottom.

3) Add zero entries to the rows of \( t \) until the resulting array is rectangular of shape \( \ell \times m \). For \( 1 \leq i < j \leq \ell \), \( 2 \leq k \leq m \) and \( (t(j, k) \neq 0 \) and also if \( t(j, k) \geq t(i, k) \) implies \( t(j, k) > t(i, k - 1) \).
INPUT:

- t – A list of lists

EXAMPLES:

```python
sage: CompositionTableau([[1],[2,2]])
[[1], [2, 2]]
sage: CompositionTableau([[1],[3,2],[4,4]])
[[1], [3, 2], [4, 4]]
sage: CompositionTableau([])
[]
```

descent_composition()

Return the composition corresponding to the set of all \( i \) that do not have \( i + 1 \) appearing strictly to the left of \( i \) in self.

EXAMPLES:

```python
sage: CompositionTableau([[1],[3,2],[4,4]]).descent_composition()
[1, 2, 2]
```

descent_set()

Return the set of all \( i \) that do not have \( i + 1 \) appearing strictly to the left of \( i \) in self.

EXAMPLES:

```python
sage: CompositionTableau([[1],[3,2],[4,4]]).descent_set()
[1, 3]
```

is_standard()

Return True if self is a standard composition tableau and False otherwise.

EXAMPLES:

```python
sage: CompositionTableau([[1],[3,2],[4,4,3]]).is_standard()
False
sage: CompositionTableau([[2],[1],[3],[4]]).is_standard()
True
```

pp()

Return a pretty print string of self.

EXAMPLES:

```python
sage: CompositionTableau([[1],[3,2],[4,4]]).pp()
1
3  2
4  4
```

shape_composition()

Return a Composition object which is the shape of self.

EXAMPLES:
sage: CompositionTableau([[1,1],[3,2],[4,4,3]]).shape_composition() [2, 2, 3]
sage: CompositionTableau([[2,1],[3],[4]]).shape_composition() [2, 1, 1]

shape_partition()

Return a partition which is the shape of self sorted into weakly decreasing order.

EXAMPLES:

sage: CompositionTableau([[1,1],[3,2],[4,4,3]]).shape_partition() [3, 2, 2]
sage: CompositionTableau([[2,1],[3],[4]]).shape_partition() [2, 1, 1]

size()

Return the number of boxes in self.

EXAMPLES:

sage: CompositionTableau([[1],[3,2],[4,4]]).size() 5

weight()

Return a composition where entry \( i \) is the number of times that \( i \) appears in self.

EXAMPLES:

sage: CompositionTableau([[1],[3,2],[4,4]]).weight() [1, 1, 1, 2, 0]

class sage.combinat.composition_tableau.CompositionTableaux(**kwds)

Composition tableaux.

INPUT:

Keyword arguments:

• size – the size of the composition tableaux
• shape – the shape of the composition tableaux
• max_entry – the maximum entry for the composition tableaux

Positional arguments:

• The first argument is interpreted as size or shape depending on whether it is an integer or a composition.

EXAMPLES:

sage: CT = CompositionTableaux(3); CT
Composition Tableaux of size 3 and maximum entry 3
sage: list(CT) [[], [1], [1, 1], [1, 2], [1, 3], [2], [2, 1], [2, 2], [2, 3], [3], [3, 1], [3, 2], [3, 3]]
\[
\begin{align*}
&[[1], [3, 3]], \\
&[[2], [3, 3]], \\
&[[1, 1], [2]], \\
&[[1, 1], [3]], \\
&[[2, 1], [3]], \\
&[[2, 2], [3]], \\
&[[1, 1, 1]], \\
&[[2, 1, 1]], \\
&[[2, 2, 1]], \\
&[[3, 1, 1]], \\
&[[3, 2, 1]], \\
&[[3, 3, 1]], \\
&[[3, 3, 2]], \\
&[[3, 3, 3]]
\end{align*}
\]

```
sage: CT = CompositionTableaux([1,2,1]); CT
Composition tableaux of shape [1, 2, 1] and maximum entry 4
sage: list(CT)
[[[1], [2, 2], [3]],
 [[1], [2, 2], [4]],
 [[1], [3, 2], [4]],
 [[1], [3, 3], [4]],
 [[2], [3, 3], [4]]]
```

```
sage: CT = CompositionTableaux(shape=[1,2,1],max_entry=3); CT
Composition tableaux of shape [1, 2, 1] and maximum entry 3
sage: list(CT)
[[[1], [2, 2], [3]]]
```

```
sage: CT = CompositionTableaux(2,max_entry=3); CT
Composition Tableaux of size 2 and maximum entry 3
sage: list(CT)
[[[1], [2]],
 [[1], [3]],
 [[2], [3]],
 [[1, 1]],
 [[2, 1]],
 [[2, 2]],
 [[3, 1]],
 [[3, 2]],
 [[3, 3]]]
```

```
sage: CT = CompositionTableaux(0); CT
Composition Tableaux of size 0 and maximum entry 0
sage: list(CT)
[[[]]]
```

**Element**

alias of **CompositionTableau**

class sage.combinat.composition_tableau.CompositionTableauxBacktracker(shape, max_entry=None)
Bases: `GenericBacktracker`

A backtracker class for generating sets of composition tableaux.

get_next_pos(ii, jj)

EXAMPLES:

```python
sage: from sage.combinat.composition_tableau import CompositionTableauxBacktracker
sage: T = CompositionTableau([[2,1],[5,4,3,2],[6],[7,7,6]])
sage: n = CompositionTableauxBacktracker(T.shape_composition())
```

```
sage: n.get_next_pos(1,1)
(1, 2)
```

class `sage.combinat.composition_tableau.CompositionTableaux_all(max_entry=None)`

Bases: `CompositionTableaux`, `DisjointUnionEnumeratedSets`

All composition tableaux.

an_element()

Return a particular element of self.

EXAMPLES:

```python
sage: CT = CompositionTableaux()
```

```
sage: CT.an_element()
[[1, 1], [2]]
```

class `sage.combinat.composition_tableau.CompositionTableaux_shape(comp, max_entry=None)`

Bases: `CompositionTableaux`

Composition tableaux of a fixed shape `comp` with a given max entry.

INPUT:

- `comp` – a composition.

- `max_entry` – a nonnegative integer. This keyword argument defaults to the size of `comp`.

an_element()

Return a particular element of `CompositionTableaux_shape`.

EXAMPLES:

```python
sage: CT = CompositionTableaux([1,2,1])
```

```
sage: CT.an_element()
[[1], [2, 2], [3]]
```

class `sage.combinat.composition_tableau.CompositionTableaux_size(n, max_entry=None)`

Bases: `CompositionTableaux`

Composition tableaux of a fixed size `n`.

INPUT:

- `n` – a nonnegative integer.

- `max_entry` – a nonnegative integer. This keyword argument defaults to `n`.

OUTPUT:
• The class of composition tableaux of size $n$.

5.1.32 Constellations

A constellation is a tuple $(g_0, g_1, \ldots, g_k)$ of permutations such that the product $g_0 g_1 \ldots g_k$ is the identity. One often assumes that the group generated by $g_0, g_1, \ldots, g_k$ acts transitively ([LZ2004] definition 1). Geometrically, it corresponds to a covering of the 2-sphere ramified over $k$ points (the transitivity condition corresponds to the connectivity of the covering).

EXAMPLES:

```python
sage: c = Constellation(['(1,2)', '(1,3)', None])
sage: c
Constellation of length 3 and degree 3
g0 (1,2)(3)
g1 (1,3)(2)
g2 (1,3,2)
sage: C = Constellations(3, 4); C
Connected constellations of length 3 and degree 4 on \{1, 2, 3, 4\}
sage: C.cardinality()  # long time
426
sage: C = Constellations(3, 4, domain=('a', 'b', 'c', 'd'))
sage: c = C(('a', 'c'), ('b', 'c'), ('a', 'd')), None)
sage: c
Constellation of length 3 and degree 4
g0 ('a','c')('b')('d')
g1 ('a','d')('b','c')
g2 ('a','d','c','b')
sage: c.is_connected()
True
sage: c.euler_characteristic()
2
sage: TestSuite(C).run()
```

```
sage.combinat.constellation.Constellation(g=None, mutable=False, connected=True, check=True)

INPUT:

• $g$ – a list of permutations

• mutable – whether the result is mutable or not. Default is False.

• connected – whether the result should be connected. Default is True.

• check – whether or not to check. If it is True, then the list $g$ must contains no None.

EXAMPLES:

Simple initialization:

```python
sage: Constellation([('0,1'), '(0,3)(1,2)', '(0,3,1,2)'])
Constellation of length 3 and degree 4
g0 (0,1)(2)(3)
```
One of the permutation can be omitted:

```
sage: Constellation(['(0,1)', None, '(0,4)(1,2,3)'])
Constellation of length 3 and degree 5
g0 (0,1)(2)(3)(4)
g1 (0,3,2,1,4)
g2 (0,4)(1,2,3)
```

One can define mutable constellations:

```
sage: Constellation(((0,2,1), [2,1,0], [1,2,0]), mutable=True)
Constellation of length 3 and degree 3
g0 (0)(1,2)
g1 (0,2)(1)
g2 (0,1,2)
```

class sage.combinat.constellation.Constellation_class(parent, g, connected, mutable, check)

Bases: Element

Constellation

A constellation or a tuple of permutations $(g_0, g_1, ..., g_k)$ such that the product $g_0 g_1 ... g_k$ is the identity.

braid_group_action\(i\)

Act on self as the braid group generator that exchanges position $i$ and $i + 1$.

INPUT:

- $i$ – integer in $[0, n - 1]$ where $n$ is the length of self

EXAMPLES:

```
sage: sigma = lambda c, i: c.braid_group_action(i)
sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', None]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: sigma(c, 1)
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0,1,3,2,4)
g2 (0,3)(1)(2)(4)
```

Check the commutation relation:

```
sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', '(2,5)(0,4)', None])
sage: d = Constellation(['(0,1,3,5)', '(2,3,4)', '(0,3,5)', None])
sage: c13 = sigma(sigma(c, 0), 2)
sage: c31 = sigma(sigma(c, 2), 0)
sage: c13 == c31
```

(continues on next page)
Check the braid relation:

```
sage: c121 = sigma(sigma(sigma(c, 1), 2), 1)
sage: c212 = sigma(sigma(sigma(c, 2), 1), 2)
sage: c121 == c212
True
sage: d121 = sigma(sigma(sigma(d, 1), 2), 1)
sage: d212 = sigma(sigma(sigma(d, 2), 1), 2)
sage: d121 == d212
True
```

```
```

braid_group_orbit()

Return the graph of the action of the braid group.

The action is considered up to isomorphism of constellation.

EXAMPLES:

```
sage: c = Constellation(['(0,1)(2,3,4)', '(1,4)', None]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: G = c.braid_group_orbit()
sage: G.num_verts() 4
sage: G.num_edges() 12
```

connected_components()

Return the connected components.

OUTPUT:

A list of connected constellations.

EXAMPLES:

```
sage: c = Constellation(['(0,1)(2)', None, '(0,1)(2)'], connected=False)
sage: cc = c.connected_components(); cc
[Constellation of length 3 and degree 2
g0 (0,1)
g1 (0)(1)
g2 (0,1),
Constellation of length 3 and degree 1
g0 (0)
g1 (0)
g2 (0)]
sage: all(c2.is_connected() for c2 in cc)
```

(continues on next page)
Combinatorics, Release 10.1

(continued from previous page)

```
True

sage: c = Constellation(['(0,1,2)', None], connected=False)
sage: c.connected_components()
[Constellation of length 2 and degree 3
g0 (0,1,2)
g1 (0,2,1)]
```

copy()

Return a copy of self.

degree()

Return the degree of the constellation.

The degree of a constellation is the number $n$ that corresponds to the symmetric group $S(n)$ in which the permutations of the constellation are defined.

EXAMPLES:

```
sage: c = Constellation([])
sage: c.degree()
0
sage: c = Constellation(['(0,1)',None])
sage: c.degree()
2
sage: c = Constellation(['(0,1)', '(0,3,2)(1,5)', None, '(4,3,2,1)'])
sage: c.degree()
6
```

euler_characteristic()

Return the Euler characteristic of the surface.

ALGORITHM:

Hurwitz formula

EXAMPLES:

```
sage: c = Constellation(['(0,1)', '(0,2)'])
sage: c.euler_characteristic()
2
sage: c = Constellation(['(0,1,2,3)', '(1,3,0,2)', '(0,3,1,2)', None])
sage: c.euler_characteristic()
-4
```

g(i=None)

Return the permutation $g_i$ of the constellation.

INPUT:

- i – integer or None (default)

If None, return instead the list of all $g_i$.

EXAMPLES:
sage: c = Constellation(['(0,1,2)(3,4)', '(0,3)', None])
sage: c.g(0)
(0,1,2)(3,4)
sage: c.g(1)
(0,3)
sage: c.g(2)
(0,4,3,2,1)
sage: c.g()
[(0,1,2)(3,4), (0,3), (0,4,3,2,1)]

genus()
Return the genus of the surface.

EXAMPLES:

sage: c = Constellation(['(0,1)', '(0,2)', None])
sage: c.genus()
0
sage: c = Constellation(['(0,1)(2,3,4)', '(1,3,4)(2,0)', None])
sage: c.genus()
1

is_connected()
Test of connectedness.

EXAMPLES:

sage: c = Constellation(['(0,1)(2)', None, '(0,1)(2)'], connected=False)
sage: c.is_connected()
False
sage: c = Constellation(['(0,1,2)', None, '(0,1,2)'], connected=False)
sage: c.is_connected()
True

is_isomorphic(other, return_map=False)
Test of isomorphism.

Return True if the constellations are isomorphic (i.e. related by a common conjugacy) and return the permutation that conjugate the two permutations if return_map is True in such a way that self.relabel(m) == other.

ALGORITHM:
uses canonical labels obtained from the method relabel().

EXAMPLES:

sage: c = Constellation([[1,0,2],[2,1,0],[0,2,1],None])
sage: d = Constellation([[2,1,0],[0,2,1],[1,0,2],None])
sage: answer, mapping = c.is_isomorphic(d, return_map=True)
sage: answer
True
sage: c.relabel(mapping) == d
True
is_mutable()
Return False as self is immutable.

EXAMPLES:

```python
sage: c = Constellation(([0, 2, 1], [2, 1, 0], [1, 2, 0]), mutable=False)
sage: c.is_mutable()
False
```

length()
Return the number of permutations.

EXAMPLES:

```python
sage: c = Constellation([('(0,1)', '(0,2)', '(0,3)', None)])
sage: c.length()
4
sage: c = Constellation([('(0,1,3)', None, '(1,2)')])
sage: c.length()
3
```

mutable_copy()
Return a mutable copy of self.

EXAMPLES:

```python
sage: c = Constellation(([0, 2, 1], [2, 1, 0], [1, 2, 0]), mutable=False)
sage: d = c.mutable_copy()
sage: d.is_mutable()
True
```

passport(i=None)
Return the profile of self.

The profile of a constellation is the tuple of partitions associated to the conjugacy classes of the permutations of the constellation.

This is also called the passport.

EXAMPLES:

```python
sage: c = Constellation([('(0,1,2)(3,4)', '(0,3)', None)])
sage: c.profile()
([3, 2], [2, 1, 1, 1], [5])
```

profile(i=None)
Return the profile of self.

The profile of a constellation is the tuple of partitions associated to the conjugacy classes of the permutations of the constellation.

This is also called the passport.

EXAMPLES:

```python
sage: c = Constellation([('(0,1,2)(3,4)', '(0,3)', None)])
sage: c.profile()
([3, 2], [2, 1, 1, 1], [5])
```
relabel(perm=None, return_map=False)

Relabel self.

If `perm` is provided then relabel with respect to `perm`. Otherwise use canonical labels. In that case, if `return_map` is provided, the return also the map used for canonical labels.

Algorithm:
the cycle for g(0) are adjacent and the cycle are joined with respect to the other permutations. The minimum is taken for all possible renumerotations.

EXAMPLES:

```
sage: c = Constellation(['(0,1)(2,3,4)','(1,4)',None]); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2)(3)
g2 (0,1,3,2,4)
sage: c2 = c.relabel(); c2
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,2)(3)(4)
g2 (0,1,4,3,2)
```

The map returned when the option `return_map` is set to `True` can be used to set the relabelling:

```
sage: c3, perm = c.relabel(return_map=True)
sage: c3 == c2 and c3 == c.relabel(perm=perm)
True
```

```
sage: S5 = SymmetricGroup(range(5))
sage: d = c.relabel(S5([4,3,1,0,2])); d
Constellation of length 3 and degree 5
g0 (0,2,1)(3,4)
g1 (0)(1)(2,3)(4)
g2 (0,1,2,4,3)
sage: d.is_isomorphic(c)
True
```

We check that after a random relabelling the new constellation is isomorphic to the initial one:

```
sage: c = Constellation(['(0,1)(2,3,4)','(1,4)','None])
sage: p = S5.random_element()
sage: cc = c.relabel(perm=p)
sage: cc.is_isomorphic(c)
True
```

Check that it works for “non standard” labels:

```
sage: c = Constellation([(['a','b'],['c','d','e']),(b',d'), None])
sage: c.relabel()
Constellation of length 3 and degree 5
g0 ('a','b')('c','d','e')
g1 ('a')('b','c')('d')('e')
g2 ('a','b','e','d','c')
```
**set_immutable()**

Do nothing, as self is already immutable.

**EXAMPLES:**

```python
sage: c = Constellation(([0,2,1],[2,1,0],[1,2,0]), mutable=False)
sage: c.set_immutable()
sage: c.is_mutable()
False
```

**switch(i, j0, j1)**

Perform the multiplication by the transposition \((j0, j1)\) between the permutations \(g_i\) and \(g_i+1\).

The modification is local in the sense that it modifies \(g_i\) and \(g_i+1\) but does not modify the product \(g_ig_{i+1}\). The new constellation is

\[
(g_0, \ldots, g_{i-1}, g_i(j0j1), (j0j1)g_{i+1}, g_{i+2}, \ldots, g_k)
\]

**EXAMPLES:**

```python
sage: c = Constellation(['(0,1)(2,3,4)','(1,4)',None], mutable=True); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2,3)
g2 (0,1,3,2,4)
sage: c.is_mutable()
True
sage: c.switch(1,2,3); c
Constellation of length 3 and degree 5
g0 (0,1)(2,3,4)
g1 (0)(1,4)(2,3)
g2 (0,1,3,4)(2)
sage: c._check()
sage: c.switch(2,1,3); c
Constellation of length 3 and degree 5
g0 (0,1,4,2,3)
g1 (0)(1,4)(2,3)
g2 (0,3,4)(1)(2)
sage: c._check()
sage: c.switch(0,0,1); c
Constellation of length 3 and degree 5
g0 (0)(1,4,2,3)
g1 (0,4,1)(2,3)
g2 (0,3,4)(1)(2)
sage: c._check()
```

`sage.combinat.constellation.Constellations(*data, **options)`

Build a set of constellations.

**INPUT:**

- profile – an optional profile
- length – an optional length
- degree – an optional degree
- connected – an optional boolean
EXAMPLES:

```
sage: Constellations(4,2)
Connected constellations of length 4 and degree 2 on \{1, 2\}
sage: Constellations([[3,2,1],[3,3],[3,3]])
Connected constellations with profile ([3, 2, 1], [3, 3], [3, 3]) on \{1, 2, 3, 4, 5, \ldots, 6\}
```

class sage.combinat.constellation(Constellations ld(length, degree, sym=None, connected=True)
Bases: UniqueRepresentation, Parent
Constellations of given length and degree.

EXAMPLES:

```
sage: C = Constellations(2,3); C
Connected constellations of length 2 and degree 3 on \{1, 2, 3\}
sage: C([[2,3,1],[3,1,2]])
Constellation of length 2 and degree 3
g0 (1,2,3)
g1 (1,3,2)
sage: C.cardinality()
2
sage: Constellations(2,3,connected=False).cardinality()
6
```

Element
alias of Constellation_class

braid_group_action()
Return a list of graphs that corresponds to the braid group action on self up to isomorphism.

OUTPUT:
• list of graphs

EXAMPLES:

```
sage: C = Constellations(3,3)
sage: C.braid_group_action()
[Looped multi-digraph on 3 vertices,
Looped multi-digraph on 1 vertex,
Looped multi-digraph on 3 vertices]
```

braid_group_orbits()
Return the orbits under the action of braid group.

EXAMPLES:

```
sage: C = Constellations(3,3)
sage: O = C.braid_group_orbits()
sage: len(O)
3
sage: [x.profile() for x in O[0]]
[([1, 1, 1], [3], [3]), ([3], [1, 1, 1], [3]), ([3], [3], [1, 1, 1])]
```
Combinatorics, Release 10.1

is_empty()
Return whether this set of constellations is empty.

EXAMPLES:

```python
sage: Constellations(2, 3).is_empty()
False
sage: Constellations(1, 2).is_empty()
True
sage: Constellations(1, 2, connected=False).is_empty()
False
```

random_element (mutable=False)
Return a random element.

This is found by trial and rejection, starting from a random list of permutations.

EXAMPLES:

```python
sage: const = Constellations(3,3)
sage: const.random_element()
Constellation of length 3 and degree 4
...  
...  
...  
sage: c = const.random_element()
sage: c.degree() == 3 and c.length() == 3
True
```

class sage.combinat.constellation.Constellations_p(profile, domain=None, connected=True)
Bases: UniqueRepresentation, Parent

Constellations with fixed profile.

EXAMPLES:

```python
sage: C = Constellations([[3,1],[3,1],[2,2]]); C
Connected constellations with profile ([3, 1], [3, 1], [2, 2]) on {1, 2, 3, 4}
sage: C.cardinality()
24
sage: C.first()
Constellation of length 3 and degree 4
g0 (1)(2,3,4)
g1 (1,2,3)(4)
g2 (1,2)(3,4)
sage: C.last()
Constellation of length 3 and degree 4
g0 (1,4,3)(2)
g1 (1,4,2)(3)
g2 (1,2)(3,4)
```
Note that the cardinality can also be computed using characters of the symmetric group (Frobenius formula):

```
sage: P = Partitions(4)
sage: p1 = Partition([3,1])
sage: p2 = Partition([3,1])
sage: p3 = Partition([2,2])
sage: i1 = P.cardinality() - P.rank(p1) - 1
sage: i2 = P.cardinality() - P.rank(p2) - 1
sage: i3 = P.cardinality() - P.rank(p3) - 1
sage: s = 0
sage: for c in SymmetricGroup(4).irreducible_characters():
    .... v = c.values()
    .... s += v[i1] * v[i2] * v[i3] / v[0]
sage: c1 = p1.conjugacy_class_size()
sage: c2 = p2.conjugacy_class_size()
sage: c3 = p3.conjugacy_class_size()
sage: c1 * c2 * c3 / factorial(4)**2 * s
1
```

The number obtained above is up to isomorphism. And we can check:

```
sage: len(C.isomorphism_representatives())
1
```

**isomorphism_representatives()**

Return a set of isomorphism representative of self.

**EXAMPLES:**

```
sage: C = Constellations([[5], [4,1], [3,2]])
sage: C.cardinality()
240
sage: ir = sorted(C.isomorphism_representatives())
sage: len(ir)
2
sage: ir[0]
Constellation of length 3 and degree 5
g0 (1,2,3,4,5)
g1 (1)(2,3,4,5)
g2 (1,5,3)(2,4)
sage: ir[1]
Constellation of length 3 and degree 5
g0 (1,2,3,4,5)
g1 (1)(2,5,3,4)
g2 (1,5)(2,3,4)
```

**sage.combinat.constellation.perm_conjugate(p, s)**

Return the conjugate of the permutation $p$ by the permutation $s$.

**INPUT:**

two permutations of $\{0,\ldots,n-1\}$ given by lists of values

**OUTPUT:**

a permutation of $\{0,\ldots,n-1\}$ given by a list of values
EXAMPLES:

```python
sage: from sage.combinat.constellation import perm_conjugate
sage: perm_conjugate([3,1,2,0], [3,2,0,1])
[0, 3, 2, 1]
```

sage.combinat.constellation.perm_conjugate(p)

Return the inverse of the permutation p.

**INPUT:**

a permutation of \{0, \ldots, n-1\} given by a list of values

**OUTPUT:**

a permutation of \{0, \ldots, n-1\} given by a list of values

**EXAMPLES:**

```python
sage: from sage.combinat.constellation import perm_invert
sage: perm_invert([3,2,0,1])
[2, 3, 1, 0]
```

sage.combinat.constellation.perm_invert(p)

Return the inverse of the permutation p.

**INPUT:**

a permutation of \{0, \ldots, n-1\} given by a list of values

**OUTPUT:**

a permutation of \{0, \ldots, n-1\} given by a list of values

**EXAMPLES:**

```python
sage: from sage.combinat.constellation import perm_sym_domain
sage: perm_sym_domain([1,2,3,4])
{1, 2, 3, 4}
sage: perm_sym_domain(((1,2),(0,4)))
{0, 1, 2, 4}
sage: sorted(perm_sym_domain((1,2,0,5)))
[0, 1, 2, 5]
```

sage.combinat.constellation.perm_sym_domain(g)

Return the domain of a single permutation (before initialization).

**EXAMPLES:**

```python
sage: from sage.combinat.constellation import perm_sym_domain
sage: perm_sym_domain((1,2,0,5))
{0, 1, 2, 5}
```

sage.combinat.constellation.perms_are_connected(g, n)

Checks that the action of the generated group is transitive

**INPUT:**

- a list of permutations of \([0, n-1]\) (in a SymmetricGroup)
- an integer \(n\)

**EXAMPLES:**

```python
sage: from sage.combinat.constellation import perms_are_connected
sage: S = SymmetricGroup(range(3))
sage: perms_are_connected([S([0,1,2]),S([0,2,1])],3)
False
sage: perms_are_connected([S([0,1,2]),S([1,2,0])],3)
True
```

sage.combinat.constellation.perms_canonical_labels(p, e=None)

Relabel a list with a common conjugation such that two conjugated lists are relabeled the same way.

**INPUT:**

- \(p\) is a list of at least 2 permutations

5.1. Comprehensive Module List
• $e$ is None or a list of integer in the domain of the permutations. If provided, then the renumbering algorithm is only performed from the elements of $e$.

OUTPUT:

• a pair made of a list of permutations (as a list of lists) and a list that corresponds to the conjugacy used.

EXAMPLES:

```sage
from sage.combinat.constellation import perms_canonical_labels
def l0 = 
  
  l, m = perms_canonical_labels(l0); l
  
  S = SymmetricGroup(range(4))
  [~S(m) * S(u) * S(m) for u in l0] == list(map(S, l))

ture
perm_canonical_labels([])

ValueError: input must have length >= 2
```

sage.combinat.constellation.perm_canonical_labels_from(x, y, j0, verbose=False)
Return canonical labels for $x, y$ that starts at $j0$

**Warning:** The group generated by $x$ and the elements of $y$ should be transitive.

INPUT:

• $x$ – list - a permutation of $[0, \ldots, n]$ as a list

• $y$ – list of permutations of $[0, \ldots, n]$ as a list of lists

• $j0$ – an index in $[0, \ldots, n]$

OUTPUT:

mapping: a permutation that specify the new labels

EXAMPLES:

```sage
from sage.combinat.constellation import perms_canonical_labels_from
perm_canonical_labels_from([[0,1,2],[[1,2,0]], 0)]

perm_canonical_labels_from([[1,0,2], [[2,0,1]], 0)]

perm_canonical_labels_from([[1,0,2], [[2,0,1]], 1)]

perm_canonical_labels_from([[1,0,2], [[2,0,1]], 2)]
```

sage.combinat.constellation.perm_sym_init(g, sym=None)
Initialize a list of permutations (in the same symmetric group).

OUTPUT:

• sym – a symmetric group
• gg – a list of permutations

EXAMPLES:

```python
sage: from sage.combinat.constellation import perms_sym_init
sage: S, g = perms_sym_init([[0,2,1,3], [1,3,2,0]])
sage: S.domain()
{0, 1, 2, 3}
sage: g
[(1,2), (0,1,3)]

sage: S, g = perms_sym_init([(2,1), (0,3)])
sage: S.domain()
{0, 1, 2, 3}
sage: g
[(1,2), (0,3)]

sage: S, g = perms_sym_init([(1,0), (2,1)])
sage: S.domain()
{0, 1, 2}
sage: g
[(0,1), (1,2)]

sage: S, g = perms_sym_init([(1,0),(2,3), (0,1,4)])
sage: S.domain()
{0, 1, 2, 3, 4}
sage: g
[(0,1)(2,3), (0,1,4)]
```

5.1.33 Cores

A $k$-core is a partition from which no rim hook of size $k$ can be removed. Alternatively, a $k$-core is an integer partition such that the Ferrers diagram for the partition contains no cells with a hook of size (a multiple of) $k$.

Authors:

- Anne Schilling and Mike Zabrocki (2011): initial version
- Travis Scrimshaw (2012): Added latex output for Core class

```python
class sage.combinat.core.Core(parent, core)
Bases: CombinatorialElement

A $k$-core is an integer partition from which no rim hook of size $k$ can be removed.

EXAMPLES:

```python
c = Core([2,1],4); c
[2, 1]
c = Core([3,1],4); c
Traceback (most recent call last):
  ... ValueError: [3, 1] is not a 4-core
```

affine_symmetric_group_action(w, transposition=False)

Return the (left) action of the affine symmetric group on self.
INPUT:

• \(w\) is a tuple of integers \([w_1, \ldots, w_m]\) with \(0 \leq w_j < k\). If transposition is set to be True, then \(w = [w_0, w_1]\) is interpreted as a transposition \(t_{w_0, w_1}\) (see \_transposition_to_reduced_word()).

The output is the (left) action of the product of the corresponding simple transpositions on \(self\), that is \(s_{w_1} \cdots s_{w_m}(self)\). See \texttt{affine_symmetric_group_simple_action()}.

EXAMPLES:

```python
sage: c = Core([4,2],3)
sage: c.affine_symmetric_group_action([0,1,0,2,1])
[8, 6, 4, 2]
sage: c.affine_symmetric_group_action([0,2], transposition=True)
[4, 2, 1, 1]
sage: c = Core([11,8,5,5,3,3,1,1,1],4)
sage: c.affine_symmetric_group_action([2,5], transposition=True)
[11, 8, 7, 6, 5, 4, 3, 2, 1]
```

\texttt{affine_symmetric_group_simple_action}(i)

Return the action of the simple transposition \(s_i\) of the affine symmetric group on \(self\).

This gives the action of the affine symmetric group of type \(A_k^{(1)}\) on the \(k\)-core \(self\). If \(self\) has outside (resp. inside) corners of content \(i\) modulo \(k\), then these corners are added (resp. removed). Otherwise the action is trivial.

EXAMPLES:

```python
sage: c = Core([4,2],3)
sage: c.affine_symmetric_group_simple_action(0)
[3, 1]
sage: c.affine_symmetric_group_simple_action(1)
[5, 3, 1]
sage: c.affine_symmetric_group_simple_action(2)
[4, 2]
```

This action corresponds to the left action by the \(i\)-th simple reflection in the affine symmetric group:

```python
sage: c = Core([4,2],3)
sage: W = c.to_grassmannian().parent()
sage: i = 0
sage: c.affine_symmetric_group_simple_action(i).to_grassmannian() == W.simple_reflection(i)*c.to_grassmannian()
True
```

\texttt{contains}(other)

Checks whether \(self\) contains other.

INPUT:

• \(other\) – another \(k\)-core or a list

OUTPUT: a boolean
This returns True if the Ferrers diagram of self contains the Ferrers diagram of other.

```
sage: c = Core([4,2],3)
sage: x = Core([4,2,2,1,1],3)
sage: x.contains(c)
True
sage: c.contains(x)
False
```

\(k()\)
Return \(k\) of the \(k\)-core self.

```
sage: c = Core([2,1],4)
sage: c.k()
4
```

\(length()\)
Return the length of self.

The length of a \(k\)-core is the size of the corresponding \((k - 1)\)-bounded partition which agrees with the length of the corresponding Grassmannian element, see \(to\_grassmannian()\).

```
sage: c = Core([4,2],3); c.length()
4
sage: c.to_grassmannian().length()
4
sage: Core([9,5,3,2,1,1], 5).length()
13
```

\(size()\)
Return the size of self as a partition.

```
sage: Core([2,1],4).size()
3
sage: Core([4,2],3).size()
6
```

\(strong\_covers()\)
Return a list of all elements that cover self in strong order.

```
sage: c = Core([1],3)
sage: c.strong_covers()
[[2], [1, 1]]
sage: c = Core([4,2],3)
sage: c.strong_covers()
[[5, 3, 1], [4, 2, 1, 1]]
```
**strong_down_list()**

Return a list of all elements that are covered by *self* in strong order.

**EXAMPLES:**

```
sage: c = Core([1],3)
sage: c.strong_down_list()
[]
sage: c = Core([5,3,1],3)
sage: c.strong_down_list()
[[4, 2], [3, 1, 1]]
```

**strong_le(other)**

Strong order (Bruhat) comparison on cores.

**INPUT:**

- *other* – another \(k\)-core

**OUTPUT:** a boolean

This returns whether *self* \(\leq\) *other* in Bruhat (or strong) order.

**EXAMPLES:**

```
sage: c = Core([4,2],3)
sage: x = Core([4,2,2,1,1],3)
sage: c.strong_le(x)
True
sage: c.strong_le([4,2,2,1,1])
True
sage: x = Core([4,1],4)
sage: c.strong_le(x)
Traceback (most recent call last):
  ...
ValueError: the two cores do not have the same k
```

**to_bounded_partition()**

Bijection between \(k\)-cores and \((k - 1)\)-bounded partitions.

This maps the \(k\)-core *self* to the corresponding \((k - 1)\)-bounded partition. This bijection is achieved by deleting all cells in *self* of hook length greater than \(k\).

**EXAMPLES:**

```
sage: gamma = Core([9,5,3,2,1,1], 5)
sage: gamma.to_bounded_partition()
[4, 3, 2, 2, 1, 1]
```

**to_grassmannian()**

Bijection between \(k\)-cores and Grassmannian elements in the affine Weyl group of type \(A_{k-1}^{(1)}\).

For further details, see the documentation of the method *from_kbounded_to_reduced_word()* and *from_kbounded_to_grassmannian()*.

**EXAMPLES:**
sage: c = Core([3,1,1],3)
sage: w = c.to_grassmannian(); w
[-1  1  1]
[-2  2  1]
[-2  1  2]
sage: c.parent()
3-Cores of length 4
sage: w.parent()
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root space)
sage: c = Core([],3)
sage: c.to_grassmannian()
[1 0 0]
[0 1 0]
[0 0 1]

to_partition()
Turn the core self into the partition identical to self.

EXAMPLES:

sage: mu = Core([2,1,1],3)
sage: mu.to_partition()
[2, 1, 1]

weak_covers()
Return a list of all elements that cover self in weak order.

EXAMPLES:

sage: c = Core([1],3)
sage: c.weak_covers()
[[1, 1], [2]]
sage: c = Core([4,2],3)
sage: c.weak_covers()
[[5, 3, 1]]

weak_le(other)
Weak order comparison on cores.

INPUT:
• other – another k-core

OUTPUT: a boolean
This returns whether self <= other in weak order.

EXAMPLES:

sage: c = Core([4,2],3)
sage: x = Core([5,3,1],3)
sage: c.weak_le(x)
True
sage: c.weak_le([5,3,1])

(continues on next page)
A $k$-core is a partition from which no rim hook of size $k$ can be removed. Alternatively, a $k$-core is an integer partition such that the Ferrers diagram for the partition contains no cells with a hook of size (a multiple of) $k$.

The $k$-cores generally have two notions of size which are useful for different applications. One is the number of cells in the Ferrers diagram with hook less than $k$, the other is the total number of cells of the Ferrers diagram. In the implementation in Sage, the first of notion is referred to as the size of the $k$-core and the second is the length of the $k$-core. The class of Cores requires that either the size or the length of the elements in the class is specified.

**EXAMPLES:**

We create the set of the 4-cores of length 6. Here the length of a $k$-core is the size of the corresponding $(k-1)$-bounded partition, see also `length()`:

```
sage: C = Cores(4, 6); C
4-Cores of length 6
sage: C.list()                                            
[[6, 3], [5, 2, 1], [4, 1, 1, 1], [4, 2, 2], [3, 3, 1, 1], [3, 2, 1, 1, 1], [2, 2, 1, 1, 1]]
sage: C.cardinality()                                     
7
sage: C.an_element()                                       
[6, 3]
```

We may also list the set of 4-cores of size 6, where the size is the number of boxes in the core, see also `size()`:

```
sage: C = Cores(4, size=6); C                              
4-Cores of size 6
sage: C.list()                                             
[[4, 1, 1], [3, 2, 1], [3, 1, 1, 1]]
sage: C.cardinality()                                      
3
sage: C.an_element()                                        
[4, 1, 1]
```

**class** `sage.combinat.core.Cores_length(k, n)`

**Bases:** `UniqueRepresentation`, `Parent`

The class of $k$-cores of length $n$.

**Element**

alias of `Core`
from_partition($part$)
Converts the partition $part$ into a core (as the identity map).
This is the inverse method to $to_partition()$.

EXAMPLES:

```
sage: C = Cores(3,4)
sage: c = C.from_partition([4,2]); c
[4, 2]

sage: mu = Partition([2,1,1])
sage: C = Cores(3,3)
sage: C.from_partition(mu).to_partition() == mu
True
```

list()
Return the list of all $k$-cores of length $n$.

EXAMPLES:

```
sage: C = Cores(3,4)
sage: C.list()
[[4, 2], [3, 1, 1], [2, 2, 1, 1]]
```

class sage.combinat.core.Cores_size($k$, $n$)
Bases: UniqueRepresentation, Parent
The class of $k$-cores of size $n$.

Element
alias of Core

from_partition($part$)
Convert the partition $part$ into a core (as the identity map).
This is the inverse method to $to_partition()$.

EXAMPLES:

```
sage: C = Cores(3,size=4)
sage: c = C.from_partition([2,1,1]); c
[2, 1, 1]

sage: mu = Partition([2,1,1])
sage: C = Cores(3,size=4)
sage: C.from_partition(mu).to_partition() == mu
True
```

(continues on next page)
sage: C.from_partition(mu).to_partition() == mu
True

list()

Return the list of all $k$-cores of size $n$.

EXAMPLES:

sage: C = Cores(3, size = 4)
sage: C.list()
[[3, 1], [2, 1, 1]]

5.1.34 Counting

- The On-Line Encyclopedia of Integer Sequences (OEIS)
- Functions that compute some of the sequences in Sloane’s tables
- Compute Bell and Uppuluri-Carpenter numbers
- $q$-Analogues, $q$-Bernoulli Numbers and Polynomials
- Binary Recurrence Sequences
- $C$-Finite Sequences
- Combinatorial Functions

Todo: Mention sage/combinat/degree_sequences?

5.1.35 Affine Crystals

class sage.combinat.crystals.affine.AffineCrystalFromClassical(cartan_type, classical_crystal, category=None)

Bases: UniqueRepresentation, Parent

This abstract class can be used for affine crystals that are constructed from a classical crystal. The zero arrows can be implemented using different methods (for example using a Dynkin diagram automorphisms or virtual crystals).

This is a helper class, mostly used to implement Kirillov-Reshetikhin crystals (see: KirillovReshetikhinCrystal()).

For general information about crystals see sage.combinat.crystals.

INPUT:

- cartan_type – the Cartan type of the resulting affine crystal
- classical_crystal – instance of a classical crystal

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: A.list()
[[[1]], [[2]], [[3]]]
sage: A.cartan_type()
['A', 2, 1]
sage: A.index_set()
(0, 1, 2)
sage: b = A(rows=[[1]])
sage: b.weight()
-Lambda[0] + Lambda[1]
sage: b.classical_weight()
(1, 0, 0)
sage: [x.s(0) for x in A.list()]
[[[3]], [[2]], [[1]]]
sage: [x.s(1) for x in A.list()]
[[[2]], [[1]], [[3]]]
```

**Element**

alias of `AffineCrystalFromClassicalElement`

**cardinality()**

Return the cardinality of self.

EXAMPLES:

```python
sage: A = crystals.AffineFromClassicalAndPromotion(['A',3,1],C,pr,pr_inverse,1)
sage: A.cardinality() == C.cardinality()
True
```

**lift(affine_elt)**

Lift an affine crystal element to the corresponding classical crystal element.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
```

**retract(classical_elt)**

Transform a classical crystal element to the corresponding affine crystal element.
EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: t = C(rows=[[1]])
sage: t.parent()
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]
sage: A.retract(t)
[[1]]
sage: A.retract(t).parent() is A
True
```

```python
class sage.combinat.crystals.affine.AffineCrystalFromClassicalAndPromotion(cartan_type, classical_crystal, p_automorphism, p_inverse_automorphism, dynkin_node, category=None)
```

Bases: `AffineCrystalFromClassical`

Crystals that are constructed from a classical crystal and a Dynkin diagram automorphism $\sigma$. In type $A_n$, the Dynkin diagram automorphism is $i \rightarrow i + 1 \mod n + 1$ and the corresponding map on the crystal is the promotion operation $pr$ on tableaux. The affine crystal operators are given by $f_0 = pr^{-1}f_{\sigma(0)}pr$.

**INPUT:**

- `cartan_type` – the Cartan type of the resulting affine crystal
- `classical_crystal` – instance of a classical crystal
- `automorphism, inverse_automorphism` – a function on the elements of the `classical_crystal`
- `dynkin_node` – an integer specifying the classical node in the image of the zero node under the automorphism $\sigma$

**EXAMPLES:**

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: A.list()
[[1], [2], [3]]
sage: A.cartan_type()
['A', 2, 1]
sage: A.index_set()
(0, 1, 2)
sage: b = A(rows=[[1]])
sage: b.weight()
-Lambda[0] + Lambda[1]
sage: b.classical_weight()
(1, 0, 0)
sage: [x.s(0) for x in A.list()]
```

(continues on next page)
Element
alias of AffineCrystalFromClassicalAndPromotionElement

automorphism(x)
Give the analogue of the affine Dynkin diagram automorphism on the level of crystals.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
raise: pr = attrcall("promotion")
raise: pr_inverse = attrcall("promotion_inverse")
raise: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
raise: b = A.list()[0]
raise: A.automorphism(b)
[[2]]
```

inverse_automorphism(x)
Give the analogue of the inverse of the affine Dynkin diagram automorphism on the level of crystals.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
raise: pr = attrcall("promotion")
raise: pr_inverse = attrcall("promotion_inverse")
raise: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
raise: b = A.list()[0]
raise: A.inverse_automorphism(b)
[[3]]
```

class sage.combinat.crystals.affine.AffineCrystalFromClassicalAndPromotionElement

Bases: AffineCrystalFromClassicalElement

Elements of crystals that are constructed from a classical crystal and a Dynkin diagram automorphism. In type $A$, the automorphism is the promotion operation on tableaux.

This class is not instantiated directly but rather __call__-ed from AffineCrystalFromClassicalAndPromotion. The syntax of this is governed by the (classical) crystal.

Since this class inherits from AffineCrystalFromClassicalElement, the methods that need to be implemented are $e_0()$, $f_0()$ and possibly $epsilon_0()$ and $phi_0()$ if more efficient algorithms exist.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
raise: pr = attrcall("promotion")
raise: pr_inverse = attrcall("promotion_inverse")
raise: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
raise: b = A.list()[0]
raise: A.automorphism(b)
[[3]]
```
sage: b = A(rows=[[1]])
sage: b._repr_()
'[[1]]'

\textbf{e}_0() \hfill (continued from previous page)

Implement $e_0$ using the automorphism as $e_0 = pr^{-1} e_{dynkin_{ode}} pr$

EXAMPLES:

\begin{Verbatim}
sage: n = 2
sage: C = crystals.Tableaux(['A', n], shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A', n, 1], C, pr, pr_inverse, 1)
sage: b = A(rows=[[1]])
sage: b.e0()
[[3]]
\end{Verbatim}

\textbf{epsilon}_0()

Implement $\epsilon_0$ using the automorphism.

EXAMPLES:

\begin{Verbatim}
sage: n = 2
sage: C = crystals.Tableaux(['A', n], shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A', n, 1], C, pr, pr_inverse, 1)
sage: [x.epsilon0() for x in A.list()]
[1, 0, 0]
\end{Verbatim}

\textbf{f}_0()

Implement $f_0$ using the automorphism as $f_0 = pr^{-1} f_{dynkin_{ode}} pr$

EXAMPLES:

\begin{Verbatim}
sage: n = 2
sage: C = crystals.Tableaux(['A', n], shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A', n, 1], C, pr, pr_inverse, 1)
sage: b = A(rows=[[3]])
sage: b.f0()
[[1]]
\end{Verbatim}

\textbf{phi}_0()

Implement $\phi_0$ using the automorphism.

EXAMPLES:

\begin{Verbatim}
sage: n = 2
sage: C = crystals.Tableaux(['A', n], shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
\end{Verbatim}
class sage.combinat.crystals.affine.AffineCrystalFromClassicalElement

Bases: ElementWrapper

Elements of crystals that are constructed from a classical crystal.

The elements inherit many of their methods from the classical crystal using lift and retract.

This class is not instantiated directly but rather __call__-ed from AffineCrystalFromClassical. The syntax of this is governed by the (classical) crystal.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[1]])
sage: b._repr_()
'[[1]]'
```

classical_weight()

Return the classical weight corresponding to self.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[1]])
sage: b.classical_weight()
(1, 0, 0)
```

e(i)

Return the action of $e_i$ on self.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A(rows=[[1]])
sage: b.e(0)
[[3]]
sage: b.e(1)
```

e0()

Assumes that $e_0$ is implemented separately.
epsilon($i$)

Return the maximal time the crystal operator $e_i$ can be applied to self.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)

sage: [x.epsilon(0) for x in A.list()]
[1, 0, 0]

sage: [x.epsilon(1) for x in A.list()]
[0, 1, 0]
```

epsilon0()

Uses $\epsilon_0$ from the super class, but should be implemented if a faster implementation exists.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)

sage: [x.epsilon0() for x in A.list()]
[1, 0, 0]
```

f($i$)

Return the action of $f_i$ on self.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)

sage: b = A(rows=[[3]])

sage: b.f(0)
[[1]]

sage: b.f(2)
```

f0()

Assumes that $f_0$ is implemented separately.

lift()

Lift an affine crystal element to the corresponding classical crystal element.

EXAMPLES:

```python
sage: n = 2
sage: C = crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
```

(continues on next page)
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: b = A.list()[0]
sage: b.lift()
[[1]]
sage: b.lift().parent()
The crystal of tableaux of type ['A', 2] and shape(s) [[1]]

\textbf{phi()}\)

Returns the maximal time the crystal operator \(f_i\) can be applied to self.

EXAMPLES:

\begin{verbatim}
sage: n = 2
crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: [x.phi(0) for x in A.list()]
[0, 0, 1]
sage: [x.phi(1) for x in A.list()]
[1, 0, 0]
\end{verbatim}

\textbf{phi0()}\)

Uses \(\varphi_0\) from the super class, but should be implemented if a faster implementation exists.

EXAMPLES:

\begin{verbatim}
sage: n = 2
crystals.Tableaux(['A',n],shape=[1])
sage: pr = attrcall("promotion")
sage: pr_inverse = attrcall("promotion_inverse")
sage: A = crystals.AffineFromClassicalAndPromotion(['A',n,1],C,pr,pr_inverse,1)
sage: [x.phi0() for x in A.list()]
[0, 0, 1]
\end{verbatim}

\textbf{pp()}\)

Method for pretty printing.

EXAMPLES:

\begin{verbatim}
sage: K = crystals.KirillovReshetikhin(['D',3,2],1,1)
sage: t=K(rows=[[1]])
sage: t.pp()
1
\end{verbatim}
5.1.36 Affine factorization crystal of type $A$

```python
class sage.combinat.crystals.affine_factorization.AffineFactorizationCrystal(w, n, x=None)
    Bases: UniqueRepresentation, Parent

    The crystal on affine factorizations with a cut-point, as introduced by [MS2015].

    INPUT:
    • $w$ – an element in an (affine) Weyl group or a skew shape of $k$-bounded partitions (if $k$ was specified)
    • $n$ – the number of factors in the factorization
    • $x$ – (default: None) the cut point; if not specified it is determined as the minimal missing residue in $w$
    • $k$ – (default: None) positive integer, specifies that $w$ is $k$-bounded or a $k+1$-core when specified

    EXAMPLES:

    sage: W = WeylGroup(['A',3,1], prefix='s')
    sage: w = W.from_reduced_word([2,3,2,1])
    sage: B = crystals.AffineFactorization(w,3); B
    Crystal on affine factorizations of type A2 associated to s2*s3*s2*s1
    sage: B.list()
    [(1, s2, s3*s2*s1),
     (1, s3*s2, s3*s1),
     (s3, s2, s3*s1),
     (s3, s2*s1, s3),
     (s3*s2, s1, s3),
     (s3*s2*s1, 1, s3),
     (s3*s2*s1, s3, 1),
     (s3*s2, 1, s3*s1),
     (s3*s2, s3, s1),
     (s3*s2, s3*s1, 1),
     (s2, 1, s3*s2*s1),
     (s2, s3, s2*s1),
     (s2, s3*s2, s1),
     (s2, s3*s2*s1, 1)]

    We can also access the crystal by specifying a skew shape in terms of $k$-bounded partitions:

    sage: crystals.AffineFactorization([[3,1,1],[1]], 3, k=3)
    Crystal on affine factorizations of type A2 associated to s2*s3*s2*s1

    We can compute the highest weight elements:

    sage: hw = [w for w in B if w.is_highest_weight()]
    sage: hw
    [(1, s2, s3*s2*s1)]
    sage: hw[0].weight()
    (3, 1, 0)

    And show that this crystal is isomorphic to the tableau model of the same weight:

    sage: C = crystals.Tableaux(['A',2],shape=[3,1])
    sage: GC = C.digraph()
```

(continues on next page)
The crystal operators themselves move elements between adjacent factors:

```python
sage: b = hw[0]; b
(1, s2, s3*s2*s1)
sage: b.f(1)
(1, s3*s2, s3*s1)
```

The cut point $x$ is not supposed to occur in the reduced words for $w$:

```python
sage: B = crystals.AffineFactorization([[3,2],[2]],4,x=0,k=3)
Traceback (most recent call last):
... ValueError: x cannot be in reduced word of s0*s3*s2
```

class Element
Bases: ElementWrapper

---

**bracketing**($i$)

Removes all bracketed letters between $i$-th and $i+1$-th entry.

**EXAMPLES:**

```python
sage: B = crystals.AffineFactorization([[3,1],[1]], 3, k=3, x=4)
sage: W = B.w.parent()
sage: t = B((W.one(),W.from_reduced_word([3]),W.from_reduced_word([2,1])));
˓→t
(1, s3, s2*s1)
sage: t.bracketing(1)
[[3], [2, 1]]
```

---

**e**($i$)

Return the action of $e_i$ on self.

**EXAMPLES:**

```python
sage: B = crystals.AffineFactorization([[3,1],[1]], 4, k=3)
sage: W = B.w.parent()
sage: t = B((W.one(),W.one(),W.from_reduced_word([3]),W.from_reduced_
˓→word([2,1]))); t
(1, 1, s3, s2*s1)
sage: t.e(1)
(1, 1, 1, s3*s2*s1)
```

---

**f**($i$)

Return the action of $f_i$ on self.

**EXAMPLES:**

```python
sage: B = crystals.AffineFactorization([[3,1],[1]], 4, k=3)
sage: W = B.w.parent()
```
sage: t = B((W.one(),W.one(),W.from_reduced_word([3]),W.from_reduced_word([2,1]))); t
(1, 1, s3, s2*s1)
sage: t.f(2)
(1, s3, 1, s2*s1)
sage: t.f(1)
(1, 1, s3*s2, s1)

to_tableau()

Return the tableau representation of self.

Uses the recording tableau of a minor variation of Edelman-Greene insertion. See Theorem 4.11 in [MS2015].

EXAMPLES:

sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: for x in B:
....:  x
....:  x.to_tableau().pp()
(1, s2*s1, s3*s2)
  1
  2
(s2, s1, s3*s2)
  1
  2
  3
(s2, s3*s1, s2)
  1
  2
  3
(s2*s1, 1, s3*s2)
  1
  3
  3
(s2*s1, s3, s2)
  1
  3
  3
(s2*s1, s3*s2, 1)
  2
  2
  3

class sage.combinat.crystals.affine_factorization.FactorizationToTableaux(parent, cartan_type=None, virtualization=None, scaling_factors=None)

Bases: CrystalMorphism

is_embedding()

Return True as this is an isomorphism.

EXAMPLES:
```python
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
True
```

```python
is_isomorphism()
```

Return True as this is an isomorphism.

EXAMPLES:

```python
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
True
```

```python
is_surjective()
```

Return True as this is an isomorphism.

EXAMPLES:

```python
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([2,1,3,2])
sage: B = crystals.AffineFactorization(w,3)
sage: phi = B._tableaux_isomorphism
sage: phi.is_isomorphism()
True
```

```python
sage.combinat.crystals.affine_factorization.affine_factorizations(w, l, weight=None)
```

Return all factorizations of \( w \) into \( l \) factors or of weight \( \text{weight} \).

INPUT:

- \( w \) – an (affine) permutation or element of the (affine) Weyl group
- \( l \) – nonnegative integer
- \( \text{weight} \) – (default: None) tuple of nonnegative integers specifying the length of the factors

EXAMPLES:

```python
sage: W = WeylGroup(['A',3,1], prefix='s')
sage: w = W.from_reduced_word([3,2,3,1,0,1])
sage: from sage.combinat.crystals.affine_factorization import affine_factorizations
sage: affine_factorizations(w,4)
[[s2, s3, s0, s2*s1*s0],
 [s2, s3, s2*s0, s1*s0],
 [s2, s3, s2*s1*s0, s1],
 [s2, s3*s2, s0, s1*s0],
 [s2, s3*s2, s1*s0, s1],
 [s3*s2, s3, s0, s1*s0],
 [s3*s2, s3, s1*s0, s1],
 [s3*s2, s3, s1*s0, s1],
]
```
Combinatorics, Release 10.1

5.1.37 Affinization Crystals

class sage.combinat.crystals.affinization.AffinizationOfCrystal(B)

Bases: UniqueRepresentation, Parent

An affinization of a crystal.

Let \( \mathfrak{g} \) be a Kac-Moody algebra of affine type. The affinization of a finite \( U'_q(\mathfrak{g}) \)-crystal \( B \) is the (infinite) \( U_q(\mathfrak{g}) \)-
crystal with underlying set:

\[
B^{\text{aff}} = \{ b(m) \mid b \in B, m \in \mathbb{Z} \}
\]
and crystal structure determined by:

\[ e_i(b(m)) = \begin{cases} 
(e_0b)(m + 1) & i = 0, \\
(e_i)b(m) & i \neq 0,
\end{cases} \]

\[ f_i(b(m)) = \begin{cases} 
(f_0b)(m - 1) & i = 0, \\
(f_i)b(m) & i \neq 0,
\end{cases} \]

\[ \text{wt}(b(m)) = \text{wt}(b) + m\delta. \]

**EXAMPLES:**

We first construct a Kirillov-Reshetikhin crystal and then take it’s corresponding affinization:

```python
sage: K = crystals.KirillovReshetikhin(
    ['A', 2, 1], 2, 2)

sage: A = K.affinization()
```

Next we construct an affinization crystal from a tensor product of KR crystals:

```python
sage: KT = crystals.TensorProductOfKirillovReshetikhinTableaux(
    ['C', 2, 1], [[1,2], [2, \rightarrow 1]])

sage: A = crystals.AffinizationOf(KT)
```

**REFERENCES:**

- [HK2002] Chapter 10

**class Element**(parent, b, m)

Bases: Element

An element in an affinization crystal.

**e(i)**

Return the action of \( e_i \) on self.

**INPUT:**

- i -- an element of the index set

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(
    ['A', 2, 1], 2, 2).affinization()

sage: mg = A.module_generators[0]

sage: mg.e(0)
[[1, 2], [2, 3]](1)

sage: mg.e(1)

sage: mg.e(0).e(1)
[[1, 1], [2, 3]](1)
```

**epsilon(i)**

Return \( \epsilon_i \) of self.

**INPUT:**

- i -- an element of the index set

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(
    ['A', 2, 1], 2, 2).affinization()

sage: mg = A.module_generators[0]

sage: mg.epsilon(0)
2
```

(continues on next page)
The action of $f_i$ on self.

**INPUT:**
- $i$ – an element of the index set

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.f(2)
[[[1, 1], [2, 3]], 0]
sage: mg.f(2).f(0)
[[[1, 2], [2, 3]], 0]
sage: mg.f_string([2,1,1])
[[[1, 1], [2, 2]], -1]
sage: mg.f_string([2,1,0])
[[[1, 1], [2, 2]], -1]
```

Return $\varphi_i$ of self.

**INPUT:**
- $i$ – an element of the index set

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.phi(0)
0
sage: mg.phi(2)
2
```

Return the weight of self.

The weight $wt$ of an element is:

$$wt(b(m)) = wt(b) + m\delta,$$

where $\delta$ is the null root.

**EXAMPLES:**

```python
sage: A = crystals.KirillovReshetikhin(['A',2,1], 2,2).affinization()
sage: mg = A.module_generators[0]
sage: mg.weight()
-2*Lambda[0] + 2*Lambda[2]
sage: mg.e(0).weight()
sage: mg.e(0).e(0).weight()
2*Lambda[0] - 2*Lambda[1] + 2*delta
```
5.1.38 Alcove paths

AUTHORS:

• Brant Jones (2008): initial version
• Arthur Lubovsky (2013-03-07): rewritten to implement affine type
• Travis Scrimshaw (2016-06-23): implemented \( \mathcal{B}(\infty) \)

Special thanks to: Nicolas Borie, Anne Schilling, Travis Scrimshaw, and Nicolas Thiéry.

class sage.combinat.crystals.alcove_path.CrystalOfAlcovePaths(starting_weight, highest_weight_crystal)

Bases: UniqueRepresentation, Parent

Crystal of alcove paths generated from a “straight-line” path to the negative of a given dominant weight.

INPUT:

• cartan_type – Cartan type of a finite or affine untwisted root system.
• weight – Dominant weight as a list of (integral) coefficients of the fundamental weights.
• highest_weight_crystal – (Default: True) If True returns the highest weight crystal. If False returns an object which is close to being isomorphic to the tensor product of Kirillov-Reshetikhin crystals of column shape in the following sense: We get all the vertices, but only some of the edges. We’ll call the included edges pseudo-Demazure. They are all non-zero edges and the 0-edges not at the end of a 0-string of edges, i.e. not those with \( f_0(b) = b' \) with \( \varphi_0(b) = 1 \). (Whereas Demazure 0-edges are those that are not at the beginning of a zero string.) In this case the weight \([c_1, c_2, \ldots, c_k]\) represents \( \sum_{i=1}^{k} c_i \omega_i \).

Note: If highest_weight_crystal = False, since we do not get the full crystal, TestSuite will fail on the Stembridge axioms.

See also:

• Crystals

EXAMPLES:

The following example appears in Figure 2 of [LP2008]:

```
sage: C = crystals.AlcovePaths(['G',2],[0,1])
sage: G = C.digraph()
sage: GG = DiGraph({
    ....: ()    : {()}   : 2 },
    ....: (0)   : {(),8} : 1 },
    ....: (0,1) : {(),1,7} : 2 },
    ....: (0,1,2) : {(),1,2,9} : 1 },
    ....: (0,1,2,3) : {(),1,2,3,4} : 2 },
    ....: (0,1,2,6) : {(),1,2,3} : 1 },
    ....: (0,1,2,9) : {(),1,2,6} : 1 },
    ....: (0,1,7) : {(),1,2} : 2 },
    ....: (0,1,7,9) : {(),1,2,9} : 2 },
    ....: (0,5) : {(),1} : 1, (0,5,7) : 2 },
    ....: (0,5,7) : {(),5,7,9} : 1 },
    ....: (0,5,7,9) : {(),1,7,9} : 1 },
```

(continues on next page)
Combinatorics, Release 10.1

(continued from previous page)

```python
....:   (0,8) : { (0,5) : 1 },
....:   }

sage: G.is_isomorphic(GG)
True

sage: for (u,v,i) in G.edges(sort=True):
    ....:   print((u.integer_sequence() , v.integer_sequence(), i))
    ([], [0], 2)
    ([0], [0, 8], 1)
    ([0, 1], [0, 1, 7], 2)
    ([0, 1, 2], [0, 1, 2, 9], 1)
    ([0, 1, 2, 3], [0, 1, 2, 3, 4], 2)
    ([0, 1, 2, 6], [0, 1, 2, 3], 1)
    ([0, 1, 2, 9], [0, 1, 2, 6], 1)
    ([0, 1, 7], [0, 1, 2], 2)
    ([0, 1, 7, 9], [0, 1, 2, 9], 2)
    ([0, 5], [0, 1], 1)
    ([0, 5], [0, 5, 7], 2)
    ([0, 5, 7], [0, 5, 7, 9], 1)
    ([0, 5, 7, 9], [0, 1, 7, 9], 1)
    ([0, 8], [0, 5], 1)
```

Alcove path crystals are a discrete version of Littelmann paths. We verify that the alcove path crystal is isomorphic to the LS path crystal:

```python
sage: C1 = crystals.AlcovePaths(['C',3],[2,1,0])
sage: g1 = C1.digraph()  # long time
sage: C2 = crystals.LSPaths(['C',3],[2,1,0])
sage: g2 = C2.digraph()  # long time
sage: g1.is_isomorphic(g2, edge_labels=True)  # long time
True
```

The preferred initialization method is via explicit weights rather than a Cartan type and the coefficients of the fundamental weights:

```python
sage: R = RootSystem(['C',3])
sage: P = R.weight_lattice()
sage: La = P.fundamental_weights()
sage: C1==C
True
```

We now explain the data structure:

```python
sage: C = crystals.AlcovePaths(['A',2],[2,0]) ; C
Highest weight crystal of alcove paths of type ['A', 2] and weight 2*Lambda[1]
sage: C._R.lambda_chain()
[(alpha[1], 0), (alpha[1] + alpha[2], 0), (alpha[1], 1), (alpha[1] + alpha[2], 1)]
```

The previous list gives the initial “straight line” path from the fundamental alcove $A_o$ to its translation $A_o - \lambda$ where $\lambda = 2\omega_1$ in this example. The initial path for weight $\lambda$ is called the $\lambda$-chain. This path is constructed from the ordered pairs $(\beta, k)$, by crossing the hyperplane orthogonal to $\beta$ at height $-k$. We can view a plot of this
path as follows:

```
sage: x = C( () )
sage: x.plot() # not tested - outputs a pdf
```

An element of the crystal is given by a subset of the $\lambda$-chain. This subset indicates the hyperplanes where the initial path should be folded. The highest weight element is given by the empty subset.

```
sage: x
()
sage: x.f(1).f(2)
((alpha[1], 1), (alpha[1] + alpha[2], 1))
sage: x.f(1).f(2).integer_sequence()
[2, 3]
sage: C([2, 3])
((alpha[1], 1), (alpha[1] + alpha[2], 1))
sage: C([2, 3]).is_admissible() #check if a valid vertex
True
sage: C([1, 3]).is_admissible() #check if a valid vertex
False
```

Alcove path crystals now works in affine type (github issue #14143):

```
sage: C = crystals.AlcovePaths(['A',2,1],[1,0,0])
Highest weight crystal of alcove paths of type ['A', 2, 1] and weight Lambda[0]
sage: x = C( () )
sage: x.f(0)
((alpha[0], 0),)
sage: C.R
Root system of type ['A', 2, 1]
sage: C.weight
Lambda[0]
```

Test that the tensor products of Kirillov-Reshetikhin crystals minus non-pseudo-Demazure arrows is in bijection with alcove path construction:

```
sage: K = crystals.KirillovReshetikhin(['B',3,1],2,1)
sage: T = crystals.TensorProduct(K,K)
sage: g = T.digraph() #long time
sage: for e in g.edges(sort=False): #long time
.....:   if e[0].phi(0) == 1 and e[2] == 0:
.....:     g.delete_edge(e)

sage: C = crystals.AlcovePaths(['B',3,1],[0,2,0], highest_weight_crystal=False)
sage: g2 = C.digraph() #long time
sage: g.is_isomorphic(g2, edge_labels = True) #long time
True
```

**Note:** In type $C_n^{(1)}$, the Kirillov-Reshetikhin crystal is not connected when restricted to pseudo-Demazure arrows, hence the previous example will fail for type $C_n^{(1)}$ crystals.
sage: R = RootSystem(['B',3])
sage: P = R.weight_lattice()
sage: La = P.fundamental_weights()
sage: D = crystals.AlcovePaths(2*La[2], highest_weight_crystal=False)
sage: C == D
True

**Warning:** Weights from finite root systems index non-highest weight crystals.

**Element**
alias of *CrystalOfAlcovePathsElement*

**vertices()**
Return a list of all the vertices of the crystal.

The vertices are represented as lists of integers recording the folding positions.

One can compute all vertices of the crystal by finding all the admissible subsets of the \( \lambda \)-chain (see method is_admissible, for definition). We use the breadth first search algorithm.

**Warning:** This method is (currently) only useful for the case when highest_weight_crystal = False, where you cannot always reach all vertices of the crystal using crystal operators, starting from the highest weight vertex. This method is typically slower than generating the crystal graph using crystal operators.

**EXAMPLES:**

```python
sage: C = crystals.AlcovePaths(['C',2],[1,0])
sage: C.vertices()
[[], [0], [0, 1], [0, 1, 2]]
sage: C = crystals.AlcovePaths(['C',2,1],[2,1],False)
sage: len(C.vertices())
80
```

The number of elements reachable using the crystal operators from the module generator:

```python
sage: len(list(C))
55
```

**class** `sage.combinat.crystals.alcove_path.CrystalOfAlcovePathsElement`
Bases: `ElementWrapper`

Crystal of alcove paths element.

**INPUT:**

- `data` – a list of folding positions in the lambda chain (indexing starts at 0) or a tuple of `RootsWithHeight` giving folding positions in the lambda chain.

**EXAMPLES:**

```python
sage: C = crystals.AlcovePaths(['A',2],[3,2])
sage: x = C ( () )
```
sage: x.f(1).f(2)
((alpha[1], 2), (alpha[1] + alpha[2], 4))
sage: x.f(1).f(2).integer_sequence()
[8, 9]
sage: C([8,9])
((alpha[1], 2), (alpha[1] + alpha[2], 4))

e(i)
Return the \(i\)-th crystal raising operator on \(self\).

INPUT:

* \(i\) – element of the index set of the underlying root system.

EXAMPLES:

```python
sage: C = crystals.AlcovePaths(['A',2],[2,0]); C
Highest weight crystal of alcove paths of type ['A', 2] and weight 2*Lambda[1]
sage: x = C( ()
```

```python
sage: x.e(1)
sage: x.f(1) == x.f(1).f(2).e(2)
True
```

epsilon(i)
Return the distance to the start of the \(i\)-string.

EXAMPLES:

```python
sage: C = crystals.AlcovePaths(['A',2],[1,1])
sage: [c.epsilon(1) for c in C]
[0, 1, 0, 0, 1, 0, 1, 2]
sage: [c.epsilon(2) for c in C]
[0, 0, 1, 2, 1, 1, 0, 0]
```

f(i)
Returns the \(i\)-th crystal lowering operator on \(self\).

INPUT:

* \(i\) – element of the index_set of the underlying root_system.

EXAMPLES:

```python
sage: C=crystals.AlcovePaths(['B',2],[1,1])
sage: x=C( ()
```

```python
sage: x.f(1)
((alpha[1], 0),)
sage: x.f(1).f(2)
((alpha[1], 0), (alpha[1] + alpha[2], 2))
```

integer_sequence()
Return a list of integers corresponding to positions in the \(\lambda\)-chain where it is folded.

Todo: Incorporate this method into the \_repr\_ for finite Cartan type.
Note: Only works for finite Cartan types and indexing starts at 0.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A',2],[3,2])
sage: x = C( () )
sage: x.f(1).f(2).integer_sequence()
[8, 9]
```

`is_admissible()`
Diagnostic test to check if `self` is a valid element of the crystal.
If `self.value` is given by

\[(\beta_1, i_1), (\beta_2, i_2), \ldots, (\beta_k, i_k),\]

for highest weight crystals this checks if the sequence

\[1 \to s_{\beta_1} \to s_{\beta_1} s_{\beta_2} \to \cdots \to s_{\beta_1} s_{\beta_2} \cdots s_{\beta_k}\]

is a path in the Bruhat graph. If `highest_weight_crystal=False`, then the method checks if the above sequence is a path in the quantum Bruhat graph.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A',2],[1,1]); C
Highest weight crystal of alcove paths of type ['A', 2] and weight Lambda[1] + \omega
˓→Lambda[2]
sage: roots = sorted(C._R._root_lattice.positive_roots()); roots
[alpha[1], alpha[1] + alpha[2], alpha[2]]
sage: r1 = C._R(roots[0],0); r1
(alpha[1], 0)
sage: r2 = C._R(roots[2],0); r2
(alpha[2], 0)
sage: r3 = C._R(roots[1],1); r3
(alpha[1] + alpha[2], 1)
sage: x = C( (r1,r2) )
sage: x.is_admissible()
True
sage: x = C( (r3,) )
((alpha[1] + alpha[2], 1),)
sage: x.is_admissible()
False
sage: C = crystals.AlcovePaths(['C',2,1],[2,1],False)
sage: C([7,8]).is_admissible()
True
sage: C = crystals.AlcovePaths(['A',2],[3,2])
sage: C([2,3]).is_admissible()
True
```

Todo: Better doctest
path()  
Return the path in the (quantum) Bruhat graph corresponding to self.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['B', 3], [3,1,2])
sage: b = C.highest_weight_vector().f_string([1,3,2,1,3,1])
sage: b.path()  
[1, s1, s3*s1, s2*s3*s1, s3*s2*s3*s1]  
sage: b = C.highest_weight_vector().f_string([2,3,3,2])
sage: b.path()  
[1, s2, s3*s2, s2*s3*s2]  
sage: b = C.highest_weight_vector().f_string([2,3,3,2,1])
sage: b.path()  
[1, s2, s3*s2, s2*s3*s2, s1*s2*s3*s2]  
```

\(\phi(i)\)  
Return the distance to the end of the \(i\)-string.

This method overrides the generic implementation in the category of crystals since this computation is more efficient.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A',2],[1,1])
sage: [c.phi(1) for c in C]  
[1, 0, 0, 1, 0, 2, 1, 0]  
sage: [c.phi(2) for c in C]  
[1, 2, 1, 0, 0, 0, 0, 1]  
```

plot()  
Return a plot self.

Note: Currently only implemented for types \(A_2\), \(B_2\), and \(C_2\).

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A',2],[2,0])
sage: x = C( () ).f(1).f(2)
sage: x.plot()  
# Not tested - creates a pdf  
```

weight()  
Return the weight of self.

EXAMPLES:

```
sage: C = crystals.AlcovePaths(['A',2],[2,0])
sage: for i in C: i.weight()  
(2, 0, 0)  
(1, 1, 0)  
(0, 2, 0)  
(0, -1, 0)  
(-1, 0, 0)  
(-2, -2, 0)  
```
sage: B = crystals.AlcovePaths(['A',2,1],[1,0,0])
sage: p = B.module_generators[0].f_string([0,1,2])
sage: p.weight()
Lambda[0] - delta

class sage.combinat.crystals.alcove_path.InfinityCrystalOfAlcovePaths(cartan_type)
    B(∞) crystal of alcove paths.

class Element(parent, elt, shift)
    Initialize self.

    EXAMPLES:

    sage: A = crystals.infinity.AlcovePaths(['F',4])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([2,3,1,4,4,2,3,1])
sage: TestSuite(x).run()

e(i)
    Return the action of e_i on self.

    INPUT:
    • i – an element of the index set

    EXAMPLES:

    sage: A = crystals.infinity.AlcovePaths(['D',5,1])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1,3,4,2,5,4,5,5])
sage: x.f(4).e(5) == x.e(5).f(4)
    True

epsilon(i)
    Return ε_i of self.

    INPUT:
    • i – an element of the index set

    EXAMPLES:

    sage: A = crystals.infinity.AlcovePaths(['A',7,2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1,0,2,3,4,4,2,3,3,3])
sage: [x.epsilon(i) for i in A.index_set()]
    [0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
sage: x = mg.f_string([2,2,1,1,0,1,0,2,3,3,3,4])
sage: [x.epsilon(i) for i in A.index_set()]
    [1, 2, 0, 1, 1]

f(i)
    Return the action of f_i on self.

    INPUT:
    • i – an element of the index set
EXAMPLES:

```python
sage: A = crystals.infinity.AlcovePaths(['E', 7, 1])
sage: mg = A.highest_weight_vector()
sage: mg.f_string([1, 3, 5, 6, 4, 2, 0, 2, 1, 0, 2, 4, 7, 4, 2])
((alpha[2], -3), (alpha[5], -1), (alpha[1], -1),
 (alpha[0] + alpha[1], -2),
 (alpha[5] + alpha[6], -1), (alpha[1] + alpha[3], -1),
 (alpha[0] + alpha[1] + alpha[3], -1),
```

**phi(i)**

Return \(\phi_i\) of self.

Let \(A \in \mathcal{B}(\infty)\) Define \(\phi_i(A) := \varepsilon_i(A) + \langle h_i, \text{wt}(A) \rangle\), where \(h_i\) is the \(i\)-th simple coroot and \(\text{wt}(A)\) is the weight() of \(A\).

**INPUT:**

- \(i\) – an element of the index set

**EXAMPLES:**

```python
sage: A = crystals.infinity.AlcovePaths(['A', 8, 2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([1, 0, 2, 3, 4, 4, 4, 2, 3, 3, 3])
sage: [x.phi(i) for i in A.index_set()]
[1, 1, 1, 3, -2]
```

**projection** *(k=None)*

Return the projection self onto \(B(k\rho)\).

**INPUT:**

- \(k\) – (optional) if not given, defaults to the smallest value such that self is not None under the projection

**EXAMPLES:**

```python
sage: A = crystals.infinity.AlcovePaths(['G', 2])
sage: mg = A.highest_weight_vector()
sage: x = mg.f_string([2, 1, 1, 2, 2, 2, 1, 1]); x
((alpha[2], -3), (alpha[1] + alpha[2], -3),
 (3*alpha[1] + 2*alpha[2], -1), (2*alpha[1] + alpha[2], -1))
sage: x.projection()
((alpha[2], 0), (alpha[1] + alpha[2], 9),
 (3*alpha[1] + 2*alpha[2], 8), (2*alpha[1] + alpha[2], 14))
sage: x.projection().parent()
Highest weight crystal of alcove paths of type ['G', 2]
```

(continues on next page)
sage: mg.f(1).projection().parent()
sage: mg.f(1).f(2).projection().parent()
sage: b = mg.f_string([1,2,2,1,2])
sage: b.projection().parent()
sage: b.projection(3).parent()

weight()
Return the weight of self.

EXAMPLES:

sage: A = crystals.infinity.AlcovePaths(['E',6])
sage: mg = A.highest_weight_vector()
sage: fstr = [1,3,4,2,1,2,3,6,5,3,2,6,2]
sage: x = mg.f_string(fstr)
sage: al = A.weight_lattice_realization().simple_roots()
sage: x.weight() == -sum(al[i]*fstr.count(i) for i in A.index_set())
True

class sage.combinat.crystals.alcove_path.RootsWithHeight(weight)
Bases: UniqueRepresentation, Parent

Data structure of the ordered pairs (\(\beta, k\)), where \(\beta\) is a positive root and \(k\) is a non-negative integer. A total order is implemented on this set, and depends on the weight.

INPUT:

- **cartan_type** – Cartan type of a finite or affine untwisted root system
- **weight** – dominant weight as a list of (integral) coefficients of the fundamental weights

EXAMPLES:

sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: R = RootsWithHeight(['A',2],[1,1]); R
sage: r1 = R._root_lattice.from_vector(vector([1,0])); r1
alpha[1]
sage: r2 = R._root_lattice.from_vector(vector([1,1])); r2
sage: x = R(r1,0); x
(alpha[1], 0)
sage: y = R(r2,1); y
(alpha[1] + alpha[2], 1)
sage: x < y
True

Element
alias of RootsWithHeightElement

lambda_chain()
Return the unfolded $\lambda$-chain.

Note: Only works in root systems of finite type.

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: R = RootsWithHeight(['A',2],[1,1]); R
sage: R.lambda_chain()
[(alpha[2], 0), (alpha[1] + alpha[2], 0), (alpha[1], 0), (alpha[1] + alpha[2], 1)]
```

word()
Gives the initial alcove path ($\lambda$-chain) in terms of simple roots. Used for plotting the path.

Note: Currently only implemented for finite Cartan types.

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: R = RootsWithHeight(['A',2],[3,2])
sage: R.word()
[2, 1, 2, 0, 1, 2, 1, 0, 1, 2]
```

class sage.combinat.crystals.alcove_path.RootsWithHeightElement(parent, root, height)

Bases: Element

Element of RootsWithHeight.

INPUT:

- root – A positive root $\beta$ in our root system
- height – Is an integer, such that $0 \leq l \leq \langle \lambda, \beta^\vee \rangle$

EXAMPLES:

```
sage: from sage.combinat.crystals.alcove_path import RootsWithHeight
sage: rl = RootSystem(['A',2]).root_lattice()
sage: x = rl.from_vector(vector([1,1])); x
sage: R = RootsWithHeight(['A',2],[1,1]); R
```

(continues on next page)
sage: y = R(x, 1); y
(alpha[1] + alpha[2], 1)

sage.combinat.crystals.alcove_path.compare_graphs(g1, g2, node1, node2)

Compare two edge-labeled graphs obtained from Crystal.digraph(), starting from the root nodes of each graph.

- g1 – graphs, first digraph
- g2 – graphs, second digraph
- node1 – element of g1
- node2 – element of g2

Traverse g1 starting at node1 and compare this graph with the one obtained by traversing g2 starting with node2. If the graphs match (including labels) then return True. Return False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.crystals.alcove_path import compare_graphs
sage: G1 = crystals.Tableaux(['A', 3], shape=[1,1]).digraph()
sage: C = crystals.AlcovePaths(['A',3],[0,1,0])
sage: G2 = C.digraph()
sage: compare_graphs(G1, G2, C(()), G2.vertices(sort=True)[0])
True
```

5.1.40 Benkart-Kang-Kashiwara crystals for the general-linear Lie superalgebra

```python
class sage.combinat.crystals.bkk_crystals.CrystalOfBKKTableaux(ct, shape):
    Bases: CrystalOfWords

    Crystal of tableaux for type $A(m|n)$.

    This is an implementation of the tableaux model of the Benkart-Kang-Kashiwara crystal [BKK2000] for the Lie superalgebra $\mathfrak{gl}(m+1,n+1)$.

    INPUT:
    • ct – a super Lie Cartan type of type $A(m|n)$
    • shape – shape specifying the highest weight; this should be a partition contained in a hook of height $n+1$ and width $m+1$

    EXAMPLES:

    sage: T = crystals.Tableaux(['A', [1,1]], shape=[2,1])
    sage: T.cardinality()
    20
```

class Element

    Bases: CrystalOfBKKTableauxElement

    **genuine_highest_weight_vectors**(index_set=None)

    Return a tuple of genuine highest weight elements.

    A fake highest weight vector is one which is annihilated by $e_i$ for all $i$ in the index set, but whose weight is not bigger in dominance order than all other elements in the crystal. A genuine highest weight vector is a highest weight element that is not fake.

    EXAMPLES:

    sage: B = crystals.Tableaux(['A', [1,1]], shape=[3,2,1])
    sage: B.genuine_highest_weight_vectors()
    ([[-2, -2, -2], [-1, -1], [1]],)
    sage: B.highest_weight_vectors()
    ([[-2, -2, -2], [-1, -1], [1]],
     [[-2, -2, 2], [-1, -1], [1]],
     [[-2, -2, 2], [-1, 2], [1]])

    **shape()**

    Return the shape of self.

    EXAMPLES:

    sage: T = crystals.Tableaux(['A', [1,2]], shape=[2,1])
    sage: T.shape()
    [2, 1]
```
5.1.41 Catalog Of Crystals

Let $I$ be an index set and let $(A, \Pi^\vee, P, P^\vee)$ be a Cartan datum associated with generalized Cartan matrix $A = (a_{ij})_{i,j \in I}$. An abstract crystal associated to this Cartan datum is a set $B$ together with maps

$$e_i, f_i : B \to B \cup \{0\}, \quad \varepsilon_i, \varphi_i : B \to \mathbb{Z} \cup \{-\infty\}, \quad \text{wt} : B \to P,$$

subject to the following conditions:

1. $\varphi_i(b) = \varepsilon_i(b) + \langle h_i, \text{wt}(b) \rangle$ for all $b \in B$ and $i \in I$;
2. $\text{wt}(e_i b) = \text{wt}(b) + \alpha_i$ if $e_i b \in B$;
3. $\text{wt}(f_i b) = \text{wt}(b) - \alpha_i$ if $f_i b \in B$;
4. $\varepsilon_i(e_i b) = \varepsilon_i(b) - 1, \varphi_i(e_i b) = \varphi_i(b) + 1$ if $e_i b \in B$;
5. $\varepsilon_i(f_i b) = \varepsilon_i(b) + 1, \varphi_i(f_i b) = \varphi_i(b) - 1$ if $f_i b \in B$;
6. $f_i b = b'$ if and only if $b = e_i b'$ for $b, b' \in B$ and $i \in I$;
7. if $\varphi_i(b) = -\infty$ for $b \in B$, then $e_i b = f_i b = 0$.

- KirillovReshetikhinTableaux
- LSPaths
- RiggedConfigurations

5.1.45 An introduction to crystals

Informally, a crystal $B$ is an oriented graph with edges colored in some set $I$ such that, for each $i \in I$, each node $x$ has:
- at most one $i$-successor, denoted $f_i x$;
- at most one $i$-predecessor, denoted $e_i x$.

By convention, one writes $f_i x = \emptyset$ and $e_i x = \emptyset$ when $x$ has no successor resp. predecessor.

One may think of $B$ as essentially a deterministic automaton whose dual is also deterministic; in this context, the $f_i$’s and $e_i$’s are respectively the transition functions of the automaton and of its dual, and $\emptyset$ is the sink.

A crystal comes further endowed with a weight function $wt : B \to L$ which satisfies appropriate conditions.

In combinatorial representation theory, crystals are used as combinatorial data to model representations of Lie algebra.

Axiomatic definition

Let $C$ be a Cartan type ($CartanType$) with index set $I$, and $L$ be a realization of the weight lattice of the type $C$. Let $\alpha_i$ and $\alpha_i^\vee$ denote the simple roots and coroots respectively.

A type $C$ crystal is a non-empty set $B$ endowed with maps $wt : B \to L$, $e_i, f_i : B \to B \cup \{\emptyset\}$, and $\varepsilon_i, \varphi_i : B \to \mathbb{Z} \cup \{-\infty\}$ for $i \in I$ satisfying the following properties for all $i \in I$:

- for $b, b' \in B$, we have $f_i b' = b$ if and only if $e_i b = b'$;
- if $e_i b \in B$, then:
  - $wt(e_i b) = wt(b) + \alpha_i$,
  - $\varepsilon_i(e_i b) = \varepsilon_i(b) - 1$,
  - $\varphi_i(e_i b) = \varphi_i(b) + 1$;
- if $f_i b \in B$, then:
  - $wt(f_i b) = wt(b) - \alpha_i$,
  - $\varepsilon_i(f_i b) = \varepsilon_i(b) + 1$,
  - $\varphi_i(f_i b) = \varphi_i(b) - 1$;
- $\varphi_i(b) = \varepsilon_i(b) + (\alpha_i^\vee, wt(b))$.
- if $\varphi_i(b) = -\infty$ for $b \in B$, then $e_i b = f_i b = \emptyset$. 
Some further conditions are required to guarantee that this data indeed models a representation of a Lie algebra. For finite simply laced types a complete characterization is given by Stembridge’s local axioms [Ste2003].

**EXAMPLES:**

We construct the type $A_5$ crystal on letters (or in representation theoretic terms, the highest weight crystal of type $A_5$ corresponding to the highest weight $\Lambda_1$):

```python
sage: C = crystals.Letters(['A',5]); C
The crystal of letters for type ['A', 5]
```

It has a single highest weight element:

```python
sage: C.highest_weight_vectors()
(1,)
```

A crystal is an enumerated set (see `EnumeratedSets`); and we can count and list its elements in the usual way:

```python
sage: C.cardinality()
6
sage: C.list()
[1, 2, 3, 4, 5, 6]
```

as well as use it in for loops:

```python
sage: [x for x in C]
[1, 2, 3, 4, 5, 6]
```

Here are some more elaborate crystals (see their respective documentations):

```python
sage: Tens = crystals.TensorProduct(C, C)
sage: Spin = crystals.Spins(['B', 3])
sage: Tab = crystals.Tableaux(['A', 3], shape = [2,1,1])
sage: Fast = crystals.FastRankTwo(['B', 2], shape = [3/2, 1/2])
sage: KR = crystals.KirillovReshetikhin(['A',2,1],1,1)
```

One can get (currently) crude plotting via:

```python
sage: Tab.plot() #optional - sage.plot
Graphics object consisting of 52 graphics primitives
```

If dot2tex is installed, one can obtain nice latex pictures via:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 1,1)
sage: view(K, pdflatex=True) # optional - dot2tex graphviz, not tested (opens external...)
```

or with colored edges:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 1,1)
sage: G = K.digraph()
sage: G.set_latex_options(color_by_label={0:"black", 1:"red", 2:"blue", 3:"green"})
sage: view(G, pdflatex=True) # optional - dot2tex graphviz, not tested (opens external...)
```

5.1. Comprehensive Module List
For rank two crystals, there is an alternative method of getting metapost pictures. For more information see C. metapost?.

The overview of crystal features in Sage

Todo:
- Vocabulary and conventions:
  - For a classical crystal: connected / highest weight / irreducible
  - ...
- Layout instructions for plot() for rank 2 types
- RestrictionOfCrystal

The crystals library in Sage grew up from an initial implementation in MuPAD-Combinat (see <MuPAD-Combinat>/lib/COMBINAT/crystals.mu).

```python
class sage.combinat.crystals.crystals.CrystalBacktracker(crystal, index_set=None)
    Bases: GenericBacktracker

    Time complexity: \( O(nF) \) amortized for each produced element, where \( n \) is the size of the index set, and \( F \) is the cost of computing \( e \) and \( f \) operators.

    Memory complexity: \( O(D) \) where \( D \) is the depth of the crystal.

    Principle of the algorithm:

    Let \( C \) be a classical crystal. It's an acyclic graph where each connected component has a unique element without predecessors (the highest weight element for this component). Let's assume for simplicity that \( C \) is irreducible (i.e. connected) with highest weight element \( u \).

    One can define a natural spanning tree of \( C \) by taking \( u \) as the root of the tree, and for any other element \( y \) taking as ancestor the element \( x \) such that there is an \( i \)-arrow from \( x \) to \( y \) with \( i \) minimal. Then, a path from \( u \) to \( y \) describes the lexicographically smallest sequence \( i_1, \ldots, i_k \) such that \( (f_{i_k} \circ f_{i_{k-1}})(u) = y \).

    Morally, the iterator implemented below just does a depth first search walk through this spanning tree. In practice, this can be achieved recursively as follows: take an element \( x \), and consider in turn each successor \( y = f_i(x) \), ignoring those such that \( y = f_j(x') \) for some \( x' \) and \( j < i \) (this can be tested by computing \( e_j(y) \) for \( j < i \)).

    EXAMPLES:

    sage: from sage.combinat.crystals.crystals import CrystalBacktracker
    sage: C = crystals.Tableaux(['B',3],shape=[3,2,1])
    sage: CB = CrystalBacktracker(C)
    sage: len(list(CB))
    1617
    sage: CB = CrystalBacktracker(C, [1,2])
    sage: len(list(CB))
    8
```
5.1.46 Direct Sum of Crystals

```python
class sage.combinat.crystals.direct_sum.DIRECTSUMOFCRYSTALS(crystals, facade, keepkey, category, **options):
    Bases: DisjointUnionEnumeratedSets

    Direct sum of crystals.

    Given a list of crystals $B_0, \ldots, B_k$ of the same Cartan type, one can form the direct sum $B_0 \oplus \cdots \oplus B_k$.

    INPUT:
    
    - crystals -- a list of crystals of the same Cartan type
    - keepkey -- a boolean

    The option keepkey is by default set to False, assuming that the crystals are all distinct. In this case the elements of the direct sum are just represented by the elements in the crystals $B_i$. If the crystals are not all distinct, one should set the keepkey option to True. In this case, the elements of the direct sum are represented as tuples $(i, b)$ where $b \in B_i$.

    EXAMPLES:

    sage: C = crystals.Letters(['A',2])
    sage: C1 = crystals.Tableaux(['A',2],shape=[1,1])
    sage: B = crystals.DirectSum([C,C1])
    sage: B.list()
    [1, 2, 3, [[1], [2]], [[1], [3]], [[2], [3]]]
    sage: [b.f(1) for b in B]
    [2, None, None, None, [[2], [3]], None]
    sage: B.module_generators
    ((1, [[1], [2]])

    sage: B = crystals.DirectSum([C,C], keepkey=True)
    sage: B.list()
    [(0, 1), (0, 2), (0, 3), (1, 1), (1, 2), (1, 3)]
    sage: B.moduleGenerators
    ((0, 1), (1, 1))
    sage: b = B( tuple([0,C(1)]) )
    sage: b
    (0, 1)
    sage: b.weight()
    (0, 0)

    The following is required, because DirectSumOfCrystals takes the same arguments as DisjointUnionEnumeratedSets (which see for details).
```

class Element

    Bases: ElementWrapper

    A class for elements of direct sums of crystals.

    e(i)

    Return the action of $e_i$ on self.

    EXAMPLES:
```
Combinatorics, Release 10.1

```python
sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: [[b, b.e(2)] for b in B]
[[[(0, 1), None], [(0, 2), None], [(0, 3), (0, 2)], [(1, 1), None], [(1, 2), None], [(1, 3), (1, 2)]]

epsilon(i)

EXAMPLES:

```python
sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: b = B( tuple([0,C(2)]) )
sage: b.epsilon(2)
0
```

f(i)

Return the action of \( f_i \) on self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: [[b,b.f(1)] for b in B]
[[[(0, 1), (0, 2)], [(0, 2), None], [(0, 3), None], [(1, 1), (1, 2)], [(1, 2), None], [(1, 3), None]]

phi(i)

EXAMPLES:

```python
sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: b = B( tuple([0,C(2)]) )
sage: b.phi(2)
1
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A',2])
sage: B = crystals.DirectSum([C,C], keepkey=True)
sage: b = B( tuple([0,C(2)]) )
sage: b.weight()
(0, 1, 0)
```

weight_lattice_realization()

Return the weight lattice realization used to express weights.

The weight lattice realization is the common parent which all weight lattice realizations of the crystals of self coerce into.

EXAMPLES:
5.1.47 Elementary Crystals

Let $\lambda$ be a weight. The crystals $T_\lambda$, $R_\lambda$, $B_i$, and $C$ are important objects in the tensor category of crystals. For example, the crystal $T_0$ is the neutral object in this category; i.e., $T_0 \otimes B \cong B \otimes T_0 \cong B$ for any crystal $B$. We list some other properties of these crystals:

- The crystal $T_\lambda \otimes B(\infty)$ is the crystal of the Verma module with highest weight $\lambda$, where $\lambda$ is a dominant integral weight.

- Let $u_\infty$ be the highest weight vector of $B(\infty)$ and $\lambda$ be a dominant integral weight. There is an embedding of crystals $B(\lambda) \to T_\lambda \otimes B(\infty)$ sending $u_\lambda \mapsto t_\lambda \otimes u_\infty$ which is not strict, but the embedding $B(\lambda) \to C \otimes T_\lambda \otimes B(\infty)$ by $u_\lambda \mapsto c \otimes t_\lambda \otimes u_\infty$ is a strict embedding.

- For any dominant integral weight $\lambda$, there is a surjective crystal morphism $\Psi_\lambda: R_\lambda \otimes B(\infty) \to B(\lambda)$. More precisely, if $B = \{r_\lambda \otimes b \in R_\lambda \otimes B(\infty) : \Psi_\lambda(r_\lambda \otimes b) \neq 0\}$, then $B \cong B(\lambda)$ as crystals.

- For all Cartan types and all weights $\lambda$, we have $R_\lambda \cong C \otimes T_\lambda$ as crystals.

- For each $i$, there is a strict crystal morphism $\Psi_i: B(\infty) \to B_i \otimes B(\infty)$ defined by $u_\infty \mapsto b_i(0) \otimes u_\infty$, where $u_\infty$ is the highest weight vector of $B(\infty)$.

For more information on $B(\infty)$, see `InfinityCrystalOfTableaux`.

Note: As with `TensorProductOfCrystals`, we are using the opposite of Kashiwara’s convention.

Combinatorics, Release 10.1

\( e(i) \)

Return \( e_i \) of \textit{self}, which is None for all \( i \).

INPUT:

\* \( i \) – An element of the index set

EXAMPLES:

\begin{verbatim}
sage: ct = CartanType(['A',2])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct,la[1])
sage: t = T.highest_weight_vector()
sage: t.e(1)
sage: t.e(2)
\end{verbatim}

\( f(i) \)

Return \( f_i \) of \textit{self}, which is None for all \( i \).

INPUT:

\* \( i \) – An element of the index set

EXAMPLES:

\begin{verbatim}
sage: ct = CartanType(['A',2])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct,la[1])
sage: t = T.highest_weight_vector()
sage: t.f(1)
sage: t.f(2)
\end{verbatim}

class \texttt{sage.combinat.crystals.elementary_crystals.ComponentCrystal}(\texttt{cartan_type}, \texttt{P})

Bases: \texttt{UniqueRepresentation}, \texttt{Parent}

The component crystal.

Defined in [Ka1993], the component crystal \( C = \{ c \} \) is the single element crystal whose crystal structure is defined by

\[
\text{wt}(c) = 0, \quad e_i c = f_i c = 0, \quad \epsilon_i(c) = \varphi_i(c) = 0.
\]

Note \( C \cong B(0) \), where \( B(0) \) is the highest weight crystal of highest weight 0.

INPUT:

\* \texttt{cartan_type} – a Cartan type

class \texttt{Element}

Bases: \texttt{AbstractSingleCrystalElement}

Element of a component crystal.

\( \epsilon(i) \)

Return \( \epsilon_i \) of \textit{self}, which is 0 for all \( i \).

INPUT:

\* \( i \) – An element of the index set

EXAMPLES:
sage: C = crystals.elementary.Component("C5")

sage: c = C.highest_weight_vector()

sage: [c.epsilon(i) for i in C.index_set()]

[0, 0, 0, 0, 0]

phi(i)

Return \( \varphi_i \) of self, which is 0 for all \( i \).

INPUT:

- \( i \) – An element of the index set

EXAMPLES:

sage: C = crystals.elementary.Component("C5")

sage: c = C.highest_weight_vector()

sage: [c.phi(i) for i in C.index_set()]

[0, 0, 0, 0, 0]

weight()

Return the weight of self, which is always 0.

EXAMPLES:

sage: C = crystals.elementary.Component("F4")

sage: c = C.highest_weight_vector()

sage: c.weight()

(0, 0, 0, 0)

cardinality()

Return the cardinality of self, which is always 1.

EXAMPLES:

sage: C = crystals.elementary.Component("E6")

sage: c = C.highest_weight_vector()

sage: C.cardinality()

1

weight_lattice_realization()

Return the weight lattice realization of self.

EXAMPLES:

sage: C = crystals.elementary.Component("A2")

sage: C.weight_lattice_realization()

Ambient space of the Root system of type ['A', 2]

sage: P = RootSystem(['A',2]).weight_lattice()

sage: C = crystals.elementary.Component(P)

sage: C.weight_lattice_realization() is P

True

class sage.combinat.crystals.elementary_crystals.ElementaryCrystal(cartan_type, i)

Bases: UniqueRepresentation, Parent

The elementary crystal \( B_i \).
For \( i \) an element of the index set of type \( X \), the crystal \( B_i \) of type \( X \) is the set
\[
B_i = \{ b_i(m) : m \in \mathbb{Z} \},
\]
where the crystal structure is given by
\[
\begin{align*}
\text{wt}(b_i(m)) &= m \alpha_i, \\
\varphi_j(b_i(m)) &= \begin{cases} 
m & \text{if } j = i, \\
-\infty & \text{if } j \neq i,
\end{cases} \\
\epsilon_j(b_i(m)) &= \begin{cases} 
-m & \text{if } j = i, \\
-\infty & \text{if } j \neq i,
\end{cases} \\
e_j b_i(m) &= \begin{cases} 
b_i(m + 1) & \text{if } j = i, \\
0 & \text{if } j \neq i,
\end{cases} \\
f_j b_i(m) &= \begin{cases} 
b_i(m - 1) & \text{if } j = i, \\
0 & \text{if } j \neq i.
\end{cases}
\end{align*}
\]
The *Kashiwara embedding theorem* asserts there is a unique strict crystal embedding of crystals
\[
B(\infty) \hookrightarrow B_i \otimes B(\infty),
\]
satisfying certain properties (see [Ka1993]). The above embedding may be iterated to obtain a new embedding
\[
B(\infty) \hookrightarrow B_{i_N} \otimes B_{i_{N-1}} \otimes \cdots \otimes B_{i_2} \otimes B_{i_1} \otimes B(\infty),
\]
which is a foundational object in the study of *polyhedral realizations of crystals* (see, for example, [NZ1997]).

```python
class Element(parent, m):
    Bases: Element
    Element of a \( B_i \) crystal.
    e(i)
    Return the action of \( e_i \) on self.
    INPUT:
    • \( i \) – An element of the index set
    EXAMPLES:

sage: B = crystals.elementary.Elementary(['E',7],1)
sage: B(3).e(1)
4
sage: B(172).e_string([1]*171)
343
sage: B(0).e(2)

epsilon(i)
Return \( \epsilon_i \) of self.
INPUT:
• \( i \) – An element of the index set
EXAMPLES:
```

Chapter 5. Comprehensive Module List

404
```python
sage: B = crystals.elementary.Elementary(['F',4],3)
sage: [[B(j).epsilon(i) for i in B.index_set()] for j in range(5)]

[-inf, -inf, 0, -inf],
[-inf, -inf, -1, -inf],
[-inf, -inf, -2, -inf],
[-inf, -inf, -3, -inf],
[-inf, -inf, -4, -inf]
```

**\( f(i) \)**

Return the action of \( f_i \) on \( self \).

**INPUT:**

- \( i \) – An element of the index set

**EXAMPLES:**

```python
sage: B = crystals.elementary.Elementary(['E',7],1)
sage: B(3).f(1)
2
sage: B(172).f_string([1]*171)
1
sage: B(0).e(2)
```

**\( \phi(i) \)**

Return \( \phi_i \) of \( self \).

**INPUT:**

- \( i \) – An element of the index set

**EXAMPLES:**

```python
sage: B = crystals.elementary.Elementary(['E',8,1],4)
sage: [[B(m).phi(j) for j in B.index_set()] for m in range(44,49)]

[-inf, -inf, -inf, -inf, 44, -inf, -inf, -inf, -inf],
[-inf, -inf, -inf, -inf, 45, -inf, -inf, -inf, -inf],
[-inf, -inf, -inf, -inf, 46, -inf, -inf, -inf, -inf],
[-inf, -inf, -inf, -inf, 47, -inf, -inf, -inf, -inf],
```

**weight()**

Return the weight of \( self \).

**EXAMPLES:**

```python
sage: B = crystals.elementary.Elementary(['C',14],12)
sage: B(-385).weight()
-385*alpha[12]
```

**weight_lattice_realization()**

Return a realization of the lattice containing the weights of \( self \).

**EXAMPLES:**

```python
sage: B = crystals.elementary.Elementary(['A',4,1], 2)
sage: B.weight_lattice_realization()
Root lattice of the Root system of type ['A', 4, 1]
```
Combinatorics, Release 10.1

class sage.combinat.crystals.elementary_crystals.RCrystal(cartan_type, weight, dual)

Bases: UniqueRepresentation, Parent

The crystal $R_\lambda$.

For a fixed weight $\lambda$, the crystal $R_\lambda = \{r_\lambda\}$ is a single element crystal with the crystal structure defined by

$$\text{wt}(r_\lambda) = \lambda, \quad e_i r_\lambda = f_i r_\lambda = 0, \quad \varepsilon_i(r_\lambda) = -\langle h_i, \lambda \rangle, \quad \varphi_i(r_\lambda) = 0,$$

where $\{h_i\}$ are the simple coroots.

Tensoring $R_\lambda$ with a crystal $B$ results in shifting the weights of the vertices in $B$ by $\lambda$ and may also cut a subset out of the original graph of $B$. That is, $\text{wt}(r_\lambda \otimes b) = \text{wt}(b) + \lambda$, where $b \in B$, provided $r_\lambda \otimes b \neq 0$. For example, the crystal graph of $B(\lambda)$ is the same as the crystal graph of $R_\lambda \otimes B(\infty)$ generated from the component $r_\lambda \otimes u_\infty$.

There is also a dual version of this crystal given by $R_\lambda^\vee = \{r_\lambda^\vee\}$ with the crystal structure defined by

$$\text{wt}(r_\lambda^\vee) = \lambda, \quad e_i r_\lambda^\vee = f_i r_\lambda^\vee = 0, \quad \varepsilon_i(r_\lambda^\vee) = 0, \quad \varphi_i(r_\lambda^\vee) = \langle h_i, \lambda \rangle.$$

INPUT:

- cartan_type – a Cartan type
- weight – an element of the weight lattice of type cartan_type
- dual – (default: False) boolean

EXAMPLES:

We check by tensoring $R_\lambda$ with $B(\infty)$ results in a component of $B(\lambda)$:

```
sage: B = crystals.infinity.Tableaux("A2")
sage: R = crystals.elementary.R("A2", B.Lambda()[1]+B.Lambda()[2])
sage: T = crystals.TensorProduct(R, B)
sage: mg = T(R.highest_weight_vector(), B.highest_weight_vector())
sage: S = T.subcrystal(generators=[mg])
sage: sorted([x.weight() for x in S], key=str)
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1),
 (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: C = crystals.Tableaux("A2", shape=[2,1])
sage: sorted([x.weight() for x in C], key=str)
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1),
 (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: GT = T.digraph(subset=S)
sage: GC = C.digraph()
sage: GT.is_isomorphic(GC, edge_labels=True)
True
```

class Element

Bases: AbstractSingleCrystalElement

Element of a $R_\lambda$ crystal.

epsilon(i)

Return $\varepsilon_i$ of self.

We have $\varepsilon_i(r_\lambda) = -\langle h_i, \lambda \rangle$ for all $i$, where $h_i$ is a simple coroot.

INPUT:

- i – An element of the index set

406 Chapter 5. Comprehensive Module List
EXAMPLES:

```python
sage: la = RootSystem(['A',2]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R("A2", la[1])
sage: r = R.highest_weight_vector()
sage: [r.epsilon(i) for i in R.index_set()]
[-1, 0]
sage: R = crystals.elementary.R("A2", la[1], dual=True)
```

\[ \phi(i) \]

Return \( \varphi_i \) of \( \text{self} \), which is 0 for all \( i \).

INPUT:

- \( i \) - An element of the index set

EXAMPLES:

```python
sage: la = RootSystem("C5").weight_lattice().fundamental_weights()
sage: r = R.highest_weight_vector()
sage: [r.phi(i) for i in R.index_set()]
[0, 0, 0, 0, 0]
```

\[ \text{weight}() \]

Return the weight of \( \text{self} \), which is always \( \lambda \).

EXAMPLES:

```python
sage: ct = CartanType(['C',5])
sage: la = RootSystem(ct).weight_lattice().fundamental_weights()
sage: t = T.highest_weight_vector()
sage: t.weight()
```

\[ \text{cardinality}() \]

Return the cardinality of \( \text{self} \), which is always 1.

EXAMPLES:

```python
sage: La = RootSystem(['C',12]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(['C',12],La[9])
sage: R.cardinality()
1
```

\[ \text{weight_lattice_realization}() \]

Return a realization of the lattice containing the weights of \( \text{self} \).
EXAMPLES:

```python
sage: La = RootSystem(['C',12]).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(['C',12], La[9])
sage: R.weight_lattice_realization()
Weight lattice of the Root system of type ['C', 12]
sage: ct = CartanMatrix([[2, -4], [-5, 2]])
sage: La = RootSystem(ct).weight_lattice().fundamental_weights()
sage: R = crystals.elementary.R(ct, La[1])
sage: R.weight_lattice_realization()
Weight lattice of the Root system of type
[ 2 -4]
[-5  2]
```

class `sage.combinat.crystals.elementary_crystals.TCrystal`(cartan_type, weight)

Bases: `UniqueRepresentation`, `Parent`

The crystal $T_\lambda$.

Let $\lambda$ be a weight. As defined in [Ka1993] the crystal $T_\lambda = \{t_\lambda\}$ is a single element crystal with the crystal structure defined by

\[
wt(t_\lambda) = \lambda, \quad e_i t_\lambda = f_i t_\lambda = 0, \quad \varepsilon_i(t_\lambda) = \varphi_i(t_\lambda) = -\infty.
\]

The crystal $T_\lambda$ shifts the weights of the vertices in a crystal $B$ by $\lambda$ when tensored with $B$, but leaves the graph structure of $B$ unchanged. That is to say, for all $b \in B$, we have $wt(b \otimes t_\lambda) = wt(b) + \lambda$.

INPUT:

- `cartan_type` – A Cartan type
- `weight` – An element of the weight lattice of type `cartan_type`

EXAMPLES:

```python
sage: ct = CartanType(['A',2])
sage: C = crystals.Tableaux(ct, shape=[1])
sage: for x in C: x.weight()
(1, 0, 0)
(0, 1, 0)
(0, 0, 1)
sage: La = RootSystem(ct).ambient_space().fundamental_weights()
sage: TLa = crystals.elementary.T(ct, 3*(La[1] + La[2]))
sage: TP = crystals.TensorProduct(TLa, C)
sage: for x in TP: x.weight()
(7, 3, 0)
(6, 4, 0)
(6, 3, 1)
sage: G = C.digraph()
sage: H = TP.digraph()
sage: G.is_isomorphic(H, edge_labels=True)
True
```

class `Element`

Bases: `AbstractSingleCrystalElement`

Element of a $T_\lambda$ crystal.
epsilon(i)

Return $\varepsilon_i$ of self, which is $-\infty$ for all $i$.

INPUT:
• $i$ – An element of the index set

EXAMPLES:

```sage
c = CartanType(['C',5])
l = RootSystem(c).weight_lattice().fundamental_weights()
T = crystals.elementary.T(c,l[4]+l[5]-l[1]-l[2])
t = T.highest_weight_vector()
[t.epsilon(i) for i in T.index_set()]
[-inf, -inf, -inf, -inf, -inf]
```

phi(i)

Return $\phi_i$ of self, which is $-\infty$ for all $i$.

INPUT:
• $i$ – An element of the index set

EXAMPLES:

```sage
c = CartanType(['C',5])
l = RootSystem(c).weight_lattice().fundamental_weights()
T = crystals.elementary.T(c,l[4]+l[5]-l[1]-l[2])
t = T.highest_weight_vector()
[t.phi(i) for i in T.index_set()]
[-inf, -inf, -inf, -inf, -inf]
```

weight()

Return the weight of self, which is always $\lambda$.

EXAMPLES:

```sage
c = CartanType(['C',5])
l = RootSystem(c).weight_lattice().fundamental_weights()
T = crystals.elementary.T(c,l[4]+l[5]-l[1]-l[2])
t = T.highest_weight_vector()
t.weight()
```

cardinality()

Return the cardinality of self, which is always 1.

EXAMPLES:

```sage
L = RootSystem(['C',12]).weight_lattice().fundamental_weights()
T = crystals.elementary.T(['C',12], L[9])
T.cardinality()
1
```

weight_lattice_realization()

Return a realization of the lattice containing the weights of self.

EXAMPLES:
5.1.48 Fast Rank Two Crystals

class sage.combinat.crystals.fast_crystals.FastCrystal(ct, shape, format)

Bases: UniqueRepresentation, Parent

An alternative implementation of rank 2 crystals. The root operators are implemented in memory by table lookup. This means that in comparison with the *CrystalsOfTableaux* class, these crystals are slow to instantiate but faster for computation. Implemented for types $A_2$, $B_2$, and $C_2$.

**INPUT:**

- cartan_type -- the Cartan type and must be either type $A_2$, $B_2$, or $C_2$
- shape -- A shape is of the form $[l_1, l_2]$ where $l_1$ and $l_2$ are either integers or (in type $B_2$) half integers such that $l_1 - l_2$ is integral. It is assumed that $l_1 \geq l_2 \geq 0$. If $l_1$ and $l_2$ are integers, this will produce a crystal isomorphic to the one obtained by `crystals.Tableaux(type, shape=[l1,l2])`. Furthermore `crystals.FastRankTwo(['B', 2], l1+1/2, l2+1/2)` produces a crystal isomorphic to the following crystal $T$:

```python
sage: ct = CartanMatrix([[2, -4], [-5, 2]])
sage: La = RootSystem(ct).weight_lattice().fundamental_weights()
sage: T = crystals.elementary.T(ct, La[1])
sage: T.weight_lattice_realization()
Weight lattice of the Root system of type
[ 2 -4]
[-5  2]
```

- format -- (default: 'string') the default representation of elements is in term of the Berenstein-Zelevinsky-Littelmann (BZL) strings $[a_1, a_2, \ldots]$ described under metapost in *crystals*. Alternative representations may be obtained by the options 'dual_string' or 'simple'. In the 'simple' format, the element is represented by an integer, and in the 'dual_string' format, it is represented by the BZL string, but the underlying decomposition of the long Weyl group element into simple reflections is changed.

```
sage: C = crystals.FastRankTwo(['B', 2], shape=[11,12])
```

```
sage: D = crystals.Spins(['B', 2])
```

```
sage: T = crystals.TensorProduct(C, D, C.list()[0], D.list()[0])
```

**EXAMPLES:**

```python
sage: C = crystals.FastRankTwo(['A', 2], shape=[2,1])
sage: c = C(0); c
[0, 0, 0]
sage: C[0].parent()
The fast crystal for A2 with shape [2,1]
sage: TestSuite(c).run()
```
Combinatorics, Release 10.1

\( e(i) \)
Return the action of \( e_i \) on self.

**EXAMPLES:**

```
sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: C(1).e(1)
[0, 0, 0]
sage: C(0).e(1) is None
True
```

\( f(i) \)
Return the action of \( f_i \) on self.

**EXAMPLES:**

```
sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: C(6).f(1)
[1, 2, 1]
sage: C(7).f(1) is None
True
```

\( \text{weight()} \)
Return the weight of self.

**EXAMPLES:**

```
sage: [v.weight() for v in crystals.FastRankTwo(['A',2], shape=[2,1])]
[(2, 1, 0), (1, 2, 0), (1, 1, 1), (1, 0, 2), (0, 1, 2), (2, 0, 1), ...
```

\( \text{cmp_elements}(x, y) \)
Return True if and only if there is a path from \( x \) to \( y \) in the crystal graph.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

**EXAMPLES:**

```
sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: x = C(0)
sage: y = C(1)
sage: C.cmp_elements(x,y)
-1
```

5.1. Comprehensive Module List 411
digraph()

Return the digraph associated to self.

EXAMPLES:

```sage
sage: C = crystals.FastRankTwo(['A',2],shape=[2,1])
sage: C.digraph()
Digraph on 8 vertices
```

## 5.1.49 Fully commutative stable Grothendieck crystal

```python
class sage.combinat.crystals.fully_commutative_stable_grothendieck.DecreasingHeckeFactorization(
    parent, t)

Bases: Element

Class of decreasing factorizations in the 0-Hecke monoid.

INPUT:
- `t` – decreasing factorization inputted as list of lists
- `max_value` – maximal value of entries

EXAMPLES:

```sage
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: t = [[3, 2], [], [2, 1]]
sage: h = DecreasingHeckeFactorization(t, 3); h
(3, 2)()(2, 1)
sage: h.excess
1
sage: h.factors
3
sage: h.max_value
3
sage: h.value
((3, 2), (), (2, 1))
sage: u = [[3, 2, 1], [3], [2, 1]]
sage: h = DecreasingHeckeFactorization(u); h
(3, 2, 1)(3)(2, 1)
sage: h.weight()
(2, 1, 3)
sage: h.parent()
Decreasing Hecke factorizations with 3 factors associated to [2, 1, 3, 2, 1] with excess 1
```
to_increasing_hecke_biword()

Return the associated increasing Hecke biword of self.

EXAMPLES:

```python
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: t = [[2], [], [2, 1], [4, 3, 1]]
sage: h = DecreasingHeckeFactorization(t, 4)
sage: h.to_increasing_hecke_biword()
[[1, 1, 1, 2, 2, 4], [1, 3, 4, 1, 2, 2]]
```

to_word()

Return the word associated to self in the 0-Hecke monoid.

EXAMPLES:

```python
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: t = [[2], [], [2, 1], [4, 3, 1]]
sage: h = DecreasingHeckeFactorization(t)
sage: h.to_word()
[2, 2, 1, 4, 3, 1]
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: t = [[2], [2, 1], [], [4, 3, 1]]
sage: h = DecreasingHeckeFactorization(t, 6)
sage: h.weight()
(3, 0, 2, 1)
```

class sage.combinat.crystals.fully_commutative_stable_grothendieck.DecreasingHeckeFactorizations(w, factors, excess)

Bases: UniqueRepresentation, Parent

Set of decreasing factorizations in the 0-Hecke monoid.

INPUT:

- w – an element in the symmetric group
- factors – the number of factors in the factorization
- excess – the total number of letters in the factorization minus the length of a reduced word for w

EXAMPLES:

```python
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorizations
```
```
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2, 1])
sage: F = DecreasingHeckeFactorizations(w, 3, 3);
Decreasing Hecke factorizations with 3 factors associated to [1, 3, 2, 1] with
excess 3
sage: F.list()
[(3, 1)(3, 1)(3, 2, 1), (3, 1)(3, 2, 1)(2, 1), (3, 2, 1)(2, 1)(2, 1)]
```

Element

alias of `DecreasingHeckeFactorization`

`list()`

Return list of all elements of `self`.

EXAMPLES:
```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorizations
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2, 1])
sage: F = DecreasingHeckeFactorizations(w, 3, 3)
sage: F.list()
[(3, 1)(3, 1)(3, 2, 1), (3, 1)(3, 2, 1)(2, 1), (3, 2, 1)(2, 1)(2, 1)]
```

```
class sage.combinat.crystals.fully_commutative_stable_grothendieck.FullyCommutativeStableGrothendieckCrystal

Bases: UniqueRepresentation, Parent

The crystal on fully commutative decreasing factorizations in the 0-Hecke monoid, as introduced by [MPPS2020].

INPUT:

- `w`: an element in the symmetric group or a (skew) shape
- `factors`: the number of factors in the factorization
- `excess`: the total number of letters in the factorization minus the length of a reduced word for `w`
- `shape`: (default: `False`) indicator for input `w`, `True` if `w` is entered as a (skew) shape and `False` otherwise.

EXAMPLES:
```
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2); B
Fully commutative stable Grothendieck crystal of type A_2 associated to [1, 3, 2] with excess 2
sage: B.list()
[(1)(3, 1)(3, 2),
 (3, 1)(1)(3, 2),
 (3, 1)(3, 1)(2),
 (3)(3, 1)(3, 2),
]```
We can also access the crystal by specifying a skew shape:

```python
sage: crystals.FullyCommutativeStableGrothendieck([[2, 2], [1]], 4, 1, shape=True)
```

Fully commutative stable Grothendieck crystal of type $A_3$ associated to $[2, 1, 3]$ with excess 1

We can compute the highest weight elements:

```python
sage: hw = [w for w in B if w.is_highest_weight()]
sage: hw
[(1)(3, 1)(3, 2), (3)(3, 1)(3, 2)]
sage: hw[0].weight()
(2, 2, 1)
```

The crystal operators themselves move elements between adjacent factors:

```python
sage: b = hw[0]; b
(1)(3, 1)(3, 2)
sage: b.f(2)
(3, 1)(1)(3, 2)
```

class `Element(parent, t)`

Bases: `DecreasingHeckeFactorization`

Create an instance `self` of element `t`.

This method takes into account the constraints on the word, the number of factors, and excess statistic associated to the parent class.

EXAMPLES:

```python
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[3], [4, 2, 1], [4, 3, 1]])
```

`bracketing(i)`

Remove all bracketed letters between $i$-th and $(i + 1)$-th entry.

EXAMPLES:

```python
sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([3, 2, 1, 4, 3])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: h = B([[3], [4, 2, 1], [4, 3, 1]])
```
\textbf{Combinatorics, Release 10.1}

(continued from previous page)

\begin{verbatim}
sage: h.bracketing(1)
[[], []]
sage: h.bracketing(2)
[[], [2, 1]]
\end{verbatim}

\textbf{\texttt{e(i)}}

Return the action of $e_i$ on \texttt{self} using the rules described in \cite{MPPS2020}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([2, 1, 4, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 4, 3)
sage: h = B([[4, 2], [4, 2, 1], [3, 2], [2]]); h
(4, 2)(4, 2, 1)(3, 2)(2)
sage: h.e(1)
(4, 2)(4, 2, 1)(3)(3, 2)
sage: h.e(2)
(4, 2)(2, 1)(4, 3, 2)(2)
sage: h.e(3)
\end{verbatim}

\textbf{\texttt{f(i)}}

Return the action of $f_i$ on \texttt{self} using the rules described in \cite{MPPS2020}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: S = SymmetricGroup(4+1)
sage: w = S.from_reduced_word([3, 2, 1, 4, 3])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 4, 3)
sage: h = B([[3, 2], [2, 1], [4, 3], [3, 1]]); h
(3, 2)(2, 1)(4, 3)(3, 1)
sage: h.f(1)
(3, 2)(2, 1)(4, 3, 1)(3)
sage: h.f(2)
sage: h.f(3)
\end{verbatim}

\textbf{\texttt{module_generators()}}

Return generators for \texttt{self} as a crystal.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: S = SymmetricGroup(3+1)
sage: w = S.from_reduced_word([1, 3, 2])
sage: B = crystals.FullyCommutativeStableGrothendieck(w, 3, 2)
sage: B.module_generators
sage: C = crystals.FullyCommutativeStableGrothendieck(w, 4, 2)
sage: C.module_generators
\end{verbatim}
5.1.50 Crystals of Generalized Young Walls

AUTHORS:

• Lucas David-Roesler: Initial version
• Ben Salisbury: Initial version
• Travis Scrimshaw: Initial version

Generalized Young walls are certain generalizations of Young tableaux introduced in [KS2010] and designed to be a realization of the crystals $\mathcal{B}(\infty)$ and $\mathcal{B}(\lambda)$ in type $A_n^{(1)}$.

REFERENCES:

• [KLRS2016]
• [KS2010]

class sage.combinat.crystals.generalized_young_walls.CrystalOfGeneralizedYoungWalls(n, La)
   Bases: InfinityCrystalOfGeneralizedYoungWalls

The crystal $\mathcal{Y}(\lambda)$ of generalized Young walls of the given type with highest weight $\lambda$.

These were characterized in Theorem 4.1 of [KS2010]. See GeneralizedYoungWall.

in_highest_weight_crystal()

INPUT:

• $n$ – type $A_n^{(1)}$
• weight – dominant integral weight

EXAMPLES:

sage: La = RootSystem(['A',3,1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: YLa = crystals.GeneralizedYoungWalls(3,La)
sage: y = YLa([[0],[1,0,3,2,1],[2,1,0],[3]])
sage: y.pp()
   3
   0|1|2|
1|2|3|0|1|
   0|
sage: y.weight()
sage: y.in_highest_weight_crystal(La)
   True
sage: y.f(1)
   [[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1]]
sage: y.f(1).f(1)
   [[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1], [], [], [1]]
sage: y.f(1)
   [[0], [1, 0, 3, 2, 1], [2, 1, 0], [3], [], [1], [], [], [1]]

sage: LS = crystals.LSPaths(['A',3,1],[1,0,0,0])

(continues on next page)
sage: C = LS.subcrystal(max_depth=4)
sage: G = LS.digraph(subset=C)
sage: P = RootSystem(['A',3,1]).weight_lattice(extended=True)
sage: La = P.fundamental_weights()
sage: YW = crystals.GeneralizedYoungWalls(3,La[0])
sage: CW = YW.subcrystal(max_depth=4)
sage: GW = YW.digraph(subset=CW)
sage: GW.is_isomorphic(G,edge_labels=True)
True
To display the crystal down to a specified depth:

sage: S = YLa.subcrystal(max_depth=4)
sage: G = YLa.digraph(subset=S)
sage: view(G)  # not tested

Element

alias of CrystalOfGeneralizedYoungWallsElement

class sage.combinat.crystals.generalized_young_walls.CrystalOfGeneralizedYoungWallsElement(parent, data)

Bases: GeneralizedYoungWall

Element of the highest weight crystal of generalized Young walls.

e(i)

Compute the action of $e_i$ restricted to the highest weight crystal.

EXAMPLES:

sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: hwy = crystals.GeneralizedYoungWalls(2,La)([[[],[1,0],[2,1]]])
sage: hwy.e(1)
[[[], [1, 0], [2]]]
sage: hwy.e(2)
sage: hwy.e(3)

f(i)

Compute the action of $f_i$ restricted to the highest weight crystal.

EXAMPLES:

sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: GYW = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = GYW([[[],[1,0],[2,1]])
sage: y.f(1)
[[[], [1, 0], [2, 1], []], [1]]
sage: hwy = crystals.GeneralizedYoungWalls(2,La)([[[],[1,0],[2,1]])
sage: hwy.f(1)

phi(i)

Return the value $\varepsilon_i(Y) + \langle h_i, \text{wt}(Y) \rangle$, where $h_i$ is the $i$-th simple coroot and $Y$ is self.
EXAMPLES:

```python
sage: La = RootSystem(['A',3,1]).weight_lattice(extended=True).fundamental_weights()
sage: y = crystals.GeneralizedYoungWalls(3,La[0])([])
sage: y.phi(1)
0
sage: y.phi(2)
0
```

weight()

Return the weight of self in the highest weight crystal as an element of the weight lattice $\bigoplus_{i=0}^{n} \mathbb{Z} \Lambda_i$.

EXAMPLES:

```python
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: hwy = crystals.GeneralizedYoungWalls(2,La)([[[],[1,0],[2,1]])
sage: hwy.weight()
```

class sage.combinat.crystals.generalized_young_walls.GeneralizedYoungWall(parent, data)

Bases: CombinatorialElement

A generalized Young wall.

For more information, see `InfinityCrystalOfGeneralizedYoungWalls`.

EXAMPLES:

```python
sage: Y = crystals.infinity.GeneralizedYoungWalls(4)
sage: mg = Y.module_generators[0]; mg.pp()
0
sage: mg.f_string([1,2,0,1]).pp()
|1|2|
\theta|1|
| |
```

Epsilon()

Return $\sum_{i=0}^{n} \varepsilon_i(Y) \Lambda_i$ where $Y$ is self.

EXAMPLES:

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0],[1,0,3,2],[2,1],[3,2,\rightarrow1,0,3,2],[0],[[],[2]])
sage: y.Epsilon()
Lambda[0] + 3*Lambda[2]
```

Phi()

Return $\sum_{i=0}^{n} \phi_i(Y) \Lambda_i$ where $Y$ is self.

EXAMPLES:

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0],[1,0,3,2],[2,1],[3,2,\rightarrow1,0,3,2],[0],[[],[2]])
sage: y.Phi()
```

(continues on next page)
\[-\Lambda[0] + 3\Lambda[1] - \Lambda[2] + 3\Lambda[3]\]

```
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([],[1,0,3,2],[2,1],[3,2,1,0,3,2],[0],[0,2])
sage: x.Phi()
2\Lambda[0] + \Lambda[1] - \Lambda[2] + \Lambda[3]
```

\(a(i, k)\)

Return the number \(a_i(k)\) of \(i\)-colored boxes in the \(k\)-th column of \(\text{self}\).

EXAMPLES:

```
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([0],[1,0,3,2],[2,1],[3,2,1,0,3,2],[0],[0,2])
sage: y.a(1,2)
1
sage: y.a(0,2)
1
sage: y.a(3,2)
0
```

\(\text{column}(k)\)

Return the list of boxes from the \(k\)-th column of \(\text{self}\).

EXAMPLES:

```
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([0],[1,0,3,2],[2,1],[3,2,1,0,3,2],[0],[0,2])
sage: y.column(2)
[None, 0, 1, 2, None, None, None]
sage: hw = crystals.infinity.GeneralizedYoungWalls(5)([])
sage: hw.column(1)
[]
```

\(\text{content}()\)

Return total number of blocks in \(\text{self}\).

EXAMPLES:

```
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([0],[1,0],[2,1,0,2],[1])
sage: y.content()
8
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([1,0,3,2],[2,1],[3,2,1,0,3,2],[0],[0,2])
sage: x.content()
13
```

\(e(i)\)

Return the application of the Kashiwara raising operator \(e_i\) on \(\text{self}\).

This will remove the \(i\)-colored box corresponding to the rightmost \(+\) in \(\text{self}.\text{signature}(i)\).
EXAMPLES:

```python
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [], [], [2]])
sage: x.e(2)
[[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2]]
sage: _.e(2)
[[], [1, 0, 3], [2, 1], [3, 2, 1, 0, 3, 2]]
sage: _.e(2)
[[], [1, 0, 3], [2, 1], [3, 2, 1, 0, 3]]
sage: _.e(2)
```

\(\epsilon(i)\)

Return the number of \(i\)-colored arrows in the \(i\)-string above \(self\) in the crystal graph.

EXAMPLES:

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [], [], [2]])
sage: y.epsilon(1)
0
sage: y.epsilon(2)
3
sage: y.epsilon(0)
0
```

\(f(i)\)

Return the application of the Kashiwara lowering operator \(f_i\) on \(self\).

This will add an \(i\)-colored colored box to the site corresponding to the leftmost plus in \(self\.

```signature(i)\)

EXAMPLES:

```python
sage: hw = crystals.infinity.GeneralizedYoungWalls(2)([[0], [1, 0], [2, 1, 0, 2], [], [1]])
sage: hw.f(1)
[[], [1]]
sage: _.f(2)
[[], [1, 2]]
sage: _.f(0)
[[], [1, 0], [2]]
sage: _.f(0)
[[0], [1, 0], [2]]
```

\(generate\_signature(i)\)

The \(i\)-signature of \(self\) (with whitespace where cancellation occurs) together with the unreduced sequence from \(+, -\). The result also records to the row and column position of the sign.

EXAMPLES:

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0], [1, 0], [2, 1, 0, 2], [], [1]])
sage: y.generate_signature(1)
([['+', 2, 5], ['-', 4, 1]], ' ')
```
**in_highest_weight_crystal**($\La$)

Return a boolean indicating if the generalized Young wall element is in the highest weight crystal cut out by the given highest weight $\La$.

By Theorem 4.1 of [KS2010], a generalized Young wall $Y$ represents a vertex in the highest weight crystal $Y(\lambda)$, with $\lambda = \Lambda_i + \Lambda_{i-1} + \ldots + \Lambda_1$, a dominant integral weight of level $\ell > 0$, if it satisfies the following condition. For each positive integer $k$, if there exists $j \in I$ such that $a_j(k) - a_j-1(k) > 0$, then for some $p = 1, \ldots, \ell$,

$$j + k \equiv i_p + 1 \mod n + 1 \text{ and } a_j(k) - a_j-1(k) \leq \lambda(h_{i_p}),$$

where $\{h_0, h_1, \ldots, h_n\}$ is the set of simple coroots attached to $A_n^{(1)}$.

**EXAMPLES:**

```python
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()[1]
sage: GYW = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = GYW([[]],[1,0],[2,1])
sage: y.in_highest_weight_crystal(La)
True
sage: x = GYW([[]],[1],[2],[1],[1],[2])
sage: x.in_highest_weight_crystal(La)
False
```

**latex_large()**

Generate LaTeX code for self but the output is larger. Requires TikZ.

**EXAMPLES:**

```python
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1,0,3,2], [2,1], [3,2,1,0,3,2], [], [], [2]])
sage: x.latex_large()
'\begin{tikzpicture}[baseline=5,scale=.45] \n \foreach \x [count=\s from 0] \n in \n{\{\},\{1,0,3,2\},\{2,1\},\{3,2,1,0,3,2\},\{\},\{\},\{\}} \n{\foreach \y [\n=count=\t from 0] \n from 0} in \x \n{\node[font=\scriptsize] at (-\t,\s) {$\y$}; \n \draw \n(-\t+.5,\s+.5) to (-\t-.5,\s+.5); \n \draw (-\t+.5,\s-.5) to (-\t-.5,\s-.5); \n \draw (-\t-.5,\s-.5) to (-\t-.5,\s+.5); } \n \draw[-,thick] \n(-.5,\s+1) to (.5,\s-.5) to (-.5,\s-.5); } \n\end{tikzpicture}'
```

**number_of_parts()**

Return the value of $\mathcal{N}$ on self.

In [KLRS2016], the statistic $\mathcal{N}$ was defined on elements in $\mathcal{Y}(\infty)$ which counts how many parts are in the corresponding Kostant partition. Specifically, the computation of $\mathcal{N}(Y)$ is done using the following algorithm:

- If $Y$ has no rows whose right-most box is colored $n$ and such that the length of this row is a multiple of $n + 1$, then $\mathcal{N}(Y)$ is the total number of distinct rows in $Y$, not counting multiplicity.
- Otherwise, search $Y$ for the longest row such that the right-most box is colored $n$ and such that the total number of boxes in the row is $k(n + 1)$ for some $k \geq 1$. Replace this row by $n + 1$ distinct rows of length $k$; reordering all rows, if necessary, so that the result is a proper wall. (Note that the resulting wall may no longer be reduced.) Repeat the search and replace process for all other rows of the above form for each $k' < k$. Then $\mathcal{N}(Y)$ is the number of distinct rows, not counting multiplicity, in the wall resulting from this process.

**EXAMPLES:**

```python
422 Chapter 5. Comprehensive Module List
```
sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: y = Y([[],[],[],[0],[0],[0],[0])
sage: y.number_of_parts()
1
sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: y = Y([[0],[1,0],[0],[0],[1,0],[0],[0]])
sage: y.number_of_parts()
4
sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = Y([[0,1],[0],[2,1],[0,1],[0],[0],[0]])
sage: y.number_of_parts()
8

\phi(i)

Return the value $\varepsilon_i(Y) + \langle h_i, \text{wt}(Y) \rangle$, where $h_i$ is the $i$-th simple coroot and $Y$ is self.

EXAMPLES:

sage: y = crystals.infinity.GeneralizedYoungWalls(3)([[0],[1,0,3,2],[2,1],[0,3,2],[0],[2]])
sage: y.phi(1)
3
sage: y.phi(2)
-1

pp()

Pretty print self.

EXAMPLES:

sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0,2,1],[1,0,2,1,0],[0],[0,2,1],[0],[0]])
sage: y.pp()

1|
| 2 0 1|
| 0|
| 0 1 2 0 1|
| 1 2 1|

raw_signature(i)

Return the sequence from \{+, -\} obtained from all $i$-admissible slots and removable $i$-boxes without canceling any $(+, -)$-pairs. The result also notes the row and column of the sign.

EXAMPLES:

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[0],[1,0,3,2],[2,1],[0,3,2],[0],[2]])
sage: x.raw_signature(2)
[['-', 3, 6], ['-', 1, 4], ['-', 6, 1]]
signature(i)

Return the $i$-signature of self.

The signature is obtained by reading self in columns bottom to top starting from the left. Then add a $-$ at every $i$-box which may be removed from self and still obtain a legal generalized Young wall, and add a $+$ at each site for which an $i$-box may be added and still obtain a valid generalized Young wall. Then successively cancel any $(+,-)$-pair to obtain a sequence of the form $-\cdots - + \cdots +$. This resulting sequence is the output.

EXAMPLES:

```python
sage: y = crystals.infinity.GeneralizedYoungWalls(2)([[0], [1, 0], [2, 1, 0, 2], [], [1]])
sage: y.signature(1)
''

sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [], [], [2]])
sage: x.signature(2)
'---'
```

sum_of_weighted_row_lengths()

Return the value of $\mathcal{M}$ on self.

Let $\mathcal{Y}_0 \subset \mathcal{Y}(\infty)$ be the set of generalized Young walls which have no rows whose right-most box is colored $n$. For $Y \in \mathcal{Y}_0$,

$$\mathcal{M}(Y) = \sum_{i=1}^{n} (i + 1)M_i(Y),$$

where $M_i(Y)$ is the number of nonempty rows in $Y$ whose right-most box is colored $i - 1$.

EXAMPLES:

```python
sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: y = Y([[0, 2, 1, 0, 2], [1, 0, 2], [], [0, 2], [1, 0], [], [0], [1, 0]])
sage: y.sum_of_weighted_row_lengths()
15
```

weight(root_lattice=False)

Return the weight of self.

INPUT:

- root_lattice – boolean determining whether weight should appear in root lattice or not in extended affine weight lattice.

EXAMPLES:

```python
sage: x = crystals.infinity.GeneralizedYoungWalls(3)([[], [1, 0, 3, 2], [2, 1], [3, 2, 1, 0, 3, 2], [], [], [2]])
sage: x.weight()
sage: x.weight(root_lattice=True)
```
class sage.combinat.crystals.generalized_young_walls.InfinityCrystalOfGeneralizedYoungWalls(n, category)

Bases: UniqueRepresentation, Parent

The crystal $\mathcal{Y}(\infty)$ of generalized Young walls of type $A_n^{(1)}$ as defined in [KS2010].

A generalized Young wall is a collection of boxes stacked on a fixed board, such that color of the box at the site located in the $j$-th row from the bottom and the $i$-th column from the right is $j - 1 \mod n + 1$. There are several growth conditions on elements in $Y \in \mathcal{Y}(\infty)$:

- Walls grow in rows from right to left. That is, for every box $y \in Y$ that is not in the rightmost column, there must be a box immediately to the right of $y$.
- For all $p > q$ such that $p - q \equiv 0 \mod n + 1$, the $p$-th row has most as many boxes as the $q$-th row.
- There does not exist a column in the walls such that if one $i$-colored box, for every $i = 0, 1, \ldots, n$, is removed from that column, then the result satisfies the above conditions.

There is a crystal structure on $\mathcal{Y}(\infty)$ defined as follows. Define maps

$$e_i, f_i : \mathcal{Y}(\infty) \rightarrow \mathcal{Y}(\infty) \sqcup \{0\}, \quad \varepsilon_i, \varphi_i : \mathcal{Y}(\infty) \rightarrow \mathbb{Z}, \quad wt : \mathcal{Y}(\infty) \rightarrow \bigoplus_{i=0}^{n} \mathbb{Z}\Lambda_i \oplus \mathbb{Z}\delta,$$

by

$$wt(Y) = -\sum_{i=0}^{n} m_i(Y)\alpha_i,$$

where $m_i(Y)$ is the number of $i$-boxes in $Y$, $\varepsilon_i(Y)$ is the number of $-i$ in the $i$-signature of $Y$, and

$$\varphi_i(Y) = \varepsilon_i(Y) + \langle h_i, wt(Y) \rangle.$$

See `GeneralizedYoungWall.e()`, `GeneralizedYoungWall.f()`, and `GeneralizedYoungWall.signature()` for more about $e_i$, $f_i$, and $i$-signatures.

INPUT:

- $n$ – type $A_n^{(1)}$

EXAMPLES:

```python
sage: Yinf = crystals.infinity.GeneralizedYoungWalls(3)
sage: y = Yinf([[0], [1, 0, 3, 2], [], [3, 2, 1], [0], [1, 0]])
sage: y.pp()
0|1|
0|
1|2|3|
| 2|3|0|1|
0|
sage: y.weight(root_lattice=True)
sage: y.f(0)
[[0], [1, 0, 3, 2], [], [3, 2, 1], [0], [1, 0], [], [], []]
sage: y.e(0).pp()
0|1|
```

(continues on next page)
To display the crystal down to depth 3:

```
sage: S = Yinf.subcrystal(max_depth=3)
sage: G = Yinf.digraph(subset=S) # long time
sage: view(G) # not tested
```

**5.1.51 Highest weight crystals**

**class** `sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE(dominant_weight)`

Bases: `TensorProductOfCrystals`

Commonalities for all finite dimensional type $E$ highest weight crystals.

Subclasses should setup an attribute `column_crystal` in their `__init__` method before calling the `__init__` method of this class.

**Element**

alias of `GeneralizedYoungWall`

**module_generator()**

This yields the module generator (or highest weight element) of the classical crystal of given dominant weight in self.

**EXAMPLES:**

```
sage: C=CartanType(['E',6])
sage: La=C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[2])
sage: T.module_generator()
[[2, -1], (1,)]
sage: T = crystals.HighestWeight(0*La[2])
sage: T.module_generator()
[]
sage: C=CartanType(['E',7])
sage: La=C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.module_generator()
[(-7, 1), (7,)]
```

**class** `sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE6(dominant_weight)`

Bases: `FiniteDimensionalHighestWeightCrystal_TypeE`

Class of finite dimensional highest weight crystals of type $E_6$.

**EXAMPLES:**
```python
sage: C = CartanType(['E', 6])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[2]); T
Finite dimensional highest weight crystal of type ['E', 6] and highest weight → Lambda[2]
sage: B1 = T.column_crystal[1]; B1
The crystal of letters for type ['E', 6]
sage: B6 = T.column_crystal[6]; B6
The crystal of letters for type ['E', 6] (dual)
sage: t = T(B6([-1]), B1([-1, 3])); t
[(-1,), (-1, 3)]
sage: [t.epsilon(i) for i in T.index_set()]
[2, 0, 0, 0, 0, 0]
sage: [t.phi(i) for i in T.index_set()]
[0, 0, 1, 0, 0, 0]
sage: TestSuite(t).run()
```

```python
class sage.combinat.crystals.highest_weight_crystals.FiniteDimensionalHighestWeightCrystal_TypeE7(dominant_weight)

Bases: FiniteDimensionalHighestWeightCrystal_TypeE

Class of finite dimensional highest weight crystals of type $E_7$.

EXAMPLES:
```
```python
sage: C = CartanType(['E', 7])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
133
sage: B7 = T.column_crystal[7]; B7
The crystal of letters for type ['E', 7]
sage: t = T(B7([-5, 6]), B7([-2, 3])); t
[(-5, 6), (-2, 3)]
sage: [t.epsilon(i) for i in T.index_set()]
[0, 1, 0, 0, 1, 0, 0]
sage: [t.phi(i) for i in T.index_set()]
[0, 0, 1, 0, 0, 1, 0]
sage: TestSuite(t).run()
```

```python
sage.combinat.crystals.highest_weight_crystals.HighestWeightCrystal(dominant_weight, model=None)

Return the highest weight crystal of highest weight dominant_weight of the given model.

INPUT:

- dominant_weight – a dominant weight
- model – (optional) if not specified, then we have the following default models:
  - types $A_n, B_n, C_n, D_n, G_2$ - tableaux
  - types $E_{6,7}$ - type $E$ finite dimensional crystal
  - all other types - LS paths
otherwise can be one of the following:
  - 'Tableaux' - KN tableaux
```

5.1. Comprehensive Module List

427
- 'TypeE' - type $E$ finite dimensional crystal
- 'NakajimaMonomials' - Nakajima monomials
- 'LSPaths' - LS paths
- 'AlcovePaths' - alcove paths
- 'GeneralizedYoungWalls' - generalized Young walls
- 'RiggedConfigurations' - rigged configurations

EXAMPLES:

```python
sage: La = RootSystem(['A',2]).weight_lattice().fundamental_weights()
sage: wt = La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['A', 2] and shape(s) [[2, 1]]
```

```python
sage: La = RootSystem(['C',2]).weight_lattice().fundamental_weights()
sage: wt = 5*La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['C', 2] and shape(s) [[6, 1]]
```

```python
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: wt = La[1] + La[2]
sage: crystals.HighestWeight(wt)
The crystal of tableaux of type ['B', 2] and shape(s) [[3/2, 1/2]]
```

Some type $E$ examples:

```python
sage: C = CartanType(['E',6])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
27
sage: T = crystals.HighestWeight(La[6])
sage: T.cardinality()
27
sage: T = crystals.HighestWeight(La[2])
sage: T.cardinality()
78
sage: T = crystals.HighestWeight(La[4])
sage: T.cardinality()
2925
sage: T = crystals.HighestWeight(La[3])
sage: T.cardinality()
351
sage: T = crystals.HighestWeight(La[5])
sage: T.cardinality()
351

sage: C = CartanType(['E',7])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: T.cardinality()
133
```

(continues on next page)
An example with an affine type:

```python
sage: C = CartanType(['C',2,1])
sage: La = C.root_system().weight_lattice().fundamental_weights()
sage: T = crystals.HighestWeight(La[1])
sage: sorted(T.subcrystal(max_depth=3), key=str)
 (-Lambda[0] + Lambda[1] + Lambda[2] - delta,),
 (2*Lambda[0] - Lambda[1],),
 (Lambda[0] + Lambda[1] - Lambda[2],),
 (Lambda[0] - Lambda[1] + Lambda[2],),
 (Lambda[1],)]
```

Using the various models:

```python
sage: La = RootSystem(['F',4]).weight_lattice().fundamental_weights()
sage: crystals.HighestWeight(wt)
The crystal of LS paths of type ['F', 4] and weight Lambda[1] + Lambda[4]
sage: crystals.HighestWeight(wt, model='NakajimaMonomials')
Highest weight crystal of modified Nakajima monomials of
sage: crystals.HighestWeight(wt, model='AlcovePaths')
sage: crystals.HighestWeight(wt, model='RiggedConfigurations')
sage: La = RootSystem(['A',3,1]).weight_lattice().fundamental_weights()
sage: wt = La[0] + La[2]
sage: crystals.HighestWeight(wt, model='GeneralizedYoungWalls')
Highest weight crystal of generalized Young walls of
  Cartan type ['A', 3, 1] and highest weight Lambda[0] + Lambda[2]
```

5.1. Comprehensive Module List
5.1.52 Induced Crystals

We construct a crystal structure on a set induced by a bijection $\Phi$.

AUTHORS:

class sage.combinat.crystals.induced_structure.InducedCrystal($X$, $phi$, $inverse$)

Bases: UniqueRepresentation, Parent

A crystal induced from an injection.

Let $X$ be a set and let $C$ be crystal and consider any injection $\Phi : X \rightarrow C$. We induce a crystal structure on $X$ by considering $\Phi$ to be a crystal morphism.

Alternatively we can induce a crystal structure on some (sub)set of $X$ by considering an injection $\Phi : C \rightarrow X$ considered as a crystal morphism. This form is also useful when the set $X$ is not explicitly known.

INPUT:

- $X$ – the base set
- $phi$ – the map $\Phi$
- $inverse$ – (optional) the inverse map $\Phi^{-1}$
- $from\_crystal$ – (default: False) if the induced structure is of the second type $\Phi : C \rightarrow X$

EXAMPLES:

We construct a crystal structure of Gelfand-Tsetlin patterns by going through their bijection with semistandard tableaux:

```python
sage: D = crystals.Tableaux(['A', 3], shapes=PartitionsInBox(4, 3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())

sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: I.digraph().is_isomorphic(D.digraph(), edge_labels=True)
True
```

Now we construct the above example but inducing the structure going the other way (from tableaux to Gelfand-Tsetlin patterns). This can also give us more information coming from the crystal.

```python
sage: D2 = crystals.Tableaux(['A', 3], shapes=PartitionsInBox(4, 1))
sage: G2 = GelfandTsetlinPatterns(4, 1)
sage: phi2 = lambda x: D2(x.to_tableau())

sage: phi2_inv = lambda x: G2(x.to_tableau())
sage: I2 = crystals.Induced(D2, phi2_inv, phi2, from_crystal=True)
sage: I2.module_generators
([[[0, 0, 0, 0], [0, 0, 0], [0, 0], [0]],
  [[1, 0, 0, 0], [1, 0, 0], [1, 0], [1]],
  [[1, 1, 0, 0], [1, 1, 0], [1, 1], [1]],
  [[1, 1, 1, 0], [1, 1, 1], [1, 1], [1]],
  [[1, 1, 1, 1], [1, 1, 1], [1, 1], [1]]])
```

We check an example when the codomain is larger than the domain (although here the crystal structure is trivial):
sage: P = Permutations(4)
sage: D = crystals.Tableaux(['A',3], shapes=Partitions(4))
sage: T = crystals.TensorProduct(D, D)
sage: phi = lambda p: T(D(RSK(p)[0]), D(RSK(p)[1]))

sage: phi_inv = lambda d: RSK_inverse(d[0].to_tableau(), d[1].to_tableau(), output='permutation')

sage: all(phi_inv(phi(p)) == p for p in P)  # Check it really is the inverse
True

sage: I = crystals.Induced(P, phi, phi_inv)

We construct an example without a specified inverse map:

sage: X = Words(2,4)
sage: L = crystals.Letters(['A',1])
sage: T = crystals.TensorProduct(*[L]*4)
sage: Phi = lambda x : T(*[L(i) for i in x])

sage: I = crystals.Induced(X, Phi)

class Element

    Bases: ElementWrapper

    An element of an induced crystal.

    e(i)

        Return $e_i$ of self.

        EXAMPLES:

        sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
        sage: G = GelfandTsetlinPatterns(4, 3)
        sage: phi = lambda x : D(x.to_tableau())
        sage: phi_inv = lambda x : G(x.to_tableau())
        sage: I = crystals.Induced(G, phi, phi_inv)
        sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
        sage: elt.e(1)
        [[1, 1, 0, 0], [1, 1, 0], [1, 1], [1]]
        sage: elt.e(2)
        [[1, 1, 0, 0], [1, 1, 0], [1, 1], [1]]
        sage: elt.e(3)

    epsilon(i)

        Return $\varepsilon_i$ of self.

        EXAMPLES:

        sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
        sage: G = GelfandTsetlinPatterns(4, 3)
        sage: phi = lambda x : D(x.to_tableau())
        sage: phi_inv = lambda x : G(x.to_tableau())
        sage: I = crystals.Induced(G, phi, phi_inv)
        sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])

(continues on next page)
sage: [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]

f(i)

Return \( f_i \) of self.

EXAMPLES:

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.f(1)
[[1, 1, 0, 0], [1, 1, 0], [1, 0], [0]]
sage: elt.f(2)
sage: elt.f(3)
[[1, 1, 0, 0], [1, 0, 0], [1, 0], [1]]

phi()

Return \( \varphi \) of self.

EXAMPLES:

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: [elt.phi(i) for i in I.index_set()]
[1, 0, 1]

weight()

Return the weight of self.

EXAMPLES:

sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,3))
sage: G = GelfandTsetlinPatterns(4, 3)
sage: phi = lambda x: D(x.to_tableau())
sage: phi_inv = lambda x: G(x.to_tableau())
sage: I = crystals.Induced(G, phi, phi_inv)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.weight()
(1, 0, 1)

cardinality()

Return the cardinality of self.

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: P = Permutations(4)
sage: D = crystals.Tableaux(['A',3], shapes=Partitions(4))
sage: T = crystals.TensorProduct(D, D)
sage: phi = lambda p: T(D(RSK(p)[0]), D(RSK(p)[1]))
sage: phi_inv = lambda d: RSK_inverse(d[0].to_tableau(), d[1].to_tableau(), output='permutation')
sage: I = crystals.Induced(P, phi, phi_inv)
sage: I.cardinality() == factorial(4)
True
```

```python
class sage.combinat.crystals.induced_structure.InducedFromCrystal(X, phi, inverse)
    Bases: UniqueRepresentation, Parent
    A crystal induced from an injection.
    Alternatively we can induce a crystal structure on some (sub)set of \( X \) by considering an injection \( \Phi : C \rightarrow X \) considered as a crystal morphism.
    See also:
    InducedCrystal
    INPUT:
    \- \( X \) – the base set
    \- \( \phi \) – the map \( \Phi \)
    \- \( \text{inverse} \) – (optional) the inverse map \( \Phi^{-1} \)
    EXAMPLES:
    We construct a crystal structure on generalized permutations with a fixed first row by using RSK:
    ```python
    sage: C = crystals.Tableaux(['A',3], shape=[2,1])
sage: def psi(x):
        ...:    ret = RSK_inverse(x.to_tableau(), Tableau([[1,1],[2]]))
        ...:    return (tuple(ret[0]), tuple(ret[1]))
    sage: def psi_inv(x):
    ...:    return D(G(x).to_tableau())
    sage: I = crystals.Induced(D, psi, psi_inv, from_crystal=True)
    sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
    sage: elt.e(1)
    sage: elt.e(2)
    ```
```

5.1. Comprehensive Module List 433
epsilon(i)

Return $\varepsilon_i$ of self.

EXAMPLES:

```python
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]
```

f(i)

Return $f_i$ of self.

EXAMPLES:

```python
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.f(1)
[[1, 1, 0, 0], [1, 1, 0], [1, 0], [0]]
sage: elt.f(2)
[[1, 1, 0, 0], [1, 0, 0], [1, 0], [1]]
```

phi(i)

Return $\varphi_i$ of self.

EXAMPLES:

```python
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: [elt.epsilon(i) for i in I.index_set()]
[0, 1, 0]
```

weight()

Return the weight of self.

EXAMPLES:
sage: D = crystals.Tableaux(['A',3], shapes=PartitionsInBox(4,1))
sage: G = GelfandTsetlinPatterns(4, 1)
sage: def phi(x): return G(x.to_tableau())
sage: def phi_inv(x): return D(G(x).to_tableau())
sage: I = crystals.Induced(D, phi, phi_inv, from_crystal=True)
sage: elt = I([[1, 1, 0, 0], [1, 1, 0], [1, 0], [1]])
sage: elt.weight()
(1, 0, 1, 0)

cardinality()

Return the cardinality of self.

EXAMPLES:

sage: C = crystals.Tableaux(['A',3], shape=[2,1])
sage: def psi(x):
....:     ret = RSK_inverse(x.to_tableau(), Tableau([[1,1],[2]]))
....:     return (tuple(ret[0]), tuple(ret[1]))
sage: psi_inv = lambda x: C(RSK(*x)[0])
sage: I = crystals.Induced(C, psi, psi_inv, from_crystal=True)

sage: I.cardinality() == C.cardinality()
True

5.1.53 \(B(\infty)\) Crystals of Tableaux in Nonexceptional Types and \(G_2\)

A tableau model for \(B(\infty)\). For more information, see \(InfinityCrystalOfTableaux\).

AUTHORS:

- Ben Salisbury: Initial version
- Travis Scrimshaw: Initial version

class sage.combinat.crystals.infinity_crystals.DualInfinityQueerCrystalOfTableaux(cartan_type)

Bases: CrystalOfWords

Initialize self.

EXAMPLES:

sage: B = crystals.infinity.Tableaux(['A',2])
sage: TestSuite(B).run() # long time

class Element

Bases: InfinityQueerCrystalOfTableauxElement

index_set()

Return the index set of self.

EXAMPLES:

sage: B = crystals.infinity.Tableaux(['Q',3])
sage: B.index_set()
(1, 2, -1)
module_generator()  
Return the module generator (or highest weight element) of self.

The module generator is the unique semistandard hook tableau of shape \((n, n - 1, \ldots, 2, 1)\) with weight 0.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['Q',5])
sage: B.module_generator()  
[[5, 5, 5, 5, 5], [4, 4, 4, 4], [3, 3, 3], [2, 2], [1]]
```

class sage.combinat.crystals.infinity_crystals.InfinityCrystalOfTableaux(cartan_type)

Bases: CrystalOfWords

\(B(\infty)\) crystal of tableaux.

A tableaux model \(T(\infty)\) for the crystal \(B(\infty)\) is introduced by Hong and Lee in [HL2008]. This model is currently valid for types \(A_n, B_n, C_n, D_n,\) and \(G_2,\) and builds on the tableaux model given by Kashiwara and Nakashima [KN1994] in types \(A_n, B_n, C_n,\) and \(D_n,\) and by Kang and Misra [KM1994] in type \(G_2.\)

**Note:** We are using the English convention for our tableaux.

We say a tableau \(T\) is *marginally large* if:

- for each \(1 \leq i \leq n\), the leftmost box in the \(i\)-th row from the top in \(T\) is an \(i\)-box,
- for each \(1 \leq i \leq n\), the number of \(i\)-boxes in the \(i\)-th row from the top in \(T\) is greater than the total number of boxes in the \((i + 1)\)-th row by exactly one.

We now will describe this tableaux model type-by-type.

**Type \(A_n\)**

\(T(\infty)\) is the set of marginally large semistandard tableaux with exactly \(n\) rows over the alphabet \(\{1 \prec 2 \prec \cdots \prec n + 1\}\).

**Type \(B_n\)**

\(T(\infty)\) is the set of marginally large semistandard tableaux with exactly \(n\) rows over the alphabet \(\{1 \prec \cdots \prec n \prec 0 \prec \pi \prec \cdots \prec \overline{T}\}\) and subject to the following constraints:

- for each \(1 \leq i \leq n\), the contents of the boxes in the \(i\)-th row are \(\leq \overline{i}\),
- the entry 0 can appear at most once in a single row.

**Type \(C_n\)**

\(T(\infty)\) is the set of marginally large semistandard tableaux with exactly \(n\) rows over the alphabet \(\{1 \prec \cdots \prec n \prec \pi \prec \cdots \prec \overline{T}\}\) and for each \(1 \leq i \leq n\), the contents of the boxes in the \(i\)-th row are \(\leq \overline{i}\).
Type $D_n$

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly $n - 1$ rows over the alphabet $\{1 \prec \cdots \prec n, n \prec \cdots \prec 1\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the $i$-th row are $\preceq i$,
- the entries $n$ and $\pi$ may not appear simultaneously in a single row.

Type $G_2$

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly 2 rows over the ordered alphabet $\{1 \prec 2 \prec 3 \prec 0 \prec 3 \prec 2 \prec 1\}$ and subject to the following constraints:

- the contents of the boxes in the first row are $\preceq i$,
- the contents of the boxes in the second row are $\preceq 3$,
- the entry 0 can appear at most once in the first row and not at all in the second row.

In particular, the shape of the tableaux is not fixed in any instance of $\mathcal{T}(\infty)$; the row lengths of a tableau can be arbitrarily long.

INPUT:

- cartan_type – One of $\{A', B', C', D', G'\}$, where $n$ is a positive integer

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux(['A',2])
sage: b = B.highest_weight_vector(); b.pp()
1 1
2
sage: b.f_string([2,1,1,2,2,2]).pp()
1 1 1 1 1 2 3
2 3 3 3

sage: B = crystals.infinity.Tableaux(['G',2])
sage: b = B(rows=[[1,1,1,1,1,2,3,0,-3,-1,-1,-1],[2,3,3,3]])
sage: b.e_string([2,1,1,1,1,1,1]).pp()
1 1 1 1 2 3 3 3 -2 -2 -2
2 3 3

sage: b.e_string([2,1,1,1,1,1,1])
```

We check that a few classical crystals embed into $\mathcal{T}(\infty)$:

```python
sage: def crystal_test(B, C):
    ....:     T = crystals.elementary.T(C.cartan_type(), C.module_generators[0].→weight())
    ....:     TP = crystals.TensorProduct(T, B)
    ....:     mg = TP(T[0], B.module_generators[0])
    ....:     g = {C.module_generators[0]: mg}
    ....:     f = C.crystal_morphism(g, category=HighestWeightCrystals())
    ....:     G = B.digraph(subset=[f(x) for x in C])
    ....:     return G.is_isomorphic(C.digraph(), edge_labels=True)

sage: B = crystals.infinity.Tableaux(['A',2])
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
```

(continues on next page)
```python
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['A',2], shape=[6,2])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['B',2])
sage: C = crystals.Tableaux(['B',2], shape=[3])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['B',2], shape=[2,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['C',3])
sage: C = crystals.Tableaux(['C',3], shape=[2,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['D',4])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['D',4], shape=[1,1,1,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['G',2])
sage: C = crystals.Tableaux(['G',2], shape=[3])
sage: crystal_test(B, C)
True
```

class Element

Bases: `InfinityCrystalOfTableauxElement`

Elements in \( B(\infty) \) crystal of tableaux.

```python
content()
```

Return the content of self.

The content \(|T|\) of \( T \in B(\infty) \) is the number of blocks added to the highest weight to obtain \( T \) with any \( \Psi \)-boxes in the \( i \)-th row counted with multiplicity 2 provided the underlying Cartan type is of type \( B, D, \) or \( G. \)

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux("D5")
sage: b = B.highest_weight_vector().f_string([5,4,3,1,1,3,4,5,3,4,5,1,4,5,2,˓→3,5,3,2,4])
sage: b.content()
13

sage: B = crystals.infinity.Tableaux("B2")
sage: b = B(rows=[[1,1,1,1,1,2,2,2,-2,-2],[2,0,-2,-2,-2]])
sage: b.content()
12

sage: B = crystals.infinity.Tableaux("C2")
```

(continues on next page)
sage: b = B(rows=[[1,1,1,1,1,2,2,2,-2,-2],[2,-2,-2,-2]])
sage: b.content()
8

\phi(i)
Return \varphi_i of self.

Let \( T \in \mathcal{B}(\infty) \) Define \( \varphi_i(T) := \varepsilon_i(T) + \langle h_i, \text{wt}(T) \rangle \), where \( h_i \) is the \( i \)-th simple coroot and \( \text{wt}(T) \) is the weight() of \( T \).

INPUT:
\begin{itemize}
  \item \( i \) – An element of the index set
\end{itemize}

EXAMPLES:

sage: B = crystals.infinity.Tableaux("A3")
sage: [B.highest_weight_vector().f_string([1,3,2,3,1,3,2,1]).phi(i) for i in B.index_set()]
[-3, 4, -3]
sage: B = crystals.infinity.Tableaux("G2")
sage: [B.highest_weight_vector().f_string([2,2,1,2,1,1,1,2]).phi(i) for i in B.index_set()]
[5, -3]

reduced_form()
Return the reduced form of self.

The reduced form of a tableaux \( T \in \mathcal{T}(\infty) \) is the (not necessarily semistandard) tableaux obtained from \( T \) by removing all \( i \)-boxes in the \( i \)-th row, subject to the condition that if the row is empty, a \( * \) is put as a placeholder. This is described in [BN2010] and [LS2012].

EXAMPLES:

sage: B = crystals.infinity.Tableaux(["A",3])
sage: b = B.highest_weight_vector().f_string([2,2,2,3,3,3,3,3])
sage: b.pp()
1 1 1 1 1 1 1
2 2 2 2 4 4 4
3 4 4
sage: b.reduced_form()
[['*'], [4, 4], [4, 4]]

seg()
Returns the statistic seg of self.

More precisely, following [LS2012], define a \( k \)-segment of a tableau \( T \) in \( \mathcal{B}(\infty) \) to be a maximal string of \( k \)-boxes in a single row of \( T \). Set \( seg(T) \) to be the number of \( k \)-segments in \( T \), as \( k \) varies over all possible values. Then \( seg(T) \) is determined type-by-type.

\begin{itemize}
  \item In types \( A_n \) and \( C_n \), define \( seg(T) := seg'(T) \).
  \item In types \( B_n \) and \( G_2 \), set \( e(T) \) to be the number of rows in \( T \) which contain both a 0-box and an \( \tau \)-box. Define \( seg(T) := seg'(T) - e(T) \).
  \item In type \( D_n \), set \( d(T) \) to be the number of rows in \( T \) which contain an \( \tau \)-box, but no \( n \)-box nor \( \pi \)-box. Define \( seg(T) := seg'(T) + d(T) \).
\end{itemize}

EXAMPLES:
sage: B = crystals.infinity.Tableaux(['A',3])
sage: b = B.highest_weight_vector().f_string([1,3,2,2,3,1,1,3])
sage: b.pp()
1 1 1 1 1 1 2 2 4
2 2 2 2 3
3 4 4
sage: b.seg()
4

sage: B = crystals.infinity.Tableaux(['D',4])
sage: b = B(rows=[[1,1,1,1,1,1,3,-2,-1],[2,2,2,4,-2],[3,3],[4]])
sage: b.pp()
1 1 1 1 1 1 3 -2 -1
2 2 2 4 -2
3 3
4
sage: b.seg()
6

sage: B = crystals.infinity.Tableaux(['G',2])
sage: b = B.highest_weight_vector().f_string([2,1,1,1,2,1,2,2,1,2,2,1,2,2,2,1,2,2,1,2])
sage: b.pp()
1 1 1 1 1 1 1 2 3 0 -3
2 3 3 3 3 3
sage: b.seg()
5

weight()

Return the weight of self.

From the definition of a crystal and that the highest weight element $b_\infty$ of $B(\infty)$ is 0, the weight of $T \in B(\infty)$ can be defined as $\text{wt}(T) := -\sum_{j} \alpha_{ij}$ where $\tilde{e}_i, \ldots, \tilde{e}_i T = b_\infty$ and $\{\alpha_i\}$ is the set of simple roots. (Note that the weight is independent of the path chosen to get to the highest weight.)

However we can also take advantage of the fact that $\rho: R_\lambda \otimes B(\infty) \rightarrow B(\lambda)$, where $\lambda$ is the shape of $T$, preserves the tableau representation of $T$. Therefore

$$\text{wt}(T) = \text{wt}(\rho(T)) - \lambda$$

where $\text{wt}(\rho(T))$ is just the usual weight of the tableau $T$.

Let $\Lambda_i$ be the $i$-th fundamental weight. In type $D$, the height $n-1$ columns corresponds to $\Lambda_{n-1} + \Lambda_n$ and the in type $B$, the height $n$ columns corresponds to $2\Lambda_n$.

EXAMPLES:

sage: B = crystals.infinity.Tableaux("C7")
sage: b = B.highest_weight_vector().f_string([1,6,4,7,4,2,4,6,2,4,6,7,1,2,4,7])
sage: b.weight()
(-2, -1, 3, -5, 5, -3, -3)

Check that the definitions agree:
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
True

Check that it works for type $B$:

sage: B = crystals.infinity.Tableaux("B2")
sage: b = B.highest_weight_vector().f_string([1,2,2,1,2])
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
True

Check that it works for type $D$:

sage: B = crystals.infinity.Tableaux("D4")
sage: b = B.highest_weight_vector().f_string([1,4,4,2,4,1,3,2,4,1,3,2,4])
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
True

module_generator()

Return the module generator (or highest weight element) of self.

The module generator is the unique tableau of shape $(n, n-1, \ldots, 2, 1)$ with weight 0.

EXAMPLES:

sage: T = crystals.infinity.Tableaux(['A',3])
sage: T.module_generator()
[[1, 1, 1], [2, 2], [3]]

class sage.combinat.crystals.infinity_crystals.InfinityCrystalOfTableauxTypeD(cartan_type)

$B(\infty)$ crystal of tableaux for type $D_n$.

This is the set $T(\infty)$ of marginally large semistandard tableaux with exactly $n-1$ rows over the alphabet $\{1 \prec \cdots \prec n, n \prec \cdots \prec 1\}$ and subject to the following constraints:

• for each $1 \leq i \leq n$, the contents of the boxes in the $i$-th row are $\leq i$,

• the entries $n$ and $\pi$ may not appear simultaneously in a single row.

For more information, see InfinityCrystalOfTableaux.

EXAMPLES:

sage: B = crystals.infinity.Tableaux("D4")
sage: b = B.highest_weight_vector().f_string([4,3,2,1,4])

(continues on next page)
class Element
    Bases: InfinityCrystalOfTableauxElementTypeD, Element
    Elements in \(B(\infty)\) crystal of tableaux for type \(D_n\).

module_generator()
    Return the module generator (or highest weight element) of self.

    The module generator is the unique tableau of shape \((n - 1, \ldots, 2, 1)\) with weight \(0\).

    EXAMPLES:

```
sage: T = crystals.infinity.Tableaux(['D',4])
sage: T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

5.1.54 Crystals of Kac modules of the general-linear Lie superalgebra

class sage.combinat.crystals.kac_modules.CrystalOfKacModule(cartan_type, la, mu)
    Bases: UniqueRepresentation, Parent
    Crystal of a Kac module.

    Let \(g\) be the general linear Lie superalgebra \(\mathfrak{gl}(m|n)\). Let \(\lambda\) and \(\mu\) be dominant weights for \(\mathfrak{gl}_m\) and \(\mathfrak{gl}_n\), respectively. Let \(K\) be the module \(K = \langle f_\alpha \rangle\), where \(\alpha\) ranges over all odd positive roots. A Kac module is the \(U_q(g)\)-module constructed from the highest weight \(U_q(\mathfrak{gl}_m \oplus \mathfrak{gl}_n)\)-module \(V(\lambda, \mu)\) (induced to a \(U_q(g)\)-module in the natural way) by

\[
K(\lambda, \mu) := K \otimes_L V(\lambda, \mu),
\]

where \(L\) is the subalgebra generated by \(e_0\) and \(U_q(\mathfrak{gl}_m \oplus \mathfrak{gl}_n)\).

The Kac module admits a \(U_q(g)\)-crystal structure by taking the crystal structure of \(K\) as given by CrystalOfOddNegativeRoots and the crystal \(B(\lambda, \mu)\) (the natural crystal structure of \(V(\lambda, \mu)\)).

Note: Our notation differs slightly from [Kwon2012] in that our last tableau is transposed.

EXAMPLES:

```
sage: K = crystals.KacModule(['A', [1,2]], [2], [1,1])
sage: K.cardinality()
576
sage: K.cardinality().factor()
2^6 * 3^2
sage: len(K.cartan_type().root_system().ambient_space().positive_odd_roots())
6
```
sage: mg = K.module_generator()
sage: mg
({}, [[-2, -2]], [[1], [2]])
sage: mg.weight()
(2, 0, 1, 1, 0)
sage: mg.f(-1)
({}, [[-2, -1]], [[1], [2]])
sage: mg.f(0)
({-e[-1]+e[1]}, [[-2, -2]], [[1], [2]])
sage: mg.f(1)
sage: mg.f(2)
({}, [[-2, -2]], [[1], [3]])

sage: sorted(K.highest_weight_vectors(), key=str)
[({-e[-1]+e[3]}, [[-2, -1]], [[1], [2]]),
 ({-e[-1]+e[3]}, [[-2, -2]], [[1], [2]]),
 ({}, [[-2, -2]], [[1], [2]])]

sage: K = crystals.KacModule(['A', [1,1]], [2], [1])
sage: K.cardinality()
96
sage: K.cardinality().factor()
2^5 * 3
sage: len(K.cartan_type().root_system().ambient_space().positive_odd_roots())
4

sage: sorted(K.highest_weight_vectors(), key=str)
[({-e[-2]+e[1], -e[-2]+e[2], -e[-1]+e[1], -e[-1]+e[2]}, [[-1, -1]], [[2]]),
 ({-e[-1]+e[2], -e[-1]+e[1], -e[-1]+e[2]}, [[-1, -1]], [[1]]),
 ({-e[-2]+e[2], -e[-1]+e[1], -e[-1]+e[2]}, [[-1, -1]], [[2]])]

REFERENCES:
• [Kwon2012]

class Element

    Bases: ElementWrapper

    An element of a Kac module crystal.

    e(i)

    Return the action of the crystal operator \(e_i\) on self.

EXAMPLES:

sage: K = crystals.KacModule(['A', [2,2]], [2,1], [1])
sage: mg = K.module_generator()
sage: mg.e(0)
sage: mg.e(1)
sage: mg.e(-1)
sage: b = mg.f_string([1,0,1,-1,-2,0,1,2,0,-2,-1,-1,-1]); b
({-e[-3]+e[2], -e[-2]+e[1], -e[-2]+e[2]}, [[-3, -1], [-2]], [[3]])
sage: b.e(-2)
sage: b.e(-1)
({-e[-3]+e[2], -e[-2]+e[1], -e[-2]+e[2]}, [[-3, -2], [-2]], [[3]])
sage: b.e(0)
sage: b.e(1)
({-e[-3]+e[1], -e[-2]+e[1], -e[-2]+e[2]}, [[-3, -1], [-2]], [[3]])
sage: b.e(2)
({-e[-3]+e[2], -e[-2]+e[1], -e[-2]+e[2]}, [[-3, -1], [-2]], [[2]])

\( f(i) \)

Return the action of the crystal operator \( f_i \) on \( \text{self} \).

EXAMPLES:

sage: K = crystals.KacModule(['A', [3,2]], [2,1], [5,1])
sage: mg = K.module_generator()
sage: mg.f(0)
(2, 1, 0, 0, 5, 1, 0)
sage: mg.weight().is_dominant()
True
sage: mg.f(0).weight()
(2, 1, 0, -1, 6, 1, 0)
sage: b = mg.f_string([2,1,-3,-2,-1,1,0,-2,-1,2,1,1,0,2,-3,-2,-1])
sage: b.weight()
(0, 0, 0, 1, 1, 4, 3)

weight()

Return weight of \( \text{self} \).

EXAMPLES:

sage: K = crystals.KacModule(['A', [3,2]], [2,1], [5,1])
sage: mg = K.module_generator()
sage: mg.weight()
(2, 1, 0, 0, 5, 1, 0)
sage: mg.weight().is_dominant()
True
sage: mg.f(0).weight()
(2, 1, 0, -1, 6, 1, 0)
sage: b = mg.f_string([2,1,-3,-2,-1,1,0,-2,-1,2,1,1,0,2,-3,-2,-1])
sage: b.weight()
(0, 0, 0, 1, 1, 4, 3)

module_generator()

Return the module generator of \( \text{self} \).
EXAMPLES:

```python
sage: K = crystals.KacModule(['A', [2,1]], [2,1], [1])
sage: K.module_generator()
({}, [[-3, -3], [-2]], [[1]])
```

class `sage.combinat.crystals.kac_modules.CrystalOfOddNegativeRoots`(`cartan_type`)

Bases: `UniqueRepresentation`, `Parent`

Crystal of the set of odd negative roots.

Let \( g \) be the general-linear Lie superalgebra \( \mathfrak{gl}(m|n) \). This is the crystal structure on the set of negative roots as given by [Kwon2012].

More specifically, this is the crystal basis of the subalgebra of \( U_q^{-}(g) \) generated by \( f_{\alpha} \), where \( \alpha \) ranges over all odd positive roots. As \( \mathbb{Q}(q) \)-modules, we have

\[
U_q^{-}(g) \cong K \otimes U_q^{-}(\mathfrak{gl}_m \oplus \mathfrak{gl}_n).
\]

EXAMPLES:

```python
sage: S = crystals.OddNegativeRoots(['A', [2,1]])
sage: mg = S.module_generator(); mg
{}
sage: mg.f(0)
{-e[-1]+e[1]}
sage: mg.f_string([0,-1,0,1,2,1,0])
{-e[-2]+e[3], -e[-1]+e[1], -e[-1]+e[2]}
```

class `Element`

Bases: `ElementWrapper`

An element of the crystal of odd negative roots.

\( e(i) \)

Return the action of the crystal operator \( e_i \) on \( \text{self} \).

EXAMPLES:

```python
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: mg.e(0)
sage: mg.e(1)
sage: b = mg.f_string([0,1,2,-1,0])
sage: b.e(-1)
sage: b.e(0)
{-e[-2]+e[3]}
sage: b.e(1)
sage: b.e(2)
{-e[-2]+e[2], -e[-1]+e[1]}
sage: b.e_string([2,1,0,-1,0])
{}
```

\( \epsilon(i) \)

Return \( \epsilon_i \) of \( \text{self} \).

EXAMPLES:
\begin{verbatim}
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: [mg.epsilon(i) for i in S.index_set()]
[0, 0, 0, 0, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1,2,-2,2]); b
{-e[-3]+e[1], -e[-3]+e[2], -e[-1]+e[1]}
sage: [b.epsilon(i) for i in S.index_set()]
[2, 0, 1, 0, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1,-2,-2,2,-1,0]); b
{-e[-3]+e[1], -e[-3]+e[3], -e[-2]+e[1], -e[-1]+e[1]}
sage: [b.epsilon(i) for i in S.index_set()]
[1, 0, 1, 0, 1]
\end{verbatim}

\textbf{f()} 

Return the action of the crystal operator $f_i$ on self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: mg.f(0)
{-e[-1]+e[1]}
sage: mg.f(1)
sage: b = mg.f_string([0,1,2,-1,0]); b
{-e[-2]+e[3], -e[-1]+e[1]}
sage: b.f(-2)
{-e[-3]+e[3], -e[-1]+e[1]}
sage: b.f(-1)
sage: b.f(0)
sage: b.f(1)
{-e[-2]+e[3], -e[-1]+e[2]}
\end{verbatim}

\textbf{phi()} 

Return $\varphi_i$ of self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: [mg.phi(i) for i in S.index_set()]
[0, 0, 1, 0, 0]
sage: b = mg.f(0)
sage: [b.phi(i) for i in S.index_set()]
[0, 1, 0, 1, 0]
sage: b = mg.f_string([0,1,0,-1,0,-1,-2,-2,-1,0]); b
{-e[-2]+e[1], -e[-2]+e[2], -e[-1]+e[1]}
sage: [b.phi(i) for i in S.index_set()]
[2, 0, 1, 0, 1]
\end{verbatim}

\textbf{weight()} 

Return the weight of self.

\textbf{EXAMPLES:}
```python
sage: S = crystals.OddNegativeRoots(['A', [2,2]])
sage: mg = S.module_generator()
sage: mg.weight()
(0, 0, 0, 0, 0, 0)
sage: mg.f_string([0,1,2,-1,-2]).weight()
(-1, 0, 0, 0, 1)
sage: mg.f_string([0,1,2,-1,-2,0,1,0,2]).weight()
(-1, 0, -2, 1, 0, 2)
```

**module_generator()**

Return the module generator of self.

EXAMPLES:

```python
sage: S = crystals.OddNegativeRoots(['A', [2,1]])
sage: S.module_generator()
{}  
```

```python
def latex_dual(elt):
    r'
    Return a latex representation of a type $A_n$ crystal tableau elt expressed in terms of dual letters.
    The dual letter of $k$ is expressed as $n + 2 - k$.
    EXAMPLES:
    sage: from sage.combinat.crystals.kac_modules import latex_dual
    sage: T = crystals.Tableaux(['A',2], shape=[2,1])
    sage: print(latex_dual(T[0]))
    \begin{array}{cc}
    \overline{3} & \overline{3} \\
    \overline{2} \\
    \end{array}
    '}

def to_dual_tableau(elt):
    r'
    Return a type $A_n$ crystal tableau elt as a tableau expressed in terms of dual letters.
    The dual letter of $k$ is expressed as $n + 2 - k$ represented as $-(n + 2 - k)$.
    EXAMPLES:
    sage: from sage.combinat.crystals.kac_modules import to_dual_tableau
    sage: T = crystals.Tableaux(['A',2], shape=[2,1])
    sage: ascii_art([to_dual_tableau(t) for t in T])
    [ -3 -3 -3 -3 -3 -3 -3 -3 -3 -3 -3 -3 -3 -3 -2 -2 -2 ]
    [ -2 , -2 , -2 , -1 , -1 , -1 , -1 , -1 , -1 ]
    '}
```
5.1.55 Kirillov-Reshetikhin Crystals

class sage.combinat.crystals.kirillov_reshetikhin.AmbientRetractMap(
    base, ambient, pdict_inv,
    index_set, similarity_factor_domain=None,
    automorphism=None)

Bases: Map

The retraction map from the ambient crystal.

Consider a crystal embedding \( \phi : X \rightarrow Y \), then the elements \( X \) can be considered as a subcrystal of the ambient crystal \( Y \). The ambient retract is the partial map \( \tilde{\phi} : Y \rightarrow X \) such that \( \tilde{\phi} \circ \phi \) is the identity on \( X \).

class sage.combinat.crystals.kirillov_reshetikhin.CrystalDiagramAutomorphism(
    C, on_hw, index_set=None,
    automorphism=None, cache=True)

Bases: CrystalMorphism

The crystal automorphism induced from the diagram automorphism.

For example, in type \( A_n^{(1)} \) this is the promotion operator and in type \( D_n^{(1)} \), this corresponds to the automorphism induced from interchanging the 0 and 1 nodes in the Dynkin diagram.

INPUT:

- \( C \) – a crystal
- \( \text{on_hw} \) – a function for the images of the \( \text{index_set} \)-highest weight elements
- \( \text{index_set} \) – (default: the empty set) the index set
- \( \text{automorphism} \) – (default: the identity) the twisting automorphism
- \( \text{cache} \) – (default: True) cache the result

is_embedding()

Return True as self is a crystal isomorphism.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```

is_isomorphism()

Return True as self is a crystal isomorphism.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```

is_strict()

Return True as self is a crystal isomorphism.

EXAMPLES:
```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```

**is_surjective()**

Return True as self is a crystal isomorphism.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.promotion().is_isomorphism()
True
```

### class sage.combinat.crystals.kirillov_reshetikhin.CrystalOfTableaux_E7(cartan_type, shapes)

**Bases:** CrystalOfTableaux

The type $E_7$ crystal $B(s\Lambda_7)$.

This is a helper class for the corresponding class $KR$ crystal $sage.combinat.crystals.kirillov_reshetikhin.KR_type_E7 > B^{7,\lambda}$.

**module_generator(shape)**

Return the module generator of self with shape shape.

**Note:** Only implemented for single rows (i.e., highest weight $s\Lambda_7$).

EXAMPLES:

```python
sage: from sage.combinat.crystals.kirillov_reshetikhin import CrystalOfTableaux_E7
sage: T = CrystalOfTableaux_E7(CartanType(['E',7]), shapes=(Partition([5]),))
sage: T.module_generator([5])
[[[7,], [7,], [7,], [7,], [7,]]]
```

### class sage.combinat.crystals.kirillov_reshetikhin.KR_type_A(cartan_type, r, s)

**Bases:** KirillovReshetikhinCrystalFromPromotion

Class of Kirillov-Reshetikhin crystals of type $A_n^{(1)}$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: b = K(rows=[[1,2],[2,4]])
sage: b.f(0)
[[1, 1], [2, 2]]
```

**classical_decomposition()**

Specifies the classical crystal underlying the KR crystal of type $A$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['A', 3] and shape(s) [[2, 2]]
```
**dynkin_diagram_automorphism(i)**

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements. The automorphism needs to map node 0 to some other Dynkin node.

For type $A$ we use the Dynkin diagram automorphism which $i \mapsto i + 1 \mod n + 1$, where $n$ is the rank.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: K.dynkin_diagram_automorphism(0)
1
sage: K.dynkin_diagram_automorphism(3)
0
```

**promotion()**

Specifies the promotion operator used to construct the affine type $A$ crystal.

For type $A$ this corresponds to the Dynkin diagram automorphism which $i \mapsto i + 1 \mod n + 1$, where $n$ is the rank.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: b = K.classical_decomposition()(rows=[[1,2],[3,4]])
sage: K.promotion()(b)
[[1, 3], [2, 4]]
```

**promotion_inverse()**

Specifies the inverse promotion operator used to construct the affine type $A$ crystal.

For type $A$ this corresponds to the Dynkin diagram automorphism which $i \mapsto i - 1 \mod n + 1$, where $n$ is the rank.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2,2)
sage: b = K.classical_decomposition()(rows=[[1,3],[2,4]])
sage: K.promotion_inverse()(b)
[[1, 2], [3, 4]]
sage: K.promotion_inverse()(K.promotion()(b))
[[1, 2], [3, 3]]
```

**class sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(cartan_type, r, s, dual=None)**

Bases: `KirillovReshetikhinGenericCrystal`

Class of Kirillov-Reshetikhin crystals $B^{r,s}$ of type $A^{(2)}_{2n}$ for $1 \leq r \leq n$ in the realization with classical subalgebra $B_n$. The Cartan type in this case is inputted as the dual of $A^{(2)}_{2n}$.

This is an alternative implementation to `KR_type_box` that uses the classical decomposition into type $C_n$ crystals.

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: K
```
Kirillov-Reshetikhin crystal of type ['BC', 2, 2]^* with (r,s)=(1,1)

```
sage: b = K(rows=[[1]])
sage: b.f(0)
[[1]]
sage: b.e(0)
```

We can now check whether the two KR crystals of type $A^{(2)}_4$ (namely the KR crystal and its dual construction) are isomorphic up to relabelling of the edges:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 3)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(2,3)
```

**Element**

alias of `KR_type_A2Element`

**ambient_crystal()**

Return the ambient crystal $B^{r,s}$ of type $B^{(1)}_{n+1}$ associated to the Kirillov-Reshetikhin crystal of type $A^{(2)}_{2n}$ dual.

This ambient crystal is used to construct the zero arrows.

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 3)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(2,3)
```

**ambient_dict_pm_diagrams()**

Return a dictionary of all self-dual ± diagrams for the ambient crystal whose keys are their inner shape.

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: K.ambient_dict_pm_diagrams()({[1]: [[0, 0], [1]]})
sage: K.ambient_dict_pm_diagrams()({[1]: [[0, 1], [0]], [2]: [[0, 0], [1]]})
sage: K.ambient_dict_pm_diagrams()({[1]: [[0, 0], [1]], [2]: [[0, 0], [1], [0]], [2, 2]: [[0, 0], [0, 0], [2]]})
```
ambient_highest_weight_dict()

Return a dictionary of all \(\{2, \ldots, n + 1\}\)-highest weight vectors in the ambient crystal.

The key is the inner shape of their corresponding \(\pm\) diagram, or equivalently, their \(\{2, \ldots, n + 1\}\) weight.

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: K.ambient_highest_weight_dict()
{[]}: [[1, -1]], [2]: [[2, 2]]
```

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type \(A_\infty\) with \(B_n\) as classical subdiagram.

It is given by \(B^r,s \cong \bigoplus \Lambda B(\Lambda)\), where \(B(\Lambda)\) is a highest weight crystal of type \(B_n\) of highest weight \(\Lambda\). The sum is over all weights \(\Lambda\) obtained from a rectangle of width \(s\) and height \(r\) by removing horizontal dominoes. Here we identify the fundamental weight \(\Lambda_i\) with a column of height \(i\).

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 2] and shape(s) [[], [2], [2, 2]]
```

from_ambient_crystal()

Return a map from the ambient crystal of type \(B_{n+1}^{(1)}\) to the Kirillov-Reshetikhin crystal of type \(A_\infty^{(2)}\).

Note that this map is only well-defined on type \(A_\infty^{(2)}\) elements that are in the image under to_ambient_crystal().

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: b = K.ambient_crystal()(rows=[[2,2]])
sage: K.from_ambient_crystal()(b)
[[1, 1]]
```

highest_weight_dict()

Return a dictionary of the classical highest weight vectors of self whose keys are their shape.

EXAMPLES:

```
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: K.highest_weight_dict()
{[]}: [[]], [2]: [[1, 1]]
```

module_generator()

Return the unique module generator of classical weight \(s\Lambda_r\) of a Kirillov-Reshetikhin crystal \(B^r,s\).

EXAMPLES:
sage: ct = CartanType(['A',8,2]).dual()
sage: K = crystals.KirillovReshetikhin(ct, 3, 5)
sage: K.module_generator()
[[1, 1, 1, 1, 1], [2, 2, 2, 2, 2], [3, 3, 3, 3, 3]]

to_ambient_crystal()

Return a map from the Kirillov-Reshetikhin crystal of type $A^{(2)}_{2n}$ to the ambient crystal of type $B^{(1)}_{n+1}$.

EXAMPLES:

sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 2)
sage: b=K(rows=[[1,1]])
sage: K.to_ambient_crystal()(b)
[[2, 2]]
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 2, 2)
sage: b=K(rows=[[1,1]])
sage: K.to_ambient_crystal()(b)
[[1, 2], [2, -1]]
sage: K.to_ambient_crystal()(b).parent()
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(2,2)

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2Element

Bases: KirillovReshetikhinGenericCrystalElement

Class for the elements in the Kirillov-Reshetikhin crystals $B^{r,s}$ of type $A^{(2)}_{2n}$ for $r < n$ with underlying classical algebra $B_n$.

EXAMPLES:

sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2_with_category.˓
element_class'>

e0()

Return $e_0$ on self by mapping self to the ambient crystal, calculating $e_1e_0$ there and pulling the element back.

EXAMPLES:

sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[1]])
sage: b.e(0) # indirect doctest
[[-1]]

epsilon0()

Calculate $\varepsilon_0$ of self by mapping the element to the ambient crystal and calculating $\varepsilon_1$ there.

EXAMPLES:

sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)

sage: b = K(rows=[[1]])
sage: b.epsilon(0)  # indirect doctest
1

\texttt{f0()}

Return $f_0$ on \texttt{self} by mapping \texttt{self} to the ambient crystal, calculating $f_1 f_0$ there and pulling the element back.

EXAMPLES:

\begin{verbatim}
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[1]])
sage: b.f(0)  # indirect doctest
[[1]]
\end{verbatim}

\texttt{phi0()}

Calculate $\varphi_0$ of \texttt{self} by mapping the element to the ambient crystal and calculating $\varphi_1$ there.

EXAMPLES:

\begin{verbatim}
sage: C = CartanType(['A',4,2]).dual()
sage: K = sage.combinat.crystals.kirillov_reshetikhin.KR_type_A2(C, 1, 1)
sage: b = K(rows=[[1]])
sage: b.phi(0)  # indirect doctest
1
\end{verbatim}

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_Bn(cartan_type, r, s, dual=None)

Bases: KirillovReshetikhinGenericCrystal

Class of Kirillov-Reshetikhin crystals $B^{n,s}$ of type $B_n^{(1)}$.

EXAMPLES:

\begin{verbatim}
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K
Kirillov-Reshetikhin crystal of type ['B', 3, 1] with (r,s)=(3,2)
sage: b = K(rows=[[1],[2],[3]])
sage: b.f(0)
sage: b.e(0)
[[3]]
\end{verbatim}

 Element

alias of \texttt{KR_type_BnElement}

\texttt{ambient_crystal()}

Return the ambient crystal $B^{n,s}$ of type $A_{2n-1}^{(2)}$ associated to the Kirillov-Reshetikhin crystal.

The ambient crystal is used to construct the zero arrows.
EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['B', 3, 1]^* with (r,s)=(3,2)
```

`ambient_highest_weight_dict()`

Return a dictionary of the classical highest weight vectors of the ambient crystal of `self` whose keys are their shape.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K.ambient_highest_weight_dict()
{(2,) : [[1, 1]], (2, 1, 1) : [[1, 1], [2], [3]], (2, 2, 2) : [[1, 1], [2, 2], [3, 3]]}
```

`classical_decomposition()`

Return the classical crystal underlying the Kirillov-Reshetikhin crystal $B_n^{r,s}$ of type $B^{(1)}_n$.

It is the same as for $r < n$, given by $B_n^{r,s} \cong \bigoplus_{\Lambda} B_{\Lambda}$, where $\Lambda$ are weights obtained from a rectangle of width $s/2$ and height $n$ by removing horizontal dominoes. Here we identify the fundamental weight $\Lambda_i$ with a column of height $i$ for $i < n$ and a column of width $1/2$ for $i = n$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[1], [1, 1, 1]]
```

`from_ambient_crystal()`

Return a map from the ambient crystal of type $A_{2n-1}^{(2)}$ to the Kirillov-Reshetikhin crystal `self`.

Note that this map is only well-defined on elements that are in the image under `to_ambient_crystal()`.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: [b == K.from_ambient_crystal()(K.to_ambient_crystal()(b)) for b in K]
[True, True, True, True, True, True, True, True]
sage: b = K.ambient_crystal()(rows=[[1],[2],[-3]])
sage: K.from_ambient_crystal()(b)
[++-, []]
```
highest_weight_dict()

Return a dictionary of the classical highest weight vectors of self whose keys are 2 times their shape.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K.highest_weight_dict()
{(2,): [[1]], (2, 2, 2): [[1], [2], [3]]}
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,3)
sage: K.highest_weight_dict()
{(3, 1, 1): [++, [[1]]], (3, 3, 3): [++, [[1], [2], [3]]]}
```

similarity_factor()

Sets the similarity factor used to map to the ambient crystal.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: K.similarity_factor()
{1: 2, 2: 2, 3: 1}
```

to_ambient_crystal()

Return a map from self to the ambient crystal of type $A_{2n-1}^{(2)}$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: [b.to_ambient_crystal()(b) for b in K]
[[[1], [2], [3]], [[1], [2], [-3]], [[1], [3], [-2]], [[2], [3], [-1]], [[1], [-3], [-2]], [[2], [-3], [-1]], [[3], [-2], [-1]], [[-3], [-2], [-1]]]
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_BnElement

Bases: KirillovReshetikhinGenericCrystalElement

Class for the elements in the Kirillov-Reshetikhin crystals $B^{n,s}$ of type $B_n^{(1)}$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Bn_with_category.Element_class'>
```

e0()

Return $e_0$ on self by mapping self to the ambient crystal, calculating $e_0$ there and pulling the element back.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.e(0) # indirect doctest
[++, []]
```
epsilon0()

Calculate $\varepsilon_0$ of self by mapping the element to the ambient crystal and calculating $\varepsilon_0$ there.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.epsilon(0)  # indirect doctest
1
```

f0()

Return $f_0$ on self by mapping self to the ambient crystal, calculating $f_0$ there and pulling the element back.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.f(0)  # indirect doctest
```

phi0()

Calculate $\varphi_0$ of self by mapping the element to the ambient crystal and calculating $\varphi_0$ there.

EXAMPLES:

```
sage: K=crystals.KirillovReshetikhin(['B',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0)  # indirect doctest
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_C(cartan_type, r, s, dual=None)

Bases: KirillovReshetikhinGenericCrystal

Class of Kirillov-Reshetikhin crystals $B_{r,s}$ of type $C_n^{(1)}$ for $r < n$.

EXAMPLES:

```
sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: K
Kirillov-Reshetikhin crystal of type ['C', 2, 1] with (r,s)=(1,2)
sage: b = K(rows=[])  
[[[1, 1]]
```

Element

alias of KR_type_CElement

ambient_crystal()

Return the ambient crystal $B_{r,s}$ of type $A_{2n+1}^{(2)}$ associated to the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$.

This ambient crystal is used to construct the zero arrows.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,3)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['B', 4, 1]^* with (r,s)=(2,3)

ambient_dict_pm_diagrams()
Return a dictionary of all self-dual ± diagrams for the ambient crystal whose keys are their inner shape.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: K.ambient_dict_pm_diagrams()
{[]}:
[1, 1], [0], [1], [0], [2]
[2]:
[0, 0], [1, 1], [0]
[2, 2]:
[0, 0], [0, 0], [2]

sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: K.ambient_dict_pm_diagrams()
{[]}:
[1, 1], [0, 0], [0], [2], [1, 1], [0]
[2, 2]:
[0, 0], [1, 1], [0, 0], [2]

ambient_highest_weight_dict()
Return a dictionary of all \{2, \ldots, n + 1\}-highest weight vectors in the ambient crystal.
The key is the inner shape of their corresponding ± diagram, or equivalently, their \{2, \ldots, n + 1\} weight.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: K.ambient_highest_weight_dict()
{[]}:
[2], [-2]
[2, 2]:
[1, 2], [2, -1], [2, 2], [3, 3]

classical_decomposition()
Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$.
It is given by $B^{r,s} \cong \bigoplus_B \Lambda$, where $\Lambda$ are weights obtained from a rectangle of width $s$ and height $r$ by removing horizontal dominoes. Here we identify the fundamental weight $\Lambda_i$ with a column of height $i$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 3] and shape(s) [[], [2], [2, 2]]

from_ambient_crystal()
Return a map from the ambient crystal of type $A_{2n+1}^{(2)}$ to the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$.
Note that this map is only well-defined on type $C_n^{(1)}$ elements that are in the image under to_ambient_crystal().

EXAMPLES:
```python
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: b = K.ambient_crystal()(rows=[[2,2],[3,3]])
sage: K.from_ambient_crystal()(b)
[[1, 1], [2, 2]]
```

**highest_weight_dict()**

Return a dictionary of the classical highest weight vectors of `self` whose keys are their shape.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['C',3,1], 2,2)
sage: K.highest_weight_dict()
{{[]}: [], [2]: [[1, 1]], [2, 2]: [[1, 1], [2, 2]]}
```

**to_ambient_crystal()**

Return a map from the Kirillov-Reshetikhin crystal of type $C_n^{(1)}$ to the ambient crystal of type $A_{2n+1}^{(2)}$.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['C',3,1],1,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_C_with_category.element_class'>
sage: b = K(rows=[[1,1]])
sage: K.to_ambient_crystal()(b)
[[1, 2], [2, -1]]
sage: b = K(rows=[])
sage: K.to_ambient_crystal()(b).parent()
Kirillov-Reshetikhin crystal of type ['B', 4, 1]^* with (r,s)=(2,2)
```

class `sage.combinat.crystals.kirillov_reshetikhin.KR_type_CElement`

Bases: `KirillovReshetikhinGenericCrystalElement`

Class for the elements in the Kirillov-Reshetikhin crystals $B_r^s$ of type $C_n^{(1)}$ for $r < n$.

**EXAMPLES:**

```python
sage: K=crystals.KirillovReshetikhin(['C',3,1],1,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_C_with_category.element_class'>
sage: e0()
```

**epsilon0()**

Calculate $\varepsilon_0$ of `self` by mapping the element to the ambient crystal and calculating $\varepsilon_1$ there.

**EXAMPLES:**

```python
sage: K=crystals.KirillovReshetikhin(['C',3,1],1,2)
sage: b = K(rows=[])# indirect doctest
[[[-1, -1]]]
sage: epsilon0()
```

5.1. Comprehensive Module List 459
sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: b=K(rows=[[1,1]])
sage: b.epsilon(0) # indirect doctest
2

\textbf{f0()} 

Return $f_0$ on self by mapping self to the ambient crystal, calculating $f_1f_0$ there and pulling the element back.

EXAMPLES:

sage: K=crystals.KirillovReshetikhin(['C',3,1],1,2)
sage: b = K(rows=[])  
sage: b.f(0) # indirect doctest
[]

\textbf{phi0()} 

Calculate $\varphi_0$ of self by mapping the element to the ambient crystal and calculating $\varphi_1$ there.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,2)
sage: b = K(rows=[[-1,-1]])
sage: b.phi(0) # indirect doctest
2

class \texttt{sage.combinat.crystals.kirillov_reshetikhin.KR_type_Cn}(\texttt{cartan_type, r, s, dual=None})

Bases: \texttt{KirillovReshetikhinGenericCrystal}

Class of Kirillov-Reshetikhin crystals $B^{n,s}$ of type $C_n^{(1)}$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: [[b,b.f(0)] for b in K]
[[[[1], [2], [3]], None], [[[1], [2], [-3]], None],
[[[1], [3], [-3]], None], [[[2], [3], [-3]], None],
[[[1], [3], [-2]], None], [[[2], [3], [-2]], None],
[[[2], [3], [-1]], [[1], [2], [3]]], [[[1], [-3], [-2]], None],
[[[2], [-3], [-2]], None], [[[2], [-3], [-1]], [[1], [2], [-3]]],
[[[3], [-3], [-2]], None], [[[3], [-3], [-1]], [[1], [3], [-3]]],
[[[3], [-2], [-1]], [[1], [3], [-2]]],
[[[-3], [-2], [-1]], [[1], [-3], [-2]]]]
Combinatorics, Release 10.1

```
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 3] and shape(s) [[2, 2, 2]]
```

**from_highest_weight_vector_to_pm_diagram(b)**
This gives the bijection between an element \(b\) in the classical decomposition of the KR crystal that is \(2, 3, \ldots, n\)-highest weight and \(\pm\) diagrams.

**EXAMPLES:**
```
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: T = K.classical_decomposition()
sage: b = T(rows=[[2, 2], [3, 3], [-3, -1]])
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b); pm
[[0, 0], [1, 0], [0, 1], [0]]
sage: pm.pp()
 .  
 . +
- - 
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3]) ]
sage: all(K.from_pm_diagram_to_highest_weight_vector(K.from_highest_weight_vector_to_pm_diagram(b)) == b for b in hw)
True
```

**from_pm_diagram_to_highest_weight_vector(pm)**
This gives the bijection between a \(\pm\) diagram and an element \(b\) in the classical decomposition of the KR crystal that is \(\{2, 3, \ldots, n\}\)-highest weight.

**EXAMPLES:**
```
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[0, 0], [1, 0], [0, 1], [0]])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[[2, 2], [3, 3], [-3, -1]]
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_CnElement
Bases: KirillovReshetikhinGenericCrystalElement

Class for the elements in the Kirillov-Reshetikhin crystals \(B^{\text{n,s}}\) of type \(\mathbb{C}^{(1)}_{n}\).

**EXAMPLES:**
```
sage: K=crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: type(K.module_generators[0])
class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Cn_with_category.element_class'
```

**e0()**
Return \(e_0\) on \(self\) by going to the \(\pm\)-diagram corresponding to the \(\{2, \ldots, n\}\)-highest weight vector in the component of \(self\), then applying [Definition 6.1, 4], and pulling back from \(\pm\)-diagrams.

**EXAMPLES:**
sage: K = crystals.KirillovReshetikhin(['C',3,1],3,2)
sage: b = K.module_generators[0]
sage: b.e(0) # indirect doctest
[[1, 2], [2, 3], [3, -1]]
sage: b = K(rows=[[1, 2], [2, 3], [3, -1]])
sage: b.e(0)
[[2, 2], [3, 3], [-1, -1]]
sage: b = K(rows=[[1, -3], [3, -2], [-3, -1]])
sage: b.e(0)
[[3, -3], [-3, -2], [-1, -1]]

epsilon0()  
Calculate $\varepsilon_0$ of self using Lemma 6.1 of [4].
EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.epsilon(0) # indirect doctest
1

f0()  
Return $e_0$ on self by going to the $\pm$-diagram corresponding to the $\{2, \ldots, n\}$-highest weight vector in the component of self, then applying [Definition 6.1, 4], and pulling back from $\pm$-diagrams.
EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.f(0) # indirect doctest

phi0()  
Calculate $\varphi_0$ of self.
EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0) # indirect doctest
0

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_D_tri1(ct, s)  
Bases: KirillovReshetikhinGenericCrystal  
Class of Kirillov-Reshetikhin crystals $B_{\lambda}^{1,*}$ of type $D_4^{(3)}$.  
The crystal structure was defined in Section 4 of [KMOY2007] using the coordinate representation.

class Element  
Bases: KirillovReshetikhinGenericCrystalElement  
coordinates()  
Return self as coordinates.
EXAMPLES:
Combinatorics, Release 10.1

sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 3)
sage: all(K.from_coordinates(x.coordinates()) == x for x in K)
True

e0()
Return the action of $e_0$ on self.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,3], 1,1)
sage: [x.e0() for x in K]
[[[-1]], [], [[-3]], [[-2]], None, None, None, None]

epsilon0()
Return $\epsilon_0$ of self.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: [mg.epsilon0() for mg in K.module_generators]
[5, 6, 7, 8, 9, 10]

f0()
Return the action of $f_0$ on self.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,3], 1,1)
sage: [x.f0() for x in K]
[[[1]], None, None, None, None, [[2]], [[3]], []]

phi0()
Return $\phi_0$ of self.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: [mg.phi0() for mg in K.module_generators]
[5, 4, 3, 2, 1, 0]

classical_decomposition()
Return the classical decomposition of self.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: K.classical_decomposition()
The crystal of tableaux of type ['G', 2]
and shape(s) [[], [1], [2], [3], [4], [5]]

from_coordinates(coords)
Return an element of self from the coordinates coords.

EXAMPLES:

5.1. Comprehensive Module List 463
sage: K = crystals.KirillovReshetikhin(['D',4,3], 1, 5)
sage: K.from_coordinates((0, 2, 3, 1, 0, 1))
[[2, 2, 3, 0, -1]]

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_Dn_twisted(cartan_type, r, s, 
dual=None)

Bases: KirillovReshetikhinGenericCrystal

Class of Kirillov-Reshetikhin crystals $B_{n,s}$ of type $D_{n+1}^{(2)}$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: [b.f(0) for b in K]
[[[+++, []], None], 
 [[++-, []], None], 
 [ [+--+, []], None], 
 [-+++, []], 
 [ [+--+, []], None], 
 [-+++, []], 
 [-+-, []]]

Element

alias of KR_type_Dn_twistedElement

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal $B_{n,s}$ of type $D_{n+1}^{(2)}$.

The classical decomposition is given by $B_{n,s} \cong B(s\Lambda_n)$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: T = K.classical_decomposition()

from_highest_weight_vector_to_pm_diagram(b)

This gives the bijection between an element $b$ in the classical decomposition of the KR crystal that is 
$\{2,3,...,n\}$-highest weight and $\pm$ diagrams.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: T = K.classical_decomposition()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3]) ]
sage: [K.from_highest_weight_vector_to_pm_diagram(b) for b in hw]
[[[0, 0], [0, 0], [1, 0], [0]], [[0, 0], [0, 0], [0, 1], [0]]]

464 Chapter 5. Comprehensive Module List
Note that, since the classical decomposition of this crystal is of type $B_n$, there can be (at most one) entry 0 in the $\{2, 3, \ldots, n\}$-highest weight elements at height $n$. In the following implementation this is realized as an empty column of height $n$ since this uniquely specifies the existence of the 0.

**EXAMPLES:**

```python
sage: b = hw[1]
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b)
sage: pm.pp()
```

### from_pm_diagram_to_highest_weight_vector($pm$)

This gives the bijection between a $\pm$ diagram and an element $b$ in the classical decomposition of the KR crystal that is $\{2, 3, \ldots, n\}$-highest weight.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D', 4, 2], 3, 2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[0, 0], [0, 0], [0, 0], [2]])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[[2], [3], [0]]
```

**class** `sage.combinat.crystals.kirillov_reshetikhin.KR_type_Dn_twistedElement`

Bases: `KirillovReshetikhinGenericCrystalElement`

Class for the elements in the Kirillov-Reshetikhin crystals $B^{n,s}$ of type $D^{(2)}_{n+1}$.

**EXAMPLES:**

```python
sage: K=crystals.KirillovReshetikhin(['D', 4, 2], 3, 3)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_Dn_twisted_with_category.element_class'>
```

### $e_0()$

Return $e_0$ on $self$ by going to the $\pm$-diagram corresponding to the $\{2, \ldots, n\}$-highest weight vector in the component of $self$, then applying [Definition 6.2, 4], and pulling back from $\pm$-diagrams.

**EXAMPLES:**

```python
sage: K=crystals.KirillovReshetikhin(['D', 4, 2], 3, 3)
sage: b = K.module_generators[0]
sage: b.e(0) # indirect doctest
[[+, [[2], [3], [0]]]
```

### $\epsilon_0()$

Calculate $\epsilon_0$ of $self$ using Lemma 6.2 of [4].

**EXAMPLES:**

```python
sage: K=crystals.KirillovReshetikhin(['D', 4, 2], 3, 1)
sage: b = K.module_generators[0]
sage: b.epsilon(0) # indirect doctest
1
```
Return \( e_0 \) on \( \text{self} \) by going to the \( \pm \)-diagram corresponding to the \( \{2, \ldots, n\} \)-highest weight vector in the component of \( \text{self} \), then applying [Definition 6.2, 4], and pulling back from \( \pm \)-diagrams.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,2)
sage: b = K.module_generators[0]
sage: b.f(0) # indirect doctest
```

Calculate \( \varphi_0 \) of \( \text{self} \).

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D',4,2],3,1)
sage: b = K.module_generators[0]
sage: b.phi(0) # indirect doctest
```

**class** `sage.combinat.crystals.kirillov_reshetikhin.KR_type_E6(cartan_type, r, s)`

Bases: `KirillovReshetikhinCrystalFromPromotion`

Class of Kirillov-Reshetikhin crystals of type \( E_6^{(1)} \) for \( r = 1, 2, 6 \).

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.module_generator().e(0)
[]
sage: K.module_generator().e(0).f(0)
[(2, -1), (1,)]
sage: K = crystals.KirillovReshetikhin(['E',6,1], 1,1)
sage: b = K.module_generator()
sage: b
[(1,)]
sage: b.e(0)
[(2, -1), (-1,)]
sage: [t for t in K if t.epsilon(1) == 1 and t.phi(3) == 1 and t.phi(2) == 0...
  and t.epsilon(2) == 0][0]
sage: b
[(-1, 3)]
sage: b.e(0)
[(-1, -2, 3)]
```

The elements of the Kirillov-Reshetikhin crystals can be constructed from a classical crystal element using `retract()`.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: La = K.cartan_type().classical().root_system().weight_lattice().fundamental...
  weights()
sage: H = crystals.HighestWeight(La[2])
sage: t = H.module_generator()
sage: t
```
affine_weight\((b)\)

Return the affine level zero weight corresponding to the element \(b\) of the classical crystal underlying \(\text{self}\).

For the coefficients to calculate the level, see Table Aff 1 in [Ka1990].

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{K = crystals.KirillovReshetikhin(['E',6,1],2,1)} \\
\text{sage: } & \text{K.affine_weight(x.lift()) for x in K} \\
& \quad \text{if all(x.epsilon(i) == 0 for i in [2,3,4,5])} \\
\end{align*}
\]

automorphism_on_affine_weight\((weight)\)

Act with the Dynkin diagram automorphism on affine weights as outputted by the affine_weight method.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{K = crystals.KirillovReshetikhin(['E',6,1],2,1)} \\
\text{sage: } & \text{sorted([x[0], K.automorphism_on_affine_weight(x[0])] for x in K.highest_weight_dict().values())} \\
\end{align*}
\]

classical_decomposition()

Specifies the classical crystal underlying the KR crystal of type \(E_6^{(1)}\).

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{K = crystals.KirillovReshetikhin(['E',6,1], 2,2)} \\
\text{sage: } & \text{K.classical_decomposition()} \\
\end{align*}
\]
Finite dimensional highest weight crystal of type ['E', 6] and highest weight \( \rightarrow 2 \Lambda[2] \)

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 1,2)
sage: K.classical_decomposition()
```

`Direct sum of the crystals Family (Finite dimensional highest weight crystal of type ['E', 6] and highest weight \( \rightarrow 2 \Lambda[1] \)),`

```
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: [K.dynkin_diagram_automorphism(i) for i in K.index_set()]
[1, 6, 3, 5, 4, 2, 0]
```

`highest_weight_dict()`

Return a dictionary between \( \{1, 2, 3, 4, 5\} \)-highest weight elements, and a tuple of affine weights and its classical component.

```
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: sorted(K.highest_weight_dict().items(), key=str)
[(
[(2, -1), (1,)], ((-2, 0, 1, 0, 0, 0, 0), 1))]
```

`highest_weight_dict_inv()`

Return a dictionary between a tuple of affine weights and a classical component, and \( \{2, 3, 4, 5, 6\} \)-highest weight elements.

```
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.highest_weight_dict_inv()
{((-2, 0, 1, 0, 0, 0, 0), 1): 
[(2, -1), (1,)]}
```

`hw_auxiliary()`

Return the \( 2, 3, 4, 5 \) highest weight elements of `self`.

```
sage: K = crystals.KirillovReshetikhin(['E',6,1],2,1)
sage: K.hw_auxiliary()
```
promotion()

Specifies the promotion operator used to construct the affine type $E_6^{(1)}$ crystal.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2,1)
sage: promotion = K.promotion()
sage: all(promotion(promotion(promotion(b))) == b for b in K.classical_decomposition())
True
```

promotion_inverse()

Return the inverse promotion. Since promotion is of order 3, the inverse promotion is the same as promotion applied twice.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',6,1], 1,1)
sage: promotion = K.promotion()
sage: all(promotion(promotion(promotion(b))) == b for b in K.classical_decomposition())
True
```

promotion_on_highest_weight_vectors()

Return a dictionary of the promotion map on $\{1, 2, 3, 4, 5\}$-highest weight elements to $\{2, 3, 4, 5, 6\}$-highest weight elements in self.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2, 1)
sage: dic = K.promotion_on_highest_weight_vectors()
sage: sorted(dic.items(), key=str)
[(
([[2, -1], (1,)], 
([[1, -3], (-1, 3)]),
([[3, -1, -6], (1,)]),
([[5, -2, -6], (-6, 2)]),
([[6, -2], (-6, 2)]),
([], 
([[-1, -3], (-1, 3)])
]`
**promotion_on_highest_weight_vectors_function()**

Return a lambda function on x defined by self.promotion_on_highest_weight_vectors()[x].

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['E',6,1], 2, 1)
sage: f = K.promotion_on_highest_weight_vectors_function()
sage: f(K.module_generator().lift())
[(-1,), (-1, 3)]
```

**class** `sage.combinat.crystals.kirillov_reshetikhin.KR_type_E7(ct, r, s)`

Bases: `KirillovReshetikhinGenericCrystal`

The Kirillov-Reshetikhin crystal $B^{7,s}$ of type $E_7^{(1)}$.

**A7_decomposition()**

Return the decomposition of self into $A_7$ highest weight crystals.

The $A_7$ decomposition of $B^{7,s}$ is given by the parameters $m_4,m_5,m_6,m_7 \geq 0$ such that $m_4 + m_5 \leq m_7$ and $s = m_4 + m_5 + m_6 + m_7$. The corresponding $A_7$ highest weight crystal has highest weight $\lambda = (m_7-m_4-m_5)\Lambda_6 + m_5\Lambda_4 + m_6\Lambda_2$.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 3)
sage: K.A7_decomposition()
The crystal of tableaux of type ['A', 7] and shape(s)
[[3, 3, 3, 3, 3, 3], [3, 3, 2, 2, 2, 2], [3, 3, 1, 1, 1, 1], [3, 3], [2, 2, 2, 2, 1, 1], [2, 2, 1, 1], [1, 1, 1, 1, 1, 1], [1, 1]]
```

class `Element`

Bases: `KirillovReshetikhinGenericCrystalElement`

**e0()**

Return the action of $e_0$ on self.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: mg = K.module_generator()
sage: mg.e0()
[[7,7], (-1, 7)]
sage: mg.e0().e0()
[[(-1, 7), (-1, 7)]
sage: mg.e_string([0,0,0]) is None
True
```

**f0()**

Return the action of $f_0$ on self.

**EXAMPLES:**

```
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: mg = K.module_generator()
sage: x = mg.f_string([7,6,5,4,3,2,4,5,6,1,3,4,5,2,4,3,1])
sage: x.f0()
(continues on next page)```
classical_decomposition()

Return the classical decomposition of self.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 4)
sage: K.classical_decomposition()
The crystal of tableaux of type ['E', 7] and shape(s) [[4]]
```

from_A7_crystal()

Return the inclusion of the KR crystal $B^{7,s}_r$ of type $E^{(1)}_7$ into type $A_7$ highest weight crystals.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: K.from_A7_crystal()
['A', 6] -> ['E', 7, 1] Virtual Crystal morphism:
  From: The crystal of tableaux of type ['A', 7] and shape(s)
    [[2, 2, 2, 2, 2, 2], [2, 2, 1, 1, 1, 1], [2, 2], [1, 1, 1, 1], []]
  To: Kirillov-Reshetikhin crystal of type ['E', 7, 1] with (r,s)=(7,2)
  Defn: ...
```

to_A7_crystal()

Return the map decomposing the KR crystal $B^{7,s}_r$ of type $E^{(1)}_7$ into type $A_7$ highest weight crystals.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['E',7,1], 7, 2)
sage: K.to_A7_crystal()
  From: Kirillov-Reshetikhin crystal of type ['E', 7, 1] with (r,s)=(7,2)
  To: The crystal of tableaux of type ['A', 7] and shape(s)
    [[2, 2, 2, 2, 2, 2], [2, 2, 1, 1, 1, 1], [2, 2], [1, 1, 1, 1], []]
  Defn: ...
```

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_box(cartan_type, r, s)

Bases: KirillovReshetikhinGenericCrystal, AffineCrystalFromClassical

Class of Kirillov-Reshetikhin crystals $B^{r,s}_r$ of type $A^{(2)}_{2n}$ for $r \leq n$ and type $D^{(2)}_{n+1}$ for $r < n$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',4,2], 1,1)
sage: b = K(rows=[])
sage: b.f(0)
[[1]]
```

(continues on next page)
Combinatorics, Release 10.1

sage: b.e(0)
\([-1]\)

Element
alias of KR_type_boxElement

ambient_crystal()

Return the ambient crystal $B_{r,s}^{(1)}$ of type $C_n^{(1)}$ associated to the Kirillov-Reshetikhin crystal.

The ambient crystal is used to construct the zero arrows.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['A',4,2], 2,2)
sage: K.ambient_crystal()
Kirillov-Reshetikhin crystal of type ['C', 2, 1] with (r,s)=(2,4)

ambient_highest_weight_dict()

Return a dictionary of the classical highest weight vectors of the ambient crystal of self whose keys are their shape.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['A',6,2], 2,2)
sage: K.ambient_highest_weight_dict()
{
    []: [],
    [2]: [[1, 1]],
    [2, 2]: [[1, 1, 1], [2, 2]],
    [4]: [[1, 1, 1, 1]],
    [4, 2]: [[1, 1, 1, 1], [2, 2]],
    [4, 4]: [[1, 1, 1, 1], [2, 2, 2, 2]]
}

classical_decomposition()

Return the classical crystal underlying the Kirillov-Reshetikhin crystal of type $A_{2n}^{(2)}$ and $D_{n+1}^{(2)}$.

It is given by $B_{r,s}^{(r,s)} \cong \bigoplus_{\Lambda} B(\Lambda)$, where $\Lambda$ are weights obtained from a rectangle of width $s$ and height $r$ by removing boxes. Here we identify the fundamental weight $\Lambda_i$ with a column of height $i$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['A',4,2], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['C', 2] and shape(s) [[], [1], [2], [1, 1], [2, 1], [2, 2]]
sage: K = crystals.KirillovReshetikhin(['D',4,2], 2,3)
sage: K.classical_decomposition()
The crystal of tableaux of type ['B', 3] and shape(s) [[], [1], [2], [1, 1], [2, 2], [3, 1], [2, 3], [3, 2], [3, 3]]

from_ambient_crystal()

Return a map from the ambient crystal of type $C_n^{(1)}$ to the Kirillov-Reshetikhin crystal self.

Note that this map is only well-defined on elements that are in the image under to_ambient_crystal().

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['D',4,2], 1,1)
  sage: b = K.ambient_crystal()(rows=[[3,-3]])
  sage: K.from_ambient_crystal()(b)
[[0]]
  sage: K = crystals.KirillovReshetikhin(['A',4,2], 1,1)
  sage: b = K.ambient_crystal()(rows=[])  
  sage: K.from_ambient_crystal()(b)
[]

highest_weight_dict()

Return a dictionary of the classical highest weight vectors of self whose keys are 2 times their shape.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['A',6,2], 2,2)
  sage: K.highest_weight_dict()
{
    []: [],
    [2]: [[1]],
    [2, 2]: [[1], [2]],
    [4]: [[1, 1]],
    [4, 2]: [[1, 1], [2]],
    [4, 4]: [[1, 1], [2, 2]]
}

similarity_factor()

Sets the similarity factor used to map to the ambient crystal.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['A',6,2], 2,2)
  sage: K.similarity_factor()
{1: 2, 2: 2, 3: 2}
  sage: K = crystals.KirillovReshetikhin(['D',5,2], 1,1)
  sage: K.similarity_factor()
{1: 2, 2: 2, 3: 2, 4: 1}

to_ambient_crystal()

Return a map from self to the ambient crystal of type $C_n^{(1)}$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,2], 1,1)
  sage: [K.to_ambient_crystal()(b) for b in K]
[[[]], [[1, 1]], [[2, 2]], [[3, 3]], [[3, -3]], [[-3, -3]], [[-2, -2]], [[-1, -1]]]
  sage: K = crystals.KirillovReshetikhin(['A',4,2], 1,1)
  sage: [K.to_ambient_crystal()(b) for b in K]
[[[]], [[1, 1]], [[2, 2]], [[-2, -2]], [[-1, -1]]]

class sage.combinat.crystals.kirillov_reshetikhin.KR_type_boxElement

Bases: KirillovReshetikhinGenericCrystalElement

Class for the elements in the Kirillov-Reshetikhin crystals $B_r^{r,s}$ of type $A_{2n}^{(2)}$ for $r \leq n$ and type $D_{n+1}^{(2)}$ for $r < n$.

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: K = crystals.KirillovReshetikhin(['A',4,2],1,2)
sage: type(K.module_generators[0])
<class 'sage.combinat.crystals.kirillov_reshetikhin.KR_type_box_with_category.element_class'>
```

\section{e0()}
Return $e_0$ on \texttt{self} by mapping \texttt{self} to the ambient crystal, calculating $e_0$ there and pulling the element back.

\textbf{EXAMPLES:}

```python
sage: K = crystals.KirillovReshetikhin(['A',4,2],1,1)
sage: b = K(rows=[[]])
sage: b.e(0) # indirect doctest
[-1]
```

\section{epsilon0()}
Return $\varepsilon_0$ of \texttt{self} by mapping the element to the ambient crystal and calculating $\varepsilon_0$ there.

\textbf{EXAMPLES:}

```python
sage: K = crystals.KirillovReshetikhin(['A',4,2],1,1)
sage: b = K(rows=[[1]])
sage: b.epsilon(0) # indirect doctest
2
```

\section{f0()}
Return $f_0$ on \texttt{self} by mapping \texttt{self} to the ambient crystal, calculating $f_0$ there and pulling the element back.

\textbf{EXAMPLES:}

```python
sage: K = crystals.KirillovReshetikhin(['A',4,2],1,1)
sage: b = K(rows=[[]])
sage: b.f(0) # indirect doctest
[[1]]
```

\section{phi0()}
Return $\varphi_0$ of \texttt{self} by mapping the element to the ambient crystal and calculating $\varphi_0$ there.

\textbf{EXAMPLES:}

```python
sage: K = crystals.KirillovReshetikhin(['D',3,2],1,1)
sage: b = K(rows=[[-1]])
sage: b.phi(0) # indirect doctest
2
```

\section{KR Type Spin}

\textbf{Class:} \texttt{sage.combinat.crystals.kirillov_reshetikhin.KR_type_spin(cartan_type, r, s)}

\textbf{Bases:} \texttt{KirillovReshetikhinCrystalFromPromotion}

Class of Kirillov-Reshetikhin crystals $B_n^s$ of type $D_n^{(1)}$.

\textbf{EXAMPLES:}
sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1); K
Kirillov-Reshetikhin crystal of type ['D', 4, 1] with (r,s)=(4,1)
sage: [[b,b.f(0)] for b in K]
[[[++++, []], None], [[++--, []], None], [[+-+-, []], None],
[[-++-, []], None], [[+--+, []], None], [[-+-+, []], None],
[[--++, []], [++++, []]], [[----, []], [++--., []]]]
sage: K = crystals.KirillovReshetikhin(['D',4,1],4,2); K
Kirillov-Reshetikhin crystal of type ['D', 4, 1] with (r,s)=(4,2)
sage: [[b,b.f(0)] for b in K]
[[[1], [2], [3], [4]], None], [[[1], [2], [-4], [4]], None],
[[[1], [3], [-4], [4]], None], [[[2], [3], [-4], [4]], None],
[[[1], [4], [-4], [4]], None], [[[2], [4], [-4], [4]], None],
[[[3], [4], [-4], [4]], [[1], [2], [3], [4]]],
[[[-4], [4], [-4], [4]], [[1], [2], [-4], [4]]],
[[[-4], [4], [-4], [-3]], [[1], [2], [-4], [-3]]],
[[[-4], [4], [-4], [-2]], [[1], [3], [-4], [-3]]],
[[[-4], [4], [-4], [-1]], [[2], [3], [-4], [-3]]],
[[[-4], [4], [-3], [-2]], [[1], [4], [-4], [-3]]],
[[[-4], [4], [-3], [-1]], [[2], [4], [-4], [-3]]],
[[[-4], [4], [-2], [-1]], [[-4], [4], [-4], [4]]],
[[[-4], [-3], [-2], [-1]], [[-4], [4], [-4], [-3]]],
[[[1], [2], [-4], [-3]], None], [[[[1], [3], [-4], [-3]], None],
[[[2], [3], [-4], [-3]], None], [[[[1], [3], [-4], [-2]], None],
[[[2], [3], [-4], [-1]], None], [[[[2], [3], [-4], [-1]], None],
[[[1], [4], [-4], [-3]], None], [[[[2], [4], [-4], [-3]], None],
[[[3], [4], [-4], [-3]], None], [[[[3], [4], [-4], [-2]], None],
[[[1], [3], [-4], [-2]], [[1], [3], [-4], [4]]],
[[[3], [4], [-4], [-1]], [[2], [3], [-4], [4]]],
[[[1], [4], [-4], [-1]], [[2], [4], [-4], [4]]],
[[[2], [4], [-4], [-1]], [[3], [4], [-4], [4]]]]

classical_decomposition()  
Return the classical crystal underlying the Kirillov-Reshetikhin crystal $B_{r,s}^{r-s}$ of type $D_n^{(1)}$ for $r = n-1, n$.  
The classical decomposition is given by $B_{n,s}^{r-s} \cong B(s\Lambda_r)$.  
EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1/2, 1/2, 1/2, 1/2]]
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1/2, 1/2, 1/2, -1/2]]
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[1, 1, 1, -1]]

dynkin_diagram_automorphism(i)
Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements.

Here we use the Dynkin diagram automorphism which interchanges nodes 0 and 1 and leaves all other
nodes unchanged.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1],4,1)
sage: K.dynkin_diagram_automorphism(0)
1
sage: K.dynkin_diagram_automorphism(1)
0
sage: K.dynkin_diagram_automorphism(4)
4
```

**promotion()**

Return the promotion operator on $B^{r,s}$ of type $D_n^{(1)}$ for $r = n - 1, n$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: T = K.classical_decomposition()
sage: promotion = K.promotion()
sage: for t in T:
    ....:     print("{} {}".format(t, promotion(t)))
[+---, []] [-+++,-[]]
[---+, []] [+--+, []]
[++-+, []] [-++, [][]]
[-++, [], [+], ++-[-]]
```

**promotion_inverse()**

Return the inverse promotion operator on $B^{r,s}$ of type $D_n^{(1)}$ for $r = n - 1, n$.

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1],3,1)
sage: T = K.classical_decomposition()
sage: promotion = K.promotion()
sage: promotion_inverse = K.promotion_inverse()
sage: all(promotion_inverse(promotion(t)) == t for t in T)
True
```

**promotion_on_highest_weight_vectors()**

Return the promotion operator on $\{2, 3, \ldots, n\}$-highest weight vectors.

A $\{2, 3, \ldots, n\}$-highest weight vector in $B(s\Lambda_n)$ of weight $w = (w_1, \ldots, w_n)$ is mapped to a
$\{2, 3, \ldots, n\}$-highest weight vector in $B(s\Lambda_{n-1})$ of weight $(-w_1, w_2, \ldots, w_n)$ and vice versa.

See also:

- **promotion_on_highest_weight_vectors_inverse()**
• promotion()

EXAMPLES:

```python
sage: KR = crystals.KirillovReshetikhin(['D',4,1],4,2)
sage: prom = KR.promotion_on_highest_weight_vectors()
sage: T = KR.classical_decomposition()
sage: HW = [t for t in T if t.is_highest_weight([2,3,4])]
sage: for t in HW:
    ....:     print("{} {}".format(t, prom[t]))
[[1], [2], [3], [4]] [[2], [3], [4], [-1]]
[[2], [3], [-4], [4]] [[2], [3], [4], [-4]]
[[2], [3], [-4], [-1]] [[1], [2], [3], [-4]]
```

```
promotion_on_highest_weight_vectors_inverse()

Return the inverse promotion operator on \{2,3,\ldots,n\}-highest weight vectors.

See also:

• promotion_on_highest_weight_vectors()
• promotion_inverse()

EXAMPLES:

```python
sage: KR = crystals.KirillovReshetikhin(['D',4,1],3,2)
sage: prom = KR.promotion_on_highest_weight_vectors()
sage: prom_inv = KR.promotion_on_highest_weight_vectors_inverse()
sage: T = KR.classical_decomposition()
sage: HW = [t for t in T if t.is_highest_weight([2,3,4])]
sage: all(prom_inv[prom[t]] == t for t in HW)
True
```
```
sage: b.e(0)  # [[-2], [-1]]
sage: b.e(0).e(0)  # [[-2, -2], [-1, -1]]

sage: K = crystals.KirillovReshetikhin(['D',5,1], 3,1)
sage: b = K(rows=[[1]])
sage: b.e(0)  # [[3], [-3], [-2]]

sage: K = crystals.KirillovReshetikhin(['B',3,1], 1,1)

[[b,b.f(0)] for b in K]  # 
[[[[1]], None], [[[2]], None], [[[3]], None], [[[0]], None],
 [=[[3]], None], [[[2]], [[1]]], [[[-3]], [[-1]], [[2]]]]

sage: K = crystals.KirillovReshetikhin(['A',5,2],1,1)

[[b,b.f(0)] for b in K]  # 
[[[[1]], None], [[[2]], None], [[[3]], None], [[[0]], None],
 [=[[3]], None], [[[2]], [[1]]], [[[-1]], [[2]]]]

classical_decomposition()

Specifies the classical crystal underlying the Kirillov-Reshetikhin crystal of type $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$.

It is given by $B^{(r,s)} \cong \bigoplus_{\Lambda} B(\Lambda)$, where $\Lambda$ are weights obtained from a rectangle of width $s$ and height $r$ by removing vertical dominoes. Here we identify the fundamental weight $\Lambda_i$ with a column of height $i$.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: K.classical_decomposition()
The crystal of tableaux of type ['D', 4] and shape(s) [[], [1, 1], [2, 2]]

dynkin_diagram_automorphism(i)

Specifies the Dynkin diagram automorphism underlying the promotion action on the crystal elements. The automorphism needs to map node 0 to some other Dynkin node.

Here we use the Dynkin diagram automorphism which interchanges nodes 0 and 1 and leaves all other nodes unchanged.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D',4,1],1,1)
sage: K.dynkin_diagram_automorphism(0)  # 1
sage: K.dynkin_diagram_automorphism(1)  # 0
sage: K.dynkin_diagram_automorphism(4)  # 4

from_highest_weight_vector_to_pm_diagram(b)

This gives the bijection between an element $b$ in the classical decomposition of the KR crystal that is $2, 3, \ldots, n$-highest weight and $\pm$ diagrams.

EXAMPLES:
```python
sage: K = crystals.KirillovReshetikhin(['D'],4,1, 2,2)
sage: T = K.classical_decomposition()
sage: b = T(rows=[[2],[-2]])
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b); pm
[[1, 1], [0, 0], [0]]
sage: pm.pp()
+
-
sage: b = T(rows=[])  
sage: pm = K.from_highest_weight_vector_to_pm_diagram(b); pm
[[0, 2], [0, 0], [0]]
sage: pm.pp()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3,4]) ]
sage: all(K.from_pm_diagram_to_highest_weight_vector(K.from_highest_weight_vector_to_pm_diagram(b)) == b for b in hw)
True
```

**from_pm_diagram_to_highest_weight_vector(pm)**
This gives the bijection between a \( \pm \) diagram and an element \( b \) in the classical decomposition of the KR crystal that is 2,3,...,\( n \)-highest weight.

**EXAMPLES:**
```python
sage: K = crystals.KirillovReshetikhin(['D'],4,1, 2,2)
sage: pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[1, 1], [0, 0], [0]])
sage: K.from_pm_diagram_to_highest_weight_vector(pm)
[[2], [-2]]
```

**promotion()**
Specifies the promotion operator used to construct the affine type \( D_{n}^{(1)} \) etc. crystal.
This corresponds to the Dynkin diagram automorphism which interchanges nodes 0 and 1, and leaves all other nodes unchanged. On the level of crystals it is constructed using \( \pm \) diagrams.

**EXAMPLES:**
```python
sage: K = crystals.KirillovReshetikhin(['D'],4,1, 2,2)
sage: promotion = K.promotion()
sage: b = K.classical_decomposition()(rows=[])  
sage: promotion(b)
[[1, 2], [-2, -1]]
sage: b = K.classical_decomposition()(rows=[[1,3],[2,-1]])
sage: promotion(b)
[[1, 3], [2, -1]]
sage: b = K.classical_decomposition()(rows=[[1],[-3]])
sage: promotion(b)
[[2, -3], [-2, -1]]
```

**promotion_inverse()**
Return inverse of promotion.
In this case promotion is an involution, so promotion inverse equals promotion.

**EXAMPLES:**
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: promotion = K.promotion()
sage: promotion_inverse = K.promotion_inverse()
sage: all( promotion_inverse(promotion(b.lift())) == b.lift() for b in K )
True

**promotion_on_highest_weight_vector(b)**

Calculates promotion on a 2, 3, ..., n highest weight vector b.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2,2)
sage: T = K.classical_decomposition()
sage: hw = [ b for b in T if all(b.epsilon(i)==0 for i in [2,3,4]) ]
sage: [K.promotion_on_highest_weight_vector(b) for b in hw]  # calculating promotion on the highest weight vectors
[[[1, 2], [-2, -1]], [[2, 2], [-2, -1]], [[1, 2], [3, -1]],
 [[2], [-2]], [[1, 2], [2, -2]], [[2, 2], [-1, -1]],
 [[2, 2], [3, -1]], [[2, 2], [3, 3]], [], [[1], [2]],
 [[1, 1], [2, 2]], [[2], [-1]], [[1, 2], [2, -1]],
 [[2], [3]], [[1, 2], [2, 3]]]
```

**sage.combinat.crystals.kirillov_reshetikhin.KashiwaraNakashimaTableaux(cartan_type, r, s)**

Return the Kashiwara-Nakashima model for the Kirillov-Reshetikhin crystal \( B_{r,s} \) in the given type.

The Kashiwara-Nakashima (KN) model constructs the KR crystal from the KN tableaux model for the corresponding classical crystals. This model is named for the underlying KN tableaux.

Many Kirillov-Reshetikhin crystals are constructed from a classical crystal together with an automorphism \( p \) on the level of crystals which corresponds to a Dynkin diagram automorphism mapping node 0 to some other node \( i \). The action of \( f_0 \) and \( e_0 \) is then constructed using \( f_0 = p^{-1} \circ f_i \circ p \).

For example, for type \( A^{(1)}_n \) the Kirillov-Reshetikhin crystal \( B_{r,s} \) is obtained from the classical crystal \( B(s\omega_r) \) using the promotion operator. For other types, see [Shi2002], [Sch2008], and [JS2010].

Other Kirillov-Reshetikhin crystals are constructed using similarity methods. See Section 4 of [FOS2009].

For more information on Kirillov-Reshetikhin crystals, see `KirillovReshetikhinCrystal()`.

**EXAMPLES:**

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2, 1)
sage: K2 = crystals.kirillov_reshetikhin.KashiwaraNakashimaTableaux(['A',3,1], 2, 1)
sage: K is K2
True
```

**sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystal(cartan_type, r, s, model='KN')**

Return the Kirillov-Reshetikhin crystal \( B_{r,s} \) of the given type in the given model.

For more information about general crystals see `sage.combinat.crystals.crystals`.

There are a variety of models for Kirillov-Reshetikhin crystals. There is one using the classical crystal with Kashiwara-Nakashima tableaux. There is one using rigged configurations. Another tableaux model comes from the bijection between rigged configurations and tensor products of tableaux called Kirillov-Reshetikhin tableaux. Lastly there is a model of Kirillov-Reshetikhin crystals for \( s = 1 \) from crystals of LS paths.

**INPUT:**
• cartan_type – an affine Cartan type
• r – a label of finite Dynkin diagram
• s – a positive integer
• model – (default: 'KN') can be one of the following:
  – 'KN' or 'KashiwaraNakashimaTableaux' - use the Kashiwara-Nakashima tableaux model
  – 'KR' or 'KirillovReshetikhinTableaux' - use the Kirillov-Reshetikhin tableaux model
  – 'RC' or 'RiggedConfiguration' - use the rigged configuration model
  – 'LSPaths' - use the LS path model

EXAMPLES:

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2, 1)
sage: K.index_set()
(0, 1, 2, 3)
sage: K.list()
[[[1], [2]], [[1], [3]], [[2], [3]], [[1], [4]], [[2], [4]], [[3], [4]]]
sage: b = K(rows=[[1],[2]])
sage: b.weight()
-Lambda[0] + Lambda[2]
```

```python
sage: K = crystals.KirillovReshetikhin(['A',3,1], 2, 2)
sage: K.automorphism(K.module_generators[0])
[[2, 2], [3, 3]]
sage: K.module_generators[0].e(0)
[[1, 2], [2, 4]]
sage: K.module_generators[0].f(2)
[[1, 1], [2, 3]]
sage: K.module_generators[0].f(1)

sage: K.module_generators[0].phi(0)
0
sage: K.module_generators[0].phi(1)
0
sage: K.module_generators[0].phi(2)
2
sage: K.module_generators[0].epsilon(0)
2
sage: K.module_generators[0].epsilon(1)
0
sage: K.module_generators[0].epsilon(2)
0
sage: b = K(rows=[[1,2],[2,3]])
sage: b
[[1, 2], [2, 3]]
sage: b.f(2)
[[1, 2], [3, 3]]
```

```python
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
sage: K.cartan_type()
['D', 4, 1]
sage: type(K.module_generators[0])
```

sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromLSPaths\((\text{cartan\_type, } r, s=1)\)

Single column Kirillov-Reshetikhin crystals.

This yields the single column Kirillov-Reshetikhin crystals from the projected level zero LS paths, see CrystalOfLSPaths. This works for all types (even exceptional types). The weight of the canonical element in this crystal is \(\Lambda_r\). For other implementation see KirillovReshetikhinCrystal().

EXAMPLES:

```python
sage: K = crystals.kirillov_reshetikhin.LSPaths(['A',2,1],2) # indirect doctest
sage: KR = crystals.KirillovReshetikhin(['A',2,1],2,1)
sage: G = K.digraph()
sage: GR = KR.digraph()
sage: G.is_isomorphic(GR, edge_labels = True)
True

sage: K = crystals.kirillov_reshetikhin.LSPaths(['C',3,1],2)
sage: KR = crystals.KirillovReshetikhin(['C',3,1],2,1)
sage: G = K.digraph()
sage: GR = KR.digraph()
sage: G.is_isomorphic(GR, edge_labels = True)
True

sage: K = crystals.kirillov_reshetikhin.LSPaths(['E',6,1],1)
sage: KR = crystals.KirillovReshetikhin(['E',6,1],1,1)
sage: G = K.digraph()
sage: GR = KR.digraph()
sage: G.is_isomorphic(GR, edge_labels = True)
True
sage: K.cardinality()
27

sage: K = crystals.kirillov_reshetikhin.LSPaths(['G',2,1],1)
sage: K.cardinality()

True

class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotion(cartan_type, r, s)

Bases: KirillovReshetikhinGenericCrystal, AffineCrystalFromClassicalAndPromotion

This generic class assumes that the Kirillov-Reshetikhin crystal is constructed from a classical crystal using the classical_decomposition and an automorphism promotion and its inverse, which corresponds to a Dynkin diagram automorphism dynkin_diagram_automorphism.

Each instance using this class needs to implement the methods:

• classical_decomposition
• promotion
• promotion_inverse
• dynkin_diagram_automorphism

Element

alias of KirillovReshetikhinCrystalFromPromotionElement

class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinCrystalFromPromotionElement

Bases: AffineCrystalFromClassicalAndPromotionElement, KirillovReshetikhinGenericCrystalElement

Element for a Kirillov-Reshetikhin crystal from promotion.

class sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystal(cartan_type, r, s, dual=None)

Bases: AffineCrystalFromClassical

Generic class for Kirillov-Reshetikhin crystal $B^{r,s}$ of the given type.

Input is a Dynkin node $r$, a positive integer $s$, and a Cartan type cartan_type.

Element

alias of KirillovReshetikhinGenericCrystalElement

classically_highest_weight_vectors()

Return the classically highest weight vectors of self.

EXAMPLES:

sage: K = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
sage: K.classically_highest_weight_vectors()
([], [[1], [2]], [[1, 1], [2, 2]])
**kirillov_reshetikhin_tableaux()**

Return the corresponding set of *KirillovReshetikhinTableaux*.

**EXAMPLES:**

```sage
sage: KRC = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2)
sage: KRC.kirillov_reshetikhin_tableaux()
Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and shape (2, 2)
```

**module_generator()**

Return the unique module generator of classical weight $s\Lambda_r$ of a Kirillov-Reshetikhin crystal $B^{r,s}$.

**EXAMPLES:**

```sage
sage: K = crystals.KirillovReshetikhin(['C',2,1],1,2)
sage: K.module_generator()
[[1, 1]]
sage: K = crystals.KirillovReshetikhin(['E',6,1],1,1)
sage: K.module_generator()
[(1,)]
sage: K = crystals.KirillovReshetikhin(['D',4,1],2,1)
sage: K.module_generator()
[[1], [2]]
```

**r()**

Return $r$ of the underlying Kirillov-Reshetikhin crystal $B^{r,s}$.

**EXAMPLES:**

```sage
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
sage: K.r()
2
```

**s()**

Return $s$ of the underlying Kirillov-Reshetikhin crystal $B^{r,s}$.

**EXAMPLES:**

```sage
sage: K = crystals.KirillovReshetikhin(['D',4,1], 2, 1)
sage: K.s()
1
```

**class**

`sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinGenericCrystalElement`

**Bases:** *AffineCrystalFromClassicalElement*

Abstract class for all Kirillov-Reshetikhin crystal elements.

**lusztig_involution()**

Return the classical Lusztig involution on self.

**EXAMPLES:**

```sage
sage: KRC = crystals.KirillovReshetikhin(['D',4,1], 2, 2)
sage: elt = KRC(-1,2); elt
```

(continues on next page)
pp()  
Pretty print self.

EXAMPLES:

```python
sage: C = crystals.KirillovReshetikhin(['D',4,1], 2,1)
sage: C(2,1).pp()
[1]
[2]
sage: C = crystals.KirillovReshetikhin(['B',3,1], 3,3)
sage: C.module_generators[0].pp()
[+]
[1]
```

to_kirillov_reshetikhin_tableau()  
Construct the corresponding `KirillovReshetikhinTableauxElement` from self.

We construct the Kirillov-Reshetikhin tableau element as follows:

1. Let $\lambda$ be the shape of self.
2. Determine a path $e_{i_1} e_{i_2} \cdots e_{i_k}$ to the highest weight.
3. Apply $f_{i_k} \cdots f_{i_2} f_{i_1}$ to a highest weight KR tableau from filling the shape $\lambda$.

EXAMPLES:

```python
sage: KRC = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1)
sage: KRC(columns=[[2,1]]).to_kirillov_reshetikhin_tableau()
[[1], [2]]
sage: KRC = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1)
sage: KRC(rows=[]).to_kirillov_reshetikhin_tableau()
[[1], [-1]]
```

to_tableau()  
Return the `Tableau` corresponding to self.

EXAMPLES:

```python
sage: C = crystals.KirillovReshetikhin(['D',4,1], 2,1)
sage: t = C(2,1).to_tableau(); t
[[1], [2]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
```

class sage.combinat.crystals.kirillov_reshetikhin.PMDiagram(pm_diagram, from_shapes=None)
Bases: CombinatorialObject

Class of $\pm$ diagrams. These diagrams are in one-to-one bijection with $X_{n-1}$ highest weight vectors in an $X_n$ highest weight crystal $X = B, C, D$. See Section 4.1 of [Sch2008].
The input is a list \( pm = [(a_0, b_0), (a_1, b_1), \ldots, (a_{n-1}, b_{n-1}), (b_n)] \) of pairs and a last 1-tuple (or list of length 1). The pair \((a_i, b_i)\) specifies the number of \(a_i + \) and \(b_i -\) in the \(i\)-th row of the \(\pm\) diagram if \(n - i\) is odd and the number of \(a_i \pm\) pairs above row \(i\) and \(b_i\) columns of height \(i\) not containing any \(+\) or \(-\) if \(n - i\) is even.

Setting the option \texttt{from\_shapes} = \texttt{True} one can also input a \(\pm\) diagram in terms of its outer, intermediate, and inner shape by specifying a list \([n, s, \text{outer}, \text{intermediate}, \text{inner}]\) where \(s\) is the width of the \(\pm\) diagram, and \text{outer}, \text{intermediate}, and \text{inner} are the outer, intermediate, and inner shapes, respectively.

**EXAMPLES:**

```python
sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0,1],[1,2],[1]])
```

```plaintext
[[0, 1], [1, 2], [1]]
```

```python
sage: pm.pm_diagram
[1, 1, 2, 0, 1]
```

```python
sage: pm.n
2
```

```python
sage: pm.width
5
```

```python
sage: pm.pp()
... . . . . .
  . + - - .
```

```python
sage: PMDiagram([2,5,[4,4],[4,2],[4,1]], from\_shapes=True)
```

```plaintext
[[0, 1], [1, 2], [1]]
```

**heights\_of\_addable\_plus()**

Return a list with the heights of all addable plus in the \(\pm\) diagram.

**EXAMPLES:**

```python
sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
```

```plaintext
[[1, 2, 3, 4, 5]
```

```python
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1,1],[1]])
```

```plaintext
[1, 2, 3, 4]
```

**heights\_of\_minus()**

Return a list with the heights of all minus in the \(\pm\) diagram.

**EXAMPLES:**

```python
sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
```

```plaintext
[5, 5, 3, 3, 1, 1]
```

```python
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1,1],[1]])
```

```plaintext
[4, 4, 2, 2]
```

**inner\_shape()**

Return the inner shape of the pm diagram

**EXAMPLES:**

```python
```
intermediate_shape()  
Return the intermediate shape of the pm diagram (inner shape plus positions of plusses)  

EXAMPLES:

```python
sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0,1],[1,2],[1]])
sage: pm.intermediate_shape()
[4, 2]
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.intermediate_shape()
[8, 6, 4, 2]
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.intermediate_shape()
[11, 8, 6, 4, 2]
sage: pm = PMDiagram([[1,0],[0,1],[2,0],[0,0],[0]])
sage: pm.intermediate_shape()
[4, 2, 2]
sage: pm = PMDiagram([[1, 0], [0, 0], [0, 0], [0, 0], [0]])
sage: pm.intermediate_shape()
[1]
```

outer_shape()  
Return the outer shape of the ± diagram  

EXAMPLES:

```python
sage: from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram
sage: pm = PMDiagram([[0,1],[1,2],[1]])
sage: pm.outer_shape()
[4, 4]
sage: pm = PMDiagram([[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.outer_shape()
[8, 8, 4, 4]
sage: pm = PMDiagram([[1,2],[1,2],[1,1],[1,1],[1,1],[1]])
sage: pm.outer_shape()
[13, 8, 8, 4, 4]
```

pp()  
Pretty print self.  

EXAMPLES:
from sage.combinat.crystals.kirillov_reshetikhin import PMDiagram

pm = PMDiagram([[1,0],[0,1],[2,0],[0,0],[0]])

pm.pp()

pm = PMDiagram([[0,2],[0,0],[0]])

pm.pp()

sigma()

Return sigma on pm diagrams as needed for the analogue of the Dynkin diagram automorphism that interchanges nodes 0 and 1 for type $D_n(1)$, $B_n(1)$, $A_{2n-1}(2)$ for Kirillov-Reshetikhin crystals.

EXAMPLES:

pm = sage.combinat.crystals.kirillov_reshetikhin.PMDiagram([[0],[1],[2],[1]])

pm.sigma()

[[1, 0], [2, 1], [1]]

sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(r,s)

Returns all partitions obtained from a rectangle of width $s$ and height $r$ by removing horizontal dominoes.

EXAMPLES:

sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(2,2)

[[], [2], [2, 2]]

sage.combinat.crystals.kirillov_reshetikhin.horizontal_dominoes_removed(3,2)

[[], [2], [2, 2], [2, 2, 2]]

sage.combinat.crystals.kirillov_reshetikhin.partitions_in_box(r,s)

Returns all partitions in a box of width $s$ and height $r$.

EXAMPLES:

sage.combinat.crystals.kirillov_reshetikhin.partitions_in_box(3,2)

[[], [1], [2], [1, 1], [2, 1], [1, 1, 1], [2, 2], [2, 1, 1],
 [2, 2, 1], [2, 2, 2]]

sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(r,s)

Returns all partitions obtained from a rectangle of width $s$ and height $r$ by removing vertical dominoes.

EXAMPLES:

sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(2,2)

[[], [1, 1], [2, 2]]

sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(3,2)

[[2], [2, 1, 1], [2, 2, 2]]

sage.combinat.crystals.kirillov_reshetikhin.vertical_dominoes_removed(4,2)

[[], [1, 1], [1, 1, 1, 1], [2, 2], [2, 2, 1, 1], [2, 2, 2, 2]]
5.1.56 Kyoto Path Model for Affine Highest Weight Crystals

class sage.combinat.crystals.kyoto_path_model.KyotoPathModel(crystals, weight, P)

Bases: TensorProductOfCrystals

The Kyoto path model for an affine highest weight crystal.

Note: Here we are using anti-Kashiwara notation and might differ from some of the literature.

Consider a Kac–Moody algebra \( g \) of affine Cartan type \( X \), and we want to model the \( U_q(g) \)-crystal \( B(\lambda) \). First we consider the set of fundamental weights \( \{ \Lambda_i \}_{i \in I} \) of \( g \) and let \( \{ \bar{\Lambda}_i \}_{i \in I_0} \) be the corresponding fundamental weights of the corresponding classical Lie algebra \( g_0 \). To model \( B(\lambda) \), we start with a sequence of perfect \( U_q(g) \)-crystals \( (B^{(i)})_i \) of level \( l \) such that

\[
\lambda \in \bar{P}^+_l = \left\{ \mu \in \bar{P}^+ \mid (c, \mu) = l \right\}
\]

where \( c \) is the canonical central element of \( U_q'(g) \) and \( \bar{P}^+ \) is the nonnegative weight lattice spanned by \( \{ \bar{\Lambda}_i \mid i \in I \} \).

Next we consider the crystal isomorphism \( \Phi_0 : B(\lambda_0) \rightarrow B^{(0)} \otimes B(\lambda_1) \) defined by \( u_{\lambda_0} \rightarrow b_{\lambda_0}^{(0)} \otimes u_{\lambda_1} \) where \( b_{\lambda_0}^{(0)} \) is the unique element in \( B^{(0)} \) such that \( \varphi \left( b_{\lambda_0}^{(0)} \right) = \lambda_0 \) and \( \lambda_1 = \varepsilon \left( b_{\lambda_0}^{(0)} \right) \) and \( u_{\mu} \) is the highest weight element in \( B(\mu) \). Iterating this, we obtain the following isomorphism:

\[
\Phi_n : B(\lambda) \rightarrow B^{(0)} \otimes B^{(1)} \otimes \cdots \otimes B^{(N)} \otimes B(\lambda_{N+1}).
\]

We note by Lemma 10.6.2 in [HK2002] that for any \( b \in B(\lambda) \) there exists a finite \( N \) such that

\[
\Phi_N(b) = \left( \bigotimes_{k=0}^{N-1} b^{(k)} \right) \otimes u_{\lambda_N}.
\]

Therefore we can model elements \( b \in B(\lambda) \) as a \( U_q'(g) \)-crystal by considering an infinite list of elements \( b^{(k)} \in B^{(k)} \) and defining the crystal structure by:

\[
\begin{align*}
\overline{\text{wt}}(b) &= \lambda_N + \sum_{k=0}^{N-1} \overline{\text{wt}} \left( b^{(k)} \right) \\
e_i(b) &= e_i \left( b' \otimes b^{(N)} \right) \otimes u_{\lambda_N}, \\
f_i(b) &= f_i \left( b' \otimes b^{(N)} \right) \otimes u_{\lambda_N}, \\
\varepsilon_i(b) &= \max \left( \varepsilon_i(b') - \varphi_i \left( b^{(N)} \right), 0 \right), \\
\varphi_i(b) &= \varphi_i(b') + \max \left( \varphi_i \left( b^{(N)} \right) - \varepsilon_i(b'), 0 \right),
\end{align*}
\]

where \( b' = b^{(0)} \otimes \cdots \otimes b^{(N-1)} \). To translate this into a finite list, we consider a finite sequence \( b^{(0)} \otimes \cdots \otimes b^{(N-1)} \otimes b^{(N)} \) and if

\[
f_i \left( b^{(0)} \otimes \cdots b^{(N-1)} \otimes b^{(N)} \right) = b_0 \otimes \cdots \otimes b^{(N-1)} \otimes f_i \left( b^{(N)}_{\lambda_N} \right),
\]

then we take the image as \( b^{(0)} \otimes \cdots \otimes f_i \left( b^{(N)}_{\lambda_N} \right) \otimes b^{(N+1)} \). Similarly we remove \( b^{(N)} \) if we have \( b_0 \otimes \cdots \otimes b^{(N-1)} \otimes b^{(N+1)} \). Additionally if

\[
e_i \left( b^{(0)} \otimes \cdots b^{(N-1)} \otimes b^{(N)} \right) = b^{(0)} \otimes \cdots \otimes b^{(N-1)} \otimes e_i \left( b^{(N)}_{\lambda_N} \right),
\]
then we consider this to be 0.

We can then lift the $U'_q(g)$-crystal structure to a $U_q(g)$-crystal structure by using a tensor product of the affinization of the crystals $B^{(i)}$ for all $i$.

INPUT:

- `B` – a single or list of $U'_q$ perfect crystal(s) of level $l$
- `weight` – a weight in $P^+_l$

EXAMPLES:

```python
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[3]]]
sage: mg.f_string([0,1,2,2])
[[[3]], [[3]], [[1]]]
sage: x = mg.f_string([0,1,2]); x
[[[2]], [[3]], [[1]]]
sage: x.weight()  
Lambda[0]
```

An example of type $A_{5}^{(2)}$:

```python
sage: B = crystals.KirillovReshetikhin(['A',5,2], 1,1)
sage: La = RootSystem(['A',5,2]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[-1]]]
sage: mg.f_string([0,2,1,3])
[[[-3]], [[2]], [[-1]]]
sage: mg.f_string([0,2,3,1])
[[[-3]], [[2]], [[-1]]]
```

An example of type $D_{3}^{(2)}$:

```python
sage: B = crystals.KirillovReshetikhin(['D',3,2], 1,1)
sage: La = RootSystem(['D',3,2]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[[[]]]
sage: mg.f_string([0,1,2,0])
[[[0]], [[1]], [[]]]
```

An example using multiple crystals of the same level:

```python
sage: B1 = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A',2,1], 2,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1, B2, B1], La[0])
sage: mg = C.module_generators[0]; mg
[[[3]]]
sage: mg.f_string([0,1,2,2])
```

(continues on next page)
By using the extended weight lattice, the Kyoto path model lifts the perfect crystals to their affinizations:

```
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: La = P.fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]; mg
[
  [[3]],
  [[2]],
  [[1]],
  [[3]],
  [[1]],
  [[3]],
  [[1]],
  [[3]],
]
sage: mg.f_string([0,1,2,2,1,0,0,2])
[
  [[3]],
  [[1]],
  [[2]],
  [[1]],
  [[3]],
  [[1]],
  [[3]],
  [[1]],
]
```

class `Element`

Bases: `TensorProductOfRegularCrystalsElement`

An element in the Kyoto path model.

\( e(i) \)

Return the action of \( e_i \) on self.

EXAMPLES:

```
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: all(mg.e(i) is None for i in C.index_set())
True
sage: mg.f(0).e(0) == mg
True
```

\( \epsilon(i) \)

Return \( \epsilon_i \) of self.

EXAMPLES:

```
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: [mg.epsilon(i) for i in C.index_set()]
[0, 0, 0]
sage: elt = mg.f(0)
sage: [elt.epsilon(i) for i in C.index_set()]
[1, 0, 0]
sage: elt = mg.f_string([0,1,2])
```
Combinatorics, Release 10.1

```python
sage: [elt.epsilon(i) for i in C.index_set()]
[0, 0, 1]
sage: elt = mg.f_string([0,1,2,2])
sage: [elt.epsilon(i) for i in C.index_set()]
[0, 0, 2]
```

**f(i)**

Return the action of $f_i$ on self.

**EXAMPLES:**

```python
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: mg.f(2)
sage: mg.f(0)
[[[1]], [[2]]]
sage: mg.f_string([0,1,2])
[[[2]], [[3]], [[1]]]
```

**phi(i)**

Return $\varphi_i$ of self.

**EXAMPLES:**

```python
sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: [mg.phi(i) for i in C.index_set()]
[1, 0, 0]
sage: elt = mg.f(0)
sage: [elt.phi(i) for i in C.index_set()]
[0, 1, 1]
sage: elt = mg.f_string([0,1])
sage: [elt.phi(i) for i in C.index_set()]
[0, 0, 2]
```

**truncate**(k=None)

Truncate self to have length $k$ and return as an element in a (finite) tensor product of crystals.

**INPUT:**

- `k` – (optional) the length to truncate to; if not specified, then returns one more than the current non-ground-state elements (i.e. the current list in self)

**EXAMPLES:**

```python
sage: B1 = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A',2,1], 2,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1,B2,B1], La[0])
sage: mg = C.highest_weight_vector()
sage: elt = mg.f_string([0,1,2,1,0]); elt
```

(continues on next page)
[[[3]], [[2], [3]], [[1]], [[2]]]
sage: t = elt.truncate(); t
[[[3]], [[2], [3]], [[1]], [[2]]]
sage: t.parent() is C.finite_tensor_product(4)
True
sage: elt.truncate(2)
[[[3]], [[2], [3]]]
sage: elt.truncate(10)
[[[3]], [[2], [3]], [[1]], [[2]], [[1], [3]],
[[2]], [[1]], [[2], [3]], [[1]], [[3]]]]

weight()
Return the weight of self.

EXAMPLES:

sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: La = P.fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: mg = C.module_generators[0]
sage: mg.weight()
Lambda[0]
sage: mg.f_string([0,1,2]).weight()
Lambda[0] - delta

finite_tensor_product(k)
Return the finite tensor product of crystals of length k from truncating self.

EXAMPLES:

sage: B1 = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: B2 = crystals.KirillovReshetikhin(['A',2,1], 2,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel([B1,B2,B1], La[0])
sage: C.finite_tensor_product(5)
Full tensor product of the crystals
Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(2,1),
Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(1,1),
Kirillov-Reshetikhin crystal of type ['A', 2, 1] with (r,s)=(2,1)]

weight_lattice_realization()
Return the weight lattice realization used to express weights.

EXAMPLES:

sage: B = crystals.KirillovReshetikhin(['A',2,1], 1,1)
sage: La = RootSystem(['A',2,1]).weight_lattice().fundamental_weights()
sage: C = crystals.KyotoPathModel(B, La[0])
sage: C.weight_lattice_realization()
Weight lattice of the Root system of type ['A', 2, 1]
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=True)
sage: C = crystals.KyotoPathModel(B, P.fundamental_weight(0))
sage: C.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]

5.1.57 Crystals of letters

class sage.combinat.crystals.letters.BKKLetter
    Bases: Letter

    e(i)
    Return the action of $e_i$ on self.

    EXAMPLES:
    sage: C = crystals.Letters(['A', [2, 1]])
    sage: c = C(-2)
    sage: c.e(-2)
    -3
    sage: c = C(1)
    sage: c.e(0)
    -1
    sage: c = C(2)
    sage: c.e(1)
    1
    sage: c.e(-2)

    f(i)
    Return the action of $f_i$ on self.

    EXAMPLES:
    sage: C = crystals.Letters(['A', [2, 1]])
    sage: c = C.an_element()
    sage: c.f(-2)
    -2
    sage: c = C(-1)
    sage: c.f(0)
    1
    sage: c = C(1)
    sage: c.f(1)
    2
    sage: c.f(-2)

    weight()
    Return weight of self.

    EXAMPLES:
    sage: C = crystals.Letters(['A', [2, 1]])
    sage: c = C(-1)
class sage.combinat.crystals.letters.ClassicalCrystalOfLetters(cartan_type, element_class, element_print_style=None, dual=None)

Bases: UniqueRepresentation, Parent

A generic class for classical crystals of letters.

All classical crystals of letters should be instances of this class or of subclasses. To define a new crystal of letters, one only needs to implement a class for the elements (which subclasses Letter), with appropriate $e_i$ and $f_i$ operations. If the module generator is not 1, one also needs to define the subclass ClassicalCrystalOfLetters for the crystal itself.

The basic assumption is that crystals of letters are small, but used intensively as building blocks. Therefore, we explicitly build in memory the list of all elements, the crystal graph and its transitive closure, so as to make the following operations constant time: list, cmp, (todo: phi, epsilon, e, and f with caching)

list()

Return a list of the elements of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A',5])
sage: C.list()
[1, 2, 3, 4, 5, 6]
```

lt_elements(x, y)

Return True if and only if there is a path from $x$ to $y$ in the crystal graph, when $x$ is not equal to $y$.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

EXAMPLES:

```python
sage: C = crystals.Letters(['A', 5])
sage: x = C(1)
sage: y = C(2)
sage: C.lt_elements(x,y)
True
sage: C.lt_elements(y,x)
False
sage: C.lt_elements(x,x)
False
```

class sage.combinat.crystals.letters.ClassicalCrystalOfLettersWrapped(cartan_type)

Bases: ClassicalCrystalOfLetters

5.1. Comprehensive Module List
Crystal of letters by wrapping another crystal.

This is used for a crystal of letters of type $E_8$ and $F_4$.

This class follows the same output as the other crystal of letters, where $b$ is represented by the “letter” with $\varphi_i(b)$ (resp., $\varepsilon_i$) number of $i$’s (resp., $-i$’s or $\bar{i}$’s). However, this uses an auxiliary crystal to construct these letters to avoid hardcoding the crystal elements and the corresponding edges; in particular, the 248 nodes of $E_8$.

class sage.combinat.crystals.letters.CrystalOfBKKLetters$\langle ct, dual \rangle$

Bases: ClassicalCrystalOfLetters

Crystal of letters for Benkart-Kang-Kashiwara supercrystals.

This implements the $\mathfrak{gl}(m|n)$ crystal of Benkart, Kang and Kashiwara [BKK2000].

EXAMPLES:

\begin{verbatim}
sage: C = crystals.Letters(['A', [1, 1]]); C
The crystal of letters for type ['A', [1, 1]]
sage: C = crystals.Letters(['A', [2, 4]], dual=True); C
The crystal of letters for type ['A', [2, 4]] (dual)
\end{verbatim}

Element

alias of BKKLetter

sage.combinat.crystals.letters.CrystalOfLetters$\langle cartan_type, element_print_style=None, dual=None \rangle$

Return the crystal of letters of the given type.

For classical types, this is a combinatorial model for the crystal with highest weight $\Lambda_1$ (the first fundamental weight).

Any irreducible classical crystal appears as the irreducible component of the tensor product of several copies of this crystal (plus possibly one copy of the spin crystal, see CrystalOfSpins). See [KN1994]. Elements of this irreducible component have a fixed shape, and can be fit inside a tableau shape. Otherwise said, any irreducible classical crystal is isomorphic to a crystal of tableaux with cells filled by elements of the crystal of letters (possibly tensored with the crystal of spins).

We also have the crystal of fundamental representation of the general linear Lie superalgebra, which are used as letters inside of tableaux following [BKK2000]. Similarly, all of these crystals appear as a subcrystal of a sufficiently large tensor power of this crystal.

INPUT:

- $T$ – a Cartan type

EXAMPLES:

\begin{verbatim}
sage: C = crystals.Letters(['A',5])
sage: C.list()
[1, 2, 3, 4, 5, 6]
sage: C.cartan_type()
['A', 5]
\end{verbatim}

For type $E_6$, one can also specify how elements are printed. This option is usually set to None and the default representation is used. If one chooses the option ‘compact’, the elements are printed in the more compact convention with 27 letters +abdefghijklmnopqrstuvwxyz and the 27 letters –ABCDEFHIJKLMNOPQRSTUVWXYZ for the dual crystal.

EXAMPLES:
sage: C = crystals.Letters(['E',6], element_print_style = 'compact')
sage: C
The crystal of letters for type ['E', 6]
sage: C.list()
[+, a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z]
sage: C = crystals.Letters(['E',6], element_print_style = 'compact', dual = True)
sage: C
The crystal of letters for type ['E', 6] (dual)
sage: C.list()

class sage.combinat.crystals.letters.CrystalOfQueerLetters
Bases: ClassicalCrystalOfLetters

Queer crystal of letters elements.
The index set is of the form \{-n, \ldots, -1, 1, \ldots, n\}. For \(1 < i \leq n\), the operators \(e_{-i}\) and \(f_{-i}\) are defined as
\[
f_{-i} = s_{w_i^{-1}} f_{-1} s_{w_i}, \quad e_{-i} = s_{w_i^{-1}} e_{-1} s_{w_i},
\]
where \(w_i = s_2 \cdots s_i s_1 \cdots s_{i-1}\) and \(s_i\) is the reflection along the \(i\)-string in the crystal. See [GJK+2014].

Element
alias of QueerLetter_element

index_set()
Return index set of self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q',3])
sage: Q.index_set()
(1, 2, -2, -1)
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_A_element
Bases: Letter

Type A crystal of letters elements.

e(i)
Return the action of \(e_i\) on self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A',4])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1), (3, 2, 2), (4, 3, 3), (5, 4, 4)]
```

epsilon(i)
Return \(\varepsilon_i\) of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A',4])
sage: [(c,i) for i in C.index_set() for c in C if c.\epsilon(i) != 0]
[(2, 1), (3, 2), (4, 3), (5, 4, 4)]
```
Return the action of $f_i$ on self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['A',4])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2), (2, 2, 3), (3, 3, 4), (4, 4, 5)]
```

Return $\varphi_i$ of self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['A',4])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (2, 2), (3, 3), (4, 4)]
```

Return the weight of self.

**EXAMPLES:**

```python
sage: [v.weight() for v in crystals.Letters(['A',3])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]
```

class ```sage.combinat.crystals.letters.Crystal_of_letters_type_B_element

Bases: ```Letter

Type $B$ crystal of letters elements.

e($i$)

Return the action of $e_i$ on self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['B',4])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1), (-1, 1, -2), (3, 2, 2), (-2, 2, -3), (4, 3, 3), (-3, 3, -4), (0, 4, 4), (-4, 4, 0)]
```

epsilon($i$)

Return $\varepsilon_i$ of self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['B',3])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (0, 3), (-3, 3)]
```
 Return the actions of $f_i$ on self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['B',4])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2),
 (-2, 1, -1),
 (2, 2, 3),
 (-3, 2, -2),
 (3, 3, 4),
 (-4, 3, -3),
 (4, 4, 0),
 (0, 4, -4)]
```

\[\phi(i)\]

 Return $\varphi_i$ of self.

**EXAMPLES:**

```python
sage: C = crystals.Letters(['B',3])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3), (0, 3)]
```

\[\text{weight()}\]

 Return the weight of self.

**EXAMPLES:**

```python
sage: [v.weight() for v in crystals.Letters(['B',3])]
[(1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (0, 0, 0),
 (0, 0, -1),
 (0, -1, 0),
 (-1, 0, 0)]
```

```
5.1. Comprehensive Module List 499
```
\((-3, 3, -4),\)
\((-4, 4, 4)\]

\(\text{epsilon}(i)\)

Return \(\varepsilon_i\) of self.

EXAMPLES:

\[
\text{sage: } C = \text{crystals.Letters('C', 3)}  \\
\text{sage: } [(c, i) \text{ for } i \text{ in } C.index_set() \text{ for } c \in C \text{ if } c.epsilon(i) \neq 0]  \\
[(2, 1), (-1, 1), (3, 2), (-2, 2), (-3, 3)]
\]

\(f(i)\)

Return the action of \(f_i\) on self.

EXAMPLES:

\[
\text{sage: } C = \text{crystals.Letters('C', 4)}  \\
\text{sage: } [(c, i, c.f(i)) \text{ for } i \text{ in } C.index_set() \text{ for } c \in C \text{ if } c.f(i) \text{ is not None}]  \\
[(1, 1, 2), (-2, 1, -1), (2, 2, 3),  \\
(-3, 2, -2), (3, 3, 4), (-4, 3, -3), (4, 4, -4)]
\]

\(\phi (i)\)

Return \(\phi_i\) of self.

EXAMPLES:

\[
\text{sage: } C = \text{crystals.Letters('C', 3)}  \\
\text{sage: } [(c, i, c.phi(i)) \text{ for } i \text{ in } C.index_set() \text{ for } c \in C \text{ if } c.phi(i) \neq 0]  \\
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3)]
\]

\(weight()\)

Return the weight of self.

EXAMPLES:

\[
\text{sage: } [v.weight() \text{ for } v \in \text{crystals.Letters('C', 3)}]  \\
[(1, 0, 0), (0, 1, 0), (0, 0, 1), (0, 0, -1), (0, -1, 0), (-1, 0, 0)]
\]

class sage.combinat.crystals.letters.Crystal_of_letters_type_D_element

Bases: Letter

Type D crystal of letters elements.

\(e(i)\)

Return the action of \(e_i\) on self.

EXAMPLES:

\[
\text{sage: } C = \text{crystals.Letters('D', 5)}  \\
\text{sage: } [(c, i, c.e(i)) \text{ for } i \text{ in } C.index_set() \text{ for } c \in C \text{ if } c.e(i) \text{ is not None}]  \\
[(2, 1, 1),  \\
(-1, 1, -2),  \\
(3, 2, 2),  \\
(-2, 2, -3),
\]

(continues on next page)
epsilon(i)
Return $\varepsilon_i$ of self.

EXAMPLES:
```python
sage: C = crystals.Letters(['D',4])
sage: [(c,i) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1), (-1, 1), (3, 2), (-2, 2), (4, 3), (-3, 3), (-4, 4), (-3, 4)]
```

f(i)
Return the action of $f_i$ on self.

EXAMPLES:
```python
sage: C = crystals.Letters(['D',5])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2), (-2, 1, -1), (2, 2, 3), (-3, 2, -2), (3, 3, 4), (-4, 3, -3), (4, 4, 5), (-5, 4, -4), (4, 5, -5), (5, 5, -4)]
```

phi(i)
Return $\varphi_i$ of self.

EXAMPLES:
```python
sage: C = crystals.Letters(['D',4])
sage: [(c,i) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1), (-2, 1), (2, 2), (-3, 2), (3, 3), (-4, 3), (3, 4), (4, 4)]
```

weight()
Return the weight of self.

EXAMPLES:
```python
sage: [v.weight() for v in crystals.Letters(['D',4])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1), (0, 0, 0, -1),
```
class sage.combinat.crystals.letters.Crystal_of_letters_type_E6_element

Bases: LetterTuple

Type $E_6$ crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_1)$.

$e(i)$

Return the action of $e_i$ on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6])
sage: C((-1,3)).e(1)
(1,

sage: C((-2,-3,4)).e(2)
(-3, 2)

sage: C((1,)).e(1)
```

$f(i)$

Return the action of $f_i$ on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6])
sage: C((1,)).f(1)
(-1, 3)

sage: C((-6,)).f(1)
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: [v.weight() for v in crystals.Letters(['E',6])]
[(0, 0, 0, 0, 0, -2/3, -2/3, 2/3),
 (-1/2, 1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, -1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, -1/2, -1/2, 1/2, -1/6, -1/6, 1/6),
 (1/2, 1/2, 1/2, 1/2, 1/2, -1/6, -1/6, 1/6),
 (0, 0, 0, 0, 0, 1, 1/3, 1/3, -1/3),
 (1/2, 1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (-1/2, -1/2, 1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, -1/2, 1/2, -1/2, -1/6, -1/6, 1/6),
 (0, 0, 0, 0, 1, 0, 1/3, 1/3, -1/3),
 (-1/2, 1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (-1/2, 1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (0, 0, 0, 0, 0, 1/3, 1/3, -1/3),
 (-1/2, 1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6),
 (1/2, -1/2, 1/2, -1/2, -1/2, -1/6, -1/6, 1/6)]
```
class sage.combinat.crystals.letters.Crystal_of_letters_type_E6_element_dual

Bases: LetterTuple

Type $E_6$ crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_6)$. This crystal is dual to $B(\Lambda_1)$ of type $E_6$.

e(i)

Return the action of $e_i$ on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: C((-1,)).e(1)
(1, -3)
```

f(i)

Return the action of $f_i$ on self.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: C((6,)).f(6)
(5, -6)
sage: C((6,)).f(1)
```

lift()

Lift an element of self to the crystal of letters crystals.Letters(['E',6]) by taking its inverse weight.

EXAMPLES:

```
sage: C = crystals.Letters(['E',6], dual = True)
sage: b = C.module_generators[0]
sage: b.lift()
(-6,)
```

retract(p)

Retract element p, which is an element in crystals.Letters(['E',6]) to an element in crystals.Letters(['E',6], dual=True) by taking its inverse weight.

EXAMPLES:

```
```
sage: C = crystals.Letters(['E',6])
sage: Cd = crystals.Letters(['E',6], dual = True)
sage: b = Cd.module_generators[0]
sage: p = C((-1,3))
sage: b.retract(p)
(1, -3)
sage: b.retract(None)

weight()

Return the weight of self.

EXAMPLES:

sage: C = crystals.Letters(['E',6], dual = True)
sage: b = C.module_generators[0]
sage: b.weight()
(0, 0, 0, 1, -1/3, -1/3, 1/3)
sage: [v.weight() for v in C]
[(0, 0, 0, 1, -1/3, -1/3, 1/3),
 (0, 0, 1, 0, -1/3, -1/3, 1/3),
 (0, 0, 0, 1, -1/3, -1/3, 1/3),
 (-1, 0, 0, 0, -1/3, -1/3, -1/3),
 (1, 0, 0, 0, -1/3, -1/3, 1/3),
 (1/2, 1/2, 1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
 (0, -1, 0, 0, 0, -1/3, -1/3, 1/3),
 (-1/2, -1/2, 1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
 (0, 0, -1, 0, 0, -1/3, -1/3, 1/3),
 (-1/2, 1/2, -1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
 (1/2, -1/2, 1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
 (0, 0, 0, -1, 0, -1/3, -1/3, 1/3),
 (-1/2, 1/2, 1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
 (1/2, -1/2, 1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
 (1/2, -1/2, -1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
 (0, 0, 0, 0, -1, -1/3, -1/3, 1/3),
 (-1/2, 1/2, 1/2, 1/2, 1/2, 1/6, 1/6, -1/6),
 (1/2, -1/2, 1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
 (1/2, -1/2, -1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
 (0, 0, 0, -1, -1/3, -1/3, -1/3),
 (-1/2, 1/2, 1/2, -1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
 (1/2, -1/2, 1/2, -1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
 (1/2, -1/2, -1/2, 1/2, -1/2, 1/2, 1/6, 1/6, -1/6),
 (0, 0, 0, 0, 0, 2/3, 2/3, -2/3)]

class sage.combinat.crystals.letters.Crystal_of_letters_type_E7_element
Bases: LetterTuple

Type $E_7$ crystal of letters elements. This crystal corresponds to the highest weight crystal $B(\Lambda_7)$.

e()

Return the action of $e_i$ on self.

EXAMPLES:
Combinatorics, Release 10.1

sage: C = crystals.Letters(['E',7])
sage: C((-7,)).e(7)

f(i)

Return the action of \(f_i\) on self.

EXAMPLES:

```python
sage: C = crystals.Letters(['E',7])
sage: C((-7,)).f(7)
sage: C((7,)).f(7)
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: [v.weight() for v in crystals.Letters(['E',7])]
```

class sage.combinat.crystals.letters.Crystal_of_letters_type_G_element

Bases: Letter

5.1. Comprehensive Module List 505
Type $G_2$ crystal of letters elements.

$e(i)$

Return the action of $e_i$ on self.

EXAMPLES:

```python
sage: C = crystals.Letters(['G',2])
sage: [(c,i,c.e(i)) for i in C.index_set() for c in C if c.e(i) is not None]
[(2, 1, 1),
 (0, 1, 3),
 (-3, 1, 0),
 (-1, 1, -2),
 (3, 2, 2),
 (-2, 2, -3)]
```

epsilon(i)

Return $\epsilon_i$ of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['G',2])
sage: [(c,i,c.epsilon(i)) for i in C.index_set() for c in C if c.epsilon(i) != 0]
[(2, 1, 1), (0, 1, 1), (-3, 1, 2), (-1, 1, 1), (3, 2, 1), (-2, 2, 1)]
```

$f(i)$

Return the action of $f_i$ on self.

EXAMPLES:

```python
sage: C = crystals.Letters(['G',2])
sage: [(c,i,c.f(i)) for i in C.index_set() for c in C if c.f(i) is not None]
[(1, 1, 2),
 (3, 1, 0),
 (0, 1, -3),
 (-2, 1, -1),
 (2, 2, 3),
 (-3, 2, -2)]
```

$\phi(i)$

Return $\varphi_i$ of self.

EXAMPLES:

```python
sage: C = crystals.Letters(['G',2])
sage: [(c,i,c.phi(i)) for i in C.index_set() for c in C if c.phi(i) != 0]
[(1, 1, 1), (3, 1, 2), (0, 1, 1), (-2, 1, 1), (2, 2, 1), (-3, 2, 1)]
```

$weight()$

Return the weight of self.

EXAMPLES:

```python
sage: [(v.weight() for v in crystals.Letters(['G',2])]
[(1, 0, -1), (1, -1, 0), (0, 1, -1), (0, 0, 0), (0, -1, 1), (-1, 1, 0), (-1, -1, -1)]
```
class sage.combinat.crystals.letters.EmptyLetter

Bases: Element

The affine letter $\emptyset$ thought of as a classical crystal letter in classical type $B_n$ and $C_n$.

**Warning:** This is not a classical letter.

Used in the rigged configuration bijections.

e($i$)

Return $e_i$ of self which is None.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').e(1)
```

epsilon($i$)

Return $\varepsilon_i$ of self.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').epsilon(1)
0
```

f($i$)

Return $f_i$ of self which is None.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').f(1)
```

phi($i$)

Return $\phi_i$ of self.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').phi(1)
0
```

value

weight()

Return the weight of self.

EXAMPLES:

```
sage: C = crystals.Letters(['C', 3])
sage: C('E').weight()
(0, 0, 0)
```
class sage.combinat.crystals.letters.Letter

Bases: Element

A class for letters.

Like ElementWrapper, plus delegates __lt__ (comparison) to the parent.

EXAMPLES:

```
sage: from sage.combinat.crystals.letters import Letter
sage: a = Letter(ZZ, 1)
sage: Letter(ZZ, 1).parent()
Integer Ring
sage: Letter(ZZ, 1)._repr_()
'1'
sage: parent1 = ZZ  # Any fake value ...
sage: parent2 = QQ  # Any fake value ...
sage: l11 = Letter(parent1, 1)
sage: l12 = Letter(parent1, 2)
sage: l21 = Letter(parent2, 1)
sage: l22 = Letter(parent2, 2)
sage: l11 == l11
True
sage: l11 == l12
False
sage: l11 == l21  # not tested
False
sage: C = crystals.Letters(['B', 3])
sage: C(0) != C(0)
False
sage: C(1) != C(-1)
True
```

value

class sage.combinat.crystals.letters.LetterTuple

Bases: Element

Abstract class for type $E$ letters.

epsilon(i)

Return $\epsilon_i$ of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 6])
sage: C((-6,)).epsilon(1)
0
sage: C((-6,)).epsilon(6)
1
```

phi(i)

Return $\phi_i$ of self.
EXAMPLES:

```
sage: C = crystals.Letters(['E', 6])
sage: C((1,)).phi(1)
1
sage: C((1,)).phi(6)
0
```

class sage.combinat.crystals.letters.LetterWrapped

Bases: sage.combinat.crystals.Element

Element which uses another crystal implementation and converts those elements to a tuple with \( \pm i \).

e(i)

Return \( e_i \) of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 8])
sage: C((-8,)).e(1)
(-7, 8)
sage: C((-8,)).e(8)
(-8, 8)
```

epsilon(i)

Return \( \epsilon_i \) of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 8])
sage: C((-8,)).epsilon(1)
0
sage: C((-8,)).epsilon(8)
1
```

f(i)

Return \( f_i \) of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 8])
sage: C((8,)).f(6)
(7, -8)
sage: C((8,)).f(8)
(8, -8)
```

phi(i)

Return \( \phi_i \) of self.

EXAMPLES:

```
sage: C = crystals.Letters(['E', 8])
sage: C((8,)).phi(8)
1
sage: C((8,)).phi(6)
0
```

5.1. Comprehensive Module List
value

class sage.combinat.crystals.letters.QueerLetter_element

Bases: Letter

Queer supercrystal letters elements.

e(i)

Return the action of $e_i$ on self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i,c.e(i)) for i in Q.index_set() for c in Q if c.e(i) is not None]
[(2, 1, 1), (3, 2, 2), (3, -2, 2), (2, -1, 1)]
```

epsilon(i)

Return $\varepsilon_i$ of self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i) for i in Q.index_set() for c in Q if c.epsilon(i) != 0]
[(2, 1), (3, 2), (3, -2), (2, -1)]
```

f(i)

Return the action of $f_i$ on self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i) for i in Q.index_set() for c in Q if c.f(i) is not None]
[(1, 1, 2), (2, 2, 3), (2, -2, 3), (1, -1, 2)]
```

phi(i)

Return $\phi_i$ of self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q',3])
sage: [(c,i) for i in Q.index_set() for c in Q if c.phi(i) != 0]
[(1, 1), (2, 2), (2, -2), (1, -1)]
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: [v.weight() for v in crystals.Letters(['Q',4])]
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]
```
5.1.58 Littelmann paths

AUTHORS:

- Mark Shimozono, Anne Schilling (2012): Initial version
- Anne Schilling (2013): Implemented `CrystalOfProjectedLevelZeroLSPaths`
- Travis Scrimshaw (2016): Implemented `InfinityCrystalOfLSPaths`

class sage.combinat.crystals.littelmann_path.CrystalOfLSPaths(starting_weight, starting_weight_parent):

Bases: UniqueRepresentation, Parent

Crystal graph of LS paths generated from the straight-line path to a given weight.

INPUT:

- `cartan_type` – (optional) the Cartan type of a finite or affine root system
- `starting_weight` – a weight; if `cartan_type` is given, then the weight should be given as a list of coefficients of the fundamental weights, otherwise it should be given in the `weight_space` basis; for affine highest weight crystals, one needs to use the extended weight space.

The crystal class of piecewise linear paths in the weight space, generated from a straight-line path from the origin to a given element of the weight lattice.

OUTPUT:

- a tuple of weights defining the directions of the piecewise linear segments

EXAMPLES:

```
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space(extended = True).basis()
sage: B = crystals.LSPaths(La[2]-La[0]); B
The crystal of LS paths of type ['A', 2, 1] and weight -Lambda[0] + Lambda[2]
sage: C = crystals.LSPaths(['A',2,1],[-1,0,1]); C
The crystal of LS paths of type ['A', 2, 1] and weight -Lambda[0] + Lambda[2]
sage: B == C
True
sage: c = C.module_generators[0]; c
(-Lambda[0] + Lambda[2],)
sage: [c.f(i) for i in C.index_set()]
[None, None, (Lambda[1] - Lambda[2],)]
sage: R = C.R; R
Root system of type ['A', 2, 1]
sage: Lambda = R.weight_space().basis(); Lambda
Finite family {0: Lambda[0], 1: Lambda[1], 2: Lambda[2]}
sage: b=C(tuple([-Lambda[0]+Lambda[2]]))
sage: b==c
True
sage: b.f(2)
(Lambda[1] - Lambda[2],)
```

For classical highest weight crystals we can also compare the results with the tableaux implementation:
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: sorted(C, key=str)
2*Lambda[2]),
\rightarrow),
sage: C.cardinality()
8
sage: B = crystals.Tableaux(['A',2],shape=[2,1])
sage: B.cardinality()
8
sage: B.digraph().is_isomorphic(C.digraph())
True

Make sure you use the weight space and not the weight lattice for your weights:

sage: R = RootSystem(['A',2,1])
sage: La = R.weight_lattice(extended = True).basis()
sage: B = crystals.LSPaths(La[2]); B
Traceback (most recent call last):
 ... ValueError: Please use the weight space, rather than weight lattice for your weights

REFERENCES:
class Element
    Bases: ElementWrapper
compress()
        Merges consecutive positively parallel steps present in the path.
        EXAMPLES:

sage: C = crystals.LSPaths(['A',2],[1,1])
sage: Lambda = C.R.weight_space().fundamental_weights(); Lambda
Finite family {1: Lambda[1], 2: Lambda[2]}
\rightarrow 2*Lambda[2]])
sage: c.compress()
(Lambda[1] + Lambda[2],)
dualize()
        Returns dualized path.
        EXAMPLES:

sage: C = crystals.LSPaths(['A',2],[1,1])
sage: for c in C:
 ....:     print("{} {}".format(c, c.dualize()))
\rightarrow 2*Lambda[2], -1/2*Lambda[1] + Lambda[2])
(continues on next page)

| (\text{-Lambda}[1] - \text{Lambda}[2],) (\text{Lambda}[1] + \text{Lambda}[2],) |
| (2*\text{Lambda}[1] - \text{Lambda}[2],) (-2*\text{Lambda}[1] + \text{Lambda}[2],) |
| (-\text{Lambda}[1] + 1/2*\text{Lambda}[2], \text{Lambda}[1] - 1/2*\text{Lambda}[2]) (-\text{Lambda}[1] + 1/2*\text{Lambda}[2], \text{Lambda}[1] - 1/2*\text{Lambda}[2]) |
| (-2*\text{Lambda}[1] + \text{Lambda}[2],) (2*\text{Lambda}[1] - \text{Lambda}[2],) |

\textbf{e}(i, \text{power=1, to_string_end=False, length_only=False})

Returns the \text{i}-th crystal raising operator on \text{self}.

\textbf{INPUT:}
- \text{i} – element of the index set of the underlying root system
- \text{power} – positive integer; specifies the power of the raising operator to be applied (default: 1)
- \text{to_string_end} – boolean; if set to True, returns the dominant end of the \text{i}-string of \text{self}. (default: False)
- \text{length_only} – boolean; if set to True, returns the distance to the dominant end of the \text{i}-string of \text{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: c = C[2]; c
sage: c.e(1)
sage: c.e(2)
(-Lambda[1] + 2*Lambda[2],)
sage: c.e(2,to_string_end=True)
(-Lambda[1] + 2*Lambda[2],)
sage: c.e(1,to_string_end=True)
sage: c.e(1,length_only=True)
0
\end{verbatim}

\textbf{endpoint(\text{)})}

Computes the endpoint of the path.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: b = C.module_generators[0]
sage: b.endpoint()
sage: b.f_string([1,2,2,1])
(-Lambda[1] - Lambda[2],)
sage: b.f_string([1,2,2,1]).endpoint()
sage: b.f_string([1,2])
sage: b.f_string([1,2]).endpoint()
0
sage: b = C([])
sage: b.endpoint()
0
\end{verbatim}
**epsilon**

Returns the distance to the beginning of the $i$-string.

This method overrides the generic implementation in the category of crystals since this computation is more efficient.

**EXAMPLES:**

```python
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: [c.epsilon(1) for c in C]
[0, 1, 0, 0, 1, 0, 1, 2]
sage: [c.epsilon(2) for c in C]
[0, 0, 1, 2, 1, 1, 0, 0]
```

**f** ($i$, $power=1$, $to_string_end=False$, $length_only=False$)

Returns the $i$-th crystal lowering operator on `self`.

**INPUT:**
- $i$ – element of the index set of the underlying root system
- $power$ – positive integer; specifies the power of the lowering operator to be applied (default: 1)
- $to_string_end$ – boolean; if set to True, returns the anti-dominant end of the $i$-string of `self`. (default: False)
- $length_only$ – boolean; if set to True, returns the distance to the anti-dominant end of the $i$-string of `self`.

**EXAMPLES:**

```python
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: c = C.module_generators[0]
sage: c.f(1)
(-Lambda[1] + 2*Lambda[2],)
sage: c.f(1,power=2)
sage: c.f(2)
sage: c.f(2,to_string_end=True)
sage: c.f(2,length_only=True)
1

sage: C = crystals.LSPaths(['A',2,1],[-1,-1,2])
sage: c = C.module_generators[0]
sage: c.f(2,power=2)
(Lambda[0] + Lambda[1] - 2*Lambda[2],)
```

**phi**

Returns the distance to the end of the $i$-string.

This method overrides the generic implementation in the category of crystals since this computation is more efficient.

**EXAMPLES:**

```python
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: [c.phi(1) for c in C]
[1, 0, 0, 1, 0, 2, 1, 0]
sage: [c.phi(2) for c in C]
[1, 2, 1, 0, 0, 0, 1]
```
reflect_step\((\text{which\_step}, i)\)

Apply the \(i\)-th simple reflection to the indicated step in self.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: b = C.module_generators[0]
sage: b.reflect_step(0,1)
(-Lambda[1] + 2*Lambda[2],)
sage: b.reflect_step(0,2)
```

\(s(i)\)

Computes the reflection of self along the \(i\)-string.

This method is more efficient than the generic implementation since it uses powers of \(e\) and \(f\) in the Littelmann model directly.

EXAMPLES:

```
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: c = C.module_generators[0]
sage: c.s(1)
(-Lambda[1] + 2*Lambda[2],)
sage: c.s(2)
```

split_step\((\text{which\_step}, r)\)

Splits indicated step into two parallel steps of relative lengths \(r\) and \(1 - r\).

INPUT:

- \(\text{which\_step}\) – a position in the tuple self
- \(r\) – a rational number between 0 and 1

EXAMPLES:

```
sage: C = crystals.LSPaths(['A',2],[1,1])
sage: b = C.module_generators[0]
sage: b.split_step(0,1/3)
```

weight()

Return the weight of self.

EXAMPLES:
sage: B = crystals.LSPaths(['A',1,1],[1,0])
sage: b = B.highest_weight_vector()
sage: b.f(0).weight()
-Lambda[0] + 2*Lambda[1] - delta

weight_lattice_realization()

Return weight lattice realization of self.

EXAMPLES:

sage: B = crystals.LSPaths(['B',3],[1,1,0])

Weight space over the Rational Field of the Root system of type ['B', 3]
sage: B = crystals.LSPaths(['B',3,1],[1,1,1,0])

Extended weight space over the Rational Field of the Root system of type ['B', 3, 1]

class sage.combinat.crystals.littelmann_path.CrystalOfProjectedLevelZeroLSPaths(starting_weight, starting_weight_parent)

Bases: CrystalOfLSPaths

Crystal of projected level zero LS paths.

INPUT:

• weight – a dominant weight of the weight space of an affine Kac-Moody root system

When weight is just a single fundamental weight \( \Lambda_r \), this crystal is isomorphic to a Kirillov-Reshetikhin (KR) crystal, see also sage.combinat.crystals.kirillov_reshetikhin.KirillovReshetikhinFromLSPaths(). For general weights, it is isomorphic to a tensor product of single-column KR crystals.

EXAMPLES:

sage: R = RootSystem(['C',3,1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[3])
sage: LS.cardinality()
84
sage: GLS = LS.digraph()

sage: K1 = crystals.KirillovReshetikhin(['C',3,1],1,1)
sage: K3 = crystals.KirillovReshetikhin(['C',3,1],3,1)
sage: T = crystals.TensorProduct(K3,K1)
sage: T.cardinality()
84
sage: GT = T.digraph() # long time
sage: GLS.is_isomorphic(GT, edge_labels = True) # long time
True

class Element

Bases: Element

Element of a crystal of projected level zero LS paths.
energy_function()

Return the energy function of self.

The energy function $D(\pi)$ of the level zero LS path $\pi \in \mathcal{B}_{cl}(\lambda)$ requires a series of definitions; for simplicity the root system is assumed to be untwisted affine.

The LS path $\pi$ is a piecewise linear map from the unit interval $[0, 1]$ to the weight lattice. It is specified by “times” $0 = \sigma_0 < \sigma_1 < \cdots < \sigma_s = 1$ and “direction vectors” $x_u \lambda$ where $x_u \in W/W_J$ for $1 \leq u \leq s$, and $W_J$ is the stabilizer of $\lambda$ in the finite Weyl group $W$. Precisely,

$$
\pi(t) = \sum_{u'=1}^{u-1} (\sigma_{u'} - \sigma_{u'-1})x_{u'} \lambda + (t - \sigma_{u-1})x_u \lambda
$$

for $1 \leq u \leq s$ and $\sigma_{u-1} \leq t \leq \sigma_u$.

For any $x, y \in W/W_J$, let

$$d : x = w_0 \beta_1 \leftarrow w_1 \beta_2 \leftarrow \cdots \leftarrow w_n = y$$

be a shortest directed path in the parabolic quantum Bruhat graph. Define

$$\text{wt}(d) := \sum_{1 \leq k \leq n} \beta_k^\vee,$$

where $\ell(w_{u-1}) < \ell(w_k)$.

It can be shown that $\text{wt}(d)$ depends only on $x, y$; call its value $\text{wt}(x, y)$. The energy function $D(\pi)$ is defined by

$$D(\pi) = -\sum_{u=1}^{s-1} (1 - \sigma_u) \langle \lambda, \text{wt}(x_u, x_{u+1}) \rangle.$$

For more information, see [LNSSS2013].

Note: In the dual-of-untwisted case the parabolic quantum Bruhat graph that is used is obtained by exchanging the roles of roots and coroots. Moreover, in the computation of the pairing the short roots must be doubled (or tripled for type $G$). This factor is determined by the translation factor of the corresponding root. Type $BC$ is viewed as untwisted type, whereas the dual of $BC$ is viewed as twisted. Except for the untwisted cases, these formulas are currently still conjectural.

EXAMPLES:

```
sage: R = RootSystem(['C',3,1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[3])
sage: b = LS.module_generators[0]
sage: c = b.f(1).f(3).f(2)
sage: c.energy_function()
0
sage: c=b.e(0)
sage: c.energy_function()
1
```

```
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1])
```

(continues on next page)
The next test checks that the energy function is constant on classically connected components:

```
sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: G = LS.digraph(index_set=[1,2])
sage: C = G.connected_components(sort=False)
sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in C]
[True, True, True, True, True, True, True, True, True, True, True, True, True, True]
```

```
sage: R = RootSystem(['D',4,2])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[2])
sage: J = R.cartan_type().classical().index_set()
sage: hw = [x for x in LS if x.is_highest_weight(J)]
sage: [(x.weight(), x.energy_function()) for x in hw]
[(-2*Lambda[0] + Lambda[2], 0), (-2*Lambda[0] + Lambda[1], 1), (0, 2)]
```

```
sage: G = LS.digraph(index_set=J)
sage: C = G.connected_components(sort=False)
sage: [all(c[0].energy_function()==a.energy_function() for a in c) for c in C]
[True, True, True, True]
```

```
sage: ct = CartanType(['BC',2,2]).dual()
sage: R = RootSystem(ct)
```

(continues on next page)
```python
sage: La = R.weight_space().basis()
sage: G = LS.digraph(index_set=R.cartan_type().classical().index_set())
sage: C = G.connected_components(sort=False)
\[ all(c[0].energy_function()==a.energy_function() \text{ for } a \text{ in } c) \text{ for } c \text{ in } C \] # long time
\[ True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True, True \]

```
Combinatorics, Release 10.1

```sage
R = RootSystem(['C',3,1])
La = R.weight_space().basis()
LS = crystalsProjectedLevelZeroLSPaths(La[1]+La[3])
b = LS.module_generators[0]
c = b.f(1).f(3).f(2)
c.weyl_group_representation()
[s2*s1*s3, s1*s3]
```

classically_highest_weight_vectors()
Return the classically highest weight vectors of self.

EXAMPLES:

```sage
R = RootSystem(['A',2,1])
La = R.weight_space().basis()
LS = crystalsProjectedLevelZeroLSPaths(2*La[1])
LS.classically_highest_weight_vectors()
((-2*Lambda[0] + 2*Lambda[1],),
 (-Lambda[0] + Lambda[1], -Lambda[1] + Lambda[2]))
```

is_perfect(level=1)
Check whether the crystal self is perfect (of level level).

INPUT:
• level – (default: 1) positive integer

A crystal \( B \) is perfect of level \( \ell \) if:

1. \( B \) is isomorphic to the crystal graph of a finite-dimensional \( U_q'\mathfrak{g} \)-module.
2. \( B \otimes B \) is connected.
3. There exists a \( \lambda \in \mathcal{X} \), such that \( \operatorname{wt}(B) \subseteq \lambda + \sum_{i \in I} \mathbb{Z}_{\leq 0} \alpha_i \) and there is a unique element in \( B \) of classical weight \( \lambda \).
4. For all \( b \in B \), \( \operatorname{level}(\varepsilon(b)) \geq \ell \).
5. For all \( \Lambda \) dominant weights of level \( \ell \), there exist unique elements \( b_\Lambda, b^\Lambda \in B \), such that \( \varepsilon(b_\Lambda) = \Lambda = \varphi(b^\Lambda) \).

Points (1)-(3) are known to hold. This method checks points (4) and (5).

EXAMPLES:

```sage
C = CartanType(['C',2,1])
R = RootSystem(C)
La = R.weight_space().basis()
LS = crystalsProjectedLevelZeroLSPaths(La[1])
LS.is_perfect()
False
LS = crystalsProjectedLevelZeroLSPaths(La[2])
LS.is_perfect()
True
```

```sage
C = CartanType(['E',6,1])
R = RootSystem(C)
La = R.weight_space().basis()
```
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1])
sage: LS.is_perfect()
True
sage: LS.is_perfect(2)
False
sage: C = CartanType(['D',4,1])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: all(crystals.ProjectedLevelZeroLSPaths(La[i]).is_perfect() for i in [1,2,3,4])
True
sage: C = CartanType(['A',6,2])
sage: R = RootSystem(C)
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(La[1]+La[2])
sage: LS.is_perfect()
True
sage: LS.is_perfect(2)
False

maximal_vector()
Return the maximal vector of self.

EXAMPLES:

sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: LS.maximal_vector()
(-3*Lambda[0] + 2*Lambda[1] + Lambda[2],)

one_dimensional_configuration_sum(q=None, group_components=True)
Compute the one-dimensional configuration sum.

INPUT:

- q – (default: None) a variable or None; if None, a variable q is set in the code
- group_components – (default: True) boolean; if True, then the terms are grouped by classical component

The one-dimensional configuration sum is the sum of the weights of all elements in the crystal weighted by the energy function. For untwisted types it uses the parabolic quantum Bruhat graph, see [LNSSS2013]. In the dual-of-untwisted case, the parabolic quantum Bruhat graph is defined by exchanging the roles of roots and coroots (which is still conjectural at this point).

EXAMPLES:

sage: R = RootSystem(['A',2,1])
sage: La = R.weight_space().basis()
sage: LS = crystals.ProjectedLevelZeroLSPaths(2*La[1])
sage: LS.one_dimensional_configuration_sum() # long time
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
+(q+1)*B[\Lambda_1 - \Lambda_2] + B[2*\Lambda_1]
+ B[-2*\Lambda_2] + (q+1)*B[\Lambda_2]

sage: R.<t> = ZZ[]

sage: LS.one_dimensional_configuration_sum(t, False) # long time
B[-2*\Lambda_1 + 2*\Lambda_2] + (t+1)*B[-\Lambda_1]
+ (t+1)*B[\Lambda_1 - \Lambda_2] + B[2*\Lambda_1]
+ B[-2*\Lambda_2] + (t+1)*B[\Lambda_2]

class sage.combinat.crystals.littelmann_path.InfinityCrystalOfLSPaths(cartan_type)

Bases: UniqueRepresentation, Parent

LS path model for $B(\infty)$.

Elements of $B(\infty)$ are equivalence classes of paths $[\pi]$ in $B(k\rho)$ for $k \gg 0$, where $\rho$ is the Weyl vector. A canonical representative for an element of $B(\infty)$ is chosen by taking $k$ to be minimal such that the endpoint of $\pi$ is strictly dominant but its representative in $B((k-1)\rho)$ is on the wall of the dominant chamber.

  • [LZ2011]

class Element

Bases: Element

e(i, power=1, length_only=False)

Return the $i$-th crystal raising operator on self.

INPUT:
  • $i$ – element of the index set
  • $power$ – (default: 1) positive integer; specifies the power of the lowering operator to be applied
  • $length_only$ – (default: False) boolean; if True, then return the distance to the anti-dominant end of the $i$-string of self

EXAMPLES:

sage: B = crystals.infinity.LSPaths(['B',3,1])

sage: mg = B.module_generator()

sage: mg.e(0)

sage: mg.e(1)

sage: mg.e(2)

sage: x = mg.f_string([1,0,2,1,0,2,1,1,0])

sage: all(x.f(i).e(i) == x for i in B.index_set())
True

sage: all(x.e(i).f(i) == x for i in B.index_set() if x.epsilon(i) > 0)
True

f(i, power=1, length_only=False)

Return the $i$-th crystal lowering operator on self.

INPUT:
  • $i$ – element of the index set
  • $power$ – (default: 1) positive integer; specifies the power of the lowering operator to be applied
  • $length_only$ – (default: False) boolean; if True, then return the distance to the anti-dominant end of the $i$-string of self

EXAMPLES:
phi(i)
Return $\varphi_i$ of self.
Let $\pi \in \mathcal{B}(\infty)$. Define

$$\varphi_i(\pi) := \varepsilon_i(\pi) + \langle h_i, \text{wt}(\pi) \rangle,$$

where $h_i$ is the $i$-th simple coroot and $\text{wt}(\pi)$ is the weight() of $\pi$.

INPUT:
• $i$ – element of the index set

EXAMPLES:

```python
sage: B = crystals.infinity.LSPaths(['D',3,2])
sage: mg = B.highest_weight_vector()
sage: mg.f(1)
(3*Lambda[0] - Lambda[1] + 3*Lambda[2],
sage: mg.f(2)
(Lambda[0] + 2*Lambda[1] - Lambda[2],
sage: mg.f(0)
(-Lambda[0] + 2*Lambda[1] + Lambda[2] - delta,
```

weight()
Return the weight of self.

Todo: This is a generic algorithm. We should find a better description and implement it.

EXAMPLES:

```python
sage: B = crystals.infinity.LSPaths(['E',6])
sage: mg = B.highest_weight_vector()
sage: f_seq = [1,4,2,6,4,2,3,1,5,5]
sage: x = mg.f_string(f_seq)
sage: x.weight()
sage: al = B.cartan_type().root_system().weight_space().simple_roots()
sage: x.weight() == -sum(al[i] for i in f_seq)
True
```

module_generator()
Return the module generator (or highest weight element) of self.

The module generator is the unique path $\pi_\infty : t \mapsto t\rho$, for $t \in [0, \infty)$.

EXAMPLES:
**Combinatorics, Release 10.1**

```python
sage: B = crystals.infinity.LSPaths(['A', 6, 2])
sage: mg = B.module_generator(); mg
(Lambda[0] + Lambda[1] + Lambda[2] + Lambda[3],)
sage: mg.weight()
0
```

`weight_lattice_realization()`

Return the weight lattice realization of `self`.

EXAMPLES:

```python
sage: B = crystals.infinity.LSPaths(['C', 4])
sage: B.weight_lattice_realization()
Weight space over the Rational Field of the Root system of type ['C', 4]
```

`sage.combinat.crystals.littelmann_path.positively_parallel_weights(v, w)`

Check whether the vectors `v` and `w` are positive scalar multiples of each other.

EXAMPLES:

```python
sage: from sage.combinat.crystals.littelmann_path import positively_parallel_weights
sage: La = RootSystem(['A', 5, 2]).weight_space(extended=True).fundamental_weights()
sage: rho = sum(La)
sage: positively_parallel_weights(rho, 4*rho)
True
sage: positively_parallel_weights(4*rho, rho)
True
sage: positively_parallel_weights(rho, -rho)
False
sage: positively_parallel_weights(rho, La[1] + La[2])
False
```

### 5.1.59 Crystals of Modified Nakajima Monomials

AUTHORS:

- Arthur Lubovsky: Initial version
- Ben Salisbury: Initial version

Let $Y_{i,k}$, for $i \in I$ and $k \in \mathbb{Z}$, be a commuting set of variables, and let 1 be a new variable which commutes with each $Y_{i,k}$. (Here, $I$ represents the index set of a Cartan datum.) One may endow the structure of a crystal on the set $\hat{M}$ of monomials of the form

$$M = \prod_{(i,k) \in I \times \mathbb{Z}_{\geq 0}} Y_{i,k}^{y_{i,k}} 1.$$  

Elements of $\hat{M}$ are called *modified Nakajima monomials*. We will omit the 1 from the end of a monomial if there
exists at least one $y_i(k) \neq 0$. The crystal structure on this set is defined by

$$\text{wt}(M) = \sum_{i \in I} \left( \sum_{k \geq 0} y_i(k) \right) \Lambda_i,$$

$$\varphi_i(M) = \max \left\{ \sum_{0 \leq j \leq k} y_i(j) : k \geq 0 \right\},$$

$$\varepsilon_i(M) = \varphi_i(M) - \langle h_i, \text{wt}(M) \rangle,$$

$$k_f = k_f(M) = \min \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\},$$

$$k_e = k_e(M) = \max \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\},$$

where $\{h_i : i \in I\}$ and $\{\Lambda_i : i \in I\}$ are the simple coroots and fundamental weights, respectively. With a chosen set of integers $C = (c_{ij})_{i \neq j}$ such that $c_{ij} + c_{ji} = 1$, one defines

$$A_{i,k} = Y_{i,k} Y_{i,k+1} \prod_{j \neq i} Y_{j,k+c_{ij}},$$

where $(a_{ij})$ is a Cartan matrix. Then

$$e_i M = \begin{cases} 0 & \text{if } \varepsilon_i(M) = 0, \\ A_{i,k} M & \text{if } \varepsilon_i(M) > 0, \end{cases}$$

$$f_i M = A_{i,k}^{-1} M.$$

It is shown in [KKS2007] that the connected component of $\hat{\mathcal{M}}$ containing the element 1, which we denote by $\mathcal{M}(\infty)$, is crystal isomorphic to the crystal $B(\infty)$.

Let $\hat{\mathcal{M}}$ be $\mathcal{M}$ as a set, and with crystal structure defined as on $\hat{\mathcal{M}}$ with the exception that

$$f_i M = \begin{cases} 0 & \text{if } \varphi_i(M) = 0, \\ A_{i,k}^{-1} M & \text{if } \varphi_i(M) > 0. \end{cases}$$

Then Kashiwara [Ka2003] showed that the connected component in $\hat{\mathcal{M}}$ containing a monomial $M$ such that $e_i M = 0$, for all $i \in I$, is crystal isomorphic to the irreducible highest weight crystal $B(\text{wt}(M))$.

**WARNING:**

Monomial crystals depend on the choice of positive integers $C = (c_{ij})_{i \neq j}$ satisfying the condition $c_{ij} + c_{ji} = 1$. We have chosen such integers uniformly such that $c_{ij} = 1$ if $i < j$ and $c_{ij} = 0$ if $i > j$.
EXAMPLES:

```python
sage: La = RootSystem("A2").weight_lattice().fundamental_weights()
sage: B = crystals.Tableaux("A2",shape=[2,1])
sage: GM = M.digraph()
sage: GB = B.digraph()
sage: GM.is_isomorphic(GB,edge_labels=True)
True

sage: La = RootSystem("G2").weight_lattice().fundamental_weights()
sage: B = crystals.Tableaux("G2",shape=[2,1])
sage: GM = M.digraph()
sage: GB = B.digraph()
sage: GM.is_isomorphic(GB,edge_labels=True)
True

sage: La = RootSystem("B2").weight_lattice().fundamental_weights()
sage: B = crystals.Tableaux("B2",shape=[3/2,1/2])
sage: GM = M.digraph()
sage: GB = B.digraph()
sage: GM.is_isomorphic(GB,edge_labels=True)
True

sage: La = RootSystem("A3,1").weight_lattice(extended=True).fundamental_weights()
sage: M = crystals.NakajimaMonomials("A3,1",La[0]+La[2])
sage: B = crystals.GeneralizedYoungWalls(3,La[0]+La[2])
sage: SM = M.subcrystal(max_depth=4)
sage: SB = B.subcrystal(max_depth=4)
sage: GM = M.digraph(subset=SM) # long time
sage: GB = B.digraph(subset=SB) # long time
sage: GM.is_isomorphic(GB,edge_labels=True) # long time
True

sage: La = RootSystem("A5,2").weight_lattice(extended=True).fundamental_weights()
sage: LA = RootSystem("A5,2").weight_space().fundamental_weights()
sage: M = crystals.NakajimaMonomials("A5,2",3*La[0])
sage: B = crystals.LSPaths(3*LA[0])
sage: SM = M.subcrystal(max_depth=4)
sage: SB = B.subcrystal(max_depth=4)
sage: GM = M.digraph(subset=SM)
sage: GB = B.digraph(subset=SB)
sage: GM.is_isomorphic(GB,edge_labels=True)
True

sage: c = matrix([[0,1,0],[0,0,1],[1,0,0]])
sage: La = RootSystem("A2,1").weight_lattice(extended=True).fundamental_weights()
sage: M = crystals.NakajimaMonomials("A2,1",c=c)
sage: sorted(M.subcrystal(max_depth=3), key=str)
[Y(0,0) Y(0,1) Y(1,0) Y(2,1)^-1,
 Y(0,0) Y(0,1)^2 Y(1,1)^-1 Y(2,0) Y(2,1)^-1,
```
\[
Y(0,0)^2 Y(0,1)^{-1} Y(2,0), \\
Y(0,1) Y(0,2)^{-1} Y(1,1)^{-1} Y(2,0)^2 Y(2,2), \\
Y(0,1) Y(1,0) Y(2,0)^{-1} Y(2,0), \\
Y(0,1)^2 Y(1,1)^{-2} Y(2,0)^2, \\
Y(1,0)^2
\]

\begin{itemize}
\item \textbf{Element}
\item \textbf{cardinality()}
\end{itemize}

Return the cardinality of \texttt{self}.

\textbf{EXAMPLES:}

\begin{center}
\begin{verbatim}
sage: La = RootSystem(['A',2]).weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials(['A',2], La[1])
sage: M.cardinality()
sage: M = crystals.NakajimaMonomials(['D',4,2], La[1])
sage: M.cardinality()
\end{verbatim}
\end{center}

\begin{itemize}
\item \textbf{class \textit{sage.combinat.crystals.monomial_crystals.CrystalOfNakajimaMonomialsElement}(parent, Y, A)}
\end{itemize}

Element class for \texttt{CrystalOfNakajimaMonomials}. The \(f_i\) operators need to be modified from the version in \texttt{monomial\_crystalsNakajimaMonomial} in order to create irreducible highest weight realizations. This modified \(f_i\) is defined as

\[
\begin{cases}
0 & \text{if } \varphi_i(M) = 0, \\
A_{i,k_j}^{-1} M & \text{if } \varphi_i(M) > 0.
\end{cases}
\]

\textbf{EXAMPLES:}

\begin{center}
\begin{verbatim}
sage: La = RootSystem(['A',5,2]).weight_lattice(extended=True).fundamental_weights()
sage: M = crystals.NakajimaMonomials(['A',5,2], La[0])
sage: m = M.module_generators[0].f(0); m
sage: TestSuite(m).run()
\end{verbatim}
\end{center}

\textbf{f()} Return the action of \(f_i\) on \texttt{self}.

\textbf{INPUT:}

\begin{itemize}
\item \texttt{i} – an element of the index set
\end{itemize}

\textbf{EXAMPLES:}
```python
sage: La = RootSystem(['A', 5, 2]).weight_lattice(extended=True).fundamental_weights()
sage: M = crystals.NakajimaMonomials(['A', 5, 2], 3*La[0])
sage: m = M.module_generators[0]
sage: [m.f(i) for i in M.index_set()]
[Y(0, 0)^2 Y(0, 1)^-1 Y(2, 0), None, None, None]
sage: M = crystals.infinity.NakajimaMonomials("E8")
sage: M.set_variables('A')
sage: m = M.module_generators[0].f_string([4, 2, 3, 8])
sage: m
A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1
sage: [m.f(i) for i in M.index_set()]
[A(1,2)^-1 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1, A(2,0)^-1 A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1, A(2,1)^-1 A(3,0)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-1, A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(4,1)^-1 A(8,0)^-1, A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(5,0)^-1 A(8,0)^-1, A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(6,0)^-1 A(8,0)^-1, A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(7,0)^-1 A(8,0)^-1, A(2,1)^-1 A(3,1)^-1 A(4,0)^-1 A(8,0)^-2]
sage: M.set_variables('Y')
```

**weight()**

Return the weight of self as an element of the weight lattice.

**EXAMPLES:**

```python
sage: La = RootSystem("A2").weight_lattice().fundamental_weights()
sage: M.module_generators[0].weight()
(2, 1, 0)
```

**class** `sage.combinat.crystals.monomial_crystals.InfinityCrystalOfNakajimaMonomials(ct, c, category=None)`

Bases: `UniqueRepresentation`, `Parent`

Crystal $B(\infty)$ in terms of (modified) Nakajima monomials.

Let $Y_{i,k}$, for $i \in I$ and $k \in \mathbb{Z}$, be a commuting set of variables, and let 1 be a new variable which commutes with each $Y_{i,k}$. (Here, $I$ represents the index set of a Cartan datum.) One may endow the structure of a crystal on the set $\hat{M}$ of monomials of the form

$$M = \prod_{(i,k) \in I \times \mathbb{Z}_{\geq 0}} Y_{i,k}^{y_{i,k}} 1.$$  

Elements of $\hat{M}$ are called *modified Nakajima monomials*. We will omit the 1 from the end of a monomial if
there exists at least one \( y_i(k) \neq 0 \). The crystal structure on this set is defined by

\[
\begin{align*}
wt(M) &= \sum_{i \in I} \left( \sum_{k \geq 0} y_i(k) \right) \Lambda_i, \\
\varphi_i(M) &= \max \left\{ \sum_{0 \leq j \leq k} y_i(j) : k \geq 0 \right\}, \\
\varepsilon_i(M) &= \varphi_i(M) - \langle h_i, wt(M) \rangle, \\
k_f &= k_f(M) = \min \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\}, \\
k_e &= k_e(M) = \max \left\{ k \geq 0 : \varphi_i(M) = \sum_{0 \leq j \leq k} y_i(j) \right\},
\end{align*}
\]

where \( \{h_i : i \in I\} \) and \( \{\Lambda_i : i \in I\} \) are the simple coroots and fundamental weights, respectively. With a chosen set of non-negative integers \( C = (c_{ij})_{i \neq j} \) such that \( c_{ii} = 0 \) for all \( i \in I \), \( c_{ij}, c_{ji} \in \mathbb{Z}_{>0} \) for all \( i, j \in I \), and \( c_{ij} + c_{ji} = 1 \) for all \( i \neq j \); the default is \( c_{ij} = 0 \) if \( i < j \) and 0 otherwise.

It is shown in [KKS2007] that the connected component of \( \widehat{\mathcal{M}} \) containing the element 1, which we denote by \( \mathcal{M}(\infty) \), is crystal isomorphic to the crystal \( B(\infty) \).

**INPUT:**
- `cartan_type` – a Cartan type
- `c` – (optional) the matrix \( (c_{ij})_{i \neq j} \) such that \( c_{ii} = 0 \) for all \( i \in I \), \( c_{ij}, c_{ji} \in \mathbb{Z}_{>0} \) for all \( i, j \in I \), and \( c_{ij} + c_{ji} = 1 \) for all \( i \neq j \); the default is \( c_{ij} = 0 \) if \( i < j \) and 0 otherwise.

**EXAMPLES:**

```python
sage: B = crystals.infinity.Tableaux("C3")
sage: S = B.subcrystal(max_depth=4)
sage: G = B.digraph(subset=S) # long time
sage: M = crystals.infinity.NakajimaMonomials("C3") # long time
sage: T = M.subcrystal(max_depth=4) # long time
sage: H = M.digraph(subset=T) # long time
sage: G.is_isomorphic(H, edge_labels=True) # long time
True
sage: M = crystals.infinity.NakajimaMonomials(['A',2,1])
sage: T = M.subcrystal(max_depth=3)
sage: H = M.digraph(subset=T) # long time
sage: Y = crystals.infinity.GeneralizedYoungWalls(2)
sage: YS = Y.subcrystal(max_depth=3)
sage: YG = Y.digraph(subset=YS) # long time
sage: YG.is_isomorphic(H, edge_labels=True) # long time
True
```

(continues on next page)
sage: M = crystals.infinity.NakajimaMonomials("D4")
sage: B = crystals.infinity.Tableaux("D4")
sage: MS = M.subcrystal(max_depth=3)
sage: BS = B.subcrystal(max_depth=3)
sage: MG = M.digraph(subset=MS) # long time
sage: BG = B.digraph(subset=BS) # long time
sage: BG.is_isomorphic(MG,edge_labels=True) # long time
True

Element

alias of NakajimaMonomial
c()

Return the matrix $c_{ij}$ of self.

EXAMPLES:

```
sage: La = RootSystem(['B',3]).weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials(La[1]+La[2])
sage: M.c()
[0 1 1]
[0 0 1]
[0 0 0]
sage: c = Matrix([[0,0,1], [1,0,0], [0,1,0]])
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: M = crystals.NakajimaMonomials(2*La[1], c=c)
sage: M.c() == c
True
```
cardinality()

Return the cardinality of self, which is always $\infty$.

EXAMPLES:

```
sage: M = crystals.infinity.NakajimaMonomials(['A',5,2])
sage: M.cardinality()
+Infinity
```

get_variables()

Return the type of monomials to use for the element output.

EXAMPLES:

```
sage: M = crystals.infinity.NakajimaMonomials(['A',4])
sage: M.get_variables()
'Y'
```

set_variables(letter)

Set the type of monomials to use for the element output.

If the $A$ variables are used, the output is written as $\prod_{i \in I} Y_i^{\lambda_i} \prod_{i,k} A_i^{c_{i,k}}$, where $\sum_{i \in I} \lambda_i \Lambda_i$ is the corresponding dominant weight.
INPUT:

- **letter** – can be one of the following:
  - 'Y' - use $Y_{i,k}$, corresponds to fundamental weights
  - 'A' - use $A_{i,k}$, corresponds to simple roots

EXAMPLES:

```python
sage: M = crystals.infinity.NakajimaMonomials(['A', 4])
sage: elt = M.highest_weight_vector().f_string([2,1,3,2,3,2,4,3])
sage: elt
Y(1,2) Y(2,0)^{-1} Y(2,2)^{-1} Y(3,0)^{-1} Y(3,2)^{-1} Y(4,0)
sage: M.set_variables('A')
sage: elt
A(1,1)^{-1} A(2,0)^{-1} A(2,1)^{-2} A(3,0)^{-2} A(3,1)^{-1} A(4,0)^{-1}
sage: M.set_variables('Y')
```

```python
sage: La = RootSystem(['A',2]).weight_lattice().fundamental_weights()
sage: M = crystals.NakajimaMonomials(La[1]+La[2])
sage: lw = M.lowest_weight_vectors()[0]
sage: lw
Y(1,2)^{-1} Y(2,1)^{-1}
sage: M.set_variables('A')
sage: lw
Y(1,0) Y(2,0) A(1,0)^{-1} A(1,1)^{-1} A(2,0)^{-2}
sage: M.set_variables('Y')
```

class `sage.combinat.crystals.monomial_crystals.NakajimaMonomial` *(parent, Y, A)*

Bases: `Element`

An element of the monomial crystal.

Monomials of the form $Y_{i_1,k_1}^{y_1} \cdots Y_{i_t,k_t}^{y_t}$, where $i_1, \ldots, i_t$ are elements of the index set, $k_1, \ldots, k_t$ are nonnegative integers, and $y_1, \ldots, y_t$ are integers.

EXAMPLES:

```python
sage: M = crystals.infinity.NakajimaMonomials(['B',3,1])
sage: mg = M.module_generators[0]
sage: mg
1
sage: mg.f_string([1,3,2,0,1,2,3,0,0,1])
Y(0,0)^{-1} Y(0,1)^{-1} Y(0,2)^{-1} Y(0,3)^{-1} Y(1,0)^{-3} Y(1,1)^{-2} Y(1,2) Y(2,0)^{3} Y(2,2) Y(3,0) Y(3,2)^{-1}
```

An example using the $A$ variables:

```python
sage: M = crystals.infinity.NakajimaMonomials("A3")
sage: M.set_variables('A')
sage: mg = M.module_generators[0]
sage: mg.f_string([1,2,3,2,1])
A(1,0)^{-1} A(1,1)^{-1} A(2,0)^{-2} A(3,0)^{-1}
sage: mg.f_string([3,2,1])
A(1,2)^{-1} A(2,1)^{-1} A(3,0)^{-1}
sage: M.set_variables('Y')
```
\texttt{e}(i)

Return the action of $e_i$ on \texttt{self}.

**INPUT:**

- $i$ – an element of the index set

**EXAMPLES:**

```python
sage: M = crystals.infinity.NakajimaMonomials(['E',7,1])
sage: m = M.module_generators[0].f_string([0,1,4,3])
sage: [m.e(i) for i in M.index_set()]
[None, None, None, None, \text{Y}(0,0)^{-1} \text{Y}(1,1)^{-1} \text{Y}(2,1) \text{Y}(3,0) \text{Y}(3,1) \text{Y}(4,0)^{-1} \text{Y}(4,1)^{-1} \text{Y}(5,0),
None, None, None, None]
```

```python
sage: M = crystals.infinity.NakajimaMonomials("C5")
sage: m = M.module_generators[0].f_string([1,3])
sage: [m.e(i) for i in M.index_set()]
[\text{Y}(2,1) \text{Y}(3,0)^{-1} \text{Y}(3,1)^{-1} \text{Y}(4,0),
None, \text{Y}(1,0)^{-1} \text{Y}(1,1)^{-1} \text{Y}(2,0), None, None]
```

```python
sage: M = crystals.infinity.NakajimaMonomials(['D',4,1])
sage: M.set_variables('A')
sage: m = M.module_generators[0].f_string([4,2,3,0])
sage: [m.e(i) for i in M.index_set()]
[A(2,1)^{-1} A(3,1)^{-1} A(4,0)^{-1},
None, None, None, None]
```

```python
sage: M.set_variables('Y')
```

\texttt{epsilon}(i)

Return the value of $\varepsilon_i$ on \texttt{self}.

**INPUT:**

- $i$ – an element of the index set

**EXAMPLES:**

```python
sage: M = crystals.infinity.NakajimaMonomials(['G',2,1])
sage: m = M.module_generators[0].f(2)
sage: [m.epsilon(i) for i in M.index_set()]
[0, 0, 1]
```

```python
sage: M = crystals.infinity.NakajimaMonomials(['C',4,1])
```

(continues on next page)
sage: m = M.module_generators[0].f_string([4,2,3])

sage: [m.epsilon(i) for i in M.index_set()]
[0, 0, 0, 1, 0]

\( f(i) \)

Return the action of \( f_i \) on \( \text{self} \).

INPUT:

- \( i \) – an element of the index set

EXAMPLES:

\[
\begin{align*}
\text{sage: } & M = \text{crystals.infinity.NakajimaMonomials("B4")} \\
\text{sage: } & m = M.module_generators[0].f_string([1,3,4]) \\
\text{sage: } & \left[ m.f(i) \text{ for } i \text{ in } M.index_set() \right] \\
& \left[ Y(1,0)^{-2} Y(1,1)^{-2} Y(2,0)^2 Y(2,1) Y(3,0)^{-1} Y(4,0) Y(4,1)^{-1}, \\
& Y(1,0)^{-1} Y(1,1)^{-1} Y(1,2) Y(2,0) Y(2,2)^{-1} Y(3,0)^{-1} Y(3,1) Y(4,0) Y(4,1)^{-1}, \\
& Y(1,0)^{-1} Y(1,1)^{-1} Y(2,0) Y(2,1)^2 Y(3,0)^{-2} Y(3,1)^{-1} Y(4,0)^3 Y(4,1)^{-1}, \\
& Y(1,0)^{-1} Y(1,1)^{-1} Y(2,0) Y(2,1) Y(3,0)^{-1} Y(3,1) Y(4,1)^{-2} \right]
\end{align*}
\]

\( \phi(i) \)

Return the value of \( \varphi_i \) on \( \text{self} \).

INPUT:

- \( i \) – an element of the index set

EXAMPLES:

\[
\begin{align*}
\text{sage: } & M = \text{crystals.infinity.NakajimaMonomials(['D',4,3])} \\
\text{sage: } & m = M.module_generators[0].f(1) \\
\text{sage: } & \left[ m.phi(i) \text{ for } i \text{ in } M.index_set() \right] \\
& \left[ 1, -1, 1 \right]
\end{align*}
\]

\( \text{weight()} \)

Return the weight of \( \text{self} \) as an element of the weight lattice.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & C = \text{crystals.infinity.NakajimaMonomials(['A',1,1])} \\
\text{sage: } & v = C.highest_weight_vector() \\
\text{sage: } & v.f(1).weight() + v.f(0).weight() - \text{delta}
\end{align*}
\]

5.1. Comprehensive Module List
weight_in_root_lattice()

Return the weight of self as an element of the root lattice.

EXAMPLES:

```
sage: M = crystals.infinity.NakajimaMonomials(['F',4])
sage: m = M.module_generators[0].f_string([3,3,1,2,4])
sage: m.weight_in_root_lattice()
sage: M = crystals.infinity.NakajimaMonomials(['B',3,1])
sage: mg = M.module_generators[0]
sage: m = mg.f_string([1,3,2,0,1,2,3,0,0,1])
sage: m.weight_in_root_lattice()
sage: M = crystals.infinity.NakajimaMonomials(['C',3,1])
sage: m = M.module_generators[0].f_string([3,0,1,2,0])
sage: m.weight_in_root_lattice()
```

5.1.60 Crystal of Bernstein-Zelevinsky Multisegments

class sage.combinat.crystals.multisegments.InfinityCrystalOfMultisegments(n)

Bases: Parent, UniqueRepresentation

The type $A_n^{(1)}$ crystal $B(\infty)$ realized using Bernstein-Zelevinsky (BZ) multisegments.

Using (a modified version of the) notation from [JL2009], for $\ell \in \mathbb{Z}_{>0}$ and $i \in \mathbb{Z}/(n+1)\mathbb{Z}$, a segment of length $\ell$ and head $i$ is the sequence of consecutive residues $[i, i+1, \ldots, i+\ell-1]$. The notation for a segment of length $\ell$ and head $i$ is simplified to $[i; \ell]$. Similarly, a segment of length $\ell$ and tail $i$ is the sequence of consecutive residues $[i-\ell+1, \ldots, i-1, i]$. The latter is denoted simply by $(\ell; i)$. Finally, a multisegment is a formal linear combination of segments, usually written in the form

$$\psi = \sum_{i \in \mathbb{Z}/(n+1)\mathbb{Z}} m_{(\ell;i)}[\ell; i].$$

Such a multisegment is called aperiodic if, for every $\ell > 0$, there exists some $i \in \mathbb{Z}/(n+1)\mathbb{Z}$ such that $(\ell; i)$ does not appear in $\psi$. Denote the set of all periodic multisegments, together with the empty multisegment $\emptyset$, by $\Psi$. We define a crystal structure on multisegments as follows. Set $S_{\ell,i} = \sum_{k \geq \ell} (m_{(k;i-1)} - m_{(k;i)})$ and let $\ell_f$ be the minimal $\ell$ that attains the value $\min_{\ell > 0} S_{\ell,i}$. Then we have

$$f_i \psi = \begin{cases} 
\psi + (1; i) & \text{if } \ell_f = 1, \\
\psi + (\ell_f; i) - (\ell_f - 1; i - 1) & \text{if } \ell_f > 1.
\end{cases}$$

Similarly, let $\ell_e$ be the maximal $\ell$ that attains the value $\min_{\ell > 0} S_{\ell,i}$. Then we have

$$e_i \psi = \begin{cases} 
0 & \text{if } \min_{\ell > 0} S_{\ell,i} = 0, \\
\psi + (1; i) & \text{if } \ell_e = 1, \\
\psi - (\ell_e; i) + (\ell_e - 1; i - 1) & \text{if } \ell_e > 1.
\end{cases}$$

Alternatively, the crystal operators may be defined using a signature rule, as detailed in Section 4 of [JL2009] (following [AJL2011]). For $\psi \in \Psi$ and $i \in \mathbb{Z}/(n+1)\mathbb{Z}$, encode all segments in $\psi$ with tail $i$ by the symbol $R$.
and all segments in \( \psi \) with tail \( i - 1 \) by \( A \). For \( \ell > 0 \), set \( w_{i,\ell} = R_{m(\ell)}^{m(\ell - 1)} A_{m(\ell - 1)} \) and \( w_i = \prod_{\ell \geq 1} w_{i,\ell} \). By successively canceling out as many \( RA \) factors as possible, set \( \tilde{w}_i = A_{m(\ell)} R_{m(\ell)} \psi \). If \( a_i(\psi) > 0 \), denote by \( \ell_f > 0 \) the length of the rightmost segment \( A \) in \( \tilde{w}_i \). If \( a_i(\psi) = 0 \), set \( \ell_f = 0 \). Then

\[
f_i \psi = \begin{cases} 
\psi + (1; i] & \text{if } a_i(\psi) = 0, \\
\psi + (\ell_f; i] - (\ell_f - 1; i - 1] & \text{if } a_i(\psi) > 0.
\end{cases}
\]

The rule for computing \( e_i \psi \) is similar.

**INPUT:**

- \( n \) – for type \( A_n^{(1)} \)

**EXAMPLES:**

```sage
sage: B = crystals.infinity.Multisegments(2)
sage: x = B([(8,1),(6,0),(5,1),(5,0),(4,0),(4,1),(4,1),(3,0),(3,0),(3,1),(3,1),(1,0),(1,2),(1,2)]); x
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] + 2 * (3; 0] + 2 * (3; 1] + (1; 0] + 2 * (1; 2]
sage: x.f(1)
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] + 2 * (3; 0] + 2 * (3; 1] + (2; 1] + 2 * (1; 2]
sage: x.f(1).f(1)
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] + 2 * (3; 0] + 2 * (3; 1] + (2; 1] + (1; 1] + 2 * (1; 2]
sage: x.e(1)
(7; 0] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] + 2 * (3; 0] + 2 * (3; 1] + (1; 0] + 2 * (1; 2]
sage: x.e(1).e(1)
sage: x.f(0)
(8; 1] + (6; 0] + (5; 0] + (5; 1] + (4; 0] + 2 * (4; 1] + 2 * (3; 0] + 2 * (3; 1] + (2; 0] + (1; 0] + (1; 2]
```

We check an \( sl_2 \) example against the generalized Young walls:

```sage
sage: G = B.subcrystal(max_depth=4).digraph()
sage: C = crystals.infinity.GeneralizedYoungWalls(1)
sage: GC = C.subcrystal(max_depth=4).digraph()
sage: G.is_isomorphic(GC, edge_labels=True)
True
```

**REFERENCES:**

- [AJL2011]
- [JL2009]
- [LTV1999]

**class Element**(parent, value)

    Bases: ElementWrapper

    An element in a BZ multisegments crystal.

    e()

    Return the action of \( e_i \) on \( \text{self} \).
INPUT:
• \( i \) – an element of the index set

EXAMPLES:

\[
\begin{align*}
\text{sage: } B &= \text{crystals.infinity.Multisegments}(2) \\
\text{sage: } b &= B([4,2], (3,0), (3,1), (1,1), (1,0)]) \\
\text{sage: } b.e(0) &\quad (4; 2] + (3; 0] + (3; 1] + (1; 1] \\
\text{sage: } b.e(1) &\quad (3; 0] + 2 \times (3; 1] + (1; 0] + (1; 1] \\
\text{sage: } b.e(2) &\quad (3; 0] + 2 \times (3; 1] + (1; 0] + (1; 1]
\end{align*}
\]

\textbf{epsilon}(i)
Return \( \varepsilon_i \) of self.

INPUT:
• \( i \) – an element of the index set

EXAMPLES:

\[
\begin{align*}
\text{sage: } B &= \text{crystals.infinity.Multisegments}(2) \\
\text{sage: } b &= B([4,2], (3,0), (3,1), (1,1), (1,0)]) \\
\text{sage: } b.epsilon(0) &\quad 1 \\
\text{sage: } b.epsilon(1) &\quad 0 \\
\text{sage: } b.epsilon(2) &\quad 1
\end{align*}
\]

\textbf{f}(i)
Return the action of \( f_i \) on self.

INPUT:
• \( i \) – an element of the index set

EXAMPLES:

\[
\begin{align*}
\text{sage: } B &= \text{crystals.infinity.Multisegments}(2) \\
\text{sage: } b &= B([4,2], (3,0), (3,1), (1,1), (1,0)]) \\
\text{sage: } b.f(0) &\quad (4; 2] + (3; 0] + (3; 1] + 2 \times (1; 0] + (1; 1] \\
\text{sage: } b.f(1) &\quad (4; 2] + (3; 0] + (3; 1] + (1; 0] + 2 \times (1; 1] \\
\text{sage: } b.f(2) &\quad 2 \times (4; 2] + (3; 0] + (1; 0] + (1; 1]
\end{align*}
\]

\textbf{phi}(i)
Return \( \varphi_i \) of self.

Let \( \psi \in \Psi \). Define \( \varphi_i(\psi) := \varepsilon_i(\psi) + \langle h_i, \text{wt}(\psi) \rangle \), where \( h_i \) is the \( i \)-th simple coroot and \( \text{wt}(\psi) \) is the \text{weight()} of \( \psi \).

INPUT:
• \( i \) – an element of the index set

EXAMPLES:
```python
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.phi(0)
1
sage: b.phi(1)
0
sage: mg = B.highest_weight_vector()
sage: mg.f(1).phi(0)
1
```

**weight()**

Return the weight of self.

EXAMPLES:

```python
sage: B = crystals.infinity.Multisegments(2)
sage: b = B([(4,2), (3,0), (3,1), (1,1), (1,0)])
sage: b.weight()
-4*delta
```

**highest_weight_vector()**

Return the highest weight vector of self.

EXAMPLES:

```python
sage: B = crystals.infinity.Multisegments(2)
sage: B.highest_weight_vector()
0
```

**weight_lattice_realization()**

Return a realization of the weight lattice of self.

EXAMPLES:

```python
sage: B = crystals.infinity.Multisegments(2)
sage: B.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

### 5.1.61 Crystal Of Mirković-Vilonen (MV) Polytopes

AUTHORS:

- Dinakar Muthiah, Travis Scrimshaw (2015-05-11): initial version

```python
class sage.combinat.crystals.mv_polytopes.MVPolytope(parent, lusztig_datum, long_word=None)
Bases: PBWCrystalElement
A Mirković-Vilonen (MV) polytope.
EXAMPLES:
    We can create an animation showing how the MV polytope changes under a string of crystal operators:
```
sage: MV = crystals.infinity.MVPolytopes(['C', 2])  
sage: u = MV.highest_weight_vector()  
sage: L = RootSystem(['C', 2, 1]).ambient_space()  
sage: s = [1, 2, 1, 2, 2, 2, 1, 1, 1, 1, 2, 2, 1, 2, 1, 2]  
sage: BB = [[-9, 2], [-10, 2]]  
sage: p = L.plot(reflection_hyperplanes=False, bounding_box=BB)  # long time  
sage: frames = [p + L.plot_mv_polytope(u.f_string(s[:i]),  # long time  
......: circle_size=0.1,  
......: wireframe='green',  
......: fill='purple',  
......: bounding_box=BB)  
......: for i in range(len(s))]  
sage: for f in frames:  # long time  
......: f.axes(False)  
sage: animate(frames).show(delay=60)  # optional -- ImageMagick # long time

plot(P=None, **options)

Plot self.

**INPUT:**

- *P* – (optional) a space to realize the polytope; default is the weight lattice realization of the crystal

**See also:**

plot_mv_polytope()

**EXAMPLES:**

```python
sage: MV = crystals.infinity.MVPolytopes(['C', 2])

sage: b = MV.highest_weight_vector().f_string([1, 2, 1, 2, 2, 2, 1, 1, 1, 1, 2, 1, 2, 2, 1, 2])

sage: b.plot()  # optional - sage.plot

Graphics object consisting of 12 graphics primitives
```

Here is the above example placed inside the ambient space of type $C_2$:

![Polytope in ambient space of type C2](image)

polytope(P=None)

Return a polytope of self.

**INPUT:**
• \( P \) – (optional) a space to realize the polytope; default is the weight lattice realization of the crystal

**EXAMPLES:**

```python
sage: MV = crystals.infinity.MVPolytopes(['C', 3])
sage: b = MV.module_generators[0].f_string([3,2,3,2,1])
sage: P = b.polytope(); P
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 6 vertices
sage: P.vertices()
(A vertex at (0, 0, 0),
 A vertex at (0, 1, -1),
 A vertex at (0, 1, 1),
 A vertex at (1, -1, 0),
 A vertex at (1, 1, -2),
 A vertex at (1, 1, 2))
```

```python
class sage.combinat.crystals.mv_polytopes.MVPolytopes(cartan_type)

Bases: `PBWCrystal`

The crystal of Mirković-Vilonen (MV) polytopes.

Let \( W \) denote the corresponding Weyl group and \( P_R = R \otimes P \). Let \( \Gamma = \{ w \Lambda_i \mid w \in W, i \in I \} \). Consider \( M = (M_{\gamma})_{\gamma \in \Gamma} \) that satisfy the tropical Plücker relations (see Proposition 7.1 of [BZ01]). The MV polytope is defined as

\[
P(M) = \{ \alpha \in P_R \mid \langle \alpha, \gamma \rangle \geq M_\gamma \text{ for all } \gamma \in \Gamma \}.
\]

The vertices \( \{\mu_w\}_{w \in W} \) are given by

\[
\langle \mu_w, \gamma \rangle = M_\gamma
\]

and are known as the GGMS datum of the MV polytope.

Each path from \( \mu_e \) to \( \mu_{w_0} \) corresponds to a reduced expression \( i = (i_1, \ldots, i_m) \) for \( w_0 \) and the corresponding edge lengths \( (n_k)_{k=1}^m \) from the Lusztig datum with respect to \( i \). Explicitly, we have

\[
n_k = -M_{w_{k-1} \Lambda_i} - M_{w_k \Lambda_i} - \sum_{j \neq i} a_{ij} M_{w_i \Lambda_j},
\]

\[
\mu_{w_k} - \mu_{w_{k-1}} = n_k w_{k-1} \alpha_{i_k},
\]

where \( w_k = s_i \cdots s_{i_k} \) and \( (a_{ij}) \) is the Cartan matrix.

MV polytopes have a crystal structure that corresponds to the crystal structure, which is isomorphic to \( B(\infty) \) with \( \mu_{w_0} = 0 \), on PBW data. Specifically, we have \( f_j P(M) \) as being the unique MV polytope given by shifting \( \mu_e \) by \(-\alpha_j \) and fixing the vertices \( \mu_w \) when \( s_j w < w \) (in Bruhat order) and the weight is given by \( \mu_e \). Furthermore, the *-involution is given by negating \( P(M) \).

**INPUT:**

• `cartan_type` – a Cartan type

**EXAMPLES:**

```python
sage: MV = crystals.infinity.MVPolytopes(['B', 3])
sage: hw = MV.highest_weight_vector()
sage: x = hw.f_string([1,2,2,3,3,1,3,3,2,3,2,1,3,1,2,3,1,2,1,3,2]); x
MV polytope with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

Elements are expressed in terms of Lusztig datum for a fixed reduced expression of \( w_0 \):

---

**5.1. Comprehensive Module List**
We can construct elements by giving it Lusztig data (with respect to the default long word reduced expression):

```python
sage: MV([1,1,1,3,1,0,0,1,1])
MV polytope with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

We can also construct elements by passing in a reduced expression for a long word:

```python
sage: x = MV([1,1,1,3,1,0,0,1,1], [3,2,1,3,2,3,2,1,2]); x
MV polytope with Lusztig datum (1, 1, 1, 0, 1, 0, 5, 1, 1)
```

The highest weight crystal $B(\lambda) \subseteq B(\infty)$ is characterized by the MV polytopes that sit inside of $W \lambda$ (translating $\mu \mapsto \lambda$):

```python
sage: MV = crystals.infinity.MVPolytopes(['A',2])
sage: La = MV.weight_lattice_realization().fundamental_weights()
sage: R = crystals.elementary.R(La[1]+La[2])
sage: T = tensor([R, MV])
sage: x = T(R.module_generators[0], MV.highest_weight_vector()); x
MV polytope with Lusztig datum (1, 1, 1)
```

REFERENCES:
Element
alias of MVPolytope
latex_options()
Return the latex options of self.
EXAMPLES:
sage: MV = crystals.infinity.MVPolytopes(['F', 4])
sage: MV.latex_options()
{'P': Ambient space of the Root system of type ['F', 4],
 'circle_size': 0.1,
 'mark_endpoints': True,
 'projection': True}

set_latex_options(**kwds)
Set the latex options for the elements of self.
INPUT:
• projection – the projection; set to True to use the default projection of the specified weight lattice realization (initial: True)
• P – the weight lattice realization to use (initial: the weight lattice realization of self)
• mark_endpoints – whether to mark the endpoints (initial: True)
• circle_size – the size of the endpoint circles (initial: 0.1)
EXAMPLES:
sage: MV = crystals.infinity.MVPolytopes(['C', 2])
sage: P = RootSystem(['C', 2]).weight_lattice()
sage: b = MV.highest_weight_vector().f_string([1,2,1,2])
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (0, -2) -- (-1, -3) -- (-1, -3) -- (-2, -2);
\draw (0, 0) -- (-1, 1) -- (-1, 1) -- (-2, 0) -- (-2, -2);
\draw[fill=black] (0, 0) circle (0.1);
\draw[fill=black] (0, -2) circle (0.1);
\end{tikzpicture}
sage: MV.set_latex_options(P=P, circle_size=float(0.2))
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (2, -2) -- (2, -3) -- (2, -3) -- (0, -2);
\draw (0, 0) -- (-2, 1) -- (-2, 1) -- (-2, 0) -- (0, -2);
\draw[fill=black] (0, 0) circle (0.2);
\draw[fill=black] (0, -2) circle (0.2);
\end{tikzpicture}
sage: MV.set_latex_options(mark_endpoints=False)
sage: latex(b)
\begin{tikzpicture}
\draw (0, 0) -- (2, -2) -- (2, -3) -- (2, -3) -- (0, -2);
\draw (0, 0) -- (-2, 1) -- (-2, 1) -- (-2, 0) -- (0, -2);
\end{tikzpicture}
5.1.62 $\mathcal{B}(\infty)$ Crystal Of PBW Monomials

AUTHORS:

- Dinakar Muthiah (2015-05-11): initial version

See also:

For information on PBW datum, see *PBW Data*.

```python
class sage.combinat.crystals.pbw_crystal.PBWCrystal(cartan_type)

Bases: Parent, UniqueRepresentation

Crystal of $\mathcal{B}(\infty)$ given by PBW monomials.

A model of the crystal $\mathcal{B}(\infty)$ whose elements are PBW datum up to equivalence by the tropical Plücker relations. The crystal structure on Lusztig data $x = (x_1, \ldots, x_m)$ for the reduced word $s_{i_1} \cdots s_{i_m} = w_0$ is given as follows. Suppose $i_1 = j$, then $f_j x = (x_1 + 1, x_2, \ldots, x_m)$. If $i_1 \neq j$, then we use the tropical Plücker relations to change the reduced expression such that $i'_1 = j$ and then we change back to the original word.

EXAMPLES:

```python
sage: PBW = crystals.infinity.PBW(['B', 3])
sage: hw = PBW.highest_weight_vector()
sage: x = hw.f_string([1,2,2,3,1,3,3,3,2,1,3,2,1,3,2]); x
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

Elements are expressed in terms of Lusztig datum for a fixed reduced expression of $w_0$:

```python
sage: PBW.default_long_word() [1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: PBW.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: x
PBW monomial with Lusztig datum (3, 1, 1, 0, 1, 0, 1, 3, 4)
sage: PBW.set_default_long_word([1, 3, 2, 3, 1, 2, 3, 1, 2])
```

We can construct elements by giving it Lusztig data (with respect to the default long word):

```python
sage: PBW([1,1,1,3,1,0,0,1,1])
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

We can also construct elements by passing in a reduced expression for a long word:

```python
sage: x = PBW([[1,1,1,3,1,0,0,1,1], [3,2,1,3,2,3,2,1,2]]); x
PBW monomial with Lusztig datum (1, 1, 1, 0, 1, 0, 5, 1, 1)
sage: x.to_highest_weight()[1] [1, 2, 2, 2, 2, 1, 3, 3, 3, 3, 3, 3, 3, 2, 3, 3, 3, 3, 2, 1, 3]
```

**Element**

alias of *PBWCrystalElement*
default_long_word()

Return the default long word used to express elements of self.

EXAMPLES:

```python
sage: B = crystals.infinity.PBW(['E', 6])
sage: B.default_long_word()
[1, 3, 4, 5, 6, 2, 4, 5, 3, 4, 1, 3, 2, 4, 5, 6, 2, 4,
  5, 3, 4, 1, 3, 2, 4, 5, 3, 4, 1, 3, 2, 4, 1, 3, 2, 1]
```

set_default_long_word(word)

Set the default long word used to express elements of self.

EXAMPLES:

```python
sage: B = crystals.infinity.PBW(['C', 3])
sage: B.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: x = B.highest_weight_vector().f_string([2,1,3,2,1,3,2,3,1])
sage: x
PBW monomial with Lusztig datum (1, 2, 2, 0, 0, 0, 0, 1)
sage: B.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: B.default_long_word()
[2, 1, 3, 2, 1, 3, 2, 3, 1]
sage: x
PBW monomial with Lusztig datum (2, 0, 0, 0, 0, 0, 1, 3, 2)
```

class sage.combinat.crystals.pbw_crystal.PBWCrystalElement(parent, lusztig_datum, long_word=None)

Bases: Element

A crystal element in the PBW model.

e(i)

Return the action of $e_i$ on self.

EXAMPLES:

```python
sage: B = crystals.infinity.PBW(['B', 3])
sage: b = B.highest_weight_vector()
sage: c = b.f_string([2,1,3,2,1,3,2,2]); c
PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 2)
sage: c.e(2)
PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 1)
sage: c.e_string([2,2,1,3,2,1,3,2]) == b
True
```

epsilon(i)

Return $\varepsilon_i$ of self.

EXAMPLES:

```python
sage: B = crystals.infinity.PBW(['A2'])
sage: s = B((3,0,0), (1,2,1))
sage: s.epsilon(1)
3
```
sage: s.epsilon(2)
0

\( f(i) \)

Return the action of \( f_i \) on self.

EXAMPLES:

```
sage: B = crystals.infinity.PBW("D4")
sage: b = B.highest_weight_vector()
sage: c = b.f_string([1,2,3,1,2,3,4]); c
PBW monomial with Lusztig datum (0, 1, 0, 0, 0, 0, 2, 0, 0, 2, 0)
sage: c == b.f_string([1,2,4,1,2,3,3])
True
```

\( \text{lusztig\_datum}(\text{word}=\text{None}) \)

Return the Lusztig datum of self with respect to the reduced expression of the long word word.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['A', 2])
sage: u = B.highest_weight_vector()
sage: b = u.f_string([2,1,2,2,2,1,2,1,2,1,2,2])
sage: b.lusztig_datum()
(6, 0, 10)
sage: b.lusztig_datum(word=[2,1,2])
(4, 6, 0)
```

\( \phi(i) \)

Return \( \phi_i \) of self.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['A', 2])
sage: s = B((3,0,0), (1,2,1))
sage: s.phi(1)
-3
sage: s.phi(2)
3
```

\( \text{star}() \)

Return the starred crystal element corresponding to self.

Let \( b \) be an element of self with Lusztig datum \((b_1, \ldots, b_N)\) with respect to \( w_0 = s_{i_1} \cdots s_{i_N} \). Then \( b^\ast \) is the element with Lusztig datum \((b_N, \ldots, b_1)\) with respect to \( w_0 = s_{i_N} \cdots s_{i_1} \), where \( i_j^\ast = \omega(i_j) \) with \( \omega \) being the automorphism given by the action of \( w_0 \) on the simple roots.

EXAMPLES:

```
sage: P = crystals.infinity.PBW(['A', 2])
sage: P((1,2,3), (1,2,1)).star() == P((3,2,1), (2,1,2))
True
sage: B = crystals.infinity.PBW(['E', 6])
```
sage: b = B.highest_weight_vector()
sage: c = b.f_string([1,2,6,3,4,2,5,2,3,4,1,6])
sage: c == c.star().star()
True

weight()
Return weight of self.

EXAMPLES:

sage: B = crystals.infinity.PBW(['A', 2])
sage: s = B((2,2,2), (1,2,1))
sage: s.weight()
(-4, 0, 4)

5.1.63 PBW Data

This contains helper classes and functions which encode PBW data in finite type.

AUTHORS:

• Dinakar Muthiah (2015-05): initial version
• Travis Scrimshaw (2016-06): simplified code and converted to Cython

class sage.combinat.crystals.pbw_datum.PBWData(cartan_type)
Bases: object
Helper class for the set of PBW data.

convert_to_new_long_word(pbw_datum, new_long_word)
Convert the PBW datum pbw_datum from its long word to new_long_word.

EXAMPLES:

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")
sage: datum = PBWDatum(P, (1,2,1), (1,0,1))
sage: new_datum = P.convert_to_new_long_word(datum,(2,1,2))
sage: new_datum
PBW Datum element of type ['A', 2] with long word (2, 1, 2)
and Lusztig datum (0, 1, 0)
sage: new_datum.long_word
(2, 1, 2)
sage: new_datum.lusztig_datum
(0, 1, 0)

class sage.combinat.crystals.pbw_datum.PBWDatum(parent, long_word, lusztig_datum)
Bases: object
Helper class which represents a PBW datum.

convert_to_long_word_with_first_letter(i)
Return a new PBWDatum equivalent to self whose long word begins with i.

EXAMPLES:
sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A3")

sage: datum = PBWDatum(P, (1,2,1,3,2,1), (1,0,1,4,2,3))

sage: datum.convert_to_long_word_with_first_letter(1)
PBW Datum element of type ['A', 3] with long word (1, 2, 3, 1, 2, 1)
and Lusztig datum (1, 0, 4, 1, 2, 3)

sage: datum.convert_to_long_word_with_first_letter(2)
PBW Datum element of type ['A', 3] with long word (2, 1, 2, 3, 2, 1)
and Lusztig datum (0, 1, 0, 4, 2, 3)

sage: datum.convert_to_long_word_with_first_letter(3)
PBW Datum element of type ['A', 3] with long word (3, 1, 2, 3, 1, 2)
and Lusztig datum (8, 1, 0, 4, 1, 2)

\textbf{convert_to_new_long_word}(new\_long\_word)

Return a new PBWDatum equivalent to self whose long word is new\_long\_word.

\textbf{EXAMPLES:}

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")

sage: datum = PBWDatum(P, (1,2,1), (1,0,1))

sage: new_datum = datum.convert_to_new_long_word((2,1,2))

sage: new_datum.long_word
(2, 1, 2)

sage: new_datum.lusztig_datum
(0, 1, 0)

\textbf{is_equivalent_to}(other\_pbw\_datum)

Return whether self is equivalent to other\_pbw\_datum modulo the tropical Plücker relations.

\textbf{EXAMPLES:}

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")

sage: L1 = PBWDatum(P, (1,2,1), (1,2,3))

sage: L1.is_equivalent_to(L2)
True

sage: L1 == L2
False

\textbf{star}()

Return the starred version of self, i.e., with reversed \texttt{long\_word} and \texttt{lusztig\_datum}

\textbf{EXAMPLES:}

sage: from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
sage: P = PBWData("A2")

sage: L1 = PBWDatum(P, (1,2,1), (1,2,3))

sage: L1.star() == PBWDatum(P, (2,1,2), (3,2,1))
True

\textbf{weight}()

Return the weight of self.
EXAMPLES:

```
from sage.combinat.crystals.pbw_datum import PBWData, PBWDatum
P = PBWData("A2")
L = PBWDatum(P, (1,2,1), (1,1,1))
L.weight()
```

```
```

```
sage.combinat.crystals.pbw_datum.compute_new_lusztigDatum(enhanced_braid_chain, initial_lusztig_datum)
```

Return the Lusztig datum obtained by applying tropical Plücker relations along enhanced_braid_chain starting with initial_lusztig_datum.

EXAMPLES:

```
ct = CartanType(['A', 2])
W = CoxeterGroup(ct)
chain = BraidMoveCalculator(W)
chain = B.chain_of_reduced_words((1,2,1),(2,1,2))
chain = enhance_braid_move_chain(chain, ct)
compute_new_lusztig_datum(enhanced_braid_chain,(1,0,1),None)
```

```
sage.combinat.crystals.pbw_datum.enhance_braid_move_chain(braid_move_chain, cartan_type)
```

Return a list of tuples that records the data of the long words in braid_move_chain plus the data of the intervals where the braid moves occur and the data of the off-diagonal entries of the 2×2 Cartan submatrices of each braid move.

INPUT:

- braid_move_chain – a chain of reduced words in the Weyl group of cartan_type
- cartan_type – a finite Cartan type

OUTPUT:

A list of 2-tuples (interval_of_change, cartan_sub_matrix) where

- interval_of_change is the (half-open) interval of indices where the braid move occurs; this is None for the first tuple
- cartan_sub_matrix is the off-diagonal entries of the 2×2 submatrix of the Cartan matrix corresponding to the braid move; this is None for the first tuple

For a matrix:

```
[2 a]
[b 2]
```

the cartan_sub_matrix is the pair (a, b).

```
sage.combinat.crystals.pbw_datum.tropical_plucker_relation(a, lusztig_datum)
```

Apply the tropical Plücker relation of type a to lusztig_datum.

The relations are obtained by tropicalizing the relations in Proposition 7.1 of [BZ01].
INPUT:

- a – a pair \((x, y)\) of the off-diagonal entries of a \(2 \times 2\) Cartan matrix

EXAMPLES:

```python
sage: from sage.combinat.crystals.pbw_datum import tropical_plucker_relation
sage: tropical_plucker_relation((0,0), (2,3))
(3, 2)
sage: tropical_plucker_relation((-1,-1), (1,2,3))
(4, 1, 2)
sage: tropical_plucker_relation((-1,-2), (1,2,3,4))
(8, 1, 2, 3)
sage: tropical_plucker_relation((-2,-1), (1,2,3,4))
(6, 1, 2, 3)
```

5.1.64 Polyhedral Realization of \(B(\infty)\)

```python
class sage.combinat.crystals.polyhedral_realization.InfinityCrystalAsPolyhedralRealization(cartan_type, seq)

Bases: TensorProductOfCrystals

The polyhedral realization of \(B(\infty)\).

Note: Here we are using anti-Kashiwara notation and might differ from some of the literature.
```

Consider a Kac-Moody algebra \(\mathfrak{g}\) of Cartan type \(X\) with index set \(I\), and consider a finite sequence \(J = (j_1, j_2, \ldots, j_m)\) whose support equals \(I\). We extend this to an infinite sequence by taking \(\bar{J} = J \cdot J \cdot J \cdots\), where \(\cdot\) denotes concatenation of sequences. Let

\[
B_J = B_{j_m} \otimes \cdots \otimes B_{j_2} \otimes B_{j_1},
\]

where \(B_i\) is an \textit{ElementaryCrystal}.

As given in Theorem 2.1.1 of [Ka1993], there exists a strict crystal embedding \(\Psi_i : B(\infty) \rightarrow B_i \otimes B(\infty)\) defined by \(u_{\infty} \mapsto b_i(0) \otimes u_{\infty}\), where \(b_i(0) \in B_i\) and \(u_{\infty}\) is the (unique) highest weight element in \(B(\infty)\). This is sometimes known as the \textit{Kashiwara embedding} [NZ1997] (though, in [NZ1997], the target of this map is denoted by \(Z^\infty\)). By iterating this embedding by taking \(\Psi_J = \Psi_{j_n} \circ \Psi_{j_{n-1}} \circ \cdots \circ \Psi_{j_1}\), we obtain the following strict crystal embedding:

\[
\Psi_J^n : B(\infty) \rightarrow B_J^{\otimes n} \otimes B(\infty).
\]

We note there is a natural analog of Lemma 10.6.2 in [HK2002] that for any \(b \in B(\infty)\), there exists a positive integer \(N\) such that

\[
\Psi_J^N(b) = \left( \bigotimes_{k=1}^{N} b^{(k)} \right) \otimes u_{\infty}.
\]

Therefore we can model elements \(b \in B(\infty)\) by considering an infinite list of elements \(b^{(k)} \in B_J\) and defining
the crystal structure by:

\[
\text{wt}(b) = \sum_{k=1}^{N} \text{wt}(b^{(k)})
\]

\[
e_i(b) = e_i \left( \bigotimes_{k=1}^{N} b^{(k)} \right) \otimes u_\infty,
\]

\[
f_i(b) = f_i \left( \bigotimes_{k=1}^{N} b^{(k)} \right) \otimes u_\infty,
\]

\[
\varepsilon_i(b) = \max_k \varepsilon_i^{(b)}(k),
\]

\[
\varphi_i(b) = \varepsilon_i(b) - \langle \text{wt}(b), h_i^\vee \rangle.
\]

To translate this into a finite list, we consider a finite sequence \( b_1 \otimes \cdots \otimes b_N \) and if

\[
f_i \left( b^{(1)} \otimes \cdots \bigotimes b^{(N-1)} \otimes b^{(N)} \right) = b^{(1)} \otimes \cdots \bigotimes b^{(N-1)} \otimes f_i \left( b^{(N)} \right),
\]

then we take the image as \( b^{(1)} \otimes \cdots \bigotimes f_i \left( b^{(N)} \right) \otimes b^{(N+1)} \). Similarly we remove \( b^{(N)} \) if we have \( b^{(N)} = \bigotimes_{k=1}^{m} b_{jk}(0) \). Additionally if

\[
e_i \left( b^{(1)} \otimes \cdots \bigotimes b^{(N-1)} \otimes b^{(N)} \right) = b^{(1)} \otimes \cdots \bigotimes b^{(N-1)} \otimes e_i \left( b^{(N)} \right),
\]

then we consider this to be 0.

**INPUT:**

- cartan_type – a Cartan type
- seq – (default: None) a finite sequence whose support equals the index set of the Cartan type; if None, then this is the index set

**EXAMPLES:**

```python
sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2,1,2,2])
[0, -3, -1, 0, 0, 0]
```

An example of type \( B_2 \):

```python
sage: B = crystals.infinity.PolyhedralRealization(['B',2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2,1,2,2])
[0, -2, -1, -1, 0, 0]
```

An example of type \( G_2 \):

```python
sage: B = crystals.infinity.PolyhedralRealization(['G',2])
sage: mg = B.module_generators[0]; mg
[0, 0]
sage: mg.f_string([2,1,2,2])
[0, -3, -1, 0, 0, 0]
```
class Element
   Bases: TensorProductOfCrystalsElement

   An element in the polyhedral realization of $B(\infty)$.

e(i)
   Return the action of $e_i$ on self.

   EXAMPLES:

   sage: B = crystals.infinity.PolyhedralRealization(['A',2])
   sage: mg = B.module_generators[0]
   sage: all(mg.e(i) is None for i in B.index_set())
   True
   sage: mg.f(1).e(1) == mg
   True

epsilon(i)
   Return $\epsilon_i$ of self.

   EXAMPLES:

   sage: B = crystals.infinity.PolyhedralRealization(['A',2,1])
   sage: mg = B.module_generators[0]
   sage: [mg.epsilon(i) for i in B.index_set()]
   [0, 0, 0]
   sage: elt = mg.f(0)
   sage: [elt.epsilon(i) for i in B.index_set()]
   [1, 0, 0]
   sage: elt = mg.f_string([0,1,2])
   sage: [elt.epsilon(i) for i in B.index_set()]
   [0, 0, 1]
   sage: elt = mg.f_string([0,1,2,2])
   sage: [elt.epsilon(i) for i in B.index_set()]
   [0, 0, 2]

f(i)
   Return the action of $f_i$ on self.

   EXAMPLES:

   sage: B = crystals.infinity.PolyhedralRealization(['A',2])
   sage: mg = B.module_generators[0]
   sage: mg.f(1)
   [-1, 0, 0, 0]
   sage: mg.f_string([1,2,2,1])
   [-1, -2, -1, 0, 0, 0]

phi(i)
   Return $\varphi_i$ of self.

   EXAMPLES:

   sage: B = crystals.infinity.PolyhedralRealization(['A',2,1])
   sage: mg = B.module_generators[0]
   sage: [mg.phi(i) for i in B.index_set()]
truncation

Truncate self to have length k and return as an element in a (finite) tensor product of crystals.

INPUT:

- k (optional) the length of the truncation; if not specified, then returns one more than the current non-ground-state elements (i.e. the current list in self)

EXAMPLES:

```python
sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: mg = B.module_generators[0]
sage: elt = mg.f_string([1,2,2,1]); elt
[-1, -2, -1, 0, 0, 0]
sage: t = elt.truncate(); t
[-1, -2, -1, 0, 0, 0]
sage: t.parent() is B.finite_tensor_product(6)
True
sage: elt.truncate(2)
[-1, -2]
sage: elt.truncate(10)
[-1, -2, -1, 0, 0, 0, 0, 0, 0, 0]
```

finite_tensor_product(k)

Return the finite tensor product of crystals of length k by truncating self.

EXAMPLES:

```python
sage: B = crystals.infinity.PolyhedralRealization(['A',2])
sage: B.finite_tensor_product(5)
Full tensor product of the crystals
[The 1-elementary crystal of type ['A', 2],
The 2-elementary crystal of type ['A', 2],
The 1-elementary crystal of type ['A', 2],
The 2-elementary crystal of type ['A', 2],
The 1-elementary crystal of type ['A', 2]]```
5.1.65 Spin Crystals

These are the crystals associated with the three spin representations: the spin representations of odd orthogonal groups (or rather their double covers); and the + and − spin representations of the even orthogonal groups.

We follow Kashiwara and Nakashima (Journal of Algebra 165, 1994) in representing the elements of the spin crystal by sequences of signs ±.

```
sage.combinat.crystals.spins.CrystalOfSpins(ct)
Return the spin crystal of the given type B.
This is a combinatorial model for the crystal with highest weight \( \Lambda_n \) (the \( n \)-th fundamental weight). It has \( 2^n \) elements, here called Spins. See also CrystalOfLetters(), CrystalOfSpinsPlus(), and CrystalOfSpinsMinus().

INPUT:
• [‘B’, n] - A Cartan type \( B_n \).

EXAMPLES:
```
sage: C = crystals.Spins(['B',3])
sage: C.list()
[++, +−, −+, +++, −−, ++, −+, ---]
sage: C.cartan_type()
['B', 3]
```
```
sage: [x.signature() for x in C]
['+++', '++-', '+-+', '+--', '-+-', '+--', '-+-', '---']
```
```
sage.combinat.crystals.spins.CrystalOfSpinsMinus(ct)
Return the minus spin crystal of the given type D.
This is the crystal with highest weight \( \Lambda_{n-1} \) (the \( (n-1) \)-st fundamental weight).

INPUT:
• [‘D’, n] - A Cartan type \( D_n \).

EXAMPLES:
```
sage: E = crystals.SpinsMinus(['D',4])
sage: E.list()
[+-+, ++−, +++, −++, ---, --+, −++, ----]
sage: [x.signature() for x in E]
['+++', '+--', '+--', '-++', '+--', '-++', '-++', '---']
```
```
sage.combinat.crystals.spins.CrystalOfSpinsPlus(ct)
Return the plus spin crystal of the given type D.
This is the crystal with highest weight \( \Lambda_n \) (the \( n \)-th fundamental weight).

INPUT:
• [‘D’, n] - A Cartan type \( D_n \).

EXAMPLES:
```
```
sage: D = crystals.SpinsPlus(['D',4])
sage: D.list()
[++++, +++-, ++--, +-+-, -++-, ++-+, +-++, -+-+, --++, ----]
sage: [x.signature() for x in D]
['++++', '++--', '+-+-', '-++-', '+--+', '-+-+', '--++', '----']
```

**class** `sage.combinat.crystals.spins.GenericCrystalOfSpins(ct, element_class, case)`

Bases: `UniqueRepresentation, Parent`

A generic crystal of spins.

```python
lt_elements(x, y)
```

Return True if and only if there is a path from $x$ to $y$ in the crystal graph.

Because the crystal graph is classical, it is a directed acyclic graph which can be interpreted as a poset. This function implements the comparison function of this poset.

**EXAMPLES:**

```
sage: C = crystals.Spins(['B',3])
sage: x = C([1,1,1])
sage: y = C([-1,-1,-1])
sage: C.lt_elements(x, y)
True
sage: C.lt_elements(y, x)
False
sage: C.lt_elements(x, x)
False
```

**class** `sage.combinat.crystals.spins.Spin`

Bases: `Element`

A spin letter in the crystal of spins.

**EXAMPLES:**

```
sage: C = crystals.Spins(['B',3])
sage: c = C([1,1,1])
sage: c
+++
sage: c.parent()
The crystal of spins for type ['B', 3]
sage: D = crystals.Spins(['B',4])
sage: a = D([1,1,1])
sage: b = D([-1,-1,-1])
sage: c = D([1,1,1,1])
sage: a == a
True
sage: a == b
False
sage: b == c
False
```
pp()  
Pretty print self as a column.

EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: b = C([1,1,-1])
sage: b.pp()
+-
```

signature()  
Return the signature of self.

EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: C([1,1,1]).signature()
+++'
sage: C([1,1,-1]).signature()
++-
```

value  
Return self as a tuple with +1 and -1.

EXAMPLES:

```python
sage: C = crystals.Spins(['B',3])
sage: C([1,1,1]).value
(1, 1, 1)
sage: C([1,1,-1]).value
(1, 1, -1)
```

weight()  
Return the weight of self.

EXAMPLES:

```python
sage: [v.weight() for v in crystals.Spins(['B',3])]
[(1/2, 1/2, 1/2), (1/2, 1/2, -1/2),
 (1/2, -1/2, 1/2), (-1/2, 1/2, 1/2),
 (1/2, -1/2, -1/2), (-1/2, 1/2, -1/2),
 (-1/2, -1/2, 1/2), (-1/2, -1/2, -1/2)]
```

class sage.combinat.crystals.spins.Spin_crystal_type_B_element

Bases: Spin

Type B spin representation crystal element

e(i)  
Return the action of $e_i$ on self.

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: C = crystals.Spins(['B', 3])
sage: [[C[m].e(i) for i in range(1,4)] for m in range(8)]
[[[None, None, None], [None, None, +++], [None, None, None],
  [None, None, ++], [None, None, None],
  [None, None, ++], [None, None, None],
  [None, None, None]]
```

**epsilon**

Return $\varepsilon_i$ of self.

**EXAMPLES:**

```python
sage: C = crystals.Spins(['B', 3])
sage: [[C[m].epsilon(i) for i in range(1,4)] for m in range(8)]
[[0, 0, 0], [0, 0, 1], [1, 0, 1], [0, 1, 0],
 [1, 0, 0], [0, 1, 0], [0, 0, 1], [0, 0, 1]]
```

**f**

Return the action of $f_i$ on self.

**EXAMPLES:**

```python
sage: C = crystals.Spins(['B', 3])
sage: [[C[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, ++--], [None, +++-, None], [-++, None, +--],
 [-+-, None, None], [None, --+, None], [None, None, None]]
```

**phi**

Return $\varphi_i$ of self.

**EXAMPLES:**

```python
sage: C = crystals.Spins(['B', 3])
sage: [[C[m].phi(i) for i in range(1,4)] for m in range(8)]
[[0, 0, 1], [0, 1, 0], [1, 0, 1], [0, 0, 1],
 [0, 0, 1], [0, 1, 0], [0, 0, 1], [0, 0, 0]]
```

```python
5.1. Comprehensive Module List 555

```
epsilon(i)

Return $\varepsilon_i$ of self.

EXAMPLES:

```
sage: C = crystals.SpinsMinus(['D',4])
sage: [[C[m].epsilon(i) for i in C.index_set()] for m in range(8)]
[[0, 0, 0, 0], [0, 0, 1, 0], [0, 1, 0, 0], [1, 0, 0, 0],
 [0, 0, 0, 1], [1, 0, 0, 1], [0, 1, 0, 0], [0, 0, 1, 0]]
```

f(i)

Return the action of $f_i$ on self.

EXAMPLES:

```
sage: D = crystals.SpinsPlus(['D',4])
sage: [[D.list()[m].f(i) for i in range(1,4)] for m in range(8)]
[[None, None, None], [None, +-+-, None], [-++-, None, ----], [None, None, +++],
 [-++++, None, None], [None, None, None], [None, None, None], [None, None, None]]
```

phi(i)

Return $\varphi_i$ of self.

EXAMPLES:

```
sage: C = crystals.SpinsPlus(['D',4])
sage: [[C[m].phi(i) for i in C.index_set()] for m in range(8)]
[[0, 0, 0, 1], [0, 1, 0, 0], [1, 0, 1, 0], [0, 0, 1, 0],
 [1, 0, 0, 0], [0, 1, 0, 0], [0, 0, 0, 1], [0, 0, 0, 0]]
```

5.1.66 Star-Crystal Structure On $B(\infty)$

AUTHORS:

- Ben Salisbury: Initial version
- Travis Scrimshaw: Initial version

class sage.combinat.crystals.star_crystal.StarCrystal(Binf)

Bases: UniqueRepresentation, Parent

The star-crystal or $*$-crystal version of a highest weight crystal.

The $*$-crystal structure on $B(\infty)$ is the structure induced by the algebra antiautomorphism $*: U_q(g) \rightarrow U_q(g)$ that stabilizes the negative half $U_q^{-}(g)$. It is defined by

$$E_i^* = E_i, \quad F_i^* = F_i, \quad q^* = q, \quad (q^h)^* = q^{-h},$$

where $E_i$ and $F_i$ are the Chevalley generators of $U_q(g)$ and $h$ is an element of the Cartan subalgebra.
The induced operation on the crystal $B(\infty)$ is called the Kashiwara involution. Its implementation here is based on the recursive algorithm from Theorem 2.2.1 of [Ka1993], which states that for any $i \in I$ there is a unique strict crystal embedding

$$\Psi_i : B(\infty) \rightarrow B_i \otimes B(\infty)$$

such that

- $u_\infty \mapsto b_i(0) \otimes u_\infty$, where $u_\infty$ is the highest weight vector in $B(\infty)$;
- if $\Psi_i(b) = f^m_i b_i(0) \otimes b_0$, then $\Psi_i(f^*_ib) = f^{m+1}_ib_i(0) \otimes b_0$ and $\varepsilon_i(b^*) = m$;
- the image of $\Psi_i$ is $\{f^m_i b_i(0) \otimes b : \varepsilon_i(b^*) = 0, m \geq 0\}$.

Here, $B_i$ is the $i$-th elementary crystal. See *ElementaryCrystal* for more information.

**INPUT:**

- `B` – a crystal from `catalog_infinity_crystals`

**EXAMPLES:**

```python
sage: B = crystals.infinity.Tableaux(['A',2])
sage: Bstar = crystals.infinity.Star(B)
sage: mg = Bstar.highest_weight_vector()
sage: mg
[[1, 1], [2]]
sage: mg.f_string([1,2,1,2,2])
[[1, 1, 1, 1, 1, 2, 2], [2, 3, 3, 3]]
```

**class Element**

**Bases:** `ElementWrapper`

**e(i)**

Return the action of $e_i^*$ on self.

**INPUT:**

- `i` – an element of the index set

**EXAMPLES:**

```python
sage: RC = crystals.infinity.RiggedConfigurations(['E',6,1])
sage: RCstar = crystals.infinity.Star(RC)
sage: nuJ = RCstar.module_generators[0].f_string([0,4,6,1,2])
sage: ascii_art(nuJ.e(1))
-1[ ]-1  (/) 0[ ]1  (/) -1[ ]-1  (/) -2[ ]-1
sage: M = crystals.infinity.NakajimaMonomials(['B',2,1])
sage: Mstar = crystals.infinity.Star(M)
sage: m = Mstar.module_generators[0].f_string([0,1,2,2,1,0])
sage: m.e(1)
Y(0,0)^-1 Y(0,2)^-1 Y(1,1) Y(1,2)^-1 Y(2,1)^2
```

**epsilon(i)**

Return $\varepsilon_i^*$ of self.

**INPUT:**

- `i` – an element of the index set

**EXAMPLES:**

```
sage: Y = crystals.infinity.GeneralizedYoungWalls(3)
sage: Ystar = crystals.infinity.Star(Y)
sage: y = Ystar.module_generators[0].f_string([0,1,3,2,1,0])
sage: [y.epsilon(i) for i in y.index_set()]
[1, 0, 1, 0]

sage: RC = crystals.infinity.RiggedConfigurations(['E',6,1])
sage: RCstar = crystals.infinity.Star(RC)
sage: nuJ = RCstar.module_generators[0].f_string([0,4,6,1,2])
sage: [nuJ.epsilon(i) for i in nuJ.index_set()]
[0, 1, 1, 0, 0, 0, 1]

\[ f(i) \]

Return the action of \( f_i^* \) on self.

**INPUT:**

- \( i \) – an element of the index set

**EXAMPLES:**

sage: T = crystals.infinity.Tableaux("G2")
sage: Tstar = crystals.infinity.Star(T)
sage: t = Tstar.module_generators[0].f_string([1,2,1,1,2])
sage: t
[[1, 1, 1, 2, 0], [2, 3]]

sage: M = crystals.infinity.NakajimaMonomials(['B',2,1])
sage: Mstar = crystals.infinity.Star(M)
sage: m = Mstar.module_generators[0].f_string([0,1,2,2,1,0])

\[ \gamma(0,0)^{-1} \gamma(0,2)^{-1} \gamma(1,0)^{-1} \gamma(1,2)^{-1} \gamma(2,0)^{2} \gamma(2,1)^{2} \]

\[ \text{jump}(i) \]

Return the \( i \)-jump of self.

For \( b \in B(\infty) \),

\[ \text{jump}_i(b) = \varepsilon_i(b) + \varepsilon_i^*(b) + \langle h_i, \text{wt}(b) \rangle, \]

where \( h_i \) is a simple coroot.

**INPUT:**

- \( i \) – an element of the index set

**EXAMPLES:**

sage: RC = crystals.infinity.RiggedConfigurations("D4")
sage: RCstar = crystals.infinity.Star(RC)
sage: nu0star = RCstar.module_generators[0]
sage: nustar = nu0star.f_string([2,1,3,4,2])

sage: nustar = nu0star.f_string([2,1,3,4,2,2,1,3,2])  # long time
sage: [nustar.jump(i) for i in RC.index_set()]  # long time
[1, 0, 1, 2]
\texttt{phi(i)}

Return $\varphi_i^*$ of \texttt{self}.

For $b \in B(\infty)$,

$$\varphi_i^*(b) = \varepsilon_i^*(b) + \langle h_i, \text{wt}(b) \rangle,$$

where $h_i$ is a simple coroot.

INPUT:

• $i$ – an element of the index set

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux("A2")
sage: Tstar = crystals.infinity.Star(T)
sage: t = Tstar.module_generators[0].f_string([1,2,1,1,2])
sage: [t.phi(i) for i in t.index_set()]
[-3, 1]
```

```
sage: M = crystals.infinity.NakajimaMonomials(['B',2,1])
sage: Mstar = crystals.infinity.Star(M)
sage: m = Mstar.module_generators[0].f_string([0,1,2,1,2,0])
sage: [m.phi(i) for i in m.index_set()]
[-1, -1, 4]
```

\texttt{weight()}

Return the weight of \texttt{self}.

EXAMPLES:

```
sage: RC = crystals.infinity.RiggedConfigurations(['E',6,1])
sage: RCstar = crystals.infinity.Star(RC)
sage: nuJ = RCstar.module_generators[0].f_string([0,4,6,1,2])
sage: nuJ.weight()
```

5.1.67 Tensor Products of Crystals

Main entry points:

• \texttt{TensorProductOfCrystals}

• \texttt{CrystalOfTableaux}

AUTHORS:

• Anne Schilling, Nicolas Thiery (2007): Initial version

• Ben Salisbury, Travis Scrimshaw (2013): Refactored tensor products to handle non-regular crystals and created new subclass to take advantage of the regularity

• Travis Scrimshaw (2020): Added queer crystal

\texttt{class} \texttt{sage.combinat.crystals.tensor_product.CrystalOfQueerTableaux(cartan_type, shape)}

\texttt{Bases: CrystalOfWords, QueerSuperCrystalsMixin}

A queer crystal of the semistandard decomposition tableaux of a given shape.
INPUT:
- cartan_type – a Cartan type
- shape – a shape

class Element
   Bases: TensorProductOfQueerSuperCrystalsElement

rows()
   Return the list of rows of self.

EXAMPLES:
\begin{verbatim}
sage: B = crystals.Tableaux(['Q',3], shape=[3,2,1])
sage: t = B.an_element()
sage: t.rows()
[[3, 3, 3], [2, 2], [1]]
\end{verbatim}

class sage.combinat.crystals.tensor_product.CrystalOfTableaux(cartan_type, shapes)
   Bases: CrystalOfWords

A class for crystals of tableaux with integer valued shapes

INPUT:
- cartan_type – a Cartan type
- shape – a partition of length at most cartan_type.rank()
- shapes – a list of such partitions

This constructs a classical crystal with the given Cartan type and highest weight(s) corresponding to the given shape(s).

If the type is $D_r$, the shape is permitted to have a negative value in the $r$-th position. Thus if the shape equals $[s_1, \ldots, s_r]$, then $s_r$ may be negative but in any case $s_1 \geq \cdots \geq s_{r-1} \geq |s_r|$. This crystal is related to that of shape $[s_1, \ldots, |s_r|]$ by the outer automorphism of $SO(2r)$.

If the type is $D_r$ or $B_r$, the shape is permitted to be of length $r$ with all parts of half integer value. This corresponds to having one spin column at the beginning of the tableau. If several shapes are provided, they currently should all or none have this property.

Crystals of tableaux are constructed using an embedding into tensor products following Kashiwara and Nakashima [KN1994]. Sage's tensor product rule for crystals differs from that of Kashiwara and Nakashima by reversing the order of the tensor factors. Sage produces the same crystals of tableaux as Kashiwara and Nakashima. With Sage's convention, the tensor product of crystals is the same as the monoid operation on tableaux and hence the plactic monoid.

See also:
sage.combinat.crystals.crystals for general help on crystals, and in particular plotting and \LaTeX{} output.

EXAMPLES:
We create the crystal of tableaux for type $A_2$, with highest weight given by the partition $[2,1,1]$: \begin{verbatim}
sage: T = crystals.Tableaux(['A',3], shape = [2,1,1])
\end{verbatim}
Here is the list of its elements:
Internally, a tableau of a given Cartan type is represented as a tensor product of letters of the same type. The order in which the tensor factors appear is by reading the columns of the tableaux left to right, top to bottom (in French notation). As an example:

```
sage: T = crystals.Tableaux(['A',2], shape = [3,2])
sage: T.module_generators[0]
[[1, 1, 1], [2, 2]]
sage: list(T.module_generators[0])
[2, 1, 2, 1, 1]
```

To create a tableau, one can use:

```
sage: Tab = crystals.Tableaux(['A',3], shape = [2,2])
sage: Tab(rows=[[1,2],[3,4]])
[[1, 2], [3, 4]]
sage: Tab(columns=[[3,1],[4,2]])
[[1, 2], [3, 4]]
```

**Todo:** FIXME:

- Do we want to specify the columns increasingly or decreasingly? That is, should this be `Tab(columns = [[1,3],[2,4]])`?
- Make this fully consistent with `Tableau()`!

We illustrate the use of a shape with a negative last entry in type $D$:

```
sage: T = crystals.Tableaux(['D',4], shape=[1,1,1,-1])
sage: T.cardinality()
35
sage: TestSuite(T).run()
```

We illustrate the construction of crystals of spin tableaux when the partitions have half integer values in type $B$ and $D$:

```
sage: T = crystals.Tableaux(['B',3],shape=[3/2,1/2,1/2]); T
The crystal of tableaux of type ['B', 3] and shape(s) [[3/2, 1/2, 1/2]]
sage: T.cardinality()
48
sage: T.module_generators
([++, [[1]]],)
sage: TestSuite(T).run()

sage: T = crystals.Tableaux(['D',3],shape=[3/2,1/2,-1/2]); T
The crystal of tableaux of type ['D', 3] and shape(s) [[3/2, 1/2, -1/2]]
sage: T.cardinality()
```

(continues on next page)
We can also construct the tableaux for $\mathfrak{gl}(m|n)$ as given by [BKK2000]:

```python
sage: T = crystals.Tableaux(['A', 1,2], shape=[4,2,1,1,1])
sage: T.cardinality()
1392
```

We can also construct the tableaux for $q(n)$ as given by [GJK+2014]:

```python
sage: T = crystals.Tableaux(['Q', 3], shape=[3,1])
sage: T.cardinality()
24
```

**class Element**

Bases: `CrystalOfTableauxElement`

*cartan_type()*

Returns the Cartan type of the associated crystal

EXAMPLES:

```python
sage: T = crystals.Tableaux(['A',3], shape = [2,2])
sage: T.cartan_type()
['A', 3]
```

*module_generator(shape)*

This yields the module generator (or highest weight element) of a classical crystal of given shape. The module generator is the unique tableau with equal shape and content.

EXAMPLES:

```python
sage: T = crystals.Tableaux(['D',4], shape=[2,2,2,-2])
sage: T.module_generator(tuple([2,2,2,-2]))
[[1, 1], [2, 2], [3, 3], [-4, -4]]
sage: T.cardinality()
294
```

```
```
class Element

Bases: TensorProductOfCrystalsElement
class sage.combinat.crystals.tensor_product.FullTensorProductOfCrystals(crystals, **options)
Bases: TensorProductOfCrystals
Full tensor product of crystals.

Todo: Merge this into TensorProductOfCrystals.

cardinality()

Return the cardinality of self.

EXAMPLES:

sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C)
sage: T.cardinality()
9

weight_lattice_realization()

Return the weight lattice realization used to express weights.
The weight lattice realization is the common parent which all weight lattice realizations of the crystals of self coerce into.

EXAMPLES:

sage: B = crystals.elementary.B(['A',4], 2)
sage: B.weight_lattice_realization()
Root lattice of the Root system of type ['A', 4]
sage: T = crystals.infinity.Tableaux(['A',4])
sage: T.weight_lattice_realization()
Ambient space of the Root system of type ['A', 4]
sage: TP = crystals.TensorProduct(B, T)
sage: TP.weight_lattice_realization()
Ambient space of the Root system of type ['A', 4]

class sage.combinat.crystals.tensor_product.FullTensorProductOfQueerSuperCrystals(crystals, **options)

Bases: FullTensorProductOfCrystals, QueerSuperCrystalsMixin
Tensor product of queer super crystals.

class Element

Bases: TensorProductOfQueerSuperCrystalsElement
class sage.combinat.crystals.tensor_product.FullTensorProductOfRegularCrystals(crystals, **options)

Bases: FullTensorProductOfCrystals
Full tensor product of regular crystals.
class Element
Bases: TensorProductOfRegularCrystalsElement

class sage.combinat.crystals.tensor_product.FullTensorProductOfSuperCrystals(crystals, **options)
Bases: FullTensorProductOfCrystals
Tensor product of super crystals.
EXAMPLES:

```
sage: L = crystals.Letters(['A', [1,1]])
sage: T = tensor([L,L,L])
sage: T.cardinality()
64
```

class Element
Bases: TensorProductOfSuperCrystalsElement

class sage.combinat.crystals.tensor_product.QueerSuperCrystalsMixin
Bases: object
Mixin class with methods for a finite queer supercrystal.

index_set()
Return the enlarged index set.
EXAMPLES:

```
sage: Q = crystals.Letters(['Q',3])
sage: T = tensor([Q,Q])
sage: T.index_set()
(-4, -3, -2, -1, 1, 2)
```

class sage.combinat.crystals.tensor_product.TensorProductOfCrystals
Bases: CrystalOfWords
Tensor product of crystals.

Given two crystals $B$ and $B'$ of the same Cartan type, one can form the tensor product $B \otimes B'$. As a set $B \otimes B'$ is the Cartesian product $B \times B'$. The crystal operators $f_i$ and $e_i$ act on $b \otimes b' \in B \otimes B'$ as follows:

$$f_i(b \otimes b') = \begin{cases} f_i(b) \otimes b' & \text{if } \varepsilon_i(b) \geq \varphi_i(b') \\ b \otimes f_i(b') & \text{otherwise} \end{cases}$$

and

$$e_i(b \otimes b') = \begin{cases} e_i(b) \otimes b' & \text{if } \varepsilon_i(b) > \varphi_i(b') \\ b \otimes e_i(b') & \text{otherwise.} \end{cases}$$

We also define:

$$\varphi_i(b \otimes b') = \max \left( \varphi_i(b), \varphi_i(b') + \langle \alpha_i^\vee, \text{wt}(b) \rangle \right),$$

$$\varepsilon_i(b \otimes b') = \max \left( \varepsilon_i(b'), \varepsilon_i(b) - \langle \alpha_i^\vee, \text{wt}(b') \rangle \right).$$

Note: This is the opposite of Kashiwara’s convention for tensor products of crystals.
Since tensor products are associative \((B \otimes C) \otimes D \cong B \otimes (C \otimes D)\) via the natural isomorphism \((b \otimes c) \otimes d \mapsto b \otimes (c \otimes d)\), we can generalizing this to arbitrary tensor products. Thus consider \(B_N \otimes \cdots \otimes B_1\), where each \(B_k\) is an abstract crystal. The underlying set of the tensor product is \(B_N \times \cdots \times B_1\), while the crystal structure is given as follows. Let \(I\) be the index set, and fix some \(i \in I\) and \(b_N \otimes \cdots \otimes b_1 \in B_N \otimes \cdots \otimes B_1\). Define

\[
a_i(k) := \varepsilon_i(b_k) - \sum_{j=1}^{k-1} (\alpha_i^\vee, \text{wt}(b_j)).
\]

Then

\[
\text{wt}(b_N \otimes \cdots \otimes b_1) = \text{wt}(b_N) + \cdots + \text{wt}(b_1),
\]

\[
\varepsilon_i(b_N \otimes \cdots \otimes b_1) = \max_{1 \leq k \leq n} \left( \sum_{j=1}^{k} \varepsilon_i(b_j) - \sum_{j=1}^{k-1} \varphi_i(b_j) \right)
\]

\[
= \max_{1 \leq k \leq N} (a_i(k)),
\]

\[
\varphi_i(b_N \otimes \cdots \otimes b_1) = \max_{1 \leq k \leq N} \left( \varphi_i(b_N) + \sum_{j=k}^{N-1} (\varphi_i(b_j) - \varepsilon_i(b_{j+1})) \right)
\]

\[
= \max_{1 \leq k \leq N} (\lambda_i + a_i(k))
\]

where \(\lambda_i = (\alpha_i^\vee, \text{wt}(b_N \otimes \cdots \otimes b_1))\). Then for \(k = 1, \ldots, N\) the action of the Kashiwara operators is determined as follows.

- If \(a_i(k) > a_i(j)\) for \(1 \leq j < k\) and \(a_i(k) \geq a_i(j)\) for \(k < j \leq N\):

  \[
e_i(b_N \otimes \cdots \otimes b_1) = b_N \otimes \cdots \otimes e_ib_k \otimes \cdots \otimes b_1.
\]

- If \(a_i(k) \geq a_i(j)\) for \(1 \leq j < k\) and \(a_i(k) > a_i(j)\) for \(k < j \leq N\):

  \[
f_i(b_N \otimes \cdots \otimes b_1) = b_N \otimes \cdots \otimes f_ib_k \otimes \cdots \otimes b_1.
\]

Note that this is just recursively applying the definition of the tensor product on two crystals. Recall that \((\alpha_i^\vee, \text{wt}(b_j)) = \varphi_i(b_j) - \varepsilon_i(b_j)\) by the definition of a crystal.

**Regular crystals**

Now if all crystals \(B_k\) are regular crystals, all \(\varepsilon_i\) and \(\varphi_i\) are non-negative and we can define tensor product by the signature rule. We start by writing a word in \(+\) and \(−\) as follows:

\[
\varphi_i(b_N) \times \varepsilon_i(b_N) \times \cdots \times \varphi_i(b_1) \times \varepsilon_i(b_1).
\]

and then canceling ordered pairs of \(+−\) until the word is in the reduced form:

\[
\varphi_i \times \varepsilon_i.
\]

Here \(\varepsilon_i\) acts on the factor corresponding to the leftmost \(+\) and \(f_i\) on the factor corresponding to the rightmost \(−\). If there is no \(+\) or \(−\) respectively, then the result is 0 (None).

**EXAMPLES:**

We construct the type \(A_2\)-crystal generated by \(2 \otimes 1 \otimes 1\):
```python
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C,generators=[[C(2),C(1),C(1)]])
```

It has 8 elements:

```python
sage: T.list()
[[2, 1, 1], [2, 1, 2], [2, 1, 3], [3, 1, 3],
 [3, 2, 3], [3, 1, 1], [3, 1, 2], [3, 2, 2]]
```

One can also check the Cartan type of the crystal:

```python
sage: T.cartan_type()
['A', 2]
```

Other examples include crystals of tableaux (which internally are represented as tensor products obtained by reading the tableaux columnwise):

```python
sage: C = crystals.Tableaux(['A',3], shape=[1,1,0])
sage: D = crystals.Tableaux(['A',3], shape=[1,0,0])
sage: T = crystals.TensorProduct(C,D, generators=[[C(rows=[[1], [2])], D(rows=[[1]])], [C(rows=[[2], [3])], D(rows=[[1]])]])
sage: T.cardinality()
24
sage: TestSuite(T).run()
sage: T.module_generators
([[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]])
```

If no module generators are specified, we obtain the full tensor product:

```python
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C)
sage: T.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
sage: T.cardinality()
9
```

For a tensor product of crystals without module generators, the default implementation of `module_generators` contains all elements in the tensor product of the crystals. If there is a subset of elements in the tensor product that still generates the crystal, this needs to be implemented for the specific crystal separately:

```python
sage: T.module_generators.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
```

For classical highest weight crystals, it is also possible to list all highest weight elements:

```python
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C,generators=[[C(2),C(1),C(1)],[C(1),C(2),-C(1)]]])
sage: T.highest_weight_vectors()
([2, 1, 1], [1, 2, 1])
```

Examples with non-regular and infinite crystals (these did not work before [github issue #14402](#14402)): 
sage: B = crystals.infinity.Tableaux(['D',10])
sage: T = crystals.TensorProduct(B,B)
sage: T
Full tensor product of the crystals
[The infinity crystal of tableaux of type ['D', 10],
The infinity crystal of tableaux of type ['D', 10]]

sage: B = crystals.infinity.GeneralizedYoungWalls(15)
sage: T = crystals.TensorProduct(B,B,B)
sage: T
Full tensor product of the crystals
[Crystal of generalized Young walls of type ['A', 15, 1],
Crystal of generalized Young walls of type ['A', 15, 1],
Crystal of generalized Young walls of type ['A', 15, 1]]

sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.GeneralizedYoungWalls(2,La[0]+La[1])
sage: C = crystals.GeneralizedYoungWalls(2,2*La[2])
sage: D = crystals.GeneralizedYoungWalls(2,3*La[0]+La[2])
sage: T = crystals.TensorProduct(B,C,D)
sage: T
Full tensor product of the crystals
[Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and highest weight Lambda[0] + Lambda[1],
Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and highest weight 2*Lambda[2],
Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and highest weight 3*Lambda[0] + Lambda[2]]

There is also a global option for setting the convention (by default Sage uses anti-Kashiwara):

```sage
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C)
sage: elt = T(C(1), C(2)); elt
[1, 2]
sage: crystals.TensorProduct.options.convention = "Kashiwara"
sage: elt
[2, 1]
sage: crystals.TensorProduct.options._reset()
```

```
options = Current options for TensorProductOfCrystals - convention: antiKashiwara
class sage.combinat.crystals.tensor_product.TensorProductOfCrystalsWithGenerators(cry...

Bases: TensorProductOfCrystals

Tensor product of crystals with a generating set.

Todo: Deprecate this class in favor of using subcrystal().
```
class sage.combinat.crystals.tensor_product.TensorProductOfRegularCrystalsWithGenerators(cry
tals, generators, cartan_type)

Bases: TensorProductOfCrystalsWithGenerators
Tensor product of regular crystals with a generating set.

class Element
    Bases: TensorProductOfRegularCrystalsElement

5.1.68 Tensor Products of Crystal Elements

AUTHORS:

• Anne Schilling, Nicolas Thiery (2007): Initial version
• Ben Salisbury, Travis Scrimshaw (2013): Refactored tensor products to handle non-regular crystals and created new subclass to take advantage of the regularity
• Travis Scrimshaw (2017): Cythonized element classes
• Franco Saliola (2017): Tensor products for crystal of super algebras
• Anne Schilling (2018): Tensor products for crystals of queer super algebras

class sage.combinat.crystals.tensor_product_element.CrystalOfBKKTableauxElement
    Bases: TensorProductOfSuperCrystalsElement
Element class for the crystal of tableaux for Lie superalgebras of [BKK2000].

pp()
    Pretty print self.

    EXAMPLES:

    sage: C = crystals.Tableaux(['A',[1,2]], shape=[1,1])
sage: c = C.an_element()
sage: c.pp()
-2
-1

to_tableau()
    Return the Tableau object corresponding to self.

    EXAMPLES:

    sage: C = crystals.Tableaux(['A',[1,2]], shape=[1,1])
sage: c = C.an_element()
sage: c.to_tableau()
[[-2], [-1]]
sage: type(c.to_tableau())
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
sage: type(c)
(continues on next page)
class sage.combinat.crystals.tensor_product_element.CrystalOfTableauxElement

Bases: TensorProductOfRegularCrystalsElement

Element in a crystal of tableaux.

pp()

EXAMPLES:

sage: T = crystals.Tableaux(['A',3], shape = [2,2])
sage: t = T(rows=[[1,2],[3,4]])
sage: t.pp()
1  2
3  4

promotion()

Return the result of applying promotion on self.

Promotion for type A crystals of tableaux of rectangular shape. This method only makes sense in type A with rectangular shapes.

EXAMPLES:

sage: C = crystals.Tableaux(['A',3], shape = [3,3,3])
sage: t = C(Tableau([[1,1,1],[2,2,3],[3,4,4]]))
sage: t
[[1, 1, 1], [2, 2, 3], [3, 4, 4]]
sage: t.promotion()
[[1, 1, 2], [2, 3, 3], [4, 4, 4]]
sage: t.promotion().parent()
The crystal of tableaux of type ['A', 3] and shape(s) [[3, 3, 3]]

promotion_inverse()

Return the result of applying inverse promotion on self.

Inverse promotion for type A crystals of tableaux of rectangular shape. This method only makes sense in type A with rectangular shapes.

EXAMPLES:

sage: C = crystals.Tableaux(['A',3], shape = [3,3,3])
sage: t = C(Tableau([[1,1,1],[2,2,3],[3,4,4]]))
sage: t
[[1, 1, 1], [2, 2, 3], [3, 4, 4]]
sage: t.promotion_inverse()
[[1, 1, 2], [2, 3, 3], [4, 4, 4]]
sage: t.promotion_inverse().parent()
The crystal of tableaux of type ['A', 3] and shape(s) [[3, 3, 3]]

shape()

Return the shape of the tableau corresponding to self.

OUTPUT: an instance of Partition
See also:

to_tableau()

EXAMPLES:

```
sage: C = crystals.Tableaux(['A', 2], shape=[2,1])
sage: x = C.an_element()
sage: x.to_tableau().shape()
[2, 1]
sage: x.shape()
[2, 1]
```

to_tableau()

Return the Tableau object corresponding to self.

EXAMPLES:

```
sage: T = crystals.Tableaux(['A', 3], shape = [2,2])
sage: t = T(rows=[[1,2],[3,4]]).to_tableau(); t
[[1, 2], [3, 4]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
sage: type(t[0][0])
<int>
sage: T = crystals.Tableaux(['D', 3], shape = [1,1])
sage: t=T(rows=[[1,-3],[3]]).to_tableau(); t
[[1, -3], [3]]
sage: t=T(rows=[[3],[1,-3]]).to_tableau(); t
[[3], [-3]]
sage: T = crystals.Tableaux(['B', 2], shape = [1,1])
sage: t = T(rows=[[0],[0]]).to_tableau(); t
[[0], [0]]
```

class sage.combinat.crystals.tensor_product_element.ImmutableListWithParent

Bases: ClonableArray

A class for lists having a parent

Specification: any subclass C should implement __init__ which accepts the following form C(parent, list=list)

class sage.combinat.crystals.tensor_product_element.InfinityCrystalOfTableauxElement

Bases: CrystalOfTableauxElement

e(i)

Return the action of \( \tilde{e}_i \) on self.

INPUT:

• i – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['B',3])
sage: b = B(rows=[[1,1,1,1,1,1,2,0,-3,-1,-1,-1,-1],[2,2,2,2,-2,-2],[3,-3,-3]])
sage: b.e(3).pp()
1 1 1 1 1 1 1 2 0 -3 -1 -1 -1 -1
```

\[ \begin{align*}
2 & 2 2 2 -2 -2 \\
3 & 0 -3 \\
\text{sage}: & \text{ b.e(1).pp()} \\
1 & 1 1 1 1 1 1 0 -3 -1 -1 -1 -1 \\
2 & 2 2 2 -2 -2 \\
3 & -3 -3
\end{align*} \]

\( f(i) \)

Return the action of \( \tilde{f}_i \) on \( \text{self} \).

INPUT:

- \( i \) – an element of the index set

EXAMPLES:

\[ \begin{align*}
\text{sage: } & \text{ B = crystals.infinity.Tableaux(['C',4])} \\
\text{sage: } & \text{ b = B.highest_weight_vector()} \\
\text{sage: } & \text{ b.f(1).pp()} \\
1 & 1 1 1 1 2 \\
2 & 2 2 \\
3 & 3 \\
4
\end{align*} \]

\[ \begin{align*}
\text{sage: } & \text{ b.f(3).pp()} \\
1 & 1 1 1 1 \\
2 & 2 2 2 \\
3 & 3 4 \\
4
\end{align*} \]

\[ \begin{align*}
\text{sage: } & \text{ b.f(3).f(4).pp()} \\
1 & 1 1 1 1 \\
2 & 2 2 2 \\
3 & 3 -4 \\
4
\end{align*} \]

class sage.combinat.crystals.tensor_product_element.InfinityCrystalOfTableauxElementTypeD

Bases: InfinityCrystalOfTableauxElement

e(i)

Return the action of \( \tilde{e}_i \) on \( \text{self} \).

INPUT:

- \( i \) – an element of the index set

EXAMPLES:

\[ \begin{align*}
\text{sage: } & \text{ B = crystals.infinity.Tableaux(['D',4])} \\
\text{sage: } & \text{ b = B.highest_weight_vector().f_string([1,4,3,1,2]); b.pp()} \\
1 & 1 1 1 2 3 \\
2 & 2 2 \\
3 & -3 \\
\text{sage: } & \text{ b.e(2).pp()} \\
1 & 1 1 1 2 2 \\
2 & 2 2 \\
3 & -3
\end{align*} \]
Return the action of $\tilde{f}_i$ on self.

INPUT:

• $i$ – an element of the index set

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux(['D',5])
sage: b = B.highest_weight_vector().f_string([1,4,3,1,5]); b.pp()
1 1 1 1 1 1 2 2
2 2 2 2 2
3 3 3 -5
4 5
sage: b.f(1).pp()
1 1 1 1 1 1 2 2 2
2 2 2 2 2
3 3 3 -5
4 5
sage: b.f(5).pp()
1 1 1 1 1 1 2 2
2 2 2 2 2
3 3 3 -5
4 -4
```

class sage.combinat.crystals.tensor_product_element.InfinityQueerCrystalOfTableauxElement

Bases: `TensorProductOfQueerSuperCrystalsElement`

Initialize self.

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([4,4,4,4,2,1],[3,3,3],[2,2,1])
sage: t
[[4, 4, 4, 4, 2, 1], [3, 3, 3], [2, 2, 1]]
sage: TestSuite(t).run()
```

Return the action of $e_i$ on self.

INPUT:

• $i$ – an element of the index set

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([4,4,4,4,2,1],[3,3,3],[2,2,1])
sage: t.e(1)
[[4, 4, 4, 4, 2, 1], [3, 3, 3, 3], [2, 2, 1, 1], [1]]
sage: t.e(3)
[[4, 4, 4, 4, 4, 2, 1], [3, 3, 3, 3], [2, 2, 1, 1]]
sage: t.e(-1)
```
\textbf{epsilon}(i)

Return $\varepsilon_i$ of self.

INPUT:

\begin{itemize}
  \item $i$ – an element of the index set
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: [t.epsilon(i) for i in B.index_set()]
[-1, 1, -2, 0]
\end{verbatim}

\textbf{f}(i)

Return the action of $f_i$ on self.

INPUT:

\begin{itemize}
  \item $i$ – an element of the index set
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.f(1)
[[4, 4, 4, 4, 4, 2, 2], [3, 3, 3, 3], [2, 2, 1], [1]]
sage: t.f(3)

sage: t.f(-1)
[[4, 4, 4, 4, 4, 2, 2], [3, 3, 3, 3], [2, 2, 1], [1]]
\end{verbatim}

\textbf{rows}()

Return the list of rows of self.

EXAMPLES:

\begin{verbatim}
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.rows()
[[1, 2, 4, 4, 4, 4, 4], [3, 3, 3, 3], [1, 2, 2], [1]]
\end{verbatim}

\textbf{weight}()

Return the weight of self.

EXAMPLES:

\begin{verbatim}
sage: B = crystals.infinity.Tableaux(['Q',4])
sage: t = B([[4,4,4,4,4,2,1],[3,3,3,3],[2,2,1],[1]])
sage: t.weight()
(4, 2, 2, 0)
\end{verbatim}

\textbf{class} \texttt{sage.combinat.crystals.tensor_product_element.TensorProductOfCrystalsElement}

Bases: \texttt{ImmutableListWithParent}

A class for elements of tensor products of crystals.
Return the action of $e_i$ on self.

**INPUT:**

- $i$ – an element of the index set

**EXAMPLES:**

```python
sage: B = crystals.infinity.Tableaux("D4")
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f_string([1,4,3])
sage: b2 = B.highest_weight_vector().f_string([2,2,3,1,4])
sage: t = T(b2, b1)
sage: t.e(1)
[[[1, 1, 1, 1, 1], [2, 2, 3, -3], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
sage: t.e(2)
sage: t.e(3)
[[[1, 1, 1, 1, 1, 2], [2, 2, 3, -4], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
sage: t.e(4)
[[[1, 1, 1, 1, 1, 2], [2, 2, 3, 4], [3]], [[1, 1, 1, 1, 2], [2, 2, 2], [3, -3]]]
```

Return $\epsilon_i$ of self.

**INPUT:**

- $i$ – an element of the index set

**EXAMPLES:**

```python
sage: B = crystals.infinity.Tableaux("G2")
sage: T = crystals.TensorProduct(B,B)
sage: b1 = B.highest_weight_vector().f(2)
sage: b2 = B.highest_weight_vector().f_string([2,2,1])
sage: t = T(b2, b1)
sage: [t.epsilon(i) for i in B.index_set()]
[0, 3]
```

Return the action of $f_i$ on self.

**INPUT:**

- $i$ – an element of the index set

**EXAMPLES:**

```python
sage: La = RootSystem(['A',3,1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.GeneralizedYoungWalls(3,La[0])
sage: T = crystals.TensorProduct(B,B,B)
sage: b1 = B.highest_weight_vector().f_string([0,3])
sage: b2 = B.highest_weight_vector().f_string([0])
sage: b3 = B.highest_weight_vector()
sage: t = T(b3, b2, b1)
sage: t.f(0)
```
phi(i)

Return $\varphi_i$ of self.

INPUT:

- $i$ – an element of the index set

EXAMPLES:

```python
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.GeneralizedYoungWalls(2, La[0] + La[1])
sage: T = crystals.TensorProduct(B, B)
sage: b1 = B.highest_weight_vector().f_string([1, 0])
sage: b2 = B.highest_weight_vector().f_string([0, 1])
sage: t = T(b2, b1)
sage: [t.phi(i) for i in B.index_set()]
```

```
[1, 1, 4]
```

pp()

Pretty print self.

EXAMPLES:

```python
sage: C = crystals.Tableaux(['A', 3], shape=[3, 1])
sage: D = crystals.Tableaux(['A', 3], shape=[1])
sage: E = crystals.Tableaux(['A', 3], shape=[2, 2, 2])
sage: T = crystals.TensorProduct(C, D, E)
sage: T.module_generators[0].pp()
```

```
1 1 1 (X) 1 (X) 1 1
2
3 3
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: B = crystals.infinity.Tableaux("A3")
sage: T = crystals.TensorProduct(B, B)
sage: b1 = B.highest_weight_vector().f_string([2, 1, 3])
sage: b2 = B.highest_weight_vector().f(1)
sage: t = T(b2, b1)
sage: t
```

```
[[[1, 1, 1, 2], [2, 2], [3]], [[1, 1, 1, 1, 2], [2, 2, 4], [3]]]
```

```python
sage: t.weight()
```

```
(-2, 1, 0, 1)
```
```python
sage: C = crystals.Letters(['A',3])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(1),C(2)).weight()
(1, 1, 0, 0)
sage: T = crystals.Tableaux(['D',4],shape=[])
sage: T.list()[0].weight()
(0, 0, 0, 0)
```

```python
class sage.combinat.crystals.tensor_product_element.TensorProductOfQueerSuperCrystalsElement

Bases: TensorProductOfRegularCrystalsElement

Element class for a tensor product of crystals for queer Lie superalgebras.

This implements the tensor product rule for crystals of Grantcharov et al. [GJK+2014]. Given crystals $B_1$ and $B_2$ of type $q_{n+1}$, we define the tensor product $b_1 \otimes b_2 \in B_1 \otimes B_2$, where $b_1 \in B_1$ and $b_2 \in B_2$, as the following:

In addition to the tensor product rule for type $A_n$, the tensor product rule for $e_{-i}$ and $f_{-i}$ on $b_1 \otimes b_2$ are given by

\[
e_{-i}(b_1 \otimes b_2) = \begin{cases} 
    b_1 \otimes e_{-i} b_2 & \text{if } \mathrm{wt}(b_1)_1 = \mathrm{wt}(b_1)_2 = 0, \\
    e_{-i} b_1 \otimes b_2 & \text{otherwise,}
\end{cases}
\]

\[
f_{-i}(b_1 \otimes b_2) = \begin{cases} 
    b_1 \otimes f_{-i} b_2 & \text{if } \mathrm{wt}(b_1)_1 = \mathrm{wt}(b_1)_2 = 0, \\
    f_{-i} b_1 \otimes b_2 & \text{otherwise.}
\end{cases}
\]

For $1 < i \leq n$, the operators $e_{-i}$ and $f_{-i}$ are defined as

\[
e_{-i} = s_{w_i}^{-1} e_{-i} s_{w_i}, \quad f_{-i} = s_{w_i}^{-1} f_{-i} s_{w_i},
\]

Here, $w_i = s_2 \cdots s_i s_1 \cdots s_{i-1}$ and $s_i$ is the reflection along the $i$-string in the crystal. Moreover, for $1 < i \leq n$, we define the operators $e_{-i'}$ and $f_{-i'}$ as

\[
e_{-i'} = s_{w_0} f_{-(n+1-i)} s_{w_0}, \quad f_{-i'} = s_{w_0} e_{-(n+1-i)} s_{w_0},
\]

where $w_0$ is the longest element in the symmetric group $S_{n+1}$ generated by $s_1, \ldots, s_n$. In this implementation, we use the integers $-2n, \ldots, -(n+1)$ to respectively denote the indices $-n', \ldots, -1'$.

```python
e(i)

Return $e_i$ on self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q,Q])
sage: t = T(Q(1),Q(1))
sage: t.e(-1)
[1, 1]
sage: t = T(Q(2),Q(1))
sage: t.e(-1)
[1, 1]
sage: t = T(Q(1),Q(3),Q(2),Q(1))
sage: t.e(-2)
[2, 2, 1, 1]
```
epsilon(i)
Return $\varepsilon_i$ on self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q, Q, Q])
sage: t = T(Q(1), Q(3), Q(2), Q(1))
sage: t.epsilon(-2)
1
```

f(i)
Return $f_i$ on self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q])
sage: t = T(Q(1), Q(1))
sage: t.f(-1)
[2, 1]
```

phi(i)
Return $\phi_i$ on self.

EXAMPLES:

```python
sage: Q = crystals.Letters(['Q', 3])
sage: T = tensor([Q, Q, Q, Q])
sage: t = T(Q(1), Q(3), Q(2), Q(1))
sage: t.phi(-2)
0
sage: t.phi(-1)
1
```

class sage.combinat.crystals.tensor_product_element.TensorProductOfRegularCrystalsElement
Bases: TensorProductOfCrystalsElement
Element class for a tensor product of regular crystals.

e(i)
Return the action of $e_i$ on self.

EXAMPLES:

```python
sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(2)).e(1) == T(C(1), C(1))
True
sage: T(C(2), C(1)).e(1) is None
True
sage: T(C(2), C(2)).e(1) == T(C(1), C(2))
True
```

epsilon(i)
Return $\varepsilon_i$ of self.
EXAMPLES:

```python
sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(1)).epsilon(1)
0
sage: T(C(1), C(2)).epsilon(1)
1
sage: T(C(2), C(1)).epsilon(1)
0
```

\( f(i) \)

Return the action of \( f_i \) on \( self \).

EXAMPLES:

```python
sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(1)).f(1)
[1, 2]
sage: T(C(1), C(2)).f(1)
[2, 2]
sage: T(C(2), C(1)).f(1) is None
True
```

\( \phi(i) \)

Return \( \phi_i \) of \( self \).

EXAMPLES:

```python
sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(1), C(1)).phi(1)
2
sage: T(C(1), C(2)).phi(1)
1
sage: T(C(2), C(1)).phi(1)
0
```

\texttt{position\_of\_first\_unmatched\_plus}(i)

Return the position of the first unmatched \(+\) or \None if there is no unmatched \(+\).

EXAMPLES:

```python
sage: C = crystals.Letters(['A', 5])
sage: T = crystals.TensorProduct(C, C)
sage: T(C(2), C(1)).position_of_first_unmatched_plus(1)
sage: T(C(1), C(2)).position_of_first_unmatched_plus(1)
1
```

\texttt{position\_of\_last\_unmatched\_minus}(i)

Return the position of the last unmatched \( - \) or \None if there is no unmatched \( - \).

EXAMPLES:
Combinatorics, Release 10.1

```
sage: C = crystals.Letters(['A',5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(2),C(1)).position_of_last_unmatched_minus(1)
0
sage: T(C(1),C(2)).position_of_last_unmatched_minus(1)
0
```

**positions_of_unmatched_minus(i, dual=False, reverse=False)**

**EXAMPLES:**

```
sage: C = crystals.Letters(['A',5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(2),C(1)).positions_of_unmatched_minus(1)
[]
sage: T(C(1),C(2)).positions_of_unmatched_minus(1)
[0]
```

**positions_of_unmatched_plus(i)**

**EXAMPLES:**

```
sage: C = crystals.Letters(['A',5])
sage: T = crystals.TensorProduct(C,C)
sage: T(C(2),C(1)).positions_of_unmatched_plus(1)
[]
sage: T(C(1),C(2)).positions_of_unmatched_plus(1)
[1]
```

**class** `sage.combinat.crystals.tensor_product_element.TensorProductOfSuperCrystalsElement`

Bases: `TensorProductOfRegularCrystalsElement`

Element class for a tensor product of crystals for Lie superalgebras.

This implements the tensor product rule for crystals of Lie superalgebras of [BKK2000].

**e(i)**

Return $e_i$ on self.

**EXAMPLES:**

```
sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.e(0)
[-1, 1]
```

**epsilon(i)**

Return $\varepsilon_i$ on self.

**EXAMPLES:**

```
sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.epsilon(0)
1
```
\( f(i) \)
Return \( f_i \) on self.

EXAMPLES:

```
sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.f(0)
sage: t.f(1)
[1, 2]
```

\( \phi(i) \)
Return \( \phi_i \) on self.

EXAMPLES:

```
sage: C = crystals.Letters(['A', [2, 1]])
sage: T = tensor([C,C])
sage: t = T(C(1),C(1))
sage: t.phi(0)
```

5.1.69 Cyclic sieving phenomenon

Implementation of the Cyclic Sieving Phenomenon as described by Reiner, Stanton, and White in [RSW2004].

We define the \texttt{CyclicSievingPolynomial()} of a finite set \( S \) together with cyclic action \( \text{cyc}_\text{act} \) (of order \( n \)) to be the unique polynomial \( P(q) \) of order \( < n \) such that the triple \( (S, \text{cyc}_\text{act}, P(q)) \) exhibits the cyclic sieving phenomenon.

AUTHORS:
• Christian Stump

REFERENCES:
sage.combinat.cyclic_sieving_phenomenon.\texttt{CyclicSievingCheck}(L, cyc\_act, f, order=None)

Return whether the triple \( (L, \text{cyc}_\text{act}, f) \) exhibits the cyclic sieving phenomenon.

If \( \text{cyc}_\text{act} \) is None, \( L \) is expected to contain the orbit lengths.

INPUT:
• \( L \) – if \( \text{cyc}_\text{act} \) is None: list of orbit sizes, otherwise list of objects
• \( \text{cyc}_\text{act} \) – (default:None) bijective function from \( L \) to \( L \)
• \( \text{order} \) – (default:None) if set to an integer, this
cyclic order of \( \text{cyc}_\text{act} \) is used (must be an integer multiple of the order of \( \text{cyc}_\text{act} \)) otherwise, the
order of \( \text{cyc}\_\text{action} \) is used

EXAMPLES:

```
sage: from sage.combinat.cyclic_sieving_phenomenon import *
sage: from sage.combinat.q_analogues import q_binomial
sage: S42 = Subsets([1,2,3,4], 2)
sage: def cyc_act(S): return Set(i.mod(4) + 1 for i in S)
```
sage: cyc_act([1,3])
{2, 4}
sage: cyc_act([1,4])
{1, 2}
sage: p = q_binomial(4,2); p
q^4 + q^3 + 2*q^2 + q + 1
sage: CyclicSievingPolynomial( S42, cyc_act )
q^3 + 2*q^2 + q + 2
sage: CyclicSievingCheck( S42, cyc_act, p )
True

sage.combinat.cyclic_sieving_phenomenon.CyclicSievingPolynomial(L, cyc_act=None, order=None, get_order=False)

Return the unique polynomial p of degree smaller than order such that the triple (L, cyc_act, p) exhibits
the Cyclic Sieving Phenomenon.

If cyc_act is None, L is expected to contain the orbit lengths.

INPUT:

• L – if cyc_act is None: list of orbit sizes, otherwise list of objects
• cyc_act – (default:None) bijective function from L to L
• order – (default:None) if set to an integer, this
cyclic order of cyc_act is used (must be an integer multiple of the order of cyc_act) otherwise, the
order of cyc_action is used
• get_order – (default:False) if True, a tuple [p,n] is returned where p is as above, and n is the order

EXAMPLES:

sage: from sage.combinat.cyclic_sieving_phenomenon import CyclicSievingPolynomial
sage: S42 = Subsets([1,2,3,4], 2)
sage: def cyc_act(S):
    return Set(i.mod(4) + 1 for i in S)
sage: cyc_act([1,3])
{2, 4}
sage: cyc_act([1,4])
{1, 2}
sage: CyclicSievingPolynomial(S42, cyc_act)
q^3 + 2*q^2 + q + 2
sage: CyclicSievingPolynomial(S42, cyc_act, get_order=True)
[q^3 + 2*q^2 + q + 2, 4]
sage: CyclicSievingPolynomial(S42, cyc_act, order=8)
q^6 + 2*q^4 + q^2 + 2
sage: CyclicSievingPolynomial([4,2])
q^3 + 2*q^2 + q + 2

sage.combinat.cyclic_sieving_phenomenon.orbit_decomposition(L, cyc_act)

Return the orbit decomposition of L by the action of cyc_act.

INPUT:

• L – list
• cyc_act – bijective function from L to L

OUTPUT:
• a list of lists, the orbits under the cyc_act acting on L

EXAMPLES:

```
sage: from sage.combinat.cyclic_sieving_phenomenon import *
sage: S42 = Subsets([1,2,3,4], 2); S42
Subsets of {1, 2, 3, 4} of size 2
sage: def cyc_act(S):
    return Set(i.mod(4) + 1 for i in S)
sage: cyc_act([1,3])
{2, 4}
sage: cyc_act([1,4])
{1, 2}
sage: orbits = orbit_decomposition(S42, cyc_act)
sage: sorted([sorted(orb, key=sorted) for orb in orbits], key=len)
[[{1, 3}, {2, 4}], [{1, 2}, {1, 4}, {2, 3}, {3, 4}]]
```

5.1.70 De Bruijn sequences

A De Bruijn sequence is defined as the shortest cyclic sequence that incorporates all substrings of a certain length of an alphabet.

For instance, the $2^3 = 8$ binary strings of length 3 are all included in the following string:

```
sage: DeBruijnSequences(2,3).an_element()
[0, 0, 0, 1, 0, 1, 1, 1]
```

They can be obtained as a subsequence of the cyclic De Bruijn sequence of parameters $k = 2$ and $n = 3$:

```
sage: seq = DeBruijnSequences(2,3).an_element()
sage: print(Word(seq).string_rep())
00010111
sage: shift = lambda i: [(i+j)%2**3 for j in range(3)]
sage: for i in range(2**3):
    w = Word([b if j in shift(i) else '*' for j, b in enumerate(seq)])
    print(w.string_rep())
00***
*01***
**010**
***011**
****011
*****11
0*****1
00*****1
```

This sequence is of length $k^n$, which is best possible as it is the number of $k$-ary strings of length $n$. One can equivalently define a De Bruijn sequence of parameters $k$ and $n$ as a cyclic sequence of length $k^n$ in which all substring of length $n$ are different.

See also Wikipedia article De_Bruijn_sequence.

AUTHOR:

• Eviatar Bach (2011): initial version
• Nathann Cohen (2011): Some work on the documentation and defined the __contain__ method
class sage.combinat.debruijn_sequence.DeBruijnSequences(k, n)

Bases: UniqueRepresentation, Parent

Represents the De Bruijn sequences of given parameters $k$ and $n$.

A De Bruijn sequence of parameters $k$ and $n$ is defined as the shortest cyclic sequence that incorporates all substrings of length $n$ a $k$-ary alphabet.

This class can be used to generate the lexicographically smallest De Bruijn sequence, to count the number of existing De Bruijn sequences or to test whether a given sequence is De Bruijn.

INPUT:

- $k$ – A natural number to define arity. The letters used are the integers $0..k - 1$.
- $n$ – A natural number that defines the length of the substring.

EXAMPLES:

Obtaining a De Bruijn sequence:

```python
sage: seq = DeBruijnSequences(2, 3).an_element()
sage: seq
[0, 0, 0, 1, 0, 1, 1, 1]
```

Testing whether it is indeed one:

```python
sage: seq in DeBruijnSequences(2, 3)
True
```

The total number for these parameters:

```python
sage: DeBruijnSequences(2, 3).cardinality()
2
```

Note: This function only generates one De Bruijn sequence (the smallest lexicographically). Support for generating all possible ones may be added in the future.

an_element()

Returns the lexicographically smallest De Bruijn sequence with the given parameters.

ALGORITHM:

The algorithm is described in the book “Combinatorial Generation” by Frank Ruskey. This program is based on a Ruby implementation by Jonas Elfström, which is based on the C program by Joe Sadawa.

EXAMPLES:

```python
sage: DeBruijnSequences(2, 3).an_element()
[0, 0, 0, 1, 0, 1, 1, 1]
```

cardinality()

Returns the number of distinct De Bruijn sequences for the object’s parameters.

EXAMPLES:

```python
sage: DeBruijnSequences(2, 5).cardinality()
2048
```
ALGORITHM:

The formula for cardinality is $k!^{kn-1}/k^n$ [Ros2002].

`sage.combinat.debruijn_sequence.debruijn_sequence(k, n)`

The generating function for De Bruijn sequences. This avoids the object creation, so is significantly faster than accessing from DeBruijnSequence. For more information, see the documentation there. The algorithm used is from Frank Ruskey’s “Combinatorial Generation”.

INPUT:

• k – Arity. Must be an integer.
• n – Substring length. Must be an integer.

EXAMPLES:

```python
sage: from sage.combinat.debruijn_sequence import debruijn_sequence
sage: debruijn_sequence(3, 1)
[0, 1, 2]
```

`sage.combinat.debruijn_sequence.is_debruijn_sequence(seq, k, n)`

Given a sequence of integer elements in $0..k-1$, tests whether it corresponds to a De Bruijn sequence of parameters $k$ and $n$.

INPUT:

• seq – Sequence of elements in $0..k-1$.
• n,k – Integers.

EXAMPLES:

```python
sage: from sage.combinat.debruijn_sequence import is_debruijn_sequence
sage: s = DeBruijnSequences(2, 3).an_element()
sage: is_debruijn_sequence(s, 2, 3)
True
sage: is_debruijn_sequence(s + [0], 2, 3)
False
sage: is_debruijn_sequence([1] + s[1:], 2, 3)
False
```

5.1.71 Degree sequences

The present module implements the `DegreeSequences` class, whose instances represent the integer sequences of length $n$:

```python
sage: DegreeSequences(6)
Degree sequences on 6 elements
```

With the object `DegreeSequences(n)`, one can:

• Check whether a sequence is indeed a degree sequence:

```python
sage: DS = DegreeSequences(5)
sage: [4, 3, 3, 3, 3] in DS
True
```

(continues on next page)
• List all the possible degree sequences of length $n$:

```python
sage: for seq in DegreeSequences(4):
......:    print(seq)
[0, 0, 0, 0]
[1, 1, 0, 0]
[2, 1, 1, 0]
[3, 1, 1, 1]
[1, 1, 1, 1]
[2, 2, 1, 1]
[2, 2, 2, 0]
[3, 2, 2, 1]
[2, 2, 2, 2]
[3, 3, 2, 2]
[3, 3, 3, 3]
```

Note: Given a degree sequence, one can obtain a graph realizing it by using `DegreeSequence()`. For instance:

```python
sage: ds = [3, 3, 2, 2, 2, 2, 2, 1, 1, 0]
sage: g = graphs.DegreeSequence(ds)
sage: g.degree_sequence()
[3, 3, 2, 2, 2, 2, 2, 1, 1, 0]
```

Definitions

A sequence of integers $d_1, \ldots, d_n$ is said to be a degree sequence (or graphic sequence) if there exists a graph in which vertex $i$ is of degree $d_i$. It is often required to be non-increasing, i.e. that $d_1 \geq \ldots \geq d_n$. Finding a graph with given degree sequence is known as graph realization problem.

An integer sequence need not necessarily be a degree sequence. Indeed, in a degree sequence of length $n$ no integer can be larger than $n - 1$ – the degree of a vertex is at most $n - 1$ – and the sum of them is at most $n(n - 1)$.

Degree sequences are completely characterized by a result from Erdos and Gallai:

**Erdos and Gallai:** The sequence of integers $d_1 \geq \cdots \geq d_n$ is a degree sequence if and only if $\sum_i d_i$ is even and $\forall i$

\[
\sum_{j \leq i} d_j \leq j(j - 1) + \sum_{j > i} \min(d_j, i).
\]

Alternatively, a degree sequence can be defined recursively:

**Havel and Hakimi:** The sequence of integers $d_1 \geq \cdots \geq d_n$ is a degree sequence if and only if $d_2 - 1, \ldots, d_{d_1+1} - 1, d_{d_1+2}, \ldots, d_n$ is also a degree sequence.

Or equivalently:

**Havel and Hakimi (bis):** If there is a realization of an integer sequence as a graph (i.e. if the sequence is a degree sequence), then it can be realized in such a way that the vertex of maximum degree $\Delta$ is adjacent to the $\Delta$ vertices of highest degree (except itself, of course).
Algorithms

Checking whether a given sequence is a degree sequence

This is tested using Erdos and Gallai’s criterion. It is also checked that the given sequence is non-increasing and has length \(n\).

Iterating through the sequences of length \(n\)

From Havel and Hakimi’s recursive definition of a degree sequence, one can build an enumeration algorithm as done in [RCES1994]. It consists in trying to extend a current degree sequence on \(n\) elements into a degree sequence on \(n + 1\) elements by adding a vertex of degree larger than those already present in the sequence. This can be seen as reversing the reduction operation described in Havel and Hakimi’s characterization. This operation can appear in several different ways:

- Extensions of a degree sequence that do not change the value of the maximum element
  - If the maximum element of a given degree sequence is 0, then one can remove it to reduce the sequence, following Havel and Hakimi’s rule. Conversely, if the maximum element of the (current) sequence is 0, then one can always extend it by adding a new element of degree 0 to the sequence.

\[
0, 0, 0 \xrightarrow{\text{Extension}} 0, 0, 0, 0 \xrightarrow{\text{Extension}} 0, 0, 0, ..., 0, 0, 0 \xrightarrow{\text{Reduction}} 0, 0, 0 \xrightarrow{\text{Reduction}} 0, 0, 0
\]

- If there are at least \(\Delta + 1\) elements of (maximum) degree \(\Delta\) in a given degree sequence, then one can reduce it by removing a vertex of degree \(\Delta\) and decreasing the values of \(\Delta\) elements of value \(\Delta\) to \(\Delta - 1\). Conversely, if the maximum element of the (current) sequence is \(\Delta\) > 0, then one can add a new element of degree \(\Delta\) to the sequence if it can be linked to \(\Delta\) elements of (current) degree \(\Delta - 1\). Those \(\Delta\) vertices of degree \(\Delta - 1\) hence become vertices of degree \(\Delta\), and so \(\Delta\) elements of degree \(\Delta - 1\) are removed from the sequence while \(\Delta + 1\) elements of degree \(\Delta\) are added to it.

\[
3, 2, 2, 1 \xrightarrow{\text{Extension}} 3, 3, (2 + 1), (2 + 1), (2 + 1), 1 = 3, 3, 3, 3, 3, 1 \xrightarrow{\text{Reduction}} 3, 2, 2, 1
\]

- Extension of a degree sequence that changes the value of the maximum element:
  - In the general case, i.e. when the number of elements of value \(\Delta, \Delta - 1\) is small compared to \(\Delta\) (i.e. the maximum element of a given degree sequence), reducing a sequence strictly decreases the value of the maximum element. According to Havel and Hakimi’s characterization there is only one way to reduce a sequence, but reversing this operation is more complicated than in the previous cases. Indeed, the following extensions are perfectly valid according to the reduction rule.

\[
2, 1, 1, 0, 0 \xrightarrow{\text{Extension}} 3, (2 + 1), (1 + 1), (1 + 1), 1, 0 = 3, 3, 3, 2, 0, 0 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0
\]

\[
2, 1, 1, 0, 0 \xrightarrow{\text{Extension}} 3, (2 + 1), (1 + 1), 1, (0 + 1), 0 = 3, 3, 2, 1, 1, 0 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0
\]

\[
2, 1, 1, 0, 0 \xrightarrow{\text{Extension}} 3, (2 + 1), 1, 1, (0 + 1), (0 + 1) = 3, 3, 1, 1, 1, 1 \xrightarrow{\text{Reduction}} 2, 1, 1, 0, 0
\]

In order to extend a current degree sequence while strictly increasing its maximum degree, it is equivalent to pick a set \(I\) of elements of the degree sequence with \(|I| > \Delta\) in such a way that the \(d_i + 1\) are the \(|I|\) maximum elements of the sequence \((d_i + 1)_{i \in I}\) \(1 \leq i \leq n\), and to add to this new sequence an element of value \(|I|\). The non-increasing sequence containing the elements \(|I|\) and \((d_i + 1)_{i \in I}\) \(1 \leq i \leq n\) can be reduced to \((d_i)_{i \leq n}\) by Havel and Hakimi’s rule.

\[
\ldots 1, 1, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, 3, 4, 4, 4, 5, 7, \ldots \xrightarrow{\text{Extension}} \ldots 1, 1, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, 3, 4, 4, 4, 5, 7, \ldots
\]

The number of possible sets \(I\) having this property (i.e. the number of possible extensions of a sequence) is smaller than it seems. Indeed, by definition, if \(j \not\in I\) then for all \(i \in I\) the inequality \(d_j \leq d_i + 1\) holds.
Hence, each set $I$ is entirely determined by the largest element $d_k$ of the sequence that it does not contain (hence $I$ contains $\{1, \ldots, k - 1\}$), and by the cardinalities of $\{i \in I : d_i = d_k\}$ and $\{i \in I : d_i = d_k - 1\}$.

$$I = \{i \in I : d_i = d_k\} \cup \{i \in I : d_i = d_k - 1\} \cup \{i : d_i > d_k\}.$$  

The number of possible extensions is hence at most cubic, and is easily enumerated.

**About the implementation**

In the actual implementation of the enumeration algorithm, the degree sequence is stored differently for reasons of efficiency.

Indeed, when enumerating all the degree sequences of length $n$, Sage first allocates an array $seq$ of $n + 1$ integers where $seq[i]$ is the number of elements of value $i$ in the current sequence. Obviously, $seq[n]=0$ holds in permanence : it is useful to allocate a larger array than necessary to simplify the code. The $seq$ array is a global variable.

The recursive function $\text{enum}(\text{depth}, \text{maximum})$ is the one building the list of sequences. It builds the list of degree sequences of length $n$ which extend the sequence currently stored in $seq[0]...seq[\text{depth}-1]$. When it is called, $\text{maximum}$ must be set to the maximum value of an element in the partial sequence $seq[0]...seq[\text{depth}-1]$.

If during its run the function $\text{enum}$ heavily works on the content of the $seq$ array, the value of $seq$ is the same before and after the run of $\text{enum}$.

**Extending the current partial sequence**

The two cases for which the maximum degree of the partial sequence does not change are easy to detect. It is (slightly) harder to enumerate all the sets $I$ corresponding to possible extensions of the partial sequence. As said previously, to each set $I$ one can associate an integer $\text{current}_\text{box}$ such that $I$ contains all the $i$ satisfying $d_i > \text{current}_\text{box}$.

The variable $\text{taken}$ represents the number of all such elements $i$, so that when enumerating all possible sets $I$ in the algorithm we have the equality

$$I = \text{taken} + \text{number of elements of value } \text{current}_\text{box} + \text{number of elements of value } \text{current}_\text{box} - 1.$$

- [RCES1994]

AUTHORS:

- Nathann Cohen

**Warning:** For the moment, iterating over all degree sequences involves building the list of them first, then iterate on this list. This is obviously bad, as it requires uselessly a lot of memory for large values of $n$.

This should be changed. Updating the code does not require more than a couple of minutes.

**class**  
sage.combinat.degree_sequences.DegreeSequences($n$)

Bases: object

Degree Sequences

An instance of this class represents the degree sequences of graphs on a given number $n$ of vertices. It can be used to list and count them, as well as to test whether a sequence is a degree sequence. For more information, please refer to the documentation of the **DegreeSequence** module.

EXAMPLES:
sage: DegreeSequences(8)
Degree sequences on 8 elements
sage: [3,3,2,2,2,2,2,2] in DegreeSequences(8)
True

5.1.72 Derangements

AUTHORS:

- Alasdair McAndrew (2010-05): Initial version
- Travis Scrimshaw (2013-03-30): Put derangements into category framework

class sage.combinat.derangements.Derangement(parent, *args, **kwds)

Bases: CombinatorialElement

A derangement.

A derangement on a set $S$ is a permutation $\sigma$ such that $\sigma(x) \neq x$ for all $x \in S$, i.e. $\sigma$ is a permutation of $S$ with no fixed points.

EXAMPLES:

sage: D = Derangements(4)
sage: elt = D([4,3,2,1])
sage: TestSuite(elt).run()
to_permutation()

Return the permutation corresponding to self.

EXAMPLES:

sage: D = Derangements(4)
sage: p = D([4,3,2,1]).to_permutation(); p
[4, 3, 2, 1]
sage: type(p)
<...>

sage: D = Derangements([1, 3, 3, 4])
sage: D[0].to_permutation()
Traceback (most recent call last):
... ValueError: can only convert to a permutation for derangements of [1, 2, ..., n]

class sage.combinat.derangements.Derangements(x)

Bases: UniqueRepresentation, Parent

The class of all derangements of a set or multiset.

A derangement on a set $S$ is a permutation $\sigma$ such that $\sigma(x) \neq x$ for all $x \in S$, i.e. $\sigma$ is a permutation of $S$ with no fixed points.

For an integer, or a list or string with all elements distinct, the derangements are obtained by a standard result described in [BV2004]. For a list or string with repeated elements, the derangements are formed by computing all permutations of the input and discarding all non-derangements.

INPUT:
• \(x\) – Can be an integer which corresponds to derangements of \(\{1, 2, 3, \ldots, x\}\), a list, or a string

REFERENCES:

• [BV2004]
• Wikipedia article Derangement

EXAMPLES:

```
sage: D1 = Derangements([2,3,4,5])
sage: D1.list()
[[3, 4, 5, 2],
 [5, 4, 2, 3],
 [3, 5, 2, 4],
 [4, 5, 3, 2],
 [4, 2, 5, 3],
 [5, 2, 3, 4],
 [5, 4, 3, 2],
 [4, 5, 2, 3],
 [3, 2, 5, 4]]
sage: D1.cardinality()
9
sage: D1.random_element() # random
[4, 2, 5, 3]
sage: D2 = Derangements([1,2,3,1,2,3])
sage: D2.cardinality()
10
sage: D2.list()
[[2, 1, 1, 3, 3, 2],
 [2, 1, 2, 3, 3, 1],
 [2, 3, 1, 2, 3, 1],
 [2, 3, 1, 3, 1, 2],
 [2, 3, 2, 3, 1, 1],
 [3, 1, 1, 2, 3, 2],
 [3, 1, 2, 2, 3, 1],
 [3, 1, 2, 3, 1, 2],
 [3, 3, 1, 2, 1, 2],
 [3, 3, 2, 2, 1, 1]]
sage: D2.random_element() # random
[2, 3, 1, 3, 1, 2]
```

### Element

alias of `Derangement`

### cardinality()

Counts the number of derangements of a positive integer, a list, or a string. The list or string may contain repeated elements. If an integer \(n\) is given, the value returned is the number of derangements of \(\{1, 2, 3, \ldots, n\}\).

For an integer, or a list or string with all elements distinct, the value is obtained by the standard result

\[
D_2 = 1, \quad D_3 = 2, \quad D_n = (n - 1)(D_{n-1} + D_{n-2}).
\]

For a list or string with repeated elements, the number of derangements is computed by Macmahon’s theorem. If the numbers of repeated elements are \(a_1, a_2, \ldots, a_k\) then the number of derangements is given by the coefficient of \(x_1 x_2 \cdots x_k\) in the expansion of \(\prod_{i=0}^{k} (S - s_i)^{a_i}\), where \(S = x_1 + x_2 + \cdots + x_k\).

EXAMPLES:
random_element()

Produces all derangements of a positive integer, a list, or a string. The list or string may contain repeated elements. If an integer \( n \) is given, then a random derangement of \([1, 2, 3, \ldots, n]\) is returned.

For an integer, or a list or string with all elements distinct, the value is obtained by an algorithm described in [MPP2008]. For a list or string with repeated elements the derangement is formed by choosing an element at random from the list of all possible derangements.

**OUTPUT:**

A single list or string containing a derangement, or an empty list if there are no derangements.

**EXAMPLES:**

```python
sage: D = Derangements(4)
sage: D.random_element() # random
[2, 3, 4, 1]
sage: D = Derangements(['A', 'AT', 'CAT', 'CATS', 'CARTS'])
sage: D.random_element() # random
['AT', 'CATS', 'A', 'CAT', 'CARETS', 'CAT']
sage: D = Derangements('UNCOPYRIGHTABLE')
sage: D.random_element() # random
sage: D = Derangements([1,1,1,2,2,2,3,3,3,3])
sage: D.random_element() # random
[3, 2, 2, 1, 1, 2, 2, 3, 3, 3, 3]
sage: D = Derangements('ESSENCES')
sage: D.random_element() # random
['N', 'E', 'E', 'C', 'S', 'S', 'S', 'E']
sage: D = Derangements([1,1,2,2,2])
sage: D.random_element()
[]
```
## 5.1.73 Descent Algebras

**AUTHORS:**

- Travis Scrimshaw (2013-07-28): Initial version

```python
class sage.combinat.descent_algebra.DescentAlgebra(R, n)
```

**Bases:** UniqueRepresentation, Parent

Solomon’s descent algebra.

The descent algebra $\Sigma_n$ over a ring $R$ is a subalgebra of the symmetric group algebra $RS_n$. (The product in the latter algebra is defined by $(pq)(i) = q(p(i))$ for any two permutations $p$ and $q$ in $S_n$ and every $i \in \{1, 2, \ldots, n\}$. The algebra $\Sigma_n$ inherits this product.)

There are three bases currently implemented for $\Sigma_n$:

- the standard basis $D_S$ of (sums of) descent classes, indexed by subsets $S$ of \{1, 2, \ldots, n - 1\},
- the subset basis $B_p$, indexed by compositions $p$ of $n$,
- the idempotent basis $I_p$, indexed by compositions $p$ of $n$, which is used to construct the mutually orthogonal idempotents of the symmetric group algebra.

The idempotent basis is only defined when $R$ is a $\mathbb{Q}$-algebra.

We follow the notations and conventions in [GR1989], apart from the order of multiplication being different from the one used in that article. Schocker’s exposition [Sch2004], in turn, uses the same order of multiplication as we are, but has different notations for the bases.

**INPUT:**

- $R$ – the base ring
- $n$ – a nonnegative integer

**REFERENCES:**

- [GR1989]
- [At1992]
- [MR1995]
- [Sch2004]

**EXAMPLES:**

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D(); D
Descent algebra of 4 over Rational Field in the standard basis
sage: B = DA.B(); B
Descent algebra of 4 over Rational Field in the subset basis
sage: I = DA.I(); I
Descent algebra of 4 over Rational Field in the idempotent basis
sage: basis_B = B.basis()
sage: elt = basis_B[Composition([1,2,1])] + 4*basis_B[Composition([1,3])]; elt
B[1, 2, 1] + 4*B[1, 3]
sage: D(elt)
5*D{} + 5*D{1} + D{1, 3} + D{3}
sage: I(elt)
7/6*I[1, 1, 1, 1] + 2*I[1, 1, 2] + 3*I[1, 2, 1] + 4*I[1, 3]
```
As syntactic sugar, one can use the notation $D[i, \ldots, 1]$ to construct elements of the basis; note that for the empty set one must use $D[[]]$ due to Python’s syntax:

```
sage: D[[]] + D[2] + 2*D[1, 2]
D{} + 2*D{1, 2} + D{2}
```

The same syntax works for the other bases:

```
```

```python
class B(alg, prefix='B')
    Bases: CombinatorialFreeModule,BindableClass
    The subset basis of a descent algebra (indexed by compositions).
    The subset basis $(B_S)_{S \subseteq \{1,2,\ldots,n-1\}}$ of $\Sigma_n$ is formed by
    
    $B_S = \sum_{T \subseteq S} D_T,$
    
    where $(D_S)_{S \subseteq \{1,2,\ldots,n-1\}}$ is the standard basis. However it is more natural to index the subset basis
    by compositions of $n$ under the bijection $\{i_1, i_2, \ldots, i_k\} \mapsto (i_1, i_2 - i_1, i_3 - i_2, \ldots, i_k - i_{k-1}, n - i_k)$
    (where $i_1 < i_2 < \cdots < i_k$), which is what Sage uses to index the basis.
    
    The basis element $B_p$ is denoted $\Xi_p$ in [Sch2004].
    
    By using compositions of $n$, the product $B_p B_q$ becomes a sum over the non-negative-integer matrices $M$
    with row sum $p$ and column sum $q$. The summand corresponding to $M$ is $B_c$, where $c$ is the composition
    obtained by reading $M$ row-by-row from left-to-right and top-to-bottom and removing all zeroes. This
    multiplication rule is commonly called “Solomon’s Mackey formula”.
```

**EXAMPLES:**

```
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: list(B.basis())
[B[1, 1, 1, 1], B[1, 1, 2], B[1, 2, 1], B[1, 3], B[2, 1, 1], B[2, 2], B[3, 1], B[4]]
```

```
B[1, 1, 1, 1], B[1, 1, 2], B[1, 2, 1], B[1, 3], B[2, 1, 1], B[2, 2], B[3, 1], B[4]]
```

```
product_on_basis(p, q)
    Return $B_p B_q$, where $p$ and $q$ are compositions of $n$.
```

**EXAMPLES:**

```
sage: DescentAlgebra(QQ, 4).B().one_basis()
[4]
sage: DescentAlgebra(QQ, 0).B().one_basis()
[]
sage: all( U * DescentAlgebra(QQ, 3).B().one() == U 
        ....:     for U in DescentAlgebra(QQ, 3).B().basis() )
True
```
Combinatorics, Release 10.1

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: p = Composition([1,2,1])
sage: q = Composition([3,1])
sage: B.product_on_basis(p, q)
B[1, 1, 1, 1] + 2*B[1, 2, 1]
```

to_D_basis(p)

Return \(B_p\) as a linear combination of \(D\)-basis elements.

EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: D = DA.D()
sage: list(map(D, B.basis())) # indirect doctest
[D{}, D{1}, D{1, 2}, D{1, 2, 3},
 D{1}, D{2}, D{2, 3}, D{1, 2},
 D{1}, D{3}, D{2},
 D{}, D{1}, D{2}, D{3}]
```

to_I_basis(p)

Return \(B_p\) as a linear combination of \(I\)-basis elements.

This is done using the formula

\[
B_p = \sum_{q \preceq p} \frac{1}{k!(q, p)} I_q,
\]

where \(\preceq\) is the refinement order and \(k!(q, p)\) is defined as follows: When \(q \preceq p\), we can write \(q\) as a concatenation \(q_1(q_2)\cdots(q_k)\) with each \(q_i\) being a composition of the \(i\)-th entry of \(p\), and then we set \(k!(q, p)\) to be \(l(q_1)!l(q_2)!\cdots l(q_k)!\), where \(l(r)\) denotes the number of parts of any composition \(r\).

EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: I = DA.I()
sage: list(map(I, B.basis())) # indirect doctest
[I[1, 1, 1, 1],
 1/2*I[1, 1, 1, 1] + I[1, 1, 2],
 1/2*I[1, 1, 1, 1] + I[1, 2, 1],
 1/6*I[1, 1, 1, 1] + 1/2*I[1, 1, 2] + 1/2*I[1, 2, 1] + I[1, 3],
 1/2*I[1, 1, 1, 1] + I[2, 1, 1],
 1/4*I[1, 1, 1, 1] + 1/2*I[1, 1, 2] + 1/2*I[2, 1, 1] + I[2, 2],
 1/6*I[1, 1, 1, 1] + 1/2*I[1, 2, 1] + 1/2*I[2, 1, 1] + I[3, 1],
 1/24*I[1, 1, 1, 1] + 1/6*I[1, 1, 2] + 1/6*I[1, 2, 1] + 1/2*I[1, 3, 1] + I[4]]
```

5.1. Comprehensive Module List 593
to_nsym$(p)$

Return $B_p$ as an element in $NSym$, the non-commutative symmetric functions.

This maps $B_p$ to $S_p$ where $S$ denotes the Complete basis of $NSym$.

EXAMPLES:

```python
sage: B = DescentAlgebra(QQ, 4).B()
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: list(map(S, B.basis()))  # indirect doctest
[S[1, 1, 1, 1],
 S[1, 1, 2],
 S[1, 2, 1],
 S[1, 3],
 S[2, 1, 1],
 S[2, 2],
 S[3, 1],
 S[4]]
```

```python
class D(alg, prefix='D')

Bases: CombinatorialFreeModule, BindableClass

The standard basis of a descent algebra.

This basis is indexed by $S \subseteq \{1, 2, \ldots, n - 1\}$, and the basis vector indexed by $S$ is the sum of all permutations, taken in the symmetric group algebra $RS_n$, whose descent set is $S$. We denote this basis vector by $D_S$.

Occasionally this basis appears in literature but indexed by compositions of $n$ rather than subsets of $\{1, 2, \ldots, n - 1\}$. The equivalence between these two indexings is owed to the bijection from the power set of $\{1, 2, \ldots, n - 1\}$ to the set of all compositions of $n$ which sends every subset $\{i_1, i_2, \ldots, i_k\}$ of $\{1, 2, \ldots, n - 1\}$ (with $i_1 < i_2 < \cdots < i_k$) to the composition $(i_1, i_2 - i_1, \ldots, i_k - i_{k-1}, n - i_k)$.

The basis element corresponding to a composition $p$ (or to the subset of $\{1, 2, \ldots, n - 1\}$) is denoted $\Delta^p$ in [Sch2004].

EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: list(D.basis())
[D{}, D{1}, D{2}, D{3}, D{1, 2}, D{1, 3}, D{2, 3}, D{1, 2, 3}]
```

```python
sage: DA = DescentAlgebra(QQ, 0)
sage: D = DA.D()
sage: list(D.basis())
[D{}]
```

```python
one_basis()

Return the identity element, as per AlgebrasWithBasis.ParentMethods.one_basis.

EXAMPLES:

```python
sage: DescentAlgebra(QQ, 4).D().one_basis() ()
sage: DescentAlgebra(QQ, 0).D().one_basis() ()
```

(continues on next page)
```python
sage: all( U * DescentAlgebra(QQ, 3).D().one() == U
....:     for U in DescentAlgebra(QQ, 3).D().basis() )
True
```

**product_on_basis($S, T$)**

Return $D_S D_T$, where $S$ and $T$ are subsets of $\{n - 1\}$.

**EXAMPLES:**

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: D.product_on_basis((1, 3), (2,))
D{} + D{1} + D{1, 2} + 2*D{1, 2, 3} + D{1, 3} + D{2} + D{2, 3} + D{3}
```

**to_B_basis($S$)**

Return $D_S$ as a linear combination of $B_p$-basis elements.

**EXAMPLES:**

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: D = DA.D()
sage: B = DA.B()
sage: list(map(B, D.basis()))  # indirect doctest
[B[4],
  B[1, 3] - B[4],
  B[2, 2] - B[4],
  B[3, 1] - B[4],
```

**to_symmetric_group_algebra_on_basis($S$)**

Return $D_S$ as a linear combination of basis elements in the symmetric group algebra.

**EXAMPLES:**

```python
sage: D = DescentAlgebra(QQ, 4).D()
sage: [D.to_symmetric_group_algebra_on_basis(tuple(b))
    ....:     for b in Subsets(3)]
[[1, 2, 3, 4],
 [2, 1, 3, 4] + [3, 1, 2, 4] + [4, 1, 2, 3],
 [1, 3, 2, 4] + [1, 4, 2, 3] + [2, 3, 1, 4] + [2, 4, 1, 3] + [3, 4, 1, 2],
 [1, 2, 4, 3] + [1, 3, 4, 2] + [2, 3, 4, 1],
 [3, 2, 1, 4] + [4, 2, 1, 3] + [4, 3, 1, 2],
 [2, 1, 4, 3] + [3, 1, 4, 2] + [3, 2, 4, 1] + [4, 1, 3, 2] + [4, 2, 3, 1],
 [1, 4, 3, 2] + [2, 4, 3, 1] + [3, 4, 2, 1],
 [4, 3, 2, 1]]
```
class I(alg, prefix='I')

Bases: CombinatorialFreeModule, BindableClass

The idempotent basis of a descent algebra.

The idempotent basis \((I_p)_{p|n}\) is a basis for \(\Sigma_n\) whenever the ground ring is a \(\mathbb{Q}\)-algebra. One way to compute it is using the formula (Theorem 3.3 in [GR1989])

\[
I_p = \sum_{q \leq p} \frac{(-1)^{l(q) - l(p)}}{k(q, p)} B_q,
\]

where \(\leq\) is the refinement order and \(l(r)\) denotes the number of parts of any composition \(r\), and where \(k(q, p)\) is defined as follows: When \(q \leq p\), we can write \(q\) as a concatenation \(q(1)q(2)\cdots q(k)\) with each \(q(i)\) being a composition of the \(i\)-th entry of \(p\), and then we set \(k(q, p)\) to be the product \(l(q(1))l(q(2))\cdots l(q(k))\).

Let \(λ(p)\) denote the partition obtained from a composition \(p\) by sorting. This basis is called the idempotent basis since for any \(q\) such that \(λ(p) = λ(q)\), we have:

\[
I_p I_q = s(λ) I_p
\]

where \(λ\) denotes \(λ(p) = λ(q)\), and where \(s(λ)\) is the stabilizer of \(λ\) in \(S_n\). (This is part of Theorem 4.2 in [GR1989].)

It is also straightforward to compute the idempotents \(E_λ\) for the symmetric group algebra by the formula (Theorem 3.2 in [GR1989]):

\[
E_λ = \frac{1}{k!} \sum_{\lambda(p) = \lambda} I_p.
\]

**Note:** The basis elements are not orthogonal idempotents.

### EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: I = DA.I()
sage: list(I.basis())
[1, 1, 1, 1], I[1, 1, 2], I[1, 2, 1], I[1, 3], I[2, 1, 1], I[2, 2], I[3, 1], I[4]
```

**idempotent(\(la\))**

Return the idempotent corresponding to the partition \(la\) of \(n\).  

**EXAMPLES:**

```python
sage: I = DescentAlgebra(QQ, 4).I()
sage: E = I.idempotent([3,1])
sage: E
1/2*I[1, 1, 1] + 1/2*I[3, 1]
sage: E^2 == E
True
sage: E2 = I.idempotent([2,1,1])
sage: E2
1/6*I[1, 1, 2] + 1/6*I[1, 2, 1] + 1/6*I[2, 1, 1]
sage: E2^2 == E2
True
sage: E^2 == I.zero()
True
```
one()

Return the identity element, which is $B_{[n]}$, in the $I$ basis.

EXAMPLES:

```python
sage: DescentAlgebra(QQ, 4).I().one()
1/24*I[1, 1, 1, 1] + 1/6*I[1, 1, 2] + 1/6*I[1, 2, 1]
```

```python
sage: DescentAlgebra(QQ, 0).I().one()
I[]
```

one_basis()

The element 1 is not (generally) a basis vector in the $I$ basis, thus this returns a `TypeError`.

EXAMPLES:

```python
sage: DescentAlgebra(QQ, 4).I().one_basis()
Traceback (most recent call last):
...
TypeError: 1 is not a basis element in the I basis
```

product_on_basis(p, q)

Return $I_p I_q$, where $p$ and $q$ are compositions of $n$.

EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: I = DA.I()
sage: p = Composition([1,2,1])
sage: q = Composition([3,1])
sage: I.product_on_basis(p, q)
0
sage: I.product_on_basis(p, p)
2*I[1, 2, 1]
```

to_B_basis(p)

Return $I_p$ as a linear combination of $B$-basis elements.

This is computed using the formula (Theorem 3.3 in [GR1989])

$$I_p = \sum_{q \leq p} \frac{(-1)^{l(q) - l(p)}}{k(q, p)} B_q,$$

where $\leq$ is the refinement order and $l(r)$ denotes the number of parts of any composition $r$, and where $k(q, p)$ is defined as follows: When $q \leq p$, we can write $q$ as a concatenation $q_{(1)} q_{(2)} \cdots q_{(k)}$ with each $q_{(i)}$ being a composition of the $i$-th entry of $p$, and then we set $k(q, p)$ to be $l(q_{(1)}) l(q_{(2)}) \cdots l(q_{(k)})$.

EXAMPLES:

```python
sage: DA = DescentAlgebra(QQ, 4)
sage: B = DA.B()
sage: I = DA.I()
sage: list(map(B, I.basis()))
# indirect doctest
[B[1, 1, 1, 1],
-1/2*B[1, 1, 1, 1] + B[1, 1, 2],
(continues on next page)
```
-\frac{1}{2}\mathcal{B}[1, 1, 1, 1] + \mathcal{B}[1, 2, 1],
\frac{1}{3}\mathcal{B}[1, 1, 1, 1] - \frac{1}{2}\mathcal{B}[1, 1, 2] - \frac{1}{2}\mathcal{B}[1, 2, 1] + \mathcal{B}[1, 3],
-\frac{1}{2}\mathcal{B}[1, 1, 1, 1] + \mathcal{B}[2, 1, 1],
\frac{1}{4}\mathcal{B}[1, 1, 1, 1] - \frac{1}{2}\mathcal{B}[1, 1, 2] - \frac{1}{2}\mathcal{B}[2, 1, 1] + \mathcal{B}[2, 2],
\frac{1}{3}\mathcal{B}[1, 1, 1, 1] - \frac{1}{2}\mathcal{B}[1, 2, 1] - \frac{1}{2}\mathcal{B}[2, 1, 1] + \mathcal{B}[3, 1],
-\frac{1}{4}\mathcal{B}[1, 1, 1, 1] + \frac{1}{3}\mathcal{B}[1, 1, 2] + \frac{1}{3}\mathcal{B}[1, 2, 1]
- \frac{1}{2}\mathcal{B}[1, 3] + \frac{1}{3}\mathcal{B}[2, 1, 1] - \frac{1}{2}\mathcal{B}[2, 2]
- \frac{1}{2}\mathcal{B}[3, 1] + \mathcal{B}[4]]

\textbf{a_realization()}

Return a particular realization of \texttt{self} (the \(B\)-basis).

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: DA = DescentAlgebra(QQ, 4)
  sage: DA.a_realization()
Descent algebra of 4 over Rational Field in the subset basis
\end{verbatim}

\textbf{idempotent}

alias of \(I\)

\textbf{standard}

alias of \(D\)

\textbf{subset}

alias of \(B\)

\textbf{class} sage.combinat.descent_algebra.DescentAlgebraBases(base)

\textbf{Bases:} Category_realization_of_parent

The category of bases of a descent algebra.

\textbf{class} ElementMethods

\textbf{Bases:} object

\textbf{to_symmetric_group_algebra()}

Return self in the symmetric group algebra.

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: B = DescentAlgebra(QQ, 4).B()
  sage: B[1,3].to_symmetric_group_algebra()
  [1, 2, 3, 4] + [2, 1, 3, 4] + [3, 1, 2, 4] + [4, 1, 2, 3]
  sage: I = DescentAlgebra(QQ, 4).I()
  sage: elt = I(B[1,3])
  sage: elt.to_symmetric_group_algebra()
  [1, 2, 3, 4] + [2, 1, 3, 4] + [3, 1, 2, 4] + [4, 1, 2, 3]
\end{verbatim}

\textbf{class} ParentMethods

\textbf{Bases:} object

\textbf{is_commutative()}

Return whether this descent algebra is commutative.

\textbf{EXAMPLES:}
sage: B = DescentAlgebra(QQ, 4).B()
sage: B.is_commutative()
False
sage: B = DescentAlgebra(QQ, 1).B()
sage: B.is_commutative()
True

is_field(proof=True)
Return whether this descent algebra is a field.

EXAMPLES:

sage: B = DescentAlgebra(QQ, 4).B()
sage: B.is_field()
False
sage: B = DescentAlgebra(QQ, 1).B()
sage: B.is_field()
True

to_symmetric_group_algebra()
Morphism from self to the symmetric group algebra.

EXAMPLES:

sage: D = DescentAlgebra(QQ, 4).D()
sage: D.to_symmetric_group_algebra(D[1,3])
[2, 1, 4, 3] + [3, 1, 4, 2] + [3, 2, 4, 1] + [4, 1, 3, 2] + [4, 2, 3, 1]
sage: B = DescentAlgebra(QQ, 4).B()
sage: B.to_symmetric_group_algebra(B[1,2,1])
[1, 2, 3, 4] + [1, 2, 4, 3] + [1, 3, 4, 2] + [2, 1, 3, 4] + [2, 1, 4, 3] + [2, 3, 4, 1] + [3, 1, 2, 4] + [3, 1, 4, 2] + [3, 2, 4, 1] + [4, 1, 2, 3] + [4, 1, 3, 2] + [4, 2, 3, 1]

to_symmetric_group_algebra_on_basis(S)
Return the basis element index by S as a linear combination of basis elements in the symmetric group algebra.

EXAMPLES:

sage: B = DescentAlgebra(QQ, 3).B()
sage: [B.to_symmetric_group_algebra_on_basis(c) for c in Compositions(3)]
[[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1],
 [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1],
 [1, 2, 3] + [1, 3, 2] + [2, 1, 3],
 [1, 2, 3]]
sage: I = DescentAlgebra(QQ, 3).I()
sage: [I.to_symmetric_group_algebra_on_basis(c) for c in Compositions(3)]
[[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1],
 1/2*[1, 2, 3] - 1/2*[1, 3, 2] + 1/2*[2, 1, 3] - 1/2*[2, 3, 1] - 1/2*[3, 1, 2] - 1/2*[3, 2, 1],
 - 1/2*[2, 3, 1] + 1/2*[3, 1, 2] - 1/2*[3, 2, 1],

(continues on next page)
\begin{align*}
1/2^*[1, 2, 3] + 1/2^*[1, 3, 2] - 1/2^*[2, 1, 3] \\
+ 1/2^*[2, 3, 1] - 1/2^*[3, 1, 2] - 1/2^*[3, 2, 1], \\
1/3^*[1, 2, 3] - 1/6^*[1, 3, 2] - 1/6^*[2, 1, 3] \\
- 1/6^*[2, 3, 1] - 1/6^*[3, 1, 2] + 1/3^*[3, 2, 1]
\end{align*}

**super_categories()**

The super categories of `self`.

**EXAMPLES:**

```
sage: from sage.combinat.descent_algebra import DescentAlgebraBases
sage: DA = DescentAlgebra(QQ, 4)
sage: bases = DescentAlgebraBases(DA)
sage: bases.super_categories()
[Category of finite dimensional algebras with basis over Rational Field,
 Category of realizations of Descent algebra of 4 over Rational Field]
```

### 5.1.74 Combinatorial designs and incidence structures

All designs can be accessed by `designs.<tab>` and are listed in the design catalog:

- **Catalog of designs**

**Design-related classes**

- **Incidence structures (i.e. hypergraphs, i.e. set systems)**
- **Covering designs: coverings of \( t \)-element subsets of a \( v \)-set by \( k \)-sets**

**Constructions**

- **Block designs**
- **Balanced Incomplete Block Designs (BIBD)**
- **Resolvable Balanced Incomplete Block Design (RBIBD)**
- **Group-Divisible Designs (GDD)**
- **Mutually Orthogonal Latin Squares (MOLS)**
- **Orthogonal arrays (OA)**
- **Orthogonal arrays (build recursive constructions)**
- **Orthogonal arrays (find recursive constructions)**
- **Difference families**
- **Difference Matrices**
- **Steiner Quadruple Systems**
- **Two-graphs**
- **Database of small combinatorial designs**
- **Database of generalised quadrangles with spread**

**Technical things**

- **External Representations of Block Designs**
5.1.75 Balanced Incomplete Block Designs (BIBD)

This module gathers everything related to Balanced Incomplete Block Designs. One can build a BIBD (or check that it can be built) with `balanced_incomplete_block_design()`:

```
sage: BIBD = designs.balanced_incomplete_block_design(7,3,1)  # needs sage.schemes
```

In particular, Sage can build a \((v,k,1)\)-BIBD when one exists for all \(k \leq 5\). The following functions are available:

- `balanced_incomplete_block_design()`: Return a BIBD of parameters \(v,k,\lambda\).
- `BIBD_from_TD()`: Return a BIBD through TD-based constructions.
- `BIBD_from_difference_family()`: Return the BIBD associated to the difference family \(D\) on the group \(G\).
- `BIBD_from_PBD()`: Return a \((v,k,1)\)-BIBD from a \((r,K)\)-PBD where \(r = (v - 1)/(k - 1)\).
- `PBD_from_TD()`: Return a \((kt,\{k,t\})\)-PBD if \(u = 0\) and a \((kt + u,\{k,k+1,t,u\})\)-PBD otherwise.
- `steiner_triple_system()`: Return a Steiner Triple System.
- `v_5_1_BIBD()`: Return a \((v,5,1)\)-BIBD.
- `v_4_1_BIBD()`: Return a \((v,4,1)\)-BIBD.
- `PBD_4_5_8_9_12()`: Return a \((v,\{4,5,8,9,12\})\)-PBD on \(v\) elements.
- `BIBD_5q_5_for_q_prime_power(q)`: Return a \((5q,5,1)\)-BIBD with \(q \equiv 1 \pmod{4}\) a prime power.

Construction of BIBD when \(k = 4\)

Decompositions of \(K_v\) into \(K_4\) (i.e. \((v,4,1)\)-BIBD) are built following Douglas Stinson's construction as presented in [Stinson2004] page 167. It is based upon the construction of \((v,\{4,5,8,9,12\})\)-PBD (see the doc of `PBD_4_5_8_9_12()`, knowing that a \((v,\{4,5,8,9,12\})\)-PBD on \(v\) points can always be transformed into a \(((k - 1)v + 1,4,1)\)-BIBD, which covers all possible cases of \((v,4,1)\)-BIBD.

Construction of BIBD when \(k = 5\)

Decompositions of \(K_v\) into \(K_4\) (i.e. \((v,4,1)\)-BIBD) are built following Clayton Smith’s construction [ClaytonSmith].

Functions

- `sage.combinat.designs.bibd.BIBD()`: alias of `BalancedIncompleteBlockDesign`
- `sage.combinat.designs.bibd.BIBD_5q_5_for_q_prime_power(q)`: Return a \((5q,5,1)\)-BIBD with \(q \equiv 1 \pmod{4}\) a prime power.

See Theorem 24 [ClaytonSmith].

**INPUT:**
- \(q\) (integer) – a prime power such that \(q \equiv 1 \pmod{4}\).

**EXAMPLES:**
sage: from sage.combinat.designs.bibd import BIBD_5q_5_for_q_prime_power
sage: for q in [25, 45, 65, 85, 125, 145, 185, 205, 305, 405, 605]: # long time
  ....: _ = BIBD_5q_5_for_q_prime_power(q/5)

sage.combinat.designs.bibd.BIBD_from_PBD(PBD, v, k, check=True, base_cases=None)

Return a (v, k, 1)-BIBD from a (r, K)-PBD where \( r = \left(\frac{v-1}{k-1}\right) \).

This is Theorem 7.20 from [Stinson2004].

INPUT:

- v, k – integers.
- PBD – A PBD on \( r = \left(\frac{v-1}{k-1}\right) \) points, such that for any block of PBD of size \( s \) there must exist a \( ((k-1)s+1, k, 1) \)-BIBD.
- check (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- base_cases – caching system, for internal use.

EXAMPLES:

sage: from sage.combinat.designs.bibd import PBD_4_5_8_9_12
sage: from sage.combinat.designs.bibd import BIBD_from_PBD
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: PBD = PBD_4_5_8_9_12(17)  # needs sage.schemes
sage: bibd = is_pairwise_balanced_design(BIBD_from_PBD(PBD,52,4),52,[4])  # needs sage.schemes

sage.combinat.designs.bibd.BIBD_from_TD(v, k, existence=False)

Return a BIBD through TD-based constructions.

INPUT:

- v, k – (integers) computes a (v, k, 1)-BIBD.
- existence – (boolean) instead of building the design, return:
  - True – meaning that Sage knows how to build the design
  - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown)
  - False – meaning that the design does not exist

This method implements three constructions:

- If there exists a \( TD(k, v) \) and a \( (v, k, 1) \)-BIBD then there exists a \( (kv, k, 1) \)-BIBD.
  The BIBD is obtained from all blocks of the \( TD \), and from the blocks of the \( (v, k, 1) \)-BIBDs defined over the \( k \) groups of the \( TD \).
- If there exists a \( TD(k, v) \) and a \( (v+1, k, 1) \)-BIBD then there exists a \( (kv+1, k, 1) \)-BIBD.
  The BIBD is obtained from all blocks of the \( TD \), and from the blocks of the \( (v+1, k, 1) \)-BIBDs defined over the sets \( V_1 \cup \infty, \ldots, V_k \cup \infty \) where the \( V_1, \ldots, V_k \) are the groups of the TD.
- If there exists a \( TD(k, v) \) and a \( (v+k, k, 1) \)-BIBD then there exists a \( (kv+k, k, 1) \)-BIBD.
The BIBD is obtained from all blocks of the \( TD \), and from the blocks of the \((v + k, k, 1)\)-BIBDs defined over the sets \( V_1 \cup \{\infty_1, \ldots, \infty_k\}, \ldots, V_k \cup \{\infty_1, \ldots, \infty_k\} \) where the \( V_1, \ldots, V_k \) are the groups of the TD. By making sure that all copies of the \((v + k, k, 1)\)-BIBD contain the block \( \{\infty_1, \ldots, \infty_k\} \), the result is also a BIBD.

These constructions can be found in [http://www.argilo.net/files/bibd.pdf](http://www.argilo.net/files/bibd.pdf).

**EXAMPLES:**

First construction:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(25,5,existence=True)  # needs sage.schemes
True
sage: _ = BlockDesign(25,BIBD_from_TD(25,5))  # needs sage.schemes
```

Second construction:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(21,5,existence=True)  # needs sage.schemes
True
sage: _ = BlockDesign(21,BIBD_from_TD(21,5))  # needs sage.schemes
```

Third construction:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(85,5,existence=True)  # needs sage.schemes
True
sage: _ = BlockDesign(85,BIBD_from_TD(85,5))  # needs sage.schemes
```

No idea:

```python
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(20,5,existence=True)
Unknown
sage: BIBD_from_TD(20,5)
Traceback (most recent call last):
...
NotImplementedError: I do not know how to build a (20,5,1)-BIBD!
```

Return a \((n, k, 1)\)-BIBD from a maximal arc in a projective plane.

This function implements a construction from Denniston [Denniston69], who describes a maximal arc in a Desarguesian Projective Plane of order \( 2^k \). From two powers of two \( n, q \) with \( n < q \), it produces a \((n - 1)(q + 1) + 1, n, 1\)-BIBD.

**INPUT:**

- \( n, k \) (integers) – must be powers of two (among other restrictions).
• existence (boolean) – whether to return the BIBD obtained through this construction (default), or to merely indicate with a boolean return value whether this method can build the requested BIBD.

EXAMPLES:

A (232, 8, 1)-BIBD:

```
sage: from sage.combinat.designs.bibd import BIBD_from_arc_in_desarguesian_projective_plane
sage: D = BIBD_from_arc_in_desarguesian_projective_plane(232, 8)  # needs sage.libs.gap sage.modules sage.rings.finite_rings
sage: BalancedIncompleteBlockDesign(232, D)  # needs sage.libs.gap sage.modules sage.rings.finite_rings
(232, 8, 1)-Balanced Incomplete Block Design
```

A (120, 8, 1)-BIBD:

```
sage: D = BIBD_from_arc_in_desarguesian_projective_plane(120, 8)  # needs sage.libs.gap sage.modules sage.rings.finite_rings
sage: BalancedIncompleteBlockDesign(120, D)  # needs sage.libs.gap sage.modules sage.rings.finite_rings
(120, 8, 1)-Balanced Incomplete Block Design
```

Other parameters:

```
sage: all(BIBD_from_arc_in_desarguesian_projective_plane(n, k, existence=True) for n, k in [(120, 8), (232, 8), (456, 8), (904, 8), (496, 16), (976, 16), (1936, 16), (2016, 32), (4000, 32), (8128, 64)])
True
```

Of course, not all can be built this way:

```
sage: BIBD_from_arc_in_desarguesian_projective_plane(7, 3, existence=True)
False
sage: BIBD_from_arc_in_desarguesian_projective_plane(7, 3)
Traceback (most recent call last):
... ValorError: This function cannot produce a (7,3,1)-BIBD
```

REFERENCE:

sage.combinat.designs.bibd.BIBD_from_difference_family(G, D, lambda=None, check=True)

Return the BIBD associated to the difference family D on the group G.

Let G be a group. A \((G, k, \lambda)\)-difference family is a family \(B = \{B_1, B_2, \ldots, B_b\}\) of \(k\)-subsets of \(G\) such that for each element of \(G \setminus \{0\}\) there exists exactly \(\lambda\) pairs of elements \((x, y)\), \(x\) and \(y\) belonging to the same block, such that \(x - y = g\) (or \(x y^{-1} = g\)) in multiplicative notation).

If \(\{B_1, B_2, \ldots, B_b\}\) is a \((G, k, \lambda)\)-difference family then its set of translates \(\{B_i \cdot g; i \in \{1, \ldots, b\}, g \in G\}\) is a \((v, k, \lambda)\)-BIBD where \(v\) is the cardinality of \(G\).

INPUT:

• G - a finite additive Abelian group
• D - a difference family on G (short blocks are allowed).
Combinatorics, Release 10.1

• \( \lambda \) - the \( \lambda \) parameter (optional, only used if check is True)

• check - whether or not we check the output (default: True)

EXAMPLES:

```python
sage: G = Zmod(21)
sage: D = [[0,1,4,14,16]]
sage: sorted(G(x-y) for x in D[0] for y in D[0] if x != y)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]
sage: from sage.combinat.designs.bibd import BIBD_from_difference_family
sage: BIBD_from_difference_family(G, D)
[[0, 1, 4, 14, 16],
 [1, 2, 5, 15, 17],
 [2, 3, 6, 16, 18],
 [3, 4, 7, 17, 19],
 [4, 5, 8, 18, 20],
 [5, 6, 9, 19, 0],
 [6, 7, 10, 20, 1],
 [7, 8, 11, 0, 2],
 [8, 9, 12, 1, 3],
 [9, 10, 13, 2, 4],
 [10, 11, 14, 3, 5],
 [11, 12, 15, 4, 6],
 [12, 13, 16, 5, 7],
 [13, 14, 17, 6, 8],
 [14, 15, 18, 7, 9],
 [15, 16, 19, 8, 10],
 [16, 17, 20, 9, 11],
 [17, 18, 0, 10, 12],
 [18, 19, 1, 11, 13],
 [19, 20, 2, 12, 14],
 [20, 0, 3, 13, 15]]
```

```python
class sage.combinat.designs.bibd.BalancedIncompleteBlockDesign(points, blocks, k=None, lambd=1, check=True, copy=True, **kwds)

Bases: PairwiseBalancedDesign

Balanced Incomplete Block Design (BIBD)

INPUT:

• points – the underlying set. If points is an integer \( v \), then the set is considered to be \{0, \ldots, v - 1\}.

• blocks – collection of blocks

• \( k \) (integer) – size of the blocks. Set to None (automatic guess) by default.

• \( \lambda \) (integer) – value of \( \lambda \), set to 1 by default.

• check (boolean) – whether to check that the design is a \( PBD \) with the right parameters.

• copy – (use with caution) if set to False then blocks must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your blocks object will become the instance’s internal data.

EXAMPLES:
```
sage: b=designs.balanced_incomplete_block_design(9,3); b
(9,3,1)-Balanced Incomplete Block Design

arc(s, solver=2, verbose=None, integrality_tolerance=0)

Return the s-arc with maximum cardinality.

A s-arc is a subset of points in a BIBD that intersects each block on at most s points. It is one possible generalization of independent set for graphs.

A simple counting shows that the cardinality of a s-arc is at most \((s-1) \times r + 1\) where \(r\) is the number of blocks incident to any point. A s-arc in a BIBD with cardinality \((s-1) \times r + 1\) is called maximal and is characterized by the following property: it is not empty and each block either contains 0 or s points of this arc. Equivalently, the trace of the BIBD on these points is again a BIBD (with block size s).

For more informations, see Wikipedia article Arc_(projective_geometry).

INPUT:

- \(s\) - (default to 2) the maximum number of points from the arc in each block
- \(solver\) – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method solve of the class MixedIntegerLinearProgram.
- \(verbose\) – integer (default: 0). Sets the level of verbosity. Set to 0 by default, which means quiet.
- \(integrality_tolerance\) – parameter for use with MILP solvers over an inexact base ring; see MixedIntegerLinearProgram.get_values().

EXAMPLES:

sage: # needs sage.schemes
sage: B = designs.balanced_incomplete_block_design(21, 5)
sage: a2 = B.arc(); a2 # random
[5, 9, 10, 12, 15, 20]
sage: len(a2)
6
sage: a4 = B.arc(4); a4 # random
[0, 1, 2, 5, 6, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 20]
sage: len(a4)
16

The 2-arc and 4-arc above are maximal. One can check that they intersect the blocks in either 0 or s points. Or equivalently that the traces are again BIBD:

sage: r = (21-1)//(5-1)
sage: 1 + r^1
6
sage: 1 + r^3
16

sage: B.trace(a2).is_t_design(2, return_parameters=True) # needs sage.schemes
(True, (2, 6, 2, 1))
sage: B.trace(a4).is_t_design(2, return_parameters=True) # needs sage.schemes
(True, (2, 16, 4, 1))
Some other examples which are not maximal:

```python
sage: B = designs.balanced_incomplete_block_design(25, 4)
sage: a2 = B.arc(2)
sage: r = (25-1)//(4-1)
sage: len(a2), 1 + r
(8, 9)
sage: sa2 = set(a2)
sage: set(len(sa2.intersection(b)) for b in B.blocks())
{0, 1, 2}
sage: B.trace(a2).is_t_design(2)
False

sage: a3 = B.arc(3)
sage: len(a3), 1 + 2*r
(15, 17)
sage: sa3 = set(a3)
sage: set(len(sa3.intersection(b)) for b in B.blocks()) == set([0,3])
False

sage.combinat.designs.bibd.BruckRyserChowla_check(v, k, lambd)
Check whether the parameters passed satisfy the Bruck-Ryser-Chowla theorem.
For more information on the theorem, see the corresponding Wikipedia entry.

INPUT:
• v, k, lambd – integers; parameters to check

OUTPUT:
• True – the parameters satisfy the theorem
• False – the theorem fails for the given parameters
• Unknown – the preconditions of the theorem are not met

EXAMPLES:
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(22,7,2) False
Nonexistence of projective planes of order 6 and 14
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(43,7,1) # needs sage.schemes False sage: BruckRyserChowla_check(211,15,1) # needs sage.schemes False
Existence of symmetric BIBDs with parameters (79, 13, 2) and (56, 11, 2)
sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(79,13,2) True sage: BruckRyserChowla_check(56,11,2) True

sage.combinat.designs.bibd.PBD_4_5_8_9_12(v, check=True)
Return a \( (v, \{4,5,8,9,12\}) \)-PBD on \( v \) elements.
```
A \((v, \{4, 5, 8, 9, 12\})\)-PBD exists if and only if \(v \equiv 0, 1 \pmod{4}\). The construction implemented here appears page 168 in [Stinson2004].

**INPUT:**

- \(v\) – an integer congruent to 0 or 1 modulo 4.
- `check` (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.

**EXAMPLES:**

```python
sage: designs.balanced_incomplete_block_design(40,4).blocks()  # indirect doctest
[[0, 1, 2, 12], [0, 3, 6, 9], [0, 4, 8, 10],
 [0, 5, 7, 11], [0, 13, 26, 39], [0, 14, 25, 28],
 [0, 15, 27, 38], [0, 16, 22, 32], [0, 17, 23, 34],
...
```

Check that github issue #16476 is fixed:

```python
sage: from sage.combinat.designs.bibd import PBD_4_5_8_9_12
sage: for v in (0,1,4,5,8,9,12,13,16,17,20,21,24,25):
    # needs sage.schemes
    ...:_ = PBD_4_5_8_9_12(v)
```

`sage.combinat.designs.bibd.PBD_from_TD(k,t,u)`

Return a \((k_t, \{k, t\})\)-PBD if \(u = 0\) and a \((k_t+u, \{k, k+1, t, u\})\)-PBD otherwise.

This is theorem 23 from [ClaytonSmith]. The PBD is obtained from the blocks a truncated \(TD(k+1, t)\), to which are added the blocks corresponding to the groups of the TD. When \(u = 0\), a \(TD(k, t)\) is used instead.

**INPUT:**

- \(k, t, u\) – integers such that \(0 \leq u \leq t\).

**EXAMPLES:**

```python
sage: from sage.combinat.designs.bibd import PBD_from_TD
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: PBD = PBD_from_TD(2,2,1); PBD
[[0, 2, 4], [0, 3], [1, 2], [1, 3, 4], [0, 1], [2, 3]]
sage: is_pairwise_balanced_design(PBD,2*2+1,[2,3])
True
```

**class** `sage.combinat.designs.bibd.PairwiseBalancedDesign(points, blocks, K=None, lambda=1, check=True, copy=True, **kwds)`

**Bases:** `GroupDivisibleDesign`

Pairwise Balanced Design (PBD)

A Pairwise Balanced Design, or \((v, K, \lambda)\)-PBD, is a collection \(B\) of blocks defined on a set \(X\) of size \(v\), such that any block pair of points \(p_1, p_2 \in X\) occurs in exactly \(\lambda\) blocks of \(B\). Besides, for every block \(B \in B\) we must have \(|B| \in K\).

**INPUT:**

- `points` – the underlying set. If `points` is an integer \(v\), then the set is considered to be \(\{0, \ldots, v-1\}\).
- `blocks` – collection of blocks
• **K** – list of integers of which the sizes of the blocks must be elements. Set to `None` (automatic guess) by default.
• **lambd** (integer) – value of \( \lambda \), set to 1 by default.
• **check** (boolean) – whether to check that the design is a PBD with the right parameters.
• **copy** – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the instance’s internal data.

```
sage.combinat.designs.bibd.balanced_incomplete_block_design(v, k, lambd=1, existence=False, use_LJCR=False)
```

Return a BIBD of parameters \( v, k, \lambda \).

A Balanced Incomplete Block Design of parameters \( v, k, \lambda \) is a collection \( \mathcal{C} \) of \( k \)-subsets of \( V = \{0, \ldots, v-1\} \) such that for any two distinct elements \( x, y \in V \) there are \( \lambda \) elements \( S \in \mathcal{C} \) such that \( x, y \in S \). For more information on BIBD, see the corresponding Wikipedia entry.

**INPUT:**
• \( v, k, \lambda \) (integers)
• **existence** (boolean) – instead of building the design, return:
  – `True` – meaning that Sage knows how to build the design
  – `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
  – `False` – meaning that the design does not exist.
• **use_LJCR** (boolean) – whether to query the La Jolla Covering Repository for the design when Sage does not know how to build it (see `best_known_covering_design_www()`). This requires internet.

**See also:**
• `steiner_triple_system()`
• `v_4_1_BIBD()`
• `v_5_1_BIBD()`

**Todo:** Implement other constructions from the Handbook of Combinatorial Designs.

**EXAMPLES:**

```
sage: designs.balanced_incomplete_block_design(7, 3, 1).blocks() # needs sage.schemes
[[0, 1, 3], [0, 2, 4], [0, 5, 6], [1, 2, 6], [1, 4, 5], [2, 3, 5], [3, 4, 6]]
sage: B = designs.balanced_incomplete_block_design(66, 6, 1, use_LJCR=True) # optional ~
```

(continues on next page)
sage.combinat.designs.bibd.bipline(n, existence=False)

Return a biplane of order $n$.

A biplane of order $n$ is a symmetric $(1 + \frac{(n+1)(n+2)}{2}, n + 2, 2)$-BIBD. A symmetric (or square) $(v, k, \lambda)$-BIBD is a $(v, k, \lambda)$-BIBD with $v$ blocks.

INPUT:

- $n$ – (integer) order of the biplane
- $existence$ (boolean) – instead of building the design, return:
  - $True$ – meaning that Sage knows how to build the design
  - $Unknown$ – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown).
  - $False$ – meaning that the design does not exist.

See also:

- balanced_incomplete_block_design()

EXAMPLES:

- \texttt{sage: designs.bipline(4)}

$\rightarrow$ needs sage.rings.finite_rings

(16,6,2)-Balanced Incomplete Block Design

- \texttt{sage: designs.bipline(7, existence=True)}

$\rightarrow$ needs sage.schemes

True

- \texttt{sage: designs.bipline(11)}

$\rightarrow$ needs sage.schemes

(79,13,2)-Balanced Incomplete Block Design

sage.combinat.designs.bibd.steiner_triple_system(n)

Return a Steiner Triple System

A Steiner Triple System (STS) of a set $\{0, ..., n - 1\}$ is a family $S$ of 3-sets such that for any $i \neq j$ there exists exactly one set of $S$ in which they are both contained.

It can alternatively be thought of as a factorization of the complete graph $K_n$ with triangles.

A Steiner Triple System of a $n$-set exists if and only if $n \equiv 1 \pmod{6}$ or $n \equiv 3 \pmod{6}$, in which case one can be found through Bose’s and Skolem’s constructions, respectively [AndHonk97].

INPUT:

- $n$ return a Steiner Triple System of $\{0, ..., n - 1\}$

EXAMPLES:

A Steiner Triple System on 9 elements
Combinatorics, Release 10.1

```
sage: sts = designs.steiner_triple_system(9)
sage: sts
(9,3,1)-Balanced Incomplete Block Design
sage: list(sts)
[[0, 1, 5], [0, 2, 4], [0, 3, 6], [0, 7, 8], [1, 2, 3],
[1, 4, 7], [1, 6, 8], [2, 5, 8], [2, 6, 7], [3, 4, 8],
[3, 5, 7], [4, 5, 6]]
```

As any pair of vertices is covered once, its parameters are

```
sage: sts.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
```

An exception is raised for invalid values of $n$

```
sage: designs.steiner_triple_system(10)
Traceback (most recent call last):
...
EmptySetError: Steiner triple systems only exist for n = 1 mod 6 or n = 3 mod 6
```

REFERENCE:

sage.combinat.designs.bibd.v_4_1_BIBD($v$, check=True)

Return a $(v, 4, 1)$-BIBD.

A $(v, 4, 1)$-BIBD is an edge-decomposition of the complete graph $K_v$ into copies of $K_4$. For more information, see `balanced_incomplete_block_design()`. It exists if and only if $v \equiv 1, 4 \pmod{12}$.

See page 167 of [Stinson2004] for the construction details.

**See also:**

- `balanced_incomplete_block_design()`

**INPUT:**

- $v$ (integer) – number of points.
- check (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

**EXAMPLES:**

```
sage: from sage.combinat.designs.bibd import v_4_1_BIBD
sage: for n in range(13,100):
    if n%12 in [1,4]:
        _ = v_4_1_BIBD(n, check = True)
```

sage.combinat.designs.bibd.v_5_1_BIBD($v$, check=True)

Return a $(v, 5, 1)$-BIBD.

This method follows the construction from [ClaytonSmith].

**INPUT:**

- $v$ (integer)

**See also:**
• `balanced_incomplete_block_design()`

**EXAMPLES:**

```python
sage: from sage.combinat.designs.bibd import v_5_1_BIBD
sage: i = 0
sage: while i<200:
    needs sage.libs.pari
    i += 20
    _ = v_5_1_BIBD(i+1)
    _ = v_5_1_BIBD(i+5)
```

### 5.1.76 Resolvable Balanced Incomplete Block Design (RBIBD)

This module contains everything related to resolvable Balanced Incomplete Block Designs. The constructions implemented here can be obtained through the `designs.<tab>` object:

```python
designs.resolvable_balanced_incomplete_block_design(15,3)
```

For Balanced Incomplete Block Design (BIBD) see the module `bibd`. A BIBD is said to be *resolvable* if its blocks can be partitioned into parallel classes, i.e. partitions of its ground set.

The main function of this module is `resolvable_balanced_incomplete_block_design()`, which calls all others.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>resolvable_balanced_incomplete_block_design(v, k)</code></td>
<td>Return a resolvable BIBD of parameters <code>v</code>, <code>k</code>.</td>
</tr>
<tr>
<td><code>kirkman_triple_system(v)</code></td>
<td>Return a Kirkman Triple System on <code>v</code> points.</td>
</tr>
<tr>
<td><code>v_4_1_rbibd(v)</code></td>
<td>Return a <code>(v, 4, 1)</code>-RBIBD</td>

**Functions**

sage.combinat.designs.resolvable_bibd.PBD_4_7(v, check=True, existence=False)

Return a `(v, {4, 7})`-PBD

For all `v` such that `n ≡ 1 (mod 3)` and `n ≠ 10, 19, 31` there exists a `(v, {4, 7})`-PBD. This is proved in Proposition IX.4.5 from [BJL99], which this method implements.

This construction of PBD is used by the construction of Kirkman Triple Systems.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.resolvable_bibd import PBD_4_7
sage: PBD_4_7(22)
```

sage.combinat.designs.resolvable_bibd.PBD_4_7_from_Y(gdd, check=True)

Return a `(3v + 1, {4, 7})`-PBD from a `(v, {4, 5, 7}, N − {3, 6, 10})`-GDD.

This implements Lemma IX.3.11 from [BJL99] (p.625). All points of the GDD are tripled, and a `+∞` point is added to the design.
A group of size \( s \in Y = N - \{3, 6, 10\} \) becomes a set of size \( 3s \). Adding \( \infty \) to it gives it size \( 3s + 1 \), and this set is then replaced by a \((3s + 1, \{4, 7\})\)-PBD.

A block of size \( s \in \{4, 5, 7\} \) becomes a \((3s, \{4, 7\}, \{3\})\)-GDD.

This lemma is part of the existence proof of \( (v, \{4, 7\})\)-PBD as explained in IX.4.5 from [BJL99]).

**INPUT:**
- \( gdd \) – a \((v, \{4, 5, 7\}, Y)\)-GDD where \( Y = N - \{3, 6, 10\} \).
- \( \text{check} \) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.resolvable_bibd import PBD_4_7_from_Y
sage: PBD_4_7_from_Y(designs.transversal_design(7,8))
Pairwise Balanced Design on 169 points with sets of sizes in \([4, 7]\)
```

**Return a Kirkman Triple System on \( v \) points.**

A Kirkman Triple System \( KTS(v) \) is a resolvable Steiner Triple System. It exists if and only if \( v \equiv 3 \pmod{6} \).

**INPUT:**
- \( n \) (integer)
- \( \text{existence} \) (boolean; False by default) – whether to build the \( KTS(n) \) or only answer whether it exists.

**See also:**

`IncidenceStructure.is_resolvable()`

**EXAMPLES:**

A solution to Kirkman’s original problem:

```python
sage: kts = designs.kirkman_triple_system(15)
sage: classes = kts.is_resolvable(1)[1]
sage: names = '0123456789abcde'
sage: def to_name(r_s_t):
    ...:     return ' ' + names[r] + names[s] + names[t] + ' '

sage: rows = [' '.join((f'Day {i}'.format(i) for i in range(1,8)))]
sage: rows.extend(' '.join(map(to_name,row)) for row in zip(*classes))
sage: print('
'.join(rows))
Day 1 Day 2 Day 3 Day 4 Day 5 Day 6 Day 7
07e 18e 29e 3ae 4be 5ce 6de
139 24a 35b 46c 05d 167 028
26b 03c 14d 257 368 049 15a
458 569 06a 01b 12c 23d 347
acd 7bd 78c 89d 79a 8ab 9bc
```

**Return a resolvable BIBD of parameters \( v, k \).**
A BIBD is said to be *resolvable* if its blocks can be partitioned into parallel classes, i.e. partitions of the ground set.

**INPUT:**
- \(v, k\) (integers)
- `existence` (boolean) – instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
  - `False` – meaning that the design does not exist.

**See also:**
- `IncidenceStructure.is_resolvable()`
- `balanced_incomplete_block_design()`

**EXAMPLES:**

```python
sage: KTS15 = designs.resolvable_balanced_incomplete_block_design(15,3); KTS15
(15,3,1)-Balanced Incomplete Block Design
sage: KTS15.is_resolvable()
True
```

```python
sage.combinat.designs.resolvable_bibd.v_4_1_rbibd(v, existence=False)
```

Return a \((v, 4, 1)\)-RBIBD.

**INPUT:**
- \(n\) (integer)
- `existence` (boolean; `False` by default) – whether to build the design or only answer whether it exists.

**See also:**
- `IncidenceStructure.is_resolvable()`
- `resolvable_balanced_incomplete_block_design()`

**Note:** A resolvable \((v, 4, 1)\)-BIBD exists whenever \(1 \equiv 4 \pmod{12}\). This function, however, only implements a construction of \((v, 4, 1)\)-BIBD such that \(v = 3q + 1 \equiv 1 \pmod{3}\) where \(q\) is a prime power (see VII.7.5.a from [BJL99]).

**EXAMPLES:**

```python
sage: rBIBD = designs.resolvable_balanced_incomplete_block_design(28,4)
sage: rBIBD.is_resolvable()
True
sage: rBIBD.is_t_design(return_parameters=True)
(True, (2, 28, 4, 1))
```
5.1.77 Group-Divisible Designs (GDD)

This module gathers everything related to Group-Divisible Designs. The constructions defined here can be accessed through designs.<tab>:

```
sage: designs.group_divisible_design(14,{4},{2})
group divisible design on 14 points of type 2^7
```

The main function implemented here is `group_divisible_design()` (which calls all others) and the main class is `GroupDivisibleDesign`. The following functions are available:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>group_divisible_design()</code></td>
<td>Return a ((v, K, G))-Group Divisible Design.</td>
</tr>
<tr>
<td><code>GDD_4_2()</code></td>
<td>Return a ((2q, {4}, {2}))-GDD for (q) a prime power with (q \equiv 1 \pmod{6}).</td>
</tr>
</tbody>
</table>

**Functions**

```
sage.combinat.designs.group_divisible_designs.GDD_4_2(q, existence=False, check=True)
```

Return a \((2q, \{4\}, \{2\})\)-GDD for \(q\) a prime power with \(q \equiv 1 \pmod{6}\).

This method implements Lemma VII.5.17 from [BJL99] (p.495).

**INPUT:**

- \(q\) (integer)
- \(existence\) (boolean) – instead of building the design, return:
  - True – meaning that Sage knows how to build the design
  - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
  - False – meaning that the design does not exist.
- \(check\) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

**EXAMPLES:**

```
sage: from sage.combinat.designs.group_divisible_designs import GDD_4_2
sage: GDD_4_2(7,existence=True)
True
sage: GDD_4_2(7)
Group Divisible Design on 14 points of type 2^7
sage: GDD_4_2(8,existence=True)
Unknown
sage: GDD_4_2(8)
Traceback (most recent call last):
  ...NotImplementedError
```

**class**

```
sage.combinat.designs.group_divisible_designs.GroupDivisibleDesign(points, groups, blocks, G=None, K=None, lambd=1, check=True, copy=True, **kwds)
```

5.1. Comprehensive Module List
Bases: \texttt{IncidenceStructure}

Group Divisible Design (GDD)

Let $K$ and $G$ be sets of positive integers and let $\lambda$ be a positive integer. A Group Divisible Design of index $\lambda$ and order $v$ is a triple $(V, G, B)$ where:

- $V$ is a set of cardinality $v$
- $G$ is a partition of $V$ into groups whose size belongs to $G$
- $B$ is a family of subsets of $V$ whose size belongs to $K$ such that any two points $p_1, p_2 \in V$ from different groups appear simultaneously in exactly $\lambda$ elements of $B$. Besides, a group and a block intersect on at most one point.

If $K = \{k_1, ..., k_l\}$ and $G$ has exactly $m_i$ groups of cardinality $k_i$ then $G$ is said to have type $k_1^{m_1} \cdots k_l^{m_l}$.

INPUT:

- \texttt{points} – the underlying set. If \texttt{points} is an integer $v$, then the set is considered to be $\{0, ..., v - 1\}$.
- \texttt{groups} – the groups of the design. Set to \texttt{None} for an automatic guess (this triggers \texttt{check=True} and can thus cost some time).
- \texttt{blocks} – collection of blocks
- \texttt{G} – list of integers of which the sizes of the groups must be elements. Set to \texttt{None} (automatic guess) by default.
- \texttt{K} – list of integers of which the sizes of the blocks must be elements. Set to \texttt{None} (automatic guess) by default.
- \texttt{lambda} (integer) – value of $\lambda$, set to 1 by default.
- \texttt{check} (boolean) – whether to check that the design is indeed a $GDD$ with the right parameters. Set to \texttt{True} by default.
- \texttt{copy} – (use with caution) if set to \texttt{False} then \texttt{blocks} must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your \texttt{blocks} object will become the instance’s internal data.

EXAMPLES:

```python
sage: from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
sage: TD = designs.transversal_design(4,10)
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: GDD = GroupDivisibleDesign(groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
With unspecified groups:

```
sage: from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
sage: TD = designs.transversal_design(4,10)
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: GDD = GroupDivisibleDesign(40,groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
sage: GDD.groups()
[[0, 1, 2, 3, 4, 5, 6, 7, 8, 9],
 [10, 11, 12, 13, 14, 15, 16, 17, 18, 19],
 [20, 21, 22, 23, 24, 25, 26, 27, 28, 29],
 [30, 31, 32, 33, 34, 35, 36, 37, 38, 39]]

sage.combinat.designs.group_divisible_designs.group_divisible_design(v, K, G, existence=False, check=False)

Return a \((v, K, G)\)-Group Divisible Design.

A \((v, K, G)\)-GDD is a pair \(\mathcal{G}, \mathcal{B}\) where:
- \(\mathcal{G}\) is a partition of \(X = \bigcup \mathcal{G}\) where \(|X| = v\)
- \(\forall S \in \mathcal{G}, |S| \in G\)
- \(\forall S \in \mathcal{B}, |S| \in K\)
- \(\mathcal{G} \cup \mathcal{B}\) is a \((v, K \cup G)\)-PBD

For more information, see the documentation of GroupDivisibleDesign or PairwiseBalancedDesign.

INPUT:
- \(v\) (integer)
- \(K, G\) (sets of integers)
- \(existence\) (boolean) – instead of building the design, return:
  - True – meaning that Sage knows how to build the design
  - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown).
  - False – meaning that the design does not exist.
- \(check\) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

Note: The GDD returned by this function are defined on range(v), and its groups are sets of consecutive integers.

EXAMPLES:

sage: designs.group_divisible_design(14,{4},{2})
Group Divisible Design on 14 points of type 2^7
5.1.78 Block designs

A block design is a set together with a family of subsets (repeated subsets are allowed) whose members are chosen to satisfy some set of properties that are deemed useful for a particular application. See Wikipedia article Block_design.

REFERENCES:

• Block design from wikipedia: Wikipedia article Block_design

AUTHORS:

• Quentin Honoré (2015): construction of Hughes plane github issue #18527
• Vincent Delecroix (2014): rewrite the part on projective planes github issue #16281
• Peter Dobcsanyi and David Joyner (2007-2008)

This is a significantly modified form of the module block_design.py (version 0.6) written by Peter Dobcsanyi peter@designtheory.org. Thanks go to Robert Miller for lots of good design suggestions.

Todo: Implement more finite non-Desarguesian plane as in [We07] and Wikipedia article Non-Desarguesian_plane.

Functions and methods

sage.combinat.designs.block_design.AffineGeometryDesign(n, d, F, point_coordinates=True, check=True)

Return an affine geometry design.

The affine geometry design $AG_d(n, q)$ is the 2-design whose blocks are the $d$-vector subspaces in $F_q^n$. It has parameters

$$v = q^n, \quad k = q^d, \quad \lambda = \binom{n-1}{d-1}_q$$

where the $q$-binomial coefficient $\binom{m}{r}_q$ is defined by

$$\binom{m}{r}_q = \frac{(q^m - 1)(q^{m-1} - 1)\cdots(q^{m-r+1} - 1)}{(q^r - 1)(q^{r-1} - 1)\cdots(q - 1)}$$

See also:

ProjectiveGeometryDesign()

INPUT:

• n (integer) – the Euclidean dimension. The number of points of the design is $v = \left|F_q^n\right|$.
• d (integer) – the dimension of the (affine) subspaces of $F_q^n$ which make up the blocks.
• F – a finite field or a prime power.
• point_coordinates – (optional, default True) whether we use coordinates in $F_q^n$ or plain integers for the points of the design.
• check – (optional, default True) whether to check the output.

EXAMPLES:
sage: BD = designs.AffineGeometryDesign(3, 1, GF(2))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 8, 2, 1))

sage: BD = designs.AffineGeometryDesign(3, 2, GF(4))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))

sage: BD = designs.AffineGeometryDesign(4, 2, GF(3))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 81, 9, 13))

With $F$ an integer instead of a finite field:

sage: BD = designs.AffineGeometryDesign(3, 2, 4)
sage: BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))

Testing the option `point_coordinates`:

sage: designs.AffineGeometryDesign(3, 1, GF(2),
                                 point_coordinates=True).blocks()[0]
[(0, 0, 0), (0, 0, 1)]

sage: designs.AffineGeometryDesign(3, 1, GF(2),
                                 point_coordinates=False).blocks()[0]
[0, 1]

`sage.combinat.designs.block_design.CremonaRichmondConfiguration()`

Return the Cremona-Richmond configuration.

The Cremona-Richmond configuration is a set system whose incidence graph is equal to the `TutteCoxeterGraph()`. It is a generalized quadrangle of parameters $(2, 2)$.

For more information, see the Wikipedia article Cremona-Richmond_configuration.

EXAMPLES:

```sage
sage: H = designs.CremonaRichmondConfiguration(); H
Incidence structure with 15 points and 15 blocks
sage: g = graphs.TutteCoxeterGraph()
sage: H.incidence_graph().is_isomorphic(g)
True
```

`sage.combinat.designs.block_design.DesarguesianProjectivePlaneDesign(n, point_coordinates=True, check=True)`

Return the Desarguesian projective plane of order $n$ as a 2-design.

The Desarguesian projective plane of order $n$ can also be defined as the projective plane over a field of order $n$. For more information, have a look at Wikipedia article Projective_plane.

INPUT:

- $n$ – an integer which must be a power of a prime number
• point_coordinates – (boolean) whether to label the points with their homogeneous coordinates (default) or with integers.

• check – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

See also:

ProjectiveGeometryDesign()

EXAMPLES:

```
sage: designs.DesarguesianProjectivePlaneDesign(2)
(7,3,1)-Balanced Incomplete Block Design
sage: designs.DesarguesianProjectivePlaneDesign(3)
(13,4,1)-Balanced Incomplete Block Design
sage: designs.DesarguesianProjectivePlaneDesign(4)
(21,5,1)-Balanced Incomplete Block Design
sage: designs.DesarguesianProjectivePlaneDesign(5)
(31,6,1)-Balanced Incomplete Block Design
sage: designs.DesarguesianProjectivePlaneDesign(6)
Traceback (most recent call last):
... ValueError: the order of a finite field must be a prime power
```

sage.combinat.designs.block_design.Hadamard3Design(n)

Return the Hadamard 3-design with parameters $3 - (n, \frac{n}{2}, \frac{n}{4} - 1)$.

This is the unique extension of the Hadamard 2-design (see HadamardDesign()). We implement the description from pp. 12 in [CvL].

INPUT:

• n (integer) – a multiple of 4 such that $n > 4$.

EXAMPLES:

```
sage: designs.Hadamard3Design(12)
Incidence structure with 12 points and 22 blocks
```

We verify that any two blocks of the Hadamard 3-design $3 - (8, 4, 1)$ design meet in 0 or 2 points. More generally, it is true that any two blocks of a Hadamard 3-design meet in 0 or $\frac{n}{4}$ points (for $n > 4$).

```
sage: D = designs.Hadamard3Design(8)
```

```
sage: N = D.incidence_matrix()
sage: N.transpose()*N
[4 2 2 2 2 2 2 2 2 2 2 2 2 0]
[2 4 2 2 2 2 2 2 2 2 2 2 0 2]
[2 2 4 2 2 2 2 2 2 2 2 0 2 2]
[2 2 2 4 2 2 2 2 2 0 2 2 2 2]
[2 2 2 2 4 2 2 2 0 2 2 2 2 2]
```
REFERENCES:
sage.combinat.designs.block_design.HadamardDesign(n)
As described in Section 1, p. 10, in [CvL]. The input n must have the property that there is a Hadamard matrix of order $n + 1$ (and that a construction of that Hadamard matrix has been implemented...).

EXAMPLES:

```python
sage: designs.HadamardDesign(7)
# needs sage.modules
Incidence structure with 7 points and 7 blocks
sage: print(designs.HadamardDesign(7))
# needs sage.modules
Incidence structure with 7 points and 7 blocks
```

For example, the Hadamard 2-design with $n = 11$ is a design whose parameters are $2 - (11, 5, 2)$. We verify that $NJ = 5J$ for this design.

```python
sage: D = designs.HadamardDesign(11); N = D.incidence_matrix()
# needs sage.modules
sage: J = matrix(ZZ, 11, 11, [1]*11*11); N*J
# needs sage.modules
```

REFERENCES:

We define a twisted multiplication on $K$ as

$$x \circ y = \begin{cases} xy & \text{if } y \text{ is a square in } K \\ x^q y & \text{otherwise} \end{cases}$$

The points of the Hughes plane are the triples $(x, y, z)$ of points in $K^3 \setminus \{0, 0, 0\}$ up to the equivalence relation $(x, y, z) \sim (x \circ k, y \circ k, z \circ k)$ where $k \in K$.

For $a = 1$ or $a \in (K \setminus F)$ we define a block $L(a)$ as the set of triples $(x, y, z)$ so that $x + a \circ y + z = 0$. The rest of the blocks are obtained by letting act the group $GL(3, F)$ by its standard action.

For more information, see Wikipedia article Hughes plane and [We07].

See also:

DesarguesianProjectivePlaneDesign() to build the Desarguesian projective planes

INPUT:

- $q2$ – an even power of an odd prime number
- check – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

EXAMPLES:

```sage
H = designs.HughesPlane(9); H
(91,10,1)-Balanced Incomplete Block Design
```

We prove in the following computations that the Desarguesian plane $H$ is not Desarguesian. Let us consider the two triangles $(0, 1, 10)$ and $(57, 70, 59)$. We show that the intersection points $D_{0,1} \cap D_{57,70}$, $D_{1,10} \cap D_{70,59}$ and $D_{10,0} \cap D_{59,57}$ are on the same line while $D_{0,70}$, $D_{1,59}$ and $D_{10,57}$ are not concurrent:

```sage
blocks = H.blocks()
line = lambda p,q: next(b for b in blocks if p in b and q in b)

b_0_1 = line(0, 1)
b_1_10 = line(1, 10)
b_10_0 = line(10, 0)
b_57_70 = line(57, 70)
b_70_59 = line(70, 59)
b_59_57 = line(59, 57)

set(b_0_1).intersection(b_57_70)
{2}
set(b_1_10).intersection(b_70_59)
{73}
set(b_10_0).intersection(b_59_57)
{60}
line(2, 73) == line(73, 60)
True

b_0_57 = line(0, 57)
b_1_70 = line(1, 70)
b_10_59 = line(10, 59)
```
sage: p = set(b_0_57).intersection(b_1_70)
sage: q = set(b_1_70).intersection(b_10_59)
sage: p == q
False

sage.combinat.designs.block_design.ProjectiveGeometryDesign(n, d, F, algorithm=None, point_coordinates=True, check=True)

Return a projective geometry design.

The projective geometry design $\mathcal{P}_G^d(n, q)$ has for points the lines of $\mathbb{F}_q^{n+1}$, and for blocks the $(d + 1)$-dimensional subspaces of $\mathbb{F}_q^{n+1}$, each of which contains $\frac{[\mathbb{F}_q^{d+1} - 1]}{\left|\mathbb{F}_q\right|^1 - 1}$ lines. It is a 2-design with parameters

$$v = \binom{n + 1}{1}_q, \quad k = \binom{d + 1}{1}_q, \quad \lambda = \binom{n - 1}{d - 1}_q$$

where the $q$-binomial coefficient $\binom{m}{r}_q$ is defined by

$$\binom{m}{r}_q = \frac{(q^m - 1)(q^{m-1} - 1)\cdots(q^{m-r+1} - 1)}{(q^r - 1)(q^{r-1} - 1)\cdots(q - 1)}$$

See also:

AffineGeometryDesign()

INPUT:

- n – the projective dimension
- d – the dimension of the subspaces which make up the blocks.
- F – a finite field or a prime power.
- algorithm – set to None by default, which results in using Sage’s own implementation. In order to use GAP’s implementation instead (i.e. its PGPointFlatBlockDesign function) set algorithm="gap". Note that GAP’s “design” package must be available in this case, and that it can be installed with the gap_packages spkg.
- point_coordinates – True by default. Ignored and assumed to be False if algorithm="gap". If True, the ground set is indexed by coordinates in $\mathbb{F}_q^{n+1}$. Otherwise the ground set is indexed by integers.
- check – (optional, default to True) whether to check the output.

EXAMPLES:

The set of $d$-dimensional subspaces in a $n$-dimensional projective space forms 2-designs (or balanced incomplete block designs):

```
sage: PG = designs.ProjectiveGeometryDesign(4, 2, GF(2)); PG
Incidence structure with 31 points and 155 blocks
sage: PG.is_t_design(return_parameters=True)
(True, (2, 31, 7, 7))
sage: PG = designs.ProjectiveGeometryDesign(3, 1, GF(4))
sage: PG.is_t_design(return_parameters=True)
(True, (2, 85, 5, 1))
```

Check with $\mathbb{F}$ being a prime power.
Combinatorics, Release 10.1

sage: PG = designs.ProjectiveGeometryDesign(3, 2, 4); PG
Incidence structure with 85 points and 85 blocks

Use coordinates:

sage: PG = designs.ProjectiveGeometryDesign(2, 1, GF(3))
sage: PG.blocks()[0]
[(1, 0, 0), (1, 0, 1), (1, 0, 2), (0, 0, 1)]

Use indexing by integers:

sage: PG = designs.ProjectiveGeometryDesign(2, 1, GF(3), point_coordinates=0)
sage: PG.blocks()[0]
[0, 1, 2, 12]

Check that the constructor using gap also works:

sage: BD = designs.ProjectiveGeometryDesign(2, 1, GF(2), algorithm="gap")  # optional - gap_package_design
sage: BD.is_t_design(return_parameters=True)  # optional - gap_package_design
(True, (2, 7, 3, 1))

sage.combinat.designs.block_design.WittDesign(n)

INPUT:

• n is in 9, 10, 11, 12, 21, 22, 23, 24.

Wraps GAP Design’s WittDesign. If n=24 then this function returns the large Witt design \(W_{24}\), the unique (up to isomorphism) 5-(24,8,1) design. If n=12 then this function returns the small Witt design \(W_{12}\), the unique (up to isomorphism) 5-(12,6,1) design. The other values of n return a block design derived from these.

Note: Requires GAP’s Design package (included in the gap_packages Sage spkg).

EXAMPLES:

sage: BD = designs.WittDesign(9)  # optional - gap_package_design
sage: BD.is_t_design(return_parameters=True)  # optional - gap_package_design
(True, (2, 9, 3, 1))
sage: BD
Incidence structure with 9 points and 12 blocks
sage: print(BD)  # optional - gap_package_design
Incidence structure with 9 points and 12 blocks

sage.combinat.designs.block_design.are_hyperplanes_in_projective_geometry_parameters(v, k, lmbda, return_parameters=False)

Return True if the parameters \((v,k,lmbda)\) are the one of hyperplanes in a (finite Desarguesian) projective space.

In other words, test whether there exists a prime power q and an integer d greater than two such that:

• \(v = (q^{d+1} - 1)/(q - 1) = q^d + q^{d-1} + ... + 1\)
Combinatorics, Release 10.1

• $k = (q^d - 1)/(q - 1) = q^{d-1} + q^{d-2} + ... + 1$

• $lmbda = (q^{d-1} - 1)/(q - 1) = q^{d-2} + q^{d-3} + ... + 1$

If it exists, such a pair $(q, d)$ is unique.

**INPUT:**

• $v, k, lmbda$ (integers)

**OUTPUT:**

• a boolean or, if return_parameters is set to True a pair (True, $(q, d)$) or (False, $(None, None)$).

**EXAMPLES:**

```
sage: from sage.combinat.designs.block_design import are_hyperplanes_in_projective_˓
geometry_parameters
sage: are_hyperplanes_in_projective_geometry_parameters(40, 13, 4)
True
sage: are_hyperplanes_in_projective_geometry_parameters(40, 13, 4, ˓
return_parameters=True)
(True, (3, 3))

sage: PG = designs.ProjectiveGeometryDesign(3, 2, GF(3))

sage: PG.is_t_design(return_parameters=True)
(True, (2, 40, 13, 4))

sage: are_hyperplanes_in_projective_geometry_parameters(15, 3, 1)
False
sage: are_hyperplanes_in_projective_geometry_parameters(15, 3, 1, ˓
return_parameters=True)
(False, (None, None))
```

sage.combinat.designs.block_design.normalize_hughes_plane_point($p$, $q$)

Return the normalized form of point $p$ as a 3-tuple.

In the Hughes projective plane over the finite field $K$, all triples $(x_k, y_k, z_k)$ with $k \in K$ represent the same point (where the multiplication is over the nearfield built from $K$). This function chooses a canonical representative among them.

This function is used in HughesPlane().

**INPUT:**

• $p$ – point with the coordinates $(x, y, z)$ (a list, a vector, a tuple...)

• $q$ – cardinality of the underlying finite field

**EXAMPLES:**

```
sage: from sage.combinat.designs.block_design import normalize_hughes_plane_point
sage: K = FiniteField(9,'x')
sage: x = K.gen()
sage: normalize_hughes_plane_point((x, x + 1, x), 9)
(1, x, 1)
sage: normalize_hughes_plane_point(vector((x,x,x)), 9)
(1, 1, 1)
sage: zero = K.zero()
sage: normalize_hughes_plane_point((2*x + 2, zero, zero), 9)
(1, 0, 0)
```
sage: one = K.one()
sage: normalize_hughes_plane_point((2*x, one, zero), 9)
(2*x, 1, 0)

sage.combinat.designs.block_design.projective_plane(n, check=True, existence=False)

Return a projective plane of order \( n \) as a 2-design.

A finite projective plane is a 2-design with \( n^2 + n + 1 \) lines (or blocks) and \( n^2 + n + 1 \) points. For more information on finite projective planes, see the Wikipedia article Projective_plane#Finite_projective_planes.

If no construction is possible, then the function raises a \texttt{EmptySetError}, whereas if no construction is available, the function raises a \texttt{NotImplementedError}.

\textbf{INPUT:}

- \( n \) – the finite projective plane’s order

\textbf{EXAMPLES:}

\begin{verbatim}
sage: designs.projective_plane(2)
(7,3,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(3)
(13,4,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(4)
(21,5,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(5)
(31,6,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(6)
Traceback (most recent call last):
  ... 
EmptySetError: By the Bruck-Ryser theorem, no projective plane of order 6 exists.
sage: designs.projective_plane(10)
Traceback (most recent call last):
  ... 
sage: designs.projective_plane(12)
Traceback (most recent call last):
  ... 
NotImplementedError: If such a projective plane exists, we do not know how to build it.
sage: designs.projective_plane(14)
Traceback (most recent call last):
  ... 
EmptySetError: By the Bruck-Ryser theorem, no projective plane of order 14 exists.
\end{verbatim}

sage.combinat.designs.block_design.projective_plane_to_OA(pplane, pt=None, check=True)

Return the orthogonal array built from the projective plane \( pplane \).

The orthogonal array \( OA(n+1, n, 2) \) is obtained from the projective plane \( pplane \) by removing the point \( pt \) and the \( n+1 \) lines that pass through it. These \( n+1 \) lines form the \( n+1 \) groups while the remaining \( n^2+n \) lines form the transversals.

\textbf{INPUT:}
• **pplane** – a projective plane as a 2-design
• **pt** – a point in the projective plane **pplane**. If it is not provided, then it is set to $n^2 + n$.
• **check** – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

**EXAMPLES:**

```python
def q3_minus_one_matrix(K):
    return K.q3_minus_one_matrix()
def tdesign_params(t, v, k, L):
    return (t, v, b, r, k, L)
sage: from sage.combinat.designs.block_design import projective_plane_to_OA
sage: p2 = designs.DesarguesianProjectivePlaneDesign(2, point_coordinates=False)
sage: projective_plane_to_OA(p2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]
sage: p3 = designs.DesarguesianProjectivePlaneDesign(3, point_coordinates=False)
sage: projective_plane_to_OA(p3)
[[0, 0, 0, 0],
 [0, 1, 2, 1],
 [0, 2, 1, 2],
 [1, 0, 2, 2],
 [1, 1, 1, 0],
 [1, 2, 0, 1],
 [2, 0, 1, 1],
 [2, 1, 0, 2],
 [2, 2, 2, 0]]
sage: pp = designs.DesarguesianProjectivePlaneDesign(16, point_coordinates=False)
sage: _ = projective_plane_to_OA(pp, pt=0)
sage: _ = projective_plane_to_OA(pp, pt=3)
sage: _ = projective_plane_to_OA(pp, pt=7)
```

```python
def q3_minus_one_matrix(K):
    return K.q3_minus_one_matrix()
def tdesign_params(t, v, k, L):
    return (t, v, b, r, k, L)
sage: from sage.combinat.designs.block_design import q3_minus_one_matrix
sage: m = q3_minus_one_matrix(GF(3))
sage: m.multiplicative_order() == 3**3 - 1
True
sage: m = q3_minus_one_matrix(GF(4, 'a'))
sage: m.multiplicative_order() == 4**3 - 1
True
sage: m = q3_minus_one_matrix(GF(5))
sage: m.multiplicative_order() == 5**3 - 1
True
sage: m = q3_minus_one_matrix(GF(9, 'a'))
sage: m.multiplicative_order() == 9**3 - 1
True
```

```python
def q3_minus_one_matrix(K):
    return K.q3_minus_one_matrix()
def tdesign_params(t, v, k, L):
    return (t, v, b, r, k, L)
sage: from sage.combinat.designs.block_design import q3_minus_one_matrix
sage: m = q3_minus_one_matrix(GF(3))
sage: m.multiplicative_order() == 3**3 - 1
True
sage: m = q3_minus_one_matrix(GF(4, 'a'))
sage: m.multiplicative_order() == 4**3 - 1
True
sage: m = q3_minus_one_matrix(GF(5))
sage: m.multiplicative_order() == 5**3 - 1
True
sage: m = q3_minus_one_matrix(GF(9, 'a'))
sage: m.multiplicative_order() == 9**3 - 1
True
```
EXAMPLES:

```python
sage: BD = BlockDesign(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: from sage.combinat.designs.block_design import tdesign_params
sage: tdesign_params(2,7,3,1)
(2, 7, 7, 3, 3, 1)
```

5.1.79 Covering designs: coverings of \( t \)-element subsets of a \( v \)-set by \( k \)-sets

A \((v, k, t)\) covering design \( C \) is an incidence structure consisting of a set of points \( P \) of order \( v \), and a set of blocks \( B \), where each block contains \( k \) points of \( P \). Every \( t \)-element subset of \( P \) must be contained in at least one block.

If every \( t \)-set is contained in exactly one block of \( C \), then we have a block design. Following the block design implementation, the standard representation of a covering design uses \( P = [0, 1, ..., v - 1] \).

In addition to the parameters and incidence structure for a covering design from this database, we include extra information:

- Best known lower bound on the size of a \((v, k, t)\)-covering design
- Name of the person(s) who produced the design
- Method of construction used
- Date when the design was added to the database

REFERENCES:

AUTHORS:

- Daniel M. Gordon (2008-12-22): initial version

Classes and methods

```python
class sage.combinat.designs.covering_design.CoveringDesign(v=0, k=0, t=0, size=0, points=None, blocks=None, low_bd=0, method='', creator='', timestamp=''):
    pass
```

Bases: `SageObject`

Covering design.

INPUT:

- \( v, k, t \) – integer parameters of the covering design
- \( size \) (integer)
- \( points \) – list of points (default points are \([0, ..., v - 1]\))
- \( blocks \)
- \( low_bd \) (integer) – lower bound for such a design
- \( method, creator, timestamp \) – database information

```python
def creator():
    return ''
```

Return the creator of the covering design

This field is optional, and is used in a database to give attribution for the covering design. It can refer to the person who submitted it, or who originally gave a construction.

EXAMPLES:
Combinatorics, Release 10.1

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
......:    [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6],
......:    [2, 4, 5]], 0, 'Projective Plane', 'Gino Fano')
sage: C.creator()
'Gino Fano'
```

**incidence_structure()**

Return the incidence structure of this design, without extra parameters.

**EXAMPLES:**

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
......:    [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
......:    [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: D = C.incidence_structure()
sage: D.ground_set()
[0, 1, 2, 3, 4, 5, 6]
sage: D.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
  [2, 3, 6], [2, 4, 5]]
```

**is_covering()**

Check all \(t\)-sets are in fact covered by the blocks of \(self\).

**Note:** This is very slow and wasteful of memory.

**EXAMPLES:**

```
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
......:    [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
......:    [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.is_covering()
True
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
......:    [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6],
......:    [2, 4, 6]], 0, 'not a covering')  # last block altered
sage: C.is_covering()
False
```

**k()**

Return \(k\), the size of blocks of the covering design.

**EXAMPLES:**

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
......:    [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6],
......:    [2, 4, 5]], 0, 'Projective Plane')
sage: C.k()
3
```
low_bd()

Return a lower bound for the number of blocks a covering design with these parameters could have.

Typically this is the Schonheim bound, but for some parameters better bounds have been shown.

EXAMPLES:

```python
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2], ....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], ....: [2, 3, 6], [2, 4, 5]], [], 'Projective Plane')
sage: C.low_bd()
7
```

method()

Return the method used to create the covering design.

This field is optional, and is used in a database to give information about how coverings were constructed.

EXAMPLES:

```python
c sage: from sage.combinat.designs.covering_design import CoveringDesign
c sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2], ....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], ....: [2, 3, 6], [2, 4, 5]], [], 'Projective Plane')
c sage: C.method()
'Projective Plane'
```

size()

Return the number of blocks in the covering design

EXAMPLES:

```python
c sage: from sage.combinat.designs.covering_design import CoveringDesign
c sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2], ....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], ....: [2, 3, 6], [2, 4, 5]], [], 'Projective Plane')
c sage: C.size()
7
```

t()

Return $t$, the size of sets which must be covered by the blocks of the covering design

EXAMPLES:

```python
c sage: from sage.combinat.designs.covering_design import CoveringDesign
c sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2], ....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], ....: [2, 3, 6], [2, 4, 5]], [], 'Projective Plane')
c sage: C.t()
2
```

timestamp()

Return the time that the covering was submitted to the database

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), 
[0, 1, 2], ....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], ....: [2, 3, 6], [2, 4, 5], 0, 'Projective Plane', ....: 'Gino Fano', '1892-01-01 00:00:00')
sage: C.timestamp()  # No exact date known; in Fano's 1892 article '1892-01-01 00:00:00'
```

**v()**

Return $v$, the number of points in the covering design.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), 
[0, 1, 2], ....: [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], ....: [2, 3, 6], [2, 4, 5], 0, 'Projective Plane')
sage: C.v()
7
```

`sage.combinat.designs.covering_design.best_known_covering_design_www(v, k, t, verbose=False)`

Return the best known $(v, k, t)$ covering design from an online database.

This uses the La Jolla Covering Repository, a database available at [https://ljcr.dmgordon.org/cover.html](https://ljcr.dmgordon.org/cover.html)

**INPUT:**

- $v$ – integer, the size of the point set for the design
- $k$ – integer, the number of points per block
- $t$ – integer, the size of sets covered by the blocks
- `verbose` – bool (default: False), print verbose message

**OUTPUT:**

A `CoveringDesign` object representing the $(v, k, t)$-covering design with smallest number of blocks available in the database.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.covering_design import (  # optional - internet ....: best_known_covering_design_www)
sage: C = best_known_covering_design_www(7, 3, 2)  # optional - internet
sage: print(C)  # optional - internet
C(7, 3, 2) = 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
  0 1 2
  0 3 4
  0 5 6
  1 3 5
  1 4 6
  2 3 6
  2 4 5
```

A `ValueError` is raised if the $(v, k, t)$ parameters are not found in the database.
sage.combinat.designs.covering_design.schonheim(v, k, t)

Return the Schonheim lower bound for the size of such a covering design.

INPUT:

• v – integer, size of point set
• k – integer, cardinality of each block
• t – integer, cardinality of sets being covered

OUTPUT:

The Schonheim lower bound for such a covering design’s size: \(C(v, k, t) \leq \lceil \frac{v}{k} \lceil \frac{v-1}{k-1} \cdots \lceil \frac{v-t+1}{k-t+1} \rceil \cdots \rceil \rceil \rceil \)

EXAMPLES:

```python
sage: from sage.combinat.designs.covering_design import schonheim
sage: schonheim(10, 3, 2)
17
sage: schonheim(32, 16, 8)
930
```

sage.combinat.designs.covering_design.trivial_covering_design(v, k, t)

Construct a trivial covering design.

INPUT:

• v – integer, size of point set
• k – integer, cardinality of each block
• t – integer, cardinality of sets being covered

OUTPUT:

A trivial \((v, k, t)\) covering design

EXAMPLES:

```python
sage: C = trivial_covering_design(8, 3, 1)
sage: print(C)
C(8, 3, 1) = 3
Method: Trivial
0  1  2
0  6  7
3  4  5
sage: C = trivial_covering_design(5, 3, 2)
sage: print(C)
4 <= C(5, 3, 2) <= 10
Method: Trivial
0  1  2
0  1  3
0  1  4
0  2  3
0  2  4
0  3  4
1  2  3
1  2  4
1  3  4
2  3  4
```
These functions can all be obtained through the Handbook of Combinatorial Designs [DesignHandbook].

This module implements combinatorial designs that cannot be obtained by more general constructions. Most of them come from the Handbook of Combinatorial Designs [DesignHandbook].

All this would only be a dream without the mathematical knowledge and help of Julian R. Abel.

These functions can all be obtained through the designs.<tab> functions.

---

**5.1.80 Database of small combinatorial designs**

This module implements combinatorial designs that cannot be obtained by more general constructions. Most of them come from the Handbook of Combinatorial Designs [DesignHandbook].

Note: Cases are:

- $t = 0$: This could be empty, but it’s a useful convention to have one block (which is empty if $k = 0$).
- $t = 1$: This contains $[v/k]$ blocks: $[0, \ldots, k - 1], [k, \ldots, 2k - 1], \ldots$. The last block wraps around if $k$ does not divide $v$.
- anything else: Just use every $k$-subset of $[0, 1, \ldots, v - 1]$. 
\[ \lambda = 1:n \ (66, 6, 1), \ (76, 6, 1), \ (96, 6, 1), \ (106, 6, 1), \ (116, 6, 1), \ (120, 8, 1), \ (126, 6, 1), \ (136, 6, 1), \ (141, 6, 1), \ (171, 6, 1), \ (196, 6, 1), \ (201, 6, 1) \]
\[ \lambda = 2:n \ (56, 11, 2), \ (79, 13, 2) \]
\[ \lambda = 8:n \ (45, 9, 8) \]
\[ \lambda = 14:n \ (176, 50, 14) \]

• \((v, k, \lambda)\)-difference families:

\[ \lambda = 1:n \ (15, 3, 1), \ (21, 3, 1), \ (25, 3, 1), \ (25, 4, 1), \ (27, 3, 1), \ (33, 3, 1), \ (37, 4, 1), \ (39, 3, 1), \ (40, 4, 1), \ (45, 3, 1), \ (45, 5, 1), \ (49, 3, 1), \ (49, 4, 1), \ (51, 3, 1), \ (52, 4, 1), \ (55, 3, 1), \ (57, 3, 1), \ (63, 3, 1), \ (64, 4, 1), \ (65, 5, 1), \ (69, 3, 1), \ (75, 3, 1), \ (76, 4, 1), \ (81, 3, 1), \ (81, 5, 1), \ (85, 4, 1), \ (91, 6, 1), \ (91, 7, 1), \ (121, 5, 1), \ (121, 6, 1), \ (141, 5, 1), \ (161, 5, 1), \ (175, 7, 1), \ (201, 5, 1), \ (217, 7, 1), \ (221, 5, 1), \ (259, 7, 1) \]

- $k = 10$: 1171, 1531, 1621, 1801

REFERENCES:

Functions

sage.combinat.designs.database.BIBD_106_6_1()
Return a $(106,6,1)$-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_106_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(106, BIBD_106_6_1())
(106,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_111_6_1()
Return a $(111,6,1)$-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_111_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(111, BIBD_111_6_1())
(111,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_126_6_1()
Return a $(126,6,1)$-BIBD.

This constructions appears in VI.16.92 from [DesignHandbook].

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_126_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(126, BIBD_126_6_1())
(126,6,1)-Balanced Incomplete Block Design
```
sage.combinat.designs.database.BIBD_136_6_1()
Return a (136,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_136_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(136, BIBD_136_6_1())
(136,6,1)-Balanced Incomplete Block Design

sage.combinat.designs.database.BIBD_141_6_1()
Return a (141,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_141_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(141, BIBD_141_6_1())
(141,6,1)-Balanced Incomplete Block Design

sage.combinat.designs.database.BIBD_171_6_1()
Return a (171,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_171_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(171, BIBD_171_6_1())
(171,6,1)-Balanced Incomplete Block Design

sage.combinat.designs.database.BIBD_196_6_1()
Return a (196,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_196_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(196, BIBD_196_6_1())
(196,6,1)-Balanced Incomplete Block Design

sage.combinat.designs.database.BIBD_201_6_1()
Return a (201,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:
sage: from sage.combinat.designs.database import BIBD_201_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(201, BIBD_201_6_1())
(201,6,1)-Balanced Incomplete Block Design
sage.combinat.designs.database.BIBD_45_9_8(from_code=False)

Return a (45, 9, 1)-BIBD.

This BIBD is obtained from the codewords of minimal weight in the ExtendedQuadraticResidueCode() of length 48. This construction appears in VII.11.2 from [DesignHandbook], which cites [HT95].

INPUT:

• from_code (boolean) – whether to build the design from hardcoded data (default) or from the code object (much longer).

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_45_9_8
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: B = BalancedIncompleteBlockDesign(45, BIBD_45_9_8(), lambda=8); B
(45,9,8)-Balanced Incomplete Block Design
```

REFERENCE:

sage.combinat.designs.database.BIBD_56_11_2()

Return a symmetric (56, 11, 2)-BIBD.

The construction implemented is given in [Hall71].

**Note:** A symmetric \((v, k, \lambda)\) BIBD is a \((v, k, \lambda)\) BIBD with \(v\) blocks.

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_56_11_2
sage: D = IncidenceStructure(BIBD_56_11_2()) # needs sage.libs.gap
sage: D.is_t_design(t=2, v=56, k=11, l=2) # needs sage.libs.gap
True
```

sage.combinat.designs.database.BIBD_66_6_1()

Return a (66,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://math.ccrwest.org/cover.html) where it is attributed to Colin Barker.

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_66_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(66, BIBD_66_6_1())
(66,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.BIBD_76_6_1()

Return a (76,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://math.ccrwest.org/cover.html) where it is attributed to Colin Barker.

EXAMPLES:

```python
sage: from sage.combinat.designs.database import BIBD_76_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(76, BIBD_76_6_1())
(76,6,1)-Balanced Incomplete Block Design
```
Combinatorics, Release 10.1

sage.combinat.designs.database.BIBD_79_13_2()
Return a symmetric (79, 13, 2)-BIBD.

The construction implemented is the one described in [Aschbacher71]. A typo in that paper was corrected in [Hall71].

**Note:** A symmetric \((v, k, \lambda)\) BIBD is a \((v, k, \lambda)\) BIBD with \(v\) blocks.

**EXAMPLES:**

sage: from sage.combinat.designs.database import BIBD_79_13_2 sage: D = IncidenceStructure(BIBD_79_13_2()) # needs sage.libs.gap sage: D.is_t_design(t=2, v=79, k=13, l=2) # needs sage.libs.gap True

sage.combinat.designs.database.BIBD_96_6_1()
Return a (96, 6, 1)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://math.ccrwest.org/cover.html) where it is attributed to Colin Barker.

**EXAMPLES:**

sage: from sage.combinat.designs.database import BIBD_96_6_1 sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign sage: BalancedIncompleteBlockDesign(96, BIBD_96_6_1()) (96, 6, 1)-Balanced Incomplete Block Design

sage.combinat.designs.database.DM_12_6_1()
Return a \((12, 6, 1)\)-difference matrix as built in [Hanani75].

This design is Lemma 3.21 from [Hanani75].

**EXAMPLES:**

sage: from sage.combinat.designs.designs_pyx import is_difference_matrix sage: from sage.combinat.designs.database import DM_12_6_1 sage: G, M = DM_12_6_1() sage: is_difference_matrix(M, G, 6, 1) True

Can be obtained from the constructor:

sage: _ = designs.difference_matrix(12, 6)

**REFERENCES:**

sage.combinat.designs.database.DM_21_6_1()
Return a \((21, 6, 1)\)-difference matrix.

As explained in the Handbook III.3.50 [DesignHandbook].

**EXAMPLES:**

sage: from sage.combinat.designs.designs_pyx import is_difference_matrix sage: from sage.combinat.designs.database import DM_21_6_1 sage: G, M = DM_21_6_1() sage: is_difference_matrix(M, G, 6, 1) True
Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(21,6)  
# needs sage.rings.finite_rings
```

`sage.combinat.designs.database.DM_24_8_1()`  
Return a (24, 8, 1)-difference matrix.  
As explained in the Handbook III.3.52 [DesignHandbook].  
EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix  
sage: from sage.combinat.designs.database import DM_24_8_1  
sage: G, M = DM_24_8_1()  
sage: is_difference_matrix(M, G, 8, 1)  
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(24,8)
```

`sage.combinat.designs.database.DM_273_17_1()`  
Return a (273, 17, 1)-difference matrix.  
Given by Julian R. Abel.  
EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix  
sage: from sage.combinat.designs.database import DM_273_17_1  
sage: G, M = DM_273_17_1()  
# needs sage.schemes  
sage: is_difference_matrix(M, G, 17, 1)  
# needs sage.schemes  
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(273,17)  
# needs sage.schemes
```

`sage.combinat.designs.database.DM_28_6_1()`  
Return a (28, 6, 1)-difference matrix.  
As explained in the Handbook III.3.54 [DesignHandbook].  
EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix  
sage: from sage.combinat.designs.database import DM_28_6_1  
sage: G, M = DM_28_6_1()  
# needs sage.modules  
sage: is_difference_matrix(M, G, 6, 1)  
# needs sage.modules  
True
```

Can be obtained from the constructor:
Combinatorics, Release 10.1

```python
sage: _ = designs.difference_matrix(28,6)  # needs sage.modules
```

```
return sage.combinat.designs.database.DM_33_6_1()

Return a (33, 6, 1)-difference matrix.

As explained in the Handbook III.3.56 [DesignHandbook].

EXAMPLES:
```
```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_33_6_1
sage: G,M = DM_33_6_1()
sage: is_difference_matrix(M,G,6,1)
```
```
True
```
```
Can be obtained from the constructor:
```
```python
sage: _ = designs.difference_matrix(33,6)  # needs sage.rings.finite_rings
```

```
return sage.combinat.designs.database.DM_35_6_1()

Return a (35, 6, 1)-difference matrix.

As explained in the Handbook III.3.58 [DesignHandbook].

EXAMPLES:
```
```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_35_6_1
sage: G,M = DM_35_6_1()
sage: is_difference_matrix(M,G,6,1)
```
```
True
```
```
Can be obtained from the constructor:
```
```python
sage: _ = designs.difference_matrix(35,6)  # needs sage.rings.finite_rings
```

```
return sage.combinat.designs.database.DM_36_9_1()

Return a (36, 9, 1)-difference matrix.

As explained in the Handbook III.3.59 [DesignHandbook].

EXAMPLES:
```
```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_36_9_1
sage: G,M = DM_36_9_1()  # needs sage.modules
sage: is_difference_matrix(M,G,9,1)  # needs sage.modules
```
```
True
```
```
Can be obtained from the constructor:
```
sage: _ = designs.difference_matrix(36,9)  
\[\text{needs sage.modules}\]

sage.combinat.designs.database.DM_39_6_1()
Return a $(39, 6, 1)$-difference matrix.
As explained in the Handbook III.3.61 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_39_6_1
sage: G,M = DM_39_6_1()
\[
\text{needs sage.rings.finite_rings}\]
sage: is_difference_matrix(M,G,6,1)
True
```

The design is available from the general constructor:

```
sage: designs.difference_matrix(39,6,existence=True)
\[\text{needs sage.rings.finite_rings}\]
True
```

sage.combinat.designs.database.DM_44_6_1()
Return a $(44, 6, 1)$-difference matrix.
As explained in the Handbook III.3.64 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_44_6_1
sage: G,M = DM_44_6_1()
\[
\text{needs sage.rings.finite_rings}\]
sage: is_difference_matrix(M,G,6,1)
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(44,6)
```

sage.combinat.designs.database.DM_45_7_1()
Return a $(45, 7, 1)$-difference matrix.
As explained in the Handbook III.3.65 [DesignHandbook].
... whose description contained a very deadly typo, kindly fixed by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_45_7_1
sage: G,M = DM_45_7_1()
\[
\text{needs sage.rings.finite_rings}\]
sage: is_difference_matrix(M,G,7,1)
True
```

Can be obtained from the constructor:
Combinatorics, Release 10.1

```python
sage: _ = designs.difference_matrix(45,7)  # needs sage.rings.finite_rings
```

`sage.combinat.designs.database.DM_48_9_1()`

Return a (48, 9, 1)-difference matrix.

As explained in the Handbook III.3.67 [DesignHandbook].

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
g, M = DM_48_9_1()  # needs sage.rings.finite_rings
sage: is_difference_matrix(M, g, 9, 1)  # needs sage.rings.finite_rings
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(48,9)  # needs sage.rings.finite_rings
```

`sage.combinat.designs.database.DM_51_6_1()`

Return a (51, 6, 1)-difference matrix.

As explained in the Handbook III.3.69 [DesignHandbook].

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
g, M = DM_51_6_1()  # needs sage.rings.finite_rings
sage: is_difference_matrix(M, g, 6, 1)  # needs sage.rings.finite_rings
True
```

Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(51,6)  # needs sage.rings.finite_rings
```

`sage.combinat.designs.database.DM_52_6_1()`

Return a (52, 6, 1)-difference matrix.

As explained in the Handbook III.3.70 [DesignHandbook].

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
g, M = DM_52_6_1()  # needs sage.rings.finite_rings
sage: is_difference_matrix(M, g, 6, 1)  # needs sage.rings.finite_rings
True
```

Can be obtained from the constructor:
sage: _ = designs.difference_matrix(52,6)  # needs sage.rings.finite_rings

sage.combinat.designs.database.DM_55_7_1()
Return a (55, 7, 1)-difference matrix.
As explained in the Handbook III.3.72 [DesignHandbook].
EXAMPLES:

```sage
from sage.combinat.designs.designs_pyx import is_difference_matrix
g,M = DM_55_7_1()
is_difference_matrix(M, g, 7, 1)
True
```

Can be obtained from the constructor:

```sage
from sage.combinat.designs.designs_pyx import is_difference_matrix
g,M = DM_55_7_1()
is_difference_matrix(M, g, 7, 1)
True
```

sage.combinat.designs.database.DM_56_8_1()
Return a (56, 8, 1)-difference matrix.
As explained in the Handbook III.3.73 [DesignHandbook].
EXAMPLES:

```sage
from sage.combinat.designs.designs_pyx import is_difference_matrix
g,M = DM_56_8_1()
is_difference_matrix(M, g, 8, 1)
True
```

Can be obtained from the constructor:

```sage
from sage.combinat.designs.designs_pyx import is_difference_matrix
g,M = DM_56_8_1()
is_difference_matrix(M, g, 8, 1)
True
```

sage.combinat.designs.database.DM_57_8_1()
Return a (57, 8, 1)-difference matrix.
Given by Julian R. Abel.
EXAMPLES:

```sage
from sage.combinat.designs.designs_pyx import is_difference_matrix
g,M = DM_57_8_1()
is_difference_matrix(M, g, 8, 1)
True
```

Can be obtained from the constructor:
sage: _ = designs.difference_matrix(57,8)  # needs sage.rings.finite_rings

sage.combinat.designs.database.DM_60_6_1()
Return a (60, 6, 1)-difference matrix.
As explained in [JulianAbel13].
REFERENCES:
EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_60_6_1
sage: G, M = DM_60_6_1()
sage: is_difference_matrix(M, G, 6, 1)
True
```
Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(60, 6)
```

sage.combinat.designs.database.DM_75_8_1()
Return a (75, 8, 1)-difference matrix.
As explained in the Handbook III.3.75 [DesignHandbook].
EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_75_8_1
sage: G, M = DM_75_8_1()
sage: is_difference_matrix(M, G, 8, 1)
True
```
Can be obtained from the constructor:

```python
sage: _ = designs.difference_matrix(75, 8)
```

sage.combinat.designs.database.DM_993_32_1()
Return a (993, 32, 1)-difference matrix.
Given by Julian R. Abel.
EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_993_32_1
sage: G, M = DM_993_32_1()  # needs sage.schemes
sage: is_difference_matrix(M, G, 32, 1)  # needs sage.schemes
True
```
Can be obtained from the constructor:
sage.combinat.designs.database.HigmanSimsDesign()

Return the Higman-Sims designs, which is a (176, 50, 14)-BIBD.

This design is built from a from the WittDesign $W$ on 24 points. We define two points $a, b$, and consider:

- The collection $W_a$ of all blocks of $W$ containing $a$ but not containing $b$.
- The collection $W_b$ of all blocks of $W$ containing $b$ but not containing $a$.

The design is then obtained from the incidence structure produced by the blocks $A \in W_a$ and $B \in W_b$ whose intersection has cardinality 2. This construction, due to M.Smith, can be found in [KY04] or in 10.A.(v) of [BL1984].

EXAMPLES:

```sage
sage: H = designs.HigmanSimsDesign(); H
Incidence structure with 176 points and 176 blocks
sage: H.is_t_design(return_parameters=1)
(True, (2, 176, 50, 14))
```

Make sure that the automorphism group of this design is isomorphic to the automorphism group of the HigmanSimsGraph(). Note that the first of those permutation groups acts on 176 points, while the second acts on 100:

```sage
sage: gH = H.automorphism_group()  # optional - gap_
sage: gG = graphs.HigmanSimsGraph().automorphism_group()  # optional - gap_
sage: gG.is_isomorphic(gG)  # long time, optional - gap_
True
```

REFERENCE:

sage.combinat.designs.database.MOLS_10_2()

Return a pair of MOLS of order 10

EXAMPLES:

```sage
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_10_2
sage: MOLS = MOLS_10_2()  # needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))  # needs sage.modules
True
```

The design is available from the general constructor:
sage: designs.orthogonal_arrays.is_available(2,10)
True

sage.combinat.designs.database.MOLS_12_5()
Return 5 MOLS of order 12
These MOLS have been found by Brendan McKay.
EXAMPLES:

sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_12_5
sage: MOLS = MOLS_12_5()
# needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True

sage.combinat.designs.database.MOLS_14_4()
Return four MOLS of order 14
These MOLS were shared by Ian Wanless. The first proof of existence was given in [Todorov12].
EXAMPLES:

sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_14_4
sage: MOLS = MOLS_14_4()
# needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
# needs sage.modules
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(4,14)
# needs sage.schemes
True

REFERENCE:
sage.combinat.designs.database.MOLS_15_4()
Return 4 MOLS of order 15.
These MOLS were shared by Ian Wanless.
EXAMPLES:

sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: from sage.combinat.designs.database import MOLS_15_4
sage: MOLS = MOLS_15_4()
# needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))
# (continues on next page)
The design is available from the general constructor:

```sage
designs.orthogonal_arrays.is_available(4,15) # needs sage.schemes
True
```

`sage.combinat.designs.database.MOLS_18_3()`

Return 3 MOLS of order 18.

These MOLS were shared by Ian Wanless.

**EXAMPLES:**

```sage
from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
from sage.combinat.designs.database import MOLS_18_3
MOLS = MOLS_18_3() # needs sage.modules
print(are_mutually_orthogonal_latin_squares(MOLS)) # needs sage.modules
True
```

The design is available from the general constructor:

```sage
designs.orthogonal_arrays.is_available(3,18)
```

`sage.combinat.designs.database.OA_10_1620()`

Returns an OA(10,1620)

This is obtained through the generalized Brouwer-van Rees construction. Indeed, 1620 = 144.11 + (36 = 4.9) and there exists an $OA(10,153) - OA(10,9)$.

**Note:** This function should be removed once `find_brouwer_van_rees_with_one_truncated_column()` can handle all incomplete orthogonal arrays obtained through `incomplete_orthogonal_array()`.

**EXAMPLES:**

```sage
from sage.combinat.designs.designs_pyx import is_orthogonal_array
from sage.combinat.designs.database import OA_10_1620
OA = OA_10_1620() # not tested -- ~7s
is_orthogonal_array(OA,10,1620,2) # not tested -- ~7s
True
```

The design is available from the general constructor:

```sage
designs.orthogonal_arrays.is_available(10,1620) # needs sage.schemes
True
```
sage.combinat.designs.database.OA_10_205()

Return an OA(10, 205).

Julian R. Abel shared the following construction, which originally appeared in Theorem 8.7 of [Greig99], and can in Lemmas 5.14-5.16 of [ColDin01]:

Consider a PG(2, 4^2) containing a Baer subplane (i.e. a PG(2, 4)) B and a point \( p \in B \). Among the \( 4^2 + 1 = 17 \) lines of PG(2, 4^2) containing \( p \):

- \( 4 + 1 = 5 \) lines intersect \( B \) on 5 points
- \( 4^2 - 4 = 12 \) lines intersect \( B \) on 1 point

As those lines are disjoint outside of \( B \) we can use them as groups to build a GDD on \( 16^2 + 16 + 1 - (4^4 + 4 + 1) = 252 \) points. By keeping only 9 lines of the second kind, however, we obtain a \( (204, \{9, 13, 17\}) \)-GDD of type 12^5.16^9.

We complete it into a PBD by adding a block \( g \cup \{204\} \) for each group \( g \). We then build an OA from this PBD using the fact that all blocks of size 9 are disjoint.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_205
sage: OA = OA_10_205()  # needs sage.schemes
sage: is_orthogonal_array(OA, 10, 205)  # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(10, 205)  # needs sage.schemes
True
```

sage.combinat.designs.database.OA_10_469()

Return an OA(10, 469)

This construction appears in [Brouwer80]. It is based on the same technique used in brouwer_separable_design().

Julian R. Abel’s instructions:

Brouwer notes that a cyclic PG(2, 37) (or (1407, 38, 1)-BIBD) can be obtained with a base block containing 13, 9, and 16 points in each residue class mod 3. Thus, by reducing the PG(2, 37) to its points congruent to 0 (mod 3) one obtains a (469, \{9, 13, 16\})-PBD which consists in 3 symmetric designs, i.e. 469 blocks of size 9, 469 blocks of size 13, and 469 blocks of size 16.

For each block size \( s \), one can build a matrix with size \( s \times 469 \) in which each block is a row, and such that each point of the PBD appears once per column. By multiplying a row of an OA(9, s) – \( s. OA(9, 1) \) with the rows of the matrix one obtains a parallel class of a resolvable OA(9, 469).

Add to this the parallel class of all blocks \( (0, 0, \ldots), (1, 1, \ldots), \ldots \) to obtain a resolvable OA(9, 469) equivalent to an OA(10, 469).

EXAMPLES:
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_469
sage: OA = OA_10_469()  # long time
# needs sage.schemes
sage: is_orthogonal_array(OA,10,469,2)  # long time
# needs sage.schemes
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(10,469)  # needs sage.schemes
True

sage.combinat.designs.database.OA_10_520()
Return an OA(10,520).

This design is built by the slightly more general construction OA_520_plus_x().

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_520
sage: OA = OA_10_520()  # needs sage.schemes
sage: is_orthogonal_array(OA,10,520,2)  # needs sage.schemes
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(10,520)  # needs sage.schemes
True

sage.combinat.designs.database.OA_10_796()
Returns an OA(10,796)

Construction shared by Julian R. Abel, from [AC07]:

Truncate one block of a $TD(17,47)$ to size 13, then add an extra point. Form a block on each group
plus the extra point: we obtain a $(796,\{13,16,17,47,48\})$-PBD in which only the extra point lies in
more than one block of size 48 (and each other point lies in exactly 1 such block).

For each block $B$ (of size $k$ say) not containing the extra point, construct a $TD(10,k) - k.TD(k,1)$ on
$I(10)XB$. For each block $B$ (of size $k = 47$ or 48) containing the extra point, construct a $TD(10,k) -
TD(k,1)$ on $I(10)XB$, the size 1 hole being on $I(10)XP$ where $P$ is the extra point. Finally form
1 extra block of size 10 on $I(10)XP$.

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_796
sage: OA = OA_10_796()  # needs sage.schemes
sage: is_orthogonal_array(OA,10,796,2)  # needs sage.schemes
True

(continues on next page)
The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10,796)  # needs sage.schemes
True
```

`sage.combinat.designs.database.OA_11_160()`

Returns an OA(11,160)

Published by Julian R. Abel in [Ab1995]. Uses the fact that $160 = 2^5 \times 5$ is a product of a power of 2 and a prime number.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_160
sage: OA = OA_11_160()  # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,11,160,2)  # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11,160)  # needs sage.schemes
True
```

`sage.combinat.designs.database.OA_11_185()`

Returns an OA(11,185)

The construction is given in [Greig99]. In Julian R. Abel’s words:

Start with a $PG(2,16)$ with a 7 points Fano subplane; outside this plane there are $7(17 - 3) = 98$ points on a line of the subplane and $273 - 98 - 7 = 168$ other points. Greig notes that the subdesign consisting of these 168 points is a $(168,\{10,12\}) - PBD$. Now add the 17 points of a line disjoint from this subdesign (e.g. a line of the Fano subplane). This line will intersect every line of the 168 point subdesign in 1 point. Thus the new line sizes are 11 and 13, plus a unique line of size 17, giving a $(185,\{11,13,17\})$-PBD and an $OA(11,185)$.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_185
sage: OA = OA_11_185()  # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,11,185,2)  # needs sage.rings.finite_rings
True
```
The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(11,185)  # needs sage.schemes
True
```

sage.combinat.designs.database.OA_11_254()

Return an OA(11,254)

This constructions appears in [Greig99].

From a cyclic $PG(2,19)$ whose base blocks contains 7,9, and 4 points in the congruence classes mod 3, build a $(254,11,13,16) - PBD$ by ignoring the points of a congruence class. There exist $OA(12,11), OA(12,13), OA(12,16)$, which gives the $OA(11,254)$.

See also:

```python
sage.combinat.designs.orthogonal_arrays.OA_from_PBD()
```

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_254
sage: OA = OA_11_254()  # needs sage.schemes
sage: is_orthogonal_array(OA,11,254,2)  # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(11,254)  # needs sage.schemes
True
```

sage.combinat.designs.database.OA_11_640()

Returns an OA(11,640)

Published by Julian R. Abel in [Abel95] (uses the fact that 640 = $2^7 \times 5$ is the product of a power of 2 and a prime number).

See also:

```python
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()
```

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_640
sage: OA = OA_11_640()  # not tested (too long)  # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,11,640,2)  # not tested (too long)  # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:
sage: designs.orthogonal_arrays.is_available(11,640) #→ needs sage.schemes
True

sage.combinat.designs.database.OA_11_80()
Return an OA(11,80)
As explained in the Handbook III.3.76 [DesignHandbook]. Uses the fact that 80 = 2^4 \times 5 and that 5 is prime.
See also:
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_80
sage: OA = OA_11_80()
```

```python
sage: is_orthogonal_array(OA,11,80,2)
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(11,80) #→ needs sage.rings.finite_rings sage.schemes
True
```

sage.combinat.designs.database.OA_12_522()
Return an OA(12,522)
This design is built by the slightly more general construction OA_520_plus_x().

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_12_522
sage: OA = OA_12_522()
```

```python
sage: is_orthogonal_array(OA,12,522,2)
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(12,522) #→ needs sage.rings.finite_rings sage.schemes
True
```

sage.combinat.designs.database.OA_14_524()
Return an OA(14,524)
This design is built by the slightly more general construction OA_520_plus_x().

EXAMPLES:
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_14_524
sage: OA = OA_14_524()
    # needs sage.schemes
sage: is_orthogonal_array(OA,14,524,2)
    # needs sage.schemes
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(14,524)
    # needs sage.schemes
True

sage.combinat.designs.database.OA_15_112()
Returns an OA(15,112)
Published by Julian R. Abel in [Ab1995]. Uses the fact that 112 = 2^4 × 7 and that 7 is prime.

See also:
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_112
sage: OA = OA_15_112()
    # not tested (too long)
    # needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA,15,112,2)
    # not tested (too long)
    # needs sage.rings.finite_rings sage.schemes
True

The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(15,112)
    # needs sage.rings.finite_rings sage.schemes
True

sage.combinat.designs.database.OA_15_224()
Returns an OA(15,224)
Published by Julian R. Abel in [Ab1995] (uses the fact that 224 = 2^5 × 7 is a product of a power of 2 and a prime number).

See also:
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_224
sage: OA = OA_15_224()
    # not tested (too long)
    # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,15,224,2)
    # not tested (too long)
    # needs sage.rings.finite_rings
True

(continues on next page)
needs sage.rings.finite_rings
True

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(15,224) #@
needs sage.schemes
True
```

sage.combinat.designs.database.OA_15_896()

Returns an OA(15,896)

Uses the fact that 896 = 2^7 × 7 is the product of a power of 2 and a prime number.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_896
sage: OA = OA_15_896() # not tested (too long, ~2min) #@
needs sage.rings.finite_rings
```

```python
sage: is_orthogonal_array(OA,15,896,2) # not tested (too long) #@
needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(15,896) #@
needs sage.schemes
True
```

sage.combinat.designs.database.OA_16_176()

Returns an OA(16,176)

Published by Julian R. Abel in [Ab1995]. Uses the fact that 176 = 2^4 × 11 is a product of a power of 2 and a prime number.

See also:

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_16_176
sage: OA = OA_16_176() # not tested (too long, ~2min) #@
needs sage.rings.finite_rings
```

```python
sage: is_orthogonal_array(OA,16,176,2) # not tested (too long) #@
needs sage.rings.finite_rings
True
```

The design is available from the general constructor:
sage: designs.orthogonal_arrays.is_available(16,176)  # needs sage.schemes
True

sage.combinat.designs.database.OA_16_208()
Returns an OA(16,208)
Published by Julian R. Abel in [Ab1995]. Uses the fact that 208 = 2^4 × 13 is a product of 2 and a prime number.
See also:
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_16_208
sage: OA = OA_16_208()  # not tested (too long)  # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,16,208,2)  # not tested (too long)  # needs sage.rings.finite_rings
True
The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(16,208)  # needs sage.schemes
True

sage.combinat.designs.database.OA_17_560()
Returns an OA(17,560)
This OA is built in Corollary 2.2 of [Thwarts].

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_17_560
sage: OA = OA_17_560()  # needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,17,560,2)  # needs sage.rings.finite_rings
True
The design is available from the general constructor:

sage: designs.orthogonal_arrays.is_available(17,560)  # needs sage.schemes
True

sage.combinat.designs.database.OA_20_352()
Returns an OA(20,352)
Published by Julian R. Abel in [Ab1995] (uses the fact that 352 = 2^5 × 11 is the product of a power of 2 and a prime number).

5.1. Comprehensive Module List
Combinatorics, Release 10.1

See also:

```
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()
```

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_352
sage: OA = OA_20_352()          # not tested (~25s)  
→ needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,20,352,2)  # not tested (~25s)     
→ needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,352)  
← needs sage.schemes
True
```

```
sage.combinat.designs.database.OA_20_416()  
```

Returns an OA(20,416)

Published by Julian R. Abel in [Ab1995] (uses the fact that 416 = 2^5 × 13 is the product of a power of 2 and a prime number).

See also:

```
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()
```

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_416
sage: OA = OA_20_416()          # not tested (~35s)  
→ needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,20,416,2)  # not tested     
→ needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,416)  
← needs sage.schemes
True
```

```
sage.combinat.designs.database.OA_20_544()  
```

Returns an OA(20,544)

Published by Julian R. Abel in [Ab1995] (uses the fact that 544 = 2^5 × 17 is the product of a power of 2 and a prime number).

See also:

```
sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()
```

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_544
sage: OA = OA_20_544()  # not tested (too long ~1mn) #→ needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,20,544,2)  # not tested #→ needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(20,544)  #→ needs sage.schemes
True
```

```python
sage: designs.orthogonal_arrays.is_available(25,1262)  #→ needs sage.schemes
True
```

```python
sage.combinat.designs.database.OA_25_1262()  
Returns an OA(25,1262)

The construction is given in [Greig99]. In Julian R. Abel's words:

Start with a cyclic $PG(2,43)$ or $(1893,44,1)$-BIBD whose base block contains respectively 12, 13 and 19 points in the residue classes mod 3. In the resulting BIBD, remove one of the three classes: the result is a $(1262,\{25,31,32\})$-PBD, from which the $OA(25,1262)$ is obtained.

EXAMPLES:

```python
sage: designs.orthogonal_arrays.is_available(10,520)  #→ needs sage.schemes
True
```

```python
sage.combinat.designs.database.OA_520_plus_x(x)  
Returns an $OA(10 + x, 520 + x)$.

The construction shared by Julian R. Abel works for $OA(10, 520)$, $OA(12, 522)$, and $OA(14, 524)$.

Let $n = 520 + x$ and $k = 10 + x$. Build a $TD(17,31)$. Remove $8 - x$ points contained in a common block, add a new point $p$ and create a block $g_i \cup \{p\}$ for every (possibly truncated) group $g_i$. The result is a $(520+x,9+x,16,17,31,32) - PBBD$. Note that all blocks of size $\geq 30$ only intersect on $p$, and that the unique block $B_9$ of size 9 intersects all blocks of size 32 on one point. Now:

- Build an $OA(k,16) - 16.OA(k,16)$ for each block of size 16
- Build an $OA(k,17) - 17.OA(k,17)$ for each block of size 17
- Build an $OA(k,31) - OA(k,1)$ for each block of size 31 (with the hole on $p$).
- Build an $OA(k,32) - 2.OA(k,1)$ for each block $B$ of size 32 (with the holes on $p$ and $B \cap B_9$).
- Build an $OA(k,9)$ on $B_9$.

Only a row $[p,p,...]$ is missing from the $OA(10 + x, 520 + x)$
```

5.1. Comprehensive Module List 657
This construction is used in $OA(10, 520)$, $OA(12, 522)$, and $OA(14, 524)$.  

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_520_plus_x
sage: OA = OA_520_plus_x(0)  # not tested (already tested in OA_10_→520)
sage: is_orthogonal_array(OA, 10, 520, 2)  # not tested (already tested in OA_10_520)
True
```

`sage.combinat.designs.database.OA_7_18()`  
Return an $OA(7, 18)$  
Proved in [JulianAbel13].  

**See also:**  
`sage.combinat.designs.orthogonal_arrays.OA_from_quasi_difference_matrix()`  

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_18
sage: OA = OA_7_18()  
sage: is_orthogonal_array(OA, 7, 18, 2)
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(7, 18)  # needs sage.schemes
True
```

`sage.combinat.designs.database.OA_7_66()`  
Return an $OA(7, 66)$  
Construction shared by Julian R. Abel.  

**See also:**  
`sage.combinat.designs.orthogonal_arrays.OA_from_PBD()`  

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_66
sage: OA = OA_7_66()  
sage: is_orthogonal_array(OA, 7, 18, 2)  # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(7, 66)  # needs sage.schemes
True
```
Return an OA(7,68)
Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_68
sage: OA = OA_7_68()  # needs sage.schemes
sage: is_orthogonal_array(OA, 7, 68, 2)  # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(7, 68)  # needs sage.schemes
True
```

Return an OA(7,74)
Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_74
sage: OA = OA_7_74()  # needs sage.schemes
sage: is_orthogonal_array(OA, 7, 74, 2)  # needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(7, 74)  # needs sage.schemes
True
```

Return an OA(8,69)
Construction shared by Julian R. Abel.

See also:

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_8_69
sage: OA = OA_8_69()
# needs sage.schemes
sage: is_orthogonal_array(OA,8,69,2)
# needs sage.schemes
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(8,69)
# needs sage.schemes
True
```

`sage.combinat.designs.database.OA_8_76()`

Return an OA(8,76)

Construction shared by Julian R. Abel.

**See also:**

`sage.combinat.designs.orthogonal_arrays.OA_from_PBD()`

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_8_76
sage: OA = OA_8_76()
# not tested -- ~3s
sage: is_orthogonal_array(OA,8,76,2)
# not tested -- ~3s
True
```

The design is available from the general constructor:

```python
sage: designs.orthogonal_arrays.is_available(8,76)
# needs sage.schemes
True
```

`sage.combinat.designs.database.OA_9_1078()`

Returns an OA(9,1078)

Returns an OA(9,1078)

This is obtained through the generalized Brouwer-van Rees construction. Indeed, $1078 = 89.11 + (99 = 9.11)^2$ and there exists an $\text{OA}(9,100) - \text{OA}(9,11)$.

**Note:** This function should be removed once `find_brouwer_van_rees_with_one_truncated_column()` can handle all incomplete orthogonal arrays obtained through `incomplete_orthogonal_array()`.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_1078
sage: OA = OA_9_1078()
# not tested -- ~3s
sage: is_orthogonal_array(OA,9,1078,2) # not tested -- ~3s
True
```
The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,1078)  # needs sage.schemes
True
```

```
sage.combinat.designs.database.OA_9_120()

Return an OA(9,120)

Construction shared by Julian R. Abel:

From a resolvable (120, 8, 1) − BIBD, one can obtain 7 MOLS(120) or a resolvable TD(8, 120) by forming a resolvable TD(8, 8) − 8.TD(8, 1) on I8 × B for each block B in the BIBD. This gives a TD(8, 120) − 120.TD(8, 1) (which is resolvable as the BIBD is resolvable).

See also:

```
RBIBD_120_8_1()
```

```
EXAMPLES:
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_120
sage: OA = OA_9_120()
# needs sage.modules sage.schemes
sage: is_orthogonal_array(OA,9,120,2)  # needs sage.modules sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,120)  # needs sage.schemes
True
```

```
sage.combinat.designs.database.OA_9_135()

Return an OA(9,135)

Construction shared by Julian R. Abel:

This design can be built by Wilson’s method (135 = 8.16 + 7) applied to an Orthogonal Array OA(9 + 7, 16) with 7 groups truncated to size 1 in such a way that a block contain 0, 1 or 3 points of the truncated groups.

This is possible, because PG(2, 2) (the projective plane over GF(2)) is a subdesign in PG(2, 16) (the projective plane over GF(16)); in a cyclic PG(2, 16) or BIBD(273, 17, 1) the points ≡ 0 (mod 39) form such a subdesign (note that 273 = 16² + 16 + 1 and 273 = 39 × 7 and 7 = 2³ + 2 + 1).

```
EXAMPLES:
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_135
sage: OA = OA_9_135()
# needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA,9,135,2)  # needs sage.rings.finite_rings sage.schemes
True
```

The design is available from the general constructor:
sage: designs.orthogonal_arrays.is_available(9,135) # needs sage.schemes
True

As this orthogonal array requires a $(273, 17, 1)$ cyclic difference set, we check that it is available:

```
sage: G,D = designs.difference_family(273,17,1); G
```

```
Ring of integers modulo 273
```

```
sage.combinat.designs.database.OA_9_1612()
```

Returns an $OA(9,1612)$

This is obtained through the generalized Brouwer-van Rees construction. Indeed, $1612 = 89.17 + (99 = 9.11)$ and there exists an $OA(9,100) − OA(9,11)$.

**Note:** This function should be removed once `find_brouwer_van_rees_with_one_truncated_column()` can handle all incomplete orthogonal arrays obtained through `incomplete_orthogonal_array()`.

**EXAMPLES:**

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_1612
sage: OA = OA_9_1612() # not tested -- ~6s
sage: is_orthogonal_array(OA,9,1612,2) # not tested -- ~6s
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,1612) # needs sage.schemes
True
```

sage.combinat.designs.database.OA_9_40()

Return an $OA(9,40)$

As explained in the Handbook III.3.62 [DesignHandbook]. Uses the fact that $40 = 2^3 \times 5$ and that $5$ is prime.

**See also:**

`sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()`

**EXAMPLES:**

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_40
sage: OA = OA_9_40() # not tested -- ~6s
sage: is_orthogonal_array(OA,9,40,2) # not tested -- ~6s
True
```

The design is available from the general constructor:
sage.combinat.designs.database.QDM_19_6_1_1_1()  
Return a (19, 6; 1, 1; 1)-quasi-difference matrix.  
Used to build an $OA(6, 20)$  

EXAMPLES:
```python
sage: from sage.combinat.designs.database import QDM_19_6_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_19_6_1_1_1()
```
```
sage: is_quasi_difference_matrix(M, G, 6, 1, 1, 1)
True
```

sage.combinat.designs.database.QDM_21_5_1_1_1()  
Return a (21, 5; 1, 1; 1)-quasi-difference matrix.  
Used to build an $OA(5, 22)$  

EXAMPLES:
```python
sage: from sage.combinat.designs.database import QDM_21_5_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_21_5_1_1_1()
```
```
sage: is_quasi_difference_matrix(M, G, 5, 1, 1, 1)
True
```

sage.combinat.designs.database.QDM_21_6_1_1_5()  
Return a (21, 6; 1, 1; 5)-quasi-difference matrix.  
Used to build an $OA(6, 26)$  

EXAMPLES:
```python
sage: from sage.combinat.designs.database import QDM_21_6_1_1_5
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_21_6_1_1_5()
```
```
sage: is_quasi_difference_matrix(M, G, 6, 1, 1, 5)
True
```

sage.combinat.designs.database.QDM_25_6_1_1_5()  
Return a (25, 6; 1, 1; 5)-quasi-difference matrix.  
Used to build an $OA(6, 30)$  

EXAMPLES:
sage: from sage.combinat.designs.database import QDM_25_6_1_1_5
sage: G,M = QDM_25_6_1_1_5()
# needs sage.modules
sage: is_quasi_difference_matrix(M,G,6,1,1,5)  # needs sage.modules
True

sage.combinat.designs.database.QDM_33_6_1_1_1()
Return a (33, 6; 1, 1; 1)-quasi-difference matrix.
Used to build an $OA(6,34)$
EXAMPLES:
sage: G,M = QDM_33_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True

sage.combinat.designs.database.QDM_35_7_1_1_7()
Return a (35, 7; 1, 1; 7)-quasi-difference matrix.
Used to build an $OA(7,42)$
As explained in the Handbook III.3.63 [DesignHandbook].
EXAMPLES:
sage: G,M = QDM_35_7_1_1_7()
sage: is_quasi_difference_matrix(M,G,7,1,1,7)
True

sage.combinat.designs.database.QDM_37_6_1_1_1()
Return a (37, 6; 1, 1; 1)-quasi-difference matrix.
Used to build an $OA(6,38)$
Given in the Handbook III.3.60 [DesignHandbook].
EXAMPLES:
sage: G,M = QDM_37_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True

sage.combinat.designs.database.QDM_45_7_1_1_9()
Return a (45, 7; 1, 1; 9)-quasi-difference matrix.
Used to build an $OA(7,54)$
As explained in the Handbook III.3.71 [DesignHandbook].
EXAMPLES:

```python
sage: from sage.combinat.designs.database import QDM_45_7_1_1_9
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_45_7_1_1_9()
```

```
True
```

```python
sage: from sage.combinat.designs.database import QDM_54_7_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_54_7_1_1_8()
```

```
True
```

```python
sage: from sage.combinat.designs.database import QDM_57_9_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_57_9_1_1_8()
```

```
True
```

```python
sage: from sage.combinat.designs.database import RBIBD_120_8_1
```

```
5.1. Comprehensive Module List 665
```
EXAMPLES:

```python
sage: from sage.combinat.designs.database import RBIBD_120_8_1
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: RBIBD = RBIBD_120_8_1()
           # needs sage.modules
sage: is_pairwise_balanced_design(RBIBD, 120, [8])
           # needs sage.modules
True
```

It is indeed resolvable, and the parallel classes are given by 17 slices of consecutive 15 blocks:

```python
sage: for i in range(17):
           # needs sage.modules
   ....: assert len(set(sum(RBIBD[i*15:(i+1)*15], []))) == 120
```

The BIBD is available from the constructor:

```python
sage: _ = designs.balanced_incomplete_block_design(120, 8)
           # needs sage.modules
```

`sage.combinat.designs.database.cyclic_shift(l, i)`

`sage.combinat.designs.database.f()`

Return a $(57, 9; 1, 1; 8)$-quasi-difference matrix.

Used to build an $OA(9, 65)$

Construction shared by Julian R. Abel

EXAMPLES:

```python
sage: from sage.combinat.designs.database import QDM_57_9_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G, M = QDM_57_9_1_1_8()
           # needs sage.schemes
sage: is_quasi_difference_matrix(M, G, 9, 1, 1, 8)
           # needs sage.schemes
True
```

5.1.81 Catalog of designs

This module gathers all designs that can be reached through `designs.<tab>`. Example with the Witt design on 24 points:

```python
sage: designs.WittDesign(24)          # optional - gap_package_  
           # design
Incidence structure with 24 points and 759 blocks
```

Or a Steiner Triple System on 19 points:

```python
sage: designs.steiner_triple_system(19)  
(19,3,1)-Balanced Incomplete Block Design
```
La Jolla Covering Repository

The La Jolla Covering Repository (LJCR, see\(^1\)) is an online database of covering designs. As it is frequently updated, it is not included in Sage, but one can query it through `designs.best_known_covering_design_from_LJCR`:

```sage
sage: C = designs.best_known_covering_design_from_LJCR(7, 3, 2) # optional - internet
sage: C
(7, 3, 2)-covering design of size 7
Lower bound: 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
sage: C.incidence_structure() # optional - internet
Incidence structure with 7 points and 7 blocks
```

Design constructors

This module gathers the following designs:

```python
    ProjectiveGeometryDesign()
    DesarguesianProjectivePlaneDesign()
    HughesPlane()
    HigmanSimsDesign()
    balanced_incomplete_block_design()
    resolvable_balanced_incomplete_block_design()
    kirkman_triple_system()
    AffineGeometryDesign()
    CremonaRichmondConfiguration()
    WittDesign()
    HadamardDesign()
    Hadamard3Design()
    mutually_orthogonal_latin_squares()
    transversal_design()
    orthogonal_array()
    incomplete_orthogonal_array()
    difference_family()
    difference_matrix()
    steiner_triple_system()
    steiner_quadruple_system()
    projective_plane()
    biplane()
    gen_quadrangles_with_spread()
```

And the `designs.best_known_covering_design_from_LJCR` function which queries the LJCR.

Todo: Implement DerivedDesign and ComplementaryDesign.

REFERENCES:

\(^1\) La Jolla Covering Repository, https://math.ccrwest.org/cover.html
5.1.82 Cython functions for combinatorial designs

This module implements the design methods that need to be somewhat efficient.

Functions

sage.combinat.designs.designs_pyx.is_difference_matrix(M, G, k, lmbda=1, verbose=False)
Test if \( M \) is a \((G, k, \lambda)\)-difference matrix.

A matrix \( M \) is a \((G, k, \lambda)\)-difference matrix if its entries are element of \( G \), and if for any two rows \( R, R' \) of \( M \) and \( x \in G \) there are exactly \( \lambda \) values \( i \) such that \( R_i - R'_i = x \).

INPUT:
- \( M \) – a matrix with entries from \( G \)
- \( G \) – a group
- \( k \) – integer
- \( \lambda \) (integer) – set to 1 by default.
- \( \text{verbose} \) (boolean) – whether to print some information when the answer is False.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: q = 3**3
sage: F = GF(q, 'x')
# needs sage.rings.finite_rings
sage: M = [[x*y for y in F] for x in F]  # needs sage.rings.finite_rings
sage: is_difference_matrix(M,F,q,verbose=1)  # needs sage.rings.finite_rings
True
sage: B = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
.....: [0, 1, 2, 3, 4, 2, 3, 4, 0, 1],
.....: [0, 2, 4, 1, 3, 3, 0, 2, 4, 1]]
sage: G = GF(5)
sage: B = [[G(b) for b in R] for R in B]
sage: is_difference_matrix(list(zip(*B)),G,3,2)
True
```

Bad input:

```
sage: # needs sage.rings.finite_rings
sage: for R in M: R.append(None)
sage: is_difference_matrix(M,F,q,verbose=1)
The matrix has 28 columns but k=27
False
sage: for R in M: _=R.pop(-1)
sage: M.append([None]*3**3)
sage: is_difference_matrix(M,F,q,verbose=1)
The matrix has 28 rows instead of lambda(|G|-1+2u)+mu=1(27-1+2.0)+1=27
False
sage: _= M.pop(-1)
```

(continues on next page)
Combinatorics, Release 10.1

sage: for R in M: R[-1] = 0
sage: is_difference_matrix(M,F,q,verbose=1)
Columns 0 and 26 generate 0 exactly 27 times instead of the expected mu(=1)
False
sage: for R in M: R[-1] = 1
sage: M[-1][-1] = 0
sage: is_difference_matrix(M,F,q,verbose=1)
Columns 0 and 26 do not generate all elements of G exactly lambda(=1) times.
The element x appeared 0 times as a difference.
False

sage.combinat.designs.designs_pyx.is_group_divisible_design(groups, blocks, v, G=None, K=None, lambd=1, verbose=False)
Checks that input is a Group Divisible Design on \{0, ..., v – 1\}
For more information on Group Divisible Designs, see GroupDivisibleDesign.

INPUT:

- groups – a partition of X. If set to None the groups are guessed automatically, and the function returns (True, guessed_groups) instead of True
- blocks – collection of blocks
- v (integers) – size of the ground set assumed to be X = \{0, ..., v – 1\}.
- G – list of integers of which the sizes of the groups must be elements. Set to None (automatic guess) by default.
- K – list of integers of which the sizes of the blocks must be elements. Set to None (automatic guess) by default.
- lambd – value of \lambda. Set to 1 by default.
- verbose (boolean) – whether to display some information when the design is not a GDD.

EXAMPLES:

sage: from sage.combinat.designs.designs_pyx import is_group_divisible_design
sage: TD = designs.transversal_design(4,10)  # needs sage.modules
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: is_group_divisible_design(groups,TD,40,lambd=1)  # needs sage.modules
True

sage.combinat.designs.designs_pyx.is_orthogonal_array(OA, k, n, t=2, verbose=False, terminology='OA')
Check that the integer matrix OA is an OA(k, n, t).
See orthogonal_array() for a definition.

INPUT:

- OA – the Orthogonal Array to be tested
- k, n, t (integers) – only implemented for t = 2.
- verbose (boolean) – whether to display some information when OA is not an orthogonal array OA(k, n).
• terminology (string) – how to phrase the information when verbose = True. Possible values are ”OA”, ”MOLS”.

EXAMPLES:

```python
sage: # needs sage.schemes
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: OA = designs.orthogonal_arrays.build(8,9)
sage: is_orthogonal_array(OA,8,9)
True
sage: is_orthogonal_array(OA,8,10)
False
sage: OA[4][3] = 1
sage: is_orthogonal_array(OA,8,9)
False
sage: is_orthogonal_array(OA,8,9,verbose=True)
Columns 0 and 3 are not orthogonal
False
sage: is_orthogonal_array(OA,8,9, verbose=True, terminology="MOLS")
Squares 0 and 3 are not orthogonal
False
```

`sage.combinat.designs.designs_pyx.is_pairwise_balanced_design(blocks, v=None, K=None, lambd=1, verbose=False)`

Checks that input is a Pairwise Balanced Design (PBD) on \{0, ..., v - 1\}

For more information on Pairwise Balanced Designs (PBD), see `PairwiseBalancedDesign`.

INPUT:

• blocks – collection of blocks
• v (integers) – size of the ground set assumed to be \(X = \{0, ..., v - 1\}\).
• K – list of integers of which the sizes of the blocks must be elements. Set to None (automatic guess) by default.
• lambd – value of \(\lambda\). Set to 1 by default.
• verbose (boolean) – whether to display some information when the design is not a PBD.

EXAMPLES:

```python
sage: from sage.combinat.designs.designs_pyx import is_pairwise_balanced_design
sage: sts = designs.steiner_triple_system(9)
sage: is_pairwise_balanced_design(sts,9,[3],1)
True
sage: TD = designs.transversal_design(4,10).blocks()
#˓→needs sage.modules
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: is_pairwise_balanced_design(TD + groups, 40, [4,10], 1, verbose=True) #˓→needs sage.modules
True
```

`sage.combinat.designs.designs_pyx.is_projective_plane(blocks, verbose=False)`

Test whether the blocks form a projective plane on \{0, ..., v - 1\}

A projective plane is an incidence structure that has the following properties:
1. Given any two distinct points, there is exactly one line incident with both of them.
2. Given any two distinct lines, there is exactly one point incident with both of them.
3. There are four points such that no line is incident with more than two of them.

For more informations, see Wikipedia article Projective plane.

is_t_design() can also check if an incidence structure is a projective plane with the parameters \( v = k^2 + k + 1 \), \( t = 2 \) and \( l = 1 \).

**INPUT:**

- blocks – collection of blocks
- verbose – whether to print additional information

**EXAMPLES:**

```python
sage: from sage.combinat.designs.designs_pyx import is_projective_plane
sage: p = designs.projective_plane(4)  # needs sage.schemes
sage: b = p.blocks()  # needs sage.schemes
sage: is_projective_plane(b, verbose=True)  # needs sage.schemes
True

sage: p = designs.projective_plane(2)
sage: b = p.blocks()
sage: is_projective_plane(b)
True
sage: b[0][2] = 5
sage: is_projective_plane(b, verbose=True)
the pair (0,5) has been seen 2 times but lambda=1
False

sage: is_projective_plane([[0,1,2],[1,2,4]], verbose=True)
the pair (0,3) has been seen 0 times but lambda=1
False

sage: is_projective_plane([[1]], verbose=True)
First block has less than 3 points.
False

sage: p = designs.projective_plane(2)
sage: b = p.blocks()
sage: b[2].append(4)
sage: is_projective_plane(b, verbose=True)
a block has size 4 while K=[3]
False
```

sage.combinat.designs.designs_pyx.is_quasi_difference_matrix(M, G, k, lambda, mu, u, verbose=False)

Test if the matrix is a \((G, k; \lambda; \mu; u)\)-quasi-difference matrix.
Let $G$ be an abelian group of order $n$. A $(n, k; \lambda, \mu; u)$-quasi-difference matrix (QDM) is a matrix $Q_{ij}$ with $\lambda(n - 1 + 2u) + \mu$ rows and $k$ columns, with each entry either equal to None (i.e. the 'missing entries') or to an element of $G$. Each column contains exactly $\lambda u$ empty entries, and each row contains at most one None. Furthermore, for each $1 \leq i < j \leq k$, the multiset

$$\{q_{ij} - q_{lj} : 1 \leq l \leq \lambda(n - 1 + 2u) + \mu, \text{ with } q_{ij} \text{ and } q_{lj} \text{ not empty}\}$$

contains $\lambda$ times every nonzero element of $G$ and contains $\mu$ times $0$.

INPUT:
- $M$ – a matrix with entries from $G$ (or equal to None for missing entries)
- $G$ – a group
- $k, \lambda, \mu, u$ – integers
- verbose (boolean) – whether to print some information when the answer is False.

EXAMPLES:

Differences matrices:

```
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: q = 3**3
sage: F = GF(q, 'x')
    # needs sage.rings.finite_rings
sage: M = [[x*y for y in F] for x in F]
    # needs sage.rings.finite_rings
sage: is_quasi_difference_matrix(M,F,q,1,1,0,verbose=1)
True

sage: B = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
       ....:[0, 1, 2, 3, 4, 2, 3, 4, 0, 1],
       ....:[0, 2, 4, 1, 3, 3, 0, 2, 4, 1]]
```

```
sage: G = GF(5)
sage: B = [[G(b) for b in R] for R in B]
sage: is_quasi_difference_matrix(list(zip(*B)),G,3,2,2,0)
True
```

A quasi-difference matrix from the database:

```
sage: from sage.combinat.designs.database import QDM
sage: G,M = QDM[38,1][37,1,1,1][1]()
sage: is_quasi_difference_matrix(M,G,k=6,lambda=1,mu=1,u=1)
True
```

Bad input:

```
sage: is_quasi_difference_matrix(M,G,k=6,lambda=1,mu=1,u=3,verbose=1)
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.3)+1=43
False
```
```
sage: is_quasi_difference_matrix(M,G,k=6,lambda=1,mu=2,u=1,verbose=1)
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.1)+2=40
False
```
```
sage: M[3][1] = None
```
```
sage: is_quasi_difference_matrix(M,G,k=6,lambda=1,mu=1,u=1,verbose=1)
```
```
Row 3 contains more than one empty entry
False
sage: M[3][1] = 1
sage: M[6][1] = None
sage: is_quasi_difference_matrix(M,G,k=6,lambda_=1,mu=1,u=1,verbose=1)
Column 1 contains 2 empty entries instead of the expected lambda.u=1.1=1
False

5.1.83 Difference families

This module gathers everything related to difference families. One can build a difference family (or check that it can be built) with \texttt{difference\_family()}:

\begin{verbatim}
    sage: G,F = designs.difference_family(13,4,1)
    # Needs sage.libs.pari sage.modules
\end{verbatim}

It defines the following functions:

\begin{itemize}
  \item \texttt{are\_complementary\_difference\_sets()}: Check if \(A\) and \(B\) are complementary difference sets over the group \(G\).
  \item \texttt{are\_hadamard\_difference\_sets()}: Check whether \((v,k,\lambda)\) is of the form \((4N^2, 2N^2 - N, N^2 - N)\).
  \item \texttt{are\_mcfarland\_1973\_parameters()}: Test whether \((v,k,\lambda)\) is a triple that can be obtained from the construction from [McF1973].
  \item \texttt{block\_stabilizer()}: Compute the left stabilizer of the block \(B\) under the action of \(G\).
  \item \texttt{complementary\_difference\_sets()}: Construct complementary difference sets over a group of order \(n = 2m + 1\).
  \item \texttt{complementary\_difference\_setsI()}: Construct complementary difference sets in a group of order \(n \approx 3 \mod 4\), \(n\) a prime power.
  \item \texttt{complementary\_difference\_setsII()}: Construct complementary difference sets in a group of order \(n = p^t\), where \(p \equiv 5 \mod 8\) and \(t \equiv 1, 2, 3 \mod 4\).
  \item \texttt{complementary\_difference\_setsIII()}: Construct complementary difference sets in a group of order \(n = 2m + 1\), where \(4m + 3\) is a prime power.
  \item \texttt{df\_q\_6\_1()}: Return a \((q,6,1)\)-difference family over the finite field \(K\).
  \item \texttt{difference\_family()}: Return a \((k,1)\)-difference family on an Abelian group of cardinality \(v\).
  \item \texttt{get\_fixed\_relative\_difference\_set()}: Construct an equivalent relative difference set fixed by the size of the set.
  \item \texttt{group\_law()}: Return a triple \((\text{identity}, \text{operation}, \text{inverse})\) that define the operations on the group \(G\).
  \item \texttt{hadamard\_difference\_set\_product()}: Make a product of two Hadamard difference sets.
  \item \texttt{is\_difference\_family()}: Check whether \(B\) forms a difference family in the group \(G\).
  \item \texttt{is\_fixed\_relative\_difference\_set()}: Check if the relative difference set \(R\) is fixed by \(q\).
  \item \texttt{is\_relative\_difference\_set()}: Check if \(R\) is a difference set of \(G\) relative to \(H\), with the given parameters.
  \item \texttt{is\_supplementary\_difference\_set()}: Check that the sets in \(Ks\) are \(n - \{v; k_1, \ldots, k_n; \lambda\}\) supplementary difference sets over group \(G\) of order \(v\).
  \item \texttt{mcfarland\_1973\_construction()}: Return a difference set.
  \item \texttt{one\_cyclic\_tiling()}: Given a subset \(A\) of the cyclic additive group \(G = \mathbb{Z}/n\mathbb{Z}\) return another subset \(B\) so that \(A + B = G\) and \(|A||B| = n\) (i.e. any element of \(G\) is uniquely expressed as a sum \(a + b\) with \(a\) in \(A\) and \(b\) in \(B\)).
  \item \texttt{one\_radical\_difference\_family()}: Search for a radical difference family on \(K\) using dancing links algorithm.
  \item \texttt{radical\_difference\_family()}: Return a \((v,k,1)\)-radical difference family.
  \item \texttt{radical\_difference\_set()}: Return a difference set made of a cyclotomic coset in the finite field \(K\) and with parameters \(k\) and \(1\).
\end{itemize}

REFERENCES:

Functions

sage.combinat.designs.difference_family.are_complementary_difference_sets($G, A, B, \verb=True$)

Check if $A$ and $B$ are complementary difference sets over the group $G$.

According to [Sze1971], two sets $A, B$ of size $m$ are complementary difference sets over a group $G$ of size $2m + 1$ if:

1. they are $2 - \{2m + 1; m, m; m - 1\}$ supplementary difference sets
2. $A$ is skew, i.e. $a \in A$ implies $-a \notin A$

INPUT:

- $G$ – a group of odd order
- $A$ – a set of elements of $G$
- $B$ – a set of elements of $G$
- $\verb$ – boolean (default: $\verb=True$); if True the function will be verbose when the sets do not satisfy the contraints

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import are_complementary_difference_sets
sage: are_complementary_difference_sets(Zmod(7), [1, 2, 4], [1, 2, 4])
True
```

If $\verb=True$, the function will be verbose.
sage: are_complementary_difference_sets(Zmod(7), [1, 2, 5], [1, 2, 4], verbose=True)
The sets are not supplementary difference sets with lambda = 2
False

See also:
is_supplementary_difference_set()
sage.combinat.designs.difference_family.are_hadamard_difference_set_parameters(v, k, lmbda)
Check whether (v,k,lmbda) is of the form (4N^2, 2N^2 - N, N^2 - N).
INPUT:
• (v,k,lmbda) – parameters of a difference set
EXAMPLES:
sage: from sage.combinat.designs.difference_family import are_hadamard_difference_set_parameters
sage: are_hadamard_difference_set_parameters(36, 15, 6)
True
sage: are_hadamard_difference_set_parameters(60, 13, 5)
False

sage.combinat.designs.difference_family.are_mcfarland_1973_parameters(v, k, lmbda, return_parameters=False)
Test whether (v,k,lmbda) is a triple that can be obtained from the construction from [McF1973].
See mcfarland_1973_construction().
INPUT:
• v, k, lmbda - integers; parameters of the difference family
• return_parameters – boolean (default False); if True, return a pair (True, (q, s)) so that (q, s) can be used in the function mcfarland_1973_construction() to actually build a (v,k,lmbda)-difference family. Or (False, None) if the construction is not possible
EXAMPLES:
sage: # needs sage.rings.finite_rings
sage: from sage.combinat.designs.difference_family import are_mcfarland_1973_parameters
sage: are_mcfarland_1973_parameters(64, 28, 12)
True
sage: are_mcfarland_1973_parameters(64, 28, 12, return_parameters=True)
(True, (2, 2))
sage: are_mcfarland_1973_parameters(98125, 19500, 3875)
True
sage: are_mcfarland_1973_parameters(98125, 19500, 3875, True)
(True, (5, 3))
sage: for v in range(1, 100):
needs sage.rings.finite_rings
for k in range(1,30):
    for l in range(1,15):
        if are_mcfarland_1973_parameters(v,k,l):
            answer, (q,s) = are_mcfarland_1973_parameters(v,k,l,return_parameters=True)
            print("{} {} {} {} ".format(v,k,l,q,s))
assert answer is True
assert designs.difference_family(v,k,l,existence=True) is True
G,D = designs.difference_family(v,k,l)
16 6 2 2 1
45 12 3 3 1
64 28 12 2 2
96 20 4 4 1

sage.combinat.designs.difference_family.block_stabilizer(G, B)
Compute the left stabilizer of the block B under the action of G.
This function return the list of all x ∈ G such that x · B = B (as a set).

INPUT:
• G – a group (additive or multiplicative)
• B – a subset of G

EXAMPLES:
sage: from sage.combinat.designs.difference_family import block_stabilizer
sage: Z8 = Zmod(8)
sage: block_stabilizer(Z8, [Z8(0),Z8(2),Z8(4),Z8(6)])
[0, 2, 4, 6]
sage: block_stabilizer(Z8, [Z8(0),Z8(2)])
[0]
sage: C = cartesian_product([Zmod(4),Zmod(3)])
sage: block_stabilizer(C, [C((0,0)),C((2,0)),C((0,1)),C((2,1))])
[(0, 0), (2, 0)]
sage: b = list(map(Zmod(45),[1, 3, 7, 10, 22, 25, 30, 35, 37, 38, 44]))
sage: block_stabilizer(Zmod(45),b)
[0]

sage.combinat.designs.difference_family.complementary_difference_sets(n, existence=False, check=True)
Compute complementary difference sets over a group of order n = 2m + 1.
According to [Sze1971], two sets A, B of size m are complementary difference sets over a group G of size n = 2m + 1 if:
1. they are 2 - \{2m + 1; m, m - 1\} supplementary difference sets
2. A is skew, i.e. a ∈ A implies −a ∉ A
This method tries to call complementary_difference_setsI(), complementary_difference_setsII()
or `complementary_difference_setsIII()` if the parameter $n$ satisfies the requirements of one of these functions.

INPUT:

- $n$ – integer; the order of the group over which the sets are constructed
- `existence` – boolean (default: `False`); if `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are complementary difference sets before returning them; setting this to `False` might speed up the computation for large values of $n$

OUTPUT:

If `existence=False`, the function returns group $G$ and two complementary difference sets, or raises an error if data for the given $n$ is not available. If `existence=True`, the function returns a boolean representing whether complementary difference sets can be constructed for the given $n$.

EXAMPLES:

```sage
sage: from sage.combinat.designs.difference_family import complementary_difference_sets
sage: complementary_difference_sets(15)                      # needs sage.libs.pari
(Ring of integers modulo 15, [1, 2, 4, 6, 7, 10, 12], [0, 1, 2, 6, 9, 13, 14])
```

If `existence=True`, the function returns a boolean:

```sage
sage: complementary_difference_sets(15, existence=True)      # needs sage.libs.pari
True
```

```sage
sage: complementary_difference_sets(16, existence=True)      # needs sage.libs.pari
False
```

See also:

`are_complementary_difference_sets()`

Construct complementary difference sets in a group of order $n \equiv 3 \mod 4$, $n$ a prime power.

Let $G$ be a Galois Field of order $n$, where $n$ satisfies the requirements above. Let $A$ be the set of non-zero quadratic elements in $G$, and $B = A$. Then $A$ and $B$ are complementary difference sets over a group of order $n$. This construction is described in [Sze1971].

INPUT:

- $n$ – integer; the order of the group $G$
- `check` – boolean (default: `True`); if `True`, check that the sets are complementary difference sets before returning them

OUTPUT:

The function returns the Galois field of order $n$ and the two sets, or raises an error if $n$ does not satisfy the requirements of this construction.

EXAMPLES:
sage: from sage.combinat.designs.difference_family import complementary_difference_setsI
sage: complementary_difference_setsI(19)
(Finite Field of size 19, [1, 4, 5, 6, 7, 9, 11, 16, 17], [1, 4, 5, 6, 7, 9, 11, 16, 17])

See also:

are_complementary_difference_sets() complementary_difference_sets()
sage.combinat.designs.difference_family.complementary_difference_setsII(n, check=True)

Construct complementary difference sets in a group of order \( n = p^t \), where \( p \equiv 5 \mod 8 \) and \( t \equiv 1, 2, 3 \mod 4 \).

Consider a finite field \( G \) of order \( n \) and let \( \rho \) be the generator of the corresponding multiplicative group. Then, there are two different constructions, depending on whether \( t \) is even or odd.

If \( t \equiv 2 \mod 4 \), let \( C_0 \) be the set of non-zero octic residues in \( G \), and let \( C_i = \rho^i C_0 \) for \( 1 \leq i \leq 7 \). Then, \( A = C_0 \cup C_1 \cup C_2 \cup C_3 \) and \( B = C_0 \cup C_1 \cup C_6 \cup C_7 \).

If \( t \) is odd, let \( C_0 \) be the set of non-zero fourth powers in \( G \), and let \( C_i = \rho^i C_0 \) for \( 1 \leq i \leq 3 \). Then, \( A = C_0 \cup C_1 \) and \( B = C_0 \cup C_3 \).

For more details on this construction, see [Sze1971].

INPUT:

• \( n \) – integer; the order of the group \( G \)
• check – boolean (default: True); if True, check that the sets are complementary difference sets before returning them; setting this to False might speed up the computation for large values of \( n \)

OUTPUT:

The function returns the Galois field of order \( n \) and the two sets, or raises an error if \( n \) does not satisfy the requirements of this construction.

EXAMPLES:

sage: from sage.combinat.designs.difference_family import complementary_difference_setsII
sage: complementary_difference_setsII(5) # needs sage.libs.pari
(Finite Field of size 5, [1, 2], [1, 3])

See also:

are_complementary_difference_sets() complementary_difference_sets()
sage.combinat.designs.difference_family.complementary_difference_setsIII(n, check=True)

Construct complementary difference sets in a group of order \( n = 2m + 1 \), where \( 4m + 3 \) is a prime power.

Consider a finite field \( G \) of order \( n \) and let \( \rho \) be a primitive element of this group. Now let \( Q \) be the set of non zero quadratic residues in \( G \), and let \( A = \{ a | \rho^{2a} - 1 \in Q \} \), \( B' = \{ b | - (\rho^{2b} + 1) \in Q \} \). Then \( A \) and \( B = Q \setminus B' \) are complementary difference sets over the ring of integers modulo \( n \). For more details, see [Sz1969].

INPUT:

• \( n \) – integer; the order of the group over which the sets are constructed
check – boolean (default: True); if True, check that the sets are complementary difference sets before returning them; setting this to False might speed up the computation for large values of \( n \)

**OUTPUT:**

The function returns the Galois field of order \( n \) and the two sets, or raises an error if \( n \) does not satisfy the requirements of this construction.

**EXAMPLES:**

```
sage: from sage.combinat.designs.difference_family import complementary_difference_setsIII
sage: complementary_difference_setsIII(11)  # needs sage.libs.pari
(Ring of integers modulo 11, [1, 2, 5, 7, 8], [0, 1, 3, 8, 10])
```

See also:

- `are_complementary_difference_sets()`
- `complementary_difference_sets()`

**Todo:** Do improvements due to Zhen and Wu 1999.

```
sage: from sage.combinat.designs.difference_family import is_difference_family, df_q_6_1
sage: parameters = [v for v in range(31, 500, 30) if is_prime_power(v)]
....: if df_q_6_1(GF(v, 'a'), existence=True) is True
sage: parameters
[31, 151, 181, 211, 241, 271, 331, 361, 421]
sage: for v in parameters:
....:     K = GF(v, 'a')
....:     df = df_q_6_1(K, check=True)
....:     assert is_difference_family(K, df, v, 6, 1)
```

5.1. Comprehensive Module List
If there is no such difference family, an `EmptySetError` is raised and if there is no construction at the moment `NotImplementedError` is raised.

**INPUT:**

- `v, k, l` – parameters of the difference family. If `l` is not provided it is assumed to be 1
- `existence` – if True, then return either True if Sage knows how to build such design, `Unknown` if it does not and False if it knows that the design does not exist
- `explain_construction` – instead of returning a difference family, returns a string that explains the construction used
- `check` – boolean (default: True); if True, then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

**OUTPUT:**

A pair `(G, D)` made of a group `G` and a difference family `D` on that group. Or, if `existence=True` a boolean or if `explain_construction=True` a string.

**EXAMPLES:**

```python
sage: G,D = designs.difference_family(73, 4)  # needs sage.libs.pari
sage: G
Finite Field of size 73
sage: D
[[0, 1, 5, 18],
 [0, 3, 15, 54],
 [0, 9, 45, 16],
 [0, 27, 62, 48],
 [0, 8, 40, 71],
 [0, 24, 47, 67]]

sage: print(designs.difference_family(73, 4, explain_construction=True))
The database contains a (73,4)-evenly distributed set

sage: # needs sage.libs.pari
sage: G,D = designs.difference_family(15, 7, 3)
sage: G
Ring of integers modulo 15
sage: D
[[0, 1, 2, 4, 5, 8, 10]]

sage: print(designs.difference_family(15, 7, 3, explain_construction=True))
Singer difference set

sage: print(designs.difference_family(91, 10, 1, explain_construction=True))  # needs sage.libs.pari
Singer difference set

sage: print(designs.difference_family(64, 28, 12, explain_construction=True))  # needs sage.libs.pari
McFarland 1973 construction

sage: print(designs.difference_family(576, 276, 132, explain_construction=True))  # needs sage.libs.pari
Hadamard difference set product from N1=2 and N2=3
```
For \( k = 6, 7 \) we look at the set of small prime powers for which a construction is available:

```python
sage: def prime_power_mod(r,m):
    ...:     k = m+r
    ...:     while True:
    ...:         if is_prime_power(k):
    ...:             yield k
    ...:         k += m

sage: from itertools import islice
sage: l6 = {True: [], False: [], Unknown: []}
sage: for q in islice(prime_power_mod(1,30), int(60)):
    # needs sage.libs.pari
    ...:     l6[designs.difference_family(q,6,existence=True)].append(q)

sage: l6[True]
[31, 121, 151, 181, 211, ..., 3061, 3121, 3181]
sage: l6[Unknown]
[61]
sage: l6[False]
[]

sage: l7 = {True: [], False: [], Unknown: []}
sage: for q in islice(prime_power_mod(1,42), int(60)):
    # needs sage.libs.pari
    ...:     l7[designs.difference_family(q,7,existence=True)].append(q)

sage: l7[True]
[169, 337, 379, 421, 463, 547, 631, 673, 757, 841, 883, 967, ..., 4621, 4957, 5167]
sage: l7[Unknown]
[43, 127, 211, 2017, 2143, 2269, 2311, 2437, 2521, 2647, ..., 4999, 5041, 5209]
sage: l7[False]
[]
```

List available constructions:

```python
sage: for v in range(2,100):
    # needs sage.libs.pari
    ...:     constructions = []
    ...:     for k in range(2,10):
    ...:         for l in range(1,10):
    ...:             ret = designs.difference_family(v,k,l,existence=True)
    ...:             if ret is True:
    ...:                 constructions.append((k,l))
    ...:             _ = designs.difference_family(v,k,l)
    ...:     if constructions:
    ...:         print("%2d: \%s\"%(v, ', '.join('(%d,%d)'%(k,l) for k,l in
    ...:     # constructions)))

Todo: Implement recursive constructions from Buratti “Recursive for difference matrices and relative difference
sage.combinat.designs.difference_family.get_fixed_relative_difference_set(G, rel_diff_set, as_elements=False)

Construct an equivalent relative difference set fixed by the size of the set.

Given a relative difference set $R(q + 1, q - 1, q, 1)$, it is possible to find a translation of this set fixed by $q$ (see Section 3 of [Spe1975]). We say that a set is fixed by $t$ if $\{td | d \in R\} = R$.

In addition, the set returned by this function will contain the element 0. This is needed in the construction of supplementary difference sets (see supplementary_difference_set_from_rel_diff_set()).

**INPUT:**

- G – a group, of which rel_diff_set is a subset
- rel_diff_set – the relative difference set
- as_elements – boolean (default: False); if True, the list returned will contain elements of the abelian group (this may slow down the computation considerably)

**OUTPUT:**

By default, this function returns the set as a list of integers. However, if as_elements=True it will return the set as a list containing elements of the abelian group. If no such set can be found, the function will raise an error.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import relative_difference_set_from_m_sequence, get_fixed_relative_difference_set
sage: G, s1 = relative_difference_set_from_m_sequence(5, 2, return_group=True) # needs sage.libs.pari sage.modules
sage: get_fixed_relative_difference_set(G, s1) # random # needs sage.libs.pari sage.modules
[2, 10, 19, 23, 0]
```

If as_elements=True, the result will contain elements of the group:

```python
sage: get_fixed_relative_difference_set(G, s1, as_elements=True) # random # needs sage.libs.pari sage.modules
[(2), (10), (19), (23), (0)]
```

sage.combinat.designs.difference_family.group_law(G)

Return a triple (identity, operation, inverse) that define the operations on the group G.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import group_law
sage: group_law(Zmod(3))
(0, <built-in function add>, <built-in function neg>)
sage: group_law(SymmetricGroup(3)) # needs sage.groups
(() , <built-in function mul>, <built-in function inv>)
sage: group_law(VectorSpace(QQ, 3)) # needs sage.modules
((0, 0, 0), <built-in function add>, <built-in function neg>)
```
sage.combinat.designs.difference_family.hadamard_difference_set_product($G_1, D_1, G_2, D_2$)

Make a product of two Hadamard difference sets.

This product construction appears in [Tu1984].

INPUT:

• $G_1, D_1, G_2, D_2$ – two Hadamard difference sets

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import hadamard_difference_set_product
sage: G1, D1 = designs.difference_family(16, 6, 2)  # needs sage.rings.finite_rings
sage: G2, D2 = designs.difference_family(36, 15, 6)  # needs sage.rings.finite_rings
sage: G11, D11 = hadamard_difference_set_product(G1, D1, G1, D1)  # needs sage.rings.finite_rings
sage: assert is_difference_family(G11, D11, 256, 120, 56)  # needs sage.rings.finite_rings
sage: assert designs.difference_family(256, 120, 56, existence=True) is True  # needs sage.rings.finite_rings
sage: G12, D12 = hadamard_difference_set_product(G1, D1, G2, D2)  # needs sage.rings.finite_rings
sage: assert is_difference_family(G12, D12, 576, 276, 132)  # needs sage.rings.finite_rings
sage: assert designs.difference_family(576, 276, 132, existence=True) is True  # needs sage.rings.finite_rings
```

sage.combinat.designs.difference_family.hadamard_difference_set_product_parameters()

Check whether a product construction is available for Hadamard difference set with parameter $N$.

This function looks for two integers $N_1$ and $N_2$ greater than 1 and so that $N = 2N_1N_2$ and there exists Hadamard difference set with parameters $(4N_2^2, 2N_2^2 - N_1, N_1^2 - N_1)$. If such pair exists, the output is the pair $(N_1, N_2)$ otherwise it is None.

INPUT:

• $N$ – positive integer

EXAMPLES:

```python
sage: hadamard_difference_set_product_parameters(8)  # needs sage.rings.finite_rings
(2, 2)
```

sage.combinat.designs.difference_family.is_difference_family($G, D, v=None, k=None, l=None, verbose=False$)

Check whether $D$ forms a difference family in the group $G$.

INPUT:
• \( G \) – group of cardinality \( v \)
• \( D \) – a set of \( k \)-subsets of \( G \)
• \( v, k \) and \( l \) – optional parameters of the difference family
• \texttt{verbose} – boolean (default: \texttt{False}); whether to print additional information

\textbf{See also:}

\texttt{difference\_family()}

\textbf{EXAMPLES:}

```python
from sage.combinat.designs.difference_family import is_difference_family
G = Zmod(21)
D = [[0, 1, 4, 14, 16]]
is_difference_family(G, D, 21, 5)
True

G = Zmod(41)
D = [[0, 1, 4, 11, 29], [0, 2, 8, 17, 21]]
is_difference_family(G, D, verbose=True)
Too few:
  5 is obtained 0 times in blocks []
  14 is obtained 0 times in blocks []
  27 is obtained 0 times in blocks []
  36 is obtained 0 times in blocks []

Too much:
  4 is obtained 2 times in blocks [0, 1]
  13 is obtained 2 times in blocks [0, 1]
  28 is obtained 2 times in blocks [0, 1]
  37 is obtained 2 times in blocks [0, 1]
False

D = [[0, 1, 4, 11, 29], [0, 2, 8, 17, 22]]
is_difference_family(G, D)
True

G = Zmod(61)
D = [[0, 1, 3, 13, 34], [0, 4, 9, 23, 45], [0, 6, 17, 24, 32]]
is_difference_family(G, D)
True

# needs sage.modules
G = AdditiveAbelianGroup([3]*4)
a, b, c, d = G.gens()
D = [[d, -a+d, -c+d, a-b-d, b+c+d],
     [c, a+b-d, -b+c, a-b+d, a+b+c],
     [-a-b+c+d, a-b-c-d, -a+c-d, b-c+d, a+b],
     [-b+d, a+b+d, a-b+c-d, a-b+c, -b+c+d]]
is_difference_family(G, D)
True
```

The following example has a third block with a non-trivial stabilizer:

```python
G = Zmod(15)
D = [[0, 1, 4], [0, 2, 9], [0, 5, 10]]
```
The function also supports multiplicative groups (non necessarily Abelian):

```
sage: # needs sage.groups
dsage: G = DihedralGroup(8)
dsage: x,y = G.gens()
dsage: i = G.one()
dsage: D1 = [[i,x,x^4], [i,x^2, y*x], [i,x^5,y], [i,x^6,y*x^2], [i,x^7,y*x^5]]
dsage: is_difference_family(G, D1, 16, 3, 2)
True
sage: from sage.combinat.designs.bibd import BIBD_from_difference_family
sage: bibd = BIBD_from_difference_family(G, D1, lambd=2)
```

```
sage.combinat.designs.difference_family.is_fixed_relative_difference_set(R, q)
Check if the relative difference set R is fixed by q.
A relative difference set R is fixed by q if \{qd | d \in R\} = R (see Section 3 of [Spe1975]).

INPUT:

• R – a list containing elements of an abelian group; the relative difference set
• q – an integer

EXAMPLES:

```
sage: # needs sage.modules
sage: from sage.combinat.designs.difference_family import relative_difference_set_from_m_sequence, get_fixed_relative_difference_set, is_fixed_relative_difference_set
sage: G, s1 = relative_difference_set_from_m_sequence(7, 2, return_group=True)  # needs sage.libs.pari
sage: s2 = get_fixed_relative_difference_set(G, s1, as_elements=True)  # needs sage.libs.pari
sage: is_fixed_relative_difference_set(s2, len(s2))  # needs sage.libs.pari
True
sage: G = AdditiveAbelianGroup([15])
sage: s3 = [G[1], G[2], G[3], G[4]]
sage: is_fixed_relative_difference_set(s3, len(s3))
False
```

If the relative difference set does not contain elements of the group, the method returns false:

```
sage: G, s1 = relative_difference_set_from_m_sequence(7, 2, return_group=True)  # needs sage.libs.pari sage.modules
sage: s2 = get_fixed_relative_difference_set(G, s1, as_elements=False)  # needs sage.libs.pari sage.modules
sage: is_fixed_relative_difference_set(s2, len(s2))  # needs sage.libs.pari sage.modules
False
```
sage.combinat.designs.difference_family.is_relative_difference_set(R, G, H, params,
    verbose=False)

Check if \( R \) is a difference set of \( G \) relative to \( H \), with the given parameters.

This function checks that \( G \), \( H \) and \( R \) have the orders specified in the parameters, and that \( R \) satisfies the definition of relative difference set (from \[EB1966\]): the collection of differences \( r - s, r, s \in R, r \neq s \) contains only elements of \( G \) which are not in \( H \), and contains every such element exactly \( d \) times.

**INPUT:**

- \( R \) – list; the relative difference set of length \( k \)
- \( G \) – an additive abelian group of order \( mn \)
- \( H \) – list; a submodule of \( G \) of order \( n \)
- \( \text{params} \) – a tuple in the form \((m, n, k, d)\)
- \( \text{verbose} \) – boolean (default: \( False \)); if \( True \), the function will be verbose when the sequences do not satisfy the contraints

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import _get_submodule_of_order, relative_difference_set_from_m_sequence, is_relative_difference_set
sage: q, N = 5, 2
sage: params = ((q^N-1) // (q-1), q - 1, q^(N-1), q^(N-2))
# needs sage.libs.pari sage.modules
sage: G, R = relative_difference_set_from_m_sequence(q, N, return_group=True)
# needs sage.libs.pari sage.modules
sage: H = _get_submodule_of_order(G, q - 1)
# needs sage.libs.pari sage.modules
sage: is_relative_difference_set(R, G, H, params)
# needs sage.libs.pari sage.modules
True
```

If we pass the \( \text{verbose} \) argument, the function will explain why it failed:

```python
sage: R2 = [G[1], G[2], G[3], G[5], G[6]]
# needs sage.libs.pari sage.modules
sage: is_relative_difference_set(R2, G, H, params, verbose=True)
# needs sage.libs.pari sage.modules
There is a value in the difference set which is not repeated \( d \) times
False
```

sage.combinat.designs.difference_family.is_supplementary_difference_set(Ks, v=None,
    \( \lambda \text{mda}=\text{None}, \)
    \( G=\text{None}, \)
    \( \text{verbose}=\text{False} \))

Check that the sets in \( Ks \) are \( n - \{v; k_1, ..., k_n; \lambda \} \) supplementary difference sets over group \( G \) of order \( v \).

From the definition in \[Spe1975\]: let \( S_1, S_2, ..., S_n \) be \( n \) subsets of a group \( G \) of order \( v \) such that \( |S_i| = k_i \). If, for each \( g \in G, g \neq 0 \), the total number of solutions of \( a_i - a_i' = g \), with \( a_i, a_i' \in S_i \) is \( \lambda \), then \( S_1, S_2, ..., S_n \) are \( n - \{v; k_1, ..., k_n; \lambda \} \) supplementary difference sets.

One of the parameters \( v \) or \( G \) must always be specified. If \( G \) is not given, the function will use an AdditiveAbelianGroup of order \( v \).

**INPUT:**

- \( Ks \) – a list of sets to be checked
Combinatorics, Release 10.1

- \( v \) – integer; the parameter \( v \) of the supplementary difference sets
- \( \lambda \) – integer; the parameter \( \lambda \) of the supplementary difference sets
- \( G \) – a group of order \( v \)
- \( \text{verbose} \) – boolean (default: False); if True, the function will be verbose when the sets do not satisfy the constraints

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import supplementary_difference_set_from_rel_diff_set, is_supplementary_difference_set
sage: G, [S1, S2, S3, S4] = supplementary_difference_set_from_rel_diff_set(17)  
    # needs sage.modules sage.rings.finite_rings
sage: is_supplementary_difference_set([S1, S2, S3, S4], lmbda=16, G=G)  
    # needs sage.modules sage.rings.finite_rings
True
```

The parameter \( v \) can be given instead of \( G \):

```python
sage: is_supplementary_difference_set([S1, S2, S3, S4], v=16, lmbda=16)  
    # needs sage.modules sage.rings.finite_rings
True
sage: is_supplementary_difference_set([S1, S2, S3, S4], v=20, lmbda=16)  
    # needs sage.modules sage.rings.finite_rings
False
```

If \( \text{verbose}=\text{True} \), the function will be verbose:

```python
sage: is_supplementary_difference_set([S1, S2, S3, S4], lmbda=14, G=G,  
    # needs sage.modules sage.rings.finite_rings
    ....: verbose=True)
Number of pairs with difference (1) is 16, but lambda is 14
False
```

See also:

- `supplementary_difference_set_from_rel_diff_set()`
- `sage.combinat.designs.difference_family.mcfarland_1973_construction(q, s)`

Return a difference set.

The difference set returned has the following parameters

\[
v = \frac{q^{s+1}(q^{s+1} + q - 2)}{q - 1}, \quad k = \frac{q^s(q^{s+1} - 1)}{q - 1}, \quad \lambda = \frac{q^s(q^s - 1)}{q - 1}
\]

This construction is due to [McF1973].

INPUT:

- \( q, s \) - integers; parameters for the difference set (see the above formulas for the expression of \( v, k, \lambda \) in terms of \( q \) and \( s \))

See also:

The function `are_mcfarland_1973_parameters()` makes the translation between the parameters \((q, s)\) corresponding to a given triple \((v, k, \lambda)\).

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import (  
    mcfarland_1973_construction, is_difference_family)

sage: G,D = mcfarland_1973_construction(3, 1)
# needs sage.modules
sage: assert is_difference_family(G, D, 45, 12, 3)
# needs sage.modules

sage: G,D = mcfarland_1973_construction(2, 2)
# needs sage.modules
sage: assert is_difference_family(G, D, 64, 28, 12)
# needs sage.modules
```

`sage.combinat.designs.difference_family.one_cyclic_tiling(A, n)`

Given a subset $A$ of the cyclic additive group $G = \mathbb{Z}/n\mathbb{Z}$ return another subset $B$ so that $A + B = G$ and $|A||B| = n$ (i.e. any element of $G$ is uniquely expressed as a sum $a + b$ with $a$ in $A$ and $b$ in $B$).

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import one_cyclic_tiling
sage: tile = [0,2,4]
sage: m = one_cyclic_tiling(tile, 6); m
[0, 3]
sage: sorted((i+j)%6 for i in tile for j in m)
[0, 1, 2, 3, 4, 5]
sage: def print_tiling(tile, translat, n):
    ....:     for x in translat:
    ....:         print(''.join('X' if (i-x)%n in tile else '.') for i in range(n))
sage: tile = [0, 1, 2, 7]
sage: m = one_cyclic_tiling(tile, 12)
sage: print_tiling(tile, m, 12)
XXX....X..
....XXX....X
...X....XXX.
sage: tile = [0, 1, 5]
sage: m = one_cyclic_tiling(tile, 12)
sage: print_tiling(tile, m, 12)
XX...X......
...XX...X...
......XX...X
..X......XX.
sage: tile = [0, 2]
sage: m = one_cyclic_tiling(tile, 8)
sage: print_tiling(tile, m, 8)
X.X.....
....X.X.
.X.X....
......X.X
```
ALGORITHM:
Uses dancing links sage.combinat.dlx

sage.combinat.designs.difference_family.one_radical_difference_family(K, k)

Search for a radical difference family on $K$ using dancing links algorithm.

For the definition of radical difference family, see radical_difference_family(). Here, we consider only radical difference family with $\lambda = 1$.

INPUT:
• $K$ – a finite field of cardinality $q$
• $k$ – a positive integer so that $k(k - 1)$ divides $q - 1$

OUTPUT:
Either a difference family or None if it does not exist.

ALGORITHM:
The existence of a radical difference family is equivalent to a one dimensional tiling (or packing) problem in a cyclic group. This subsequent problem is solved by a call to the function one_cyclic_tiling().

Let $K^*$ be the multiplicative group of the finite field $K$. A radical family has the form $B = \{x_1B, \ldots, x_kB\}$, where $B = \{x : x^k = 1\}$ (for $k$ odd) or $B = \{x : x^{k-1} = 1\} \cup \{0\}$ (for $k$ even). Equivalently, $K^*$ decomposes as:

$$K^* = \Delta(x_1B) \cup \cdots \cup \Delta(x_kB) = x_1\Delta B \cup \cdots \cup x_k\Delta B.$$

We observe that $C = B\backslash 0$ is a subgroup of the (cyclic) group $K^*$, that can thus be generated by some element $r$. Furthermore, we observe that $\Delta B$ is always a union of cosets of $\pm C$ (which is twice larger than $C$).

\[
\begin{align*}
(k \text{ odd}) & \quad \Delta B = \{ r^i - r^j : r^i \neq r^j \} = \pm C \cdot \{ r^i - 1 : 0 < i \leq m \} \\
(k \text{ even}) & \quad \Delta B = \{ r^i - r^j : r^i \neq r^j \} \cup C = \pm C \cdot \{ r^i - 1 : 0 < i < m \} \cup \pm C
\end{align*}
\]

where

\[
(k \text{ odd}) \quad m = (k - 1)/2 \quad \text{and} \quad (k \text{ even}) \quad m = k/2.
\]

Consequently, $B = \{x_1B, \ldots, x_kB\}$ is a radical difference family if and only if $\{x_1(\Delta B/(\pm C)), \ldots, x_k(\Delta B/(\pm C))\}$ is a partition of the cyclic group $K^*/(\pm C)$.

EXAMPLES:

```sage
from sage.combinat.designs.difference_family import (  
....: one_radical_difference_family,  
....: is_difference_family)

sage: one_radical_difference_family(GF(13), 4)  
....: # needs sage.rings.finite_rings  
[[0, 1, 3, 9]]
```

The parameters that appear in [Bu95]:

```sage
sage: df = one_radical_difference_family(GF(449), 8); df  
....: # needs sage.rings.finite_rings  
[[0, 1, 18, 25, 176, 324, 359, 444]],
```

(continues on next page)
Return a \((v,k,1)\)-radical difference family.

Let fix an integer \(k\) and a prime power \(q = tk(k - 1) + 1\). Let \(K\) be a field of cardinality \(q\). A \((q,k,1)\)-difference family is **radical** if its base blocks are either: a coset of the \(k\)-th root of unity for \(k\) odd or a coset of \(k - 1\)-th root of unity and \(0\) if \(k\) is even (the number \(t\) is the number of blocks of that difference family).

The terminology comes from M. Buratti article [Bu95] but the first constructions go back to R. Wilson [Wi72].

**INPUT:**

- \(K\) - a finite field
- \(k\) – positive integer; the size of the blocks
- \(l\) – integer (default: 1); the \(\lambda\) parameter
- \(\text{existence}\) – if True, then return either True if Sage knows how to build such design, Unknown if it does not and False if it knows that the design does not exist
- \(\text{check}\) – boolean (default: True); if True then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

**EXAMPLES:**

```python
sage: radical_difference_family(GF(73), 9)   # needs sage.rings.finite_rings
[[1, 2, 4, 8, 16, 32, 37, 55, 64]]
```

```python
sage: radical_difference_family(GF(281), 5)   # needs sage.rings.finite_rings
[[1, 86, 90, 153, 232],
 [4, 50, 63, 79, 85],
 [5, 36, 149, 169, 203],
 [7, 40, 68, 219, 228],
 [9, 121, 212, 248, 253],
 [29, 81, 222, 246, 265],
 [31, 137, 167, 247, 261],
 [32, 70, 118, 119, 223],
 [39, 56, 66, 138, 263],
 [43, 45, 116, 141, 217],
 [98, 101, 109, 256, 279],
```

sage.combinat.designs.difference_family.radical_difference_set(K, k, l=1, existence=False, check=True)

Return a difference set made of a cyclotomic coset in the finite field $K$ and with parameters $k$ and $1$.

Most of these difference sets appear in chapter VI.18.48 of the Handbook of combinatorial designs.

EXAMPLES:

sage: from sage.combinat.designs.difference_family import radical_difference_set

sage: D = radical_difference_set(GF(7), 3, 1); D
[[1, 2, 4]]

sage: sorted(x-y for x in D[0] for y in D[0] if x != y)

sage.combinat.designs.difference_family.relative_difference_set_from_homomorphism(q, N, d, 
    check=True, 
    return_group=False)
Given a prime power \( q \), a number \( N \geq 2 \) and integers \( d \) such that \( d \mid q - 1 \) we create the relative difference set using the construction from Corollary 5.1.1 of [EB1966].

INPUT:

- \( q \) – a prime power
- \( N \) – an integer greater than 1
- \( d \) – an integer which divides \( q - 1 \)
- \( \text{check} \) – boolean (default: \( \text{True} \)); if \( \text{True} \), check that the result is a relative difference set before returning it
- \( \text{return_group} \) – boolean (default: \( \text{False} \)); if \( \text{True} \), the function will also return the group from which the set is created

OUTPUT:

If \( \text{return_group}=\text{False} \), the function return only the relative difference set. Otherwise, it returns a tuple containing the group and the set.

EXAMPLES:

```python
sage: from sage.combinat.designs.difference_family import relative_difference_set_from_homomorphism
sage: relative_difference_set_from_homomorphism(7, 2, 3)  # random #
(needs sage.modules sage.rings.finite_rings
[(0), (3), (4), (2), (13), (7), (14)]

sage: relative_difference_set_from_homomorphism(9, 2, 4, # random #
(needs sage.modules sage.rings.finite_rings
[[0], (3), (4), (2), (13), (7), (14)]

sage: relative_difference_set_from_homomorphism(9, 2, 5) #
(needs sage.modules sage.rings.finite_rings
Traceback (most recent call last):
... ValueErro... q-1 must be a multiple of d
```

Construct \( R((q^N - 1)/(q - 1), n, q^{N-1}, q^{N-2}d) \) where \( nd = q - 1 \).

The relative difference set is constructed over the set of additive integers modulo \( q^N - 1 \), as described in Theorem 5.1 of [EB1966]. Given an m-sequence \( (a_i) \) of period \( q^N - 1 \), the set is: \( R = \{ i | 0 \leq i \leq q^{N-1}, a_i = 1 \} \).

INPUT:

- \( q \) – a prime power
- \( N \) – a nonnegative number
- \( \text{check} \) – boolean (default: \( \text{True} \)); if \( \text{True} \), check that the result is a relative difference set before returning it
• return_group – boolean (default: False); if True, the function will also return the group from which the set is created.

**OUTPUT:**

If `return_group=False`, the function return only the relative difference set. Otherwise, it returns a tuple containing the group and the set.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import relative_difference_set_from_m_sequence
sage: relative_difference_set_from_m_sequence(2, 4, return_group=True)  # random
((Additive abelian group isomorphic to Z/15, [(0), (4), (5), (6), (7), (9), (11), (12)]))

sage: relative_difference_set_from_m_sequence(8, 2, check=False)  # random
([0), (6), (30), (40), (41), (44), (56), (61)]

sage: relative_difference_set_from_m_sequence(6, 2)
Traceback (most recent call last):
... ValueError: q must be a prime power
```

```python
sage.combinat.designs.difference_family.singer_difference_set(q, d)
```

Return a difference set associated to the set of hyperplanes in a projective space of dimension `d` over $GF(q)$.

A Singer difference set has parameters:

$$v = \frac{q^{d+1} - 1}{q - 1}, \quad k = \frac{q^d - 1}{q - 1}, \quad \lambda = \frac{q^{d-1} - 1}{q - 1}.$$ 

The idea of the construction is as follows. One consider the finite field $GF(q^{d+1})$ as a vector space of dimension $d + 1$ over $GF(q)$. The set of $GF(q)$-lines in $GF(q^{d+1})$ is a projective plane and its set of hyperplanes form a balanced incomplete block design.

Now, considering a multiplicative generator $z$ of $GF(q^{d+1})$, we get a transitive action of a cyclic group on our projective plane from which it is possible to build a difference set.

The construction is given in details in [Stinson2004], section 3.3.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import singer_difference_set, is_difference_family
sage: G, D = singer_difference_set(3, 2)  # random
sage: is_difference_family(G, D, verbose=True)  # random
It is a (13,4,1)-difference family True

sage: G, D = singer_difference_set(4, 2)  # random
sage: is_difference_family(G, D, verbose=True)  # random
```

(continues on next page)
sage.combinat.designs.difference_family.skew_supplementary_difference_set(n, existence=False, check=True, return_group=False)

Construct $4 - \{n; n_1, n_2, n_3, n_4; \lambda\}$ supplementary difference sets, where $S_1$ is skew and $n_1 + n_2 + n_3 + n_4 = n + \lambda$.

These sets are constructed from available data, as described in [Djo1994a]. The set $S_1 \subset G$ is always skew, i.e. $S_1 \cap (-S_1) = \emptyset$ and $S_1 \cup (-S_1) = G \setminus \{0\}$.

The data is taken from:

- $n = 103, 151$: [Djo1994a]
- $n = 67, 113, 127, 157, 163, 181, 241$: [Djo1992a]
- $n = 37, 43$: [Djo1992b]
- $n = 39, 49, 65, 93, 121, 129, 133, 217, 219, 267$: [Djo1992c]
- $n = 97$: [Djo2008a]
- $n = 109, 145, 247$: [Djo2008b]
- $n = 73$: [Djo2023b]
- $n = 213, 631$: [DGK2014]
- $n = 331$: [DK2016]

Additional skew Supplementary difference sets are built using the function skew_supplementary_difference_set_over_polynomial_ring() and skew_supplementary_difference_set_with_paley_todd().

**INPUT:**

- $n$ – integer; the parameter of the supplementary difference set
- $existence$ – boolean (default: False); if True, only check whether the supplementary difference sets can be constructed
- $check$ – boolean (default: True); if True, check that the sets are supplementary difference sets with $S_1$ skew before returning them; setting this parameter to False may speed up the computation considerably
**return_group** – boolean (default: False); if True, the function will also return the group from which the sets are created

**OUTPUT:**

If **existence=False**, the function returns a list containing 4 sets, or raises an error if data for the given \( n \) is not available. If **return_group=True** the function will additionally return the group from which the sets are created. If **existence=True**, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import skew_supplementary_difference_set
sage: [S1, S2, S3, S4] = skew_supplementary_difference_set(39)
```

If **return_group=True**, the function will also return the group:

```python
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set(103, return_group=True)
```

If **existence=True**, the function returns a boolean:

```python
sage: skew_supplementary_difference_set(103, existence=True)  
True
sage: skew_supplementary_difference_set(17, existence=True)
False
```

**Note:** The data for \( n = 247 \) in [Djo2008b] contains a typo: the set \( \alpha_2 \) should contain 223 instead of 233. This can be verified by checking the resulting sets, which are given explicitly in the paper.

```
sage.combinat.designs.difference_family.skew_supplementary_difference_set_over_polynomial_ring(n, existence=False, check=True)
```

Construct skew supplementary difference sets over a polynomial ring of order \( n \).

The skew supplementary difference sets for \( n = 81, 169 \) are taken from [Djo1994a].

**INPUT:**

- **n** – integer; the parameter of the supplementary difference sets
- **existence** – boolean (default: False); if True, only check whether the supplementary difference sets can be constructed
- **check** – boolean (default: True); if True, check that the sets are supplementary difference sets with \( S_1 \) skew before returning them; setting this parameter to False may speed up the computation considerably

**OUTPUT:**

If **existence=False**, the function returns a Polynomial Ring of order \( n \) and a list containing 4 sets, or raises an error if data for the given \( n \) is not available. If **existence=True**, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

**EXAMPLES:**

5.1. Comprehensive Module List
sage: from sage.combinat.designs.difference_family import skew_supplementary_difference_set_over_polynomial_ring
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set_over_polynomial_ring(81)  # needs sage.libs.pari

If existence=True, the function returns a boolean:

sage: skew_supplementary_difference_set_over_polynomial_ring(81, existence=True)
True
sage: skew_supplementary_difference_set_over_polynomial_ring(17, existence=True)
False

sage.combinat.designs.difference_family.skew_supplementary_difference_set_with_paley_todd(n, existence=False, check=True)

Construct \( 4 - \{n; n_1, n_2, n_3, n_4; \lambda\} \) skew supplementary difference sets where \( S_1 \) is the Paley-Todd difference set.

The skew SDS returned have the property that \( n_1 + n_2 + n_3 + n_4 = n + \lambda \).

This construction is described in [DK2016]. The function contains, for each value of \( n \), a set \( H \) containing integers modulo \( n \), and four sets \( J, K, L \). Then, these are used to construct \( (n; k_2, k_3, k_4; \lambda_2) \) difference family, with \( \lambda_2 = k_2 + k_3 + k_4 + (3n - 1)/4 \). Finally, these sets together with the Paley-Todd difference set form a skew supplementary difference set.

INPUT:

- \( n \) – integer; the parameter of the supplementary difference set
- \( \text{existence} \) – boolean (default: False); if True, only check whether the supplementary difference sets can be constructed
- \( \text{check} \) – boolean (default: True); if True, check that the sets are supplementary difference sets with \( S_1 \) skew before returning them; setting this parameter to False may speed up the computation considerably

OUTPUT:

If \( \text{existence}=\text{False} \), the function returns the group \( G \) of integers modulo \( n \) and a list containing 4 sets, or raises an error if data for the given \( n \) is not available. If \( \text{existence}=\text{True} \), the function returns a boolean representing whether skew supplementary difference sets can be constructed.

EXAMPLES:

sage: from sage.combinat.designs.difference_family import skew_supplementary_difference_set_with_paley_todd
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set_with_paley_todd(239)

If existence is True, the function returns a boolean:

sage: skew_supplementary_difference_set_with_paley_todd(239, existence=True)
True
sage: skew_supplementary_difference_set_with_paley_todd(17, existence=True)
False

sage.combinat.designs.difference_family.supplementary_difference_set(q, existence=False, check=True)
Construct $4 - \{2v; v, v + 1, v, v; 2v\}$ supplementary difference sets where $q = 2v + 1$.

This is a deprecated version of \texttt{supplementary_difference_set_from_rel_diff_set()}, please use that instead.

\texttt{sage.combinat.designs.difference_family.supplementary_difference_set_from_rel_diff_set}(q, existence=False, check=True)

Construct $4 - \{2v; v, v + 1, v, v; 2v\}$ supplementary difference sets where $q = 2v + 1$.

The sets are created from relative difference sets as detailed in Theorem 3.3 of [Spe1975]. This construction requires that $q$ is an odd prime power and that there exists $s \geq 0$ such that $(q - (2s^2 + 1))/2s^2 + 1$ is an odd prime power.

Note that the construction from [Spe1975] states that the resulting sets are $4 - \{2v; v + 1, v, v, v; 2v\}$ supplementary difference sets. However, the implementation of that construction returns $4 - \{2v; v, v + 1, v, v; 2v\}$ supplementary difference sets. This is not important, since the supplementary difference sets are not ordered.

**INPUT:**

- \texttt{q} – an odd prime power
- \texttt{existence} – boolean (default: \texttt{False}); If \texttt{True}, only check whether the supplementary difference sets can be constructed
- \texttt{check} – boolean (default: \texttt{True}); If \texttt{True}, check that the sets are supplementary difference sets before returning them

**OUTPUT:**

If \texttt{existence= False}, the function returns the 4 sets (containing integers), or raises an error if \texttt{q} does not satisfy the constraints. If \texttt{existence= True}, the function returns a boolean representing whether supplementary difference sets can be constructed.

**EXAMPLES:**

\begin{verbatim}
sage: from sage.combinat.designs.difference_family import supplementary_difference_set_from_rel_diff_set
sage: supplementary_difference_set_from_rel_diff_set(17) #random # needs sage.libs.pari
(Additive abelian group isomorphic to Z/16,
[[[1], [5], [6], [7], [9], [13], [14], [15]],
[[0], [2], [3], [5], [6], [10], [11], [13], [14]],
[[0], [1], [2], [3], [5], [6], [7], [12]],
[[0], [2], [3], [5], [6], [7], [9], [12]])
\end{verbatim}

If \texttt{existence= True}, the function returns a boolean:

\begin{verbatim}
sage: supplementary_difference_set_from_rel_diff_set(7, existence=True)
False
sage: supplementary_difference_set_from_rel_diff_set(17, existence=True)
True
\end{verbatim}

\texttt{is_supplementary_difference_set()}
Combinatorics, Release 10.1

sage.combinat.designs.difference_family.supplementary_difference_set_hadamard(n, existence=False, check=True)

Construct $4 - \{n; n_1, n_2, n_3, n_4; \lambda\}$ supplementary difference sets, where $n_1 + n_2 + n_3 + n_4 = n + \lambda$.

These sets are constructed from available data, as described in [Djo1994a]. The data is taken from:

- $n = 191$: [Djo2008c]
- $n = 239$: [Djo1994b]
- $n = 251$: [DGK2014]

Additional SDS are constructed using `skew_supplementary_difference_set()`.

**INPUT:**
- $n$ – integer; the parameter of the supplementary difference set
- `existence` – boolean (default: `False`); if `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are supplementary difference sets before returning them; Setting this parameter to `False` may speed up the computation considerably

**OUTPUT:**

If `existence=False`, the function returns the ring of integers modulo $n$ and a list containing the 4 sets, or raises an error if data for the given $n$ is not available. If `existence=True`, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import supplementary_difference_set_hadamard
sage: G, [S1, S2, S3, S4] = supplementary_difference_set_hadamard(191)
```

If `existence=True`, the function returns a boolean:

```python
sage: supplementary_difference_set_hadamard(191, existence=True)
True
sage: supplementary_difference_set_hadamard(17, existence=True)
False
```

sage.combinat.designs.difference_family.turyn_1965_3x3xK(k=4)

Return a difference set in either $C_3 \times C_3 \times C_4$ or $C_3 \times C_3 \times C_2 \times C_2$ with parameters $v = 36, k = 15, \lambda = 6$.

This example appears in [Tu1965].

**INPUT:**
- $k$ – either 2 (to get a difference set in $C_3 \times C_3 \times C_2 \times C_2$) or 4 (to get a difference set in $C_3 \times C_3 \times C_3 \times C_4$)

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import turyn_1965_3x3xK
sage: G,D = turyn_1965_3x3xK(4)
sage: assert is_difference_family(G, D, 36, 15, 6)
sage: G,D = turyn_1965_3x3xK(2)
sage: assert is_difference_family(G, D, 36, 15, 6)
```
Return a difference set on $GF(p) \times GF(p+2)$.

The difference set is built from the following element of the Cartesian product of finite fields $GF(p) \times GF(p+2)$:

- $(x,0)$ with any $x$
- $(x,y)$ with $x$ and $y$ squares
- $(x,y)$ with $x$ and $y$ non-squares

For more information see Wikipedia article Difference set.

**INPUT:**
- `check` – boolean (default: True); if True, then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_family import twin_prime_powers_difference_set
sage: G, D = twin_prime_powers_difference_set(3)
sage: G
The Cartesian product of (Finite Field of size 3, Finite Field of size 5)
sage: D
[[[1, 1], [1, 4], [2, 2], [2, 3], [0, 0], [1, 0], [2, 0]]]
```

### 5.1.84 Difference Matrices

This module gathers code related to difference matrices. One can build those objects (or know if they can be built) with `difference_matrix()`:

```python
sage: G, DM = designs.difference_matrix(9,5,1)
```

**Functions**

```python
sage.combinat.designs.difference_matrices.difference_matrix(g, k, lmbda=1, existence=False, check=True)
```

Return a $(g,k,\lambda)$-difference matrix

A matrix $M$ is a $(g,k,\lambda)$-difference matrix if it has size $\lambda g \times k$, its entries belong to the group $G$ of cardinality $g$, and for any two rows $R, R'$ of $M$ and $x \in G$ there are exactly $\lambda$ values $i$ such that $R_i - R'_i = x$.

**INPUT:**
- `k` – (integer) number of columns. If `k=None` it is set to the largest value available.
- `g` – (integer) cardinality of the group $G$
- `lmbda` – (integer; default: 1) – number of times each element of $G$ appears as a difference.
- `check` – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- `existence` (boolean) – instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
– Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown).
– False – meaning that the design does not exist.

Note: When k=None and existence=True the function returns an integer, i.e. the largest $k$ such that we can build a $(g, k, \lambda)$-DM.

EXAMPLES:

```python
sage: G,M = designs.difference_matrix(25,10); G
Finite Field in x of size 5^2
sage: designs.difference_matrix(993,None,existence=True)
32
```

Here we print for each $g$ the maximum possible $k$ for which Sage knows how to build a $(g, k, 1)$-difference matrix:

```python
sage: for g in range(2,30):
    ...:     k_max = designs.difference_matrix(g=g,k=None,existence=True)
    ...:     print("{:2} {}".format(g, k_max))
    ...:     _ = designs.difference_matrix(g,k_max)
2 2
3 3
4 4
5 5
6 2
7 7
8 8
9 9
10 2
11 11
12 6
13 13
14 2
15 3
16 16
17 17
18 2
19 19
20 4
21 6
22 2
23 23
24 8
25 25
26 2
27 27
28 6
29 29
```

`sage.combinat.designs.difference_matrices.difference_matrix_product(k, M1, G1, lmbda1, M2, G2, lmbda2, check=True)`

Return the product of the $(G1,k,lmbda1)$ and $(G2,k,lmbda2)$ difference matrices $M1$ and $M2$. 

702 Chapter 5. Comprehensive Module List
The result is a \((G_1 \times G_2, k, \lambda_1 \lambda_2)\)-difference matrix.

**INPUT:**
- \(k, \lambda_1, \lambda_2\) – positive integer
- \(G_1, G_2\) – groups
- \(M_1, M_2\) – \((G_1,k,\lambda_1)\) and \((G,k,\lambda_2)\) difference matrices
- check (boolean) – if True (default), the output is checked before being returned.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_matrices import (difference_matrix_product, is_difference_matrix)

sage: G1, M1 = designs.difference_matrix(11,6)
sage: G2, M2 = designs.difference_matrix(7,6)
sage: G, M = difference_matrix_product(6,M1,G1,1,M2,G2,1)
sage: G1
Finite Field of size 11
sage: G2
Finite Field of size 7
sage: G
The Cartesian product of (Finite Field of size 11, Finite Field of size 7)
sage: is_difference_matrix(M,G,6,1)
True
```

Try to find a product decomposition construction for difference matrices.

**INPUT:**
- \(g, k, \lambda\) – integers, parameters of the difference matrix

**OUTPUT:**
A pair of pairs \((g_1, \lambda_1), (g_2, \lambda_2)\) if Sage knows how to build \((g_1, k, \lambda_1)\) and \((g_2, k, \lambda_2)\) difference matrices and False otherwise.

**EXAMPLES:**

```python
sage: from sage.combinat.designs.difference_matrices import find_product_decomposition

sage: find_product_decomposition(77,6)
((7, 1), (11, 1))
sage: find_product_decomposition(616,7)
((7, 1), (88, 1))
sage: find_product_decomposition(24,10)
False
```
5.1.85 Evenly distributed sets in finite fields

This module consists of a simple class `EvenlyDistributedSetsBacktracker`. Its main purpose is to iterate through the evenly distributed sets of a given finite field.

The naive backtracker implemented here is not directly used to generate difference family as even for small parameters it already takes time to run. Instead, its output has been stored into a database `sage.combinat.designs.database`. If the backtracker is improved, then one might want to update this database with more values.

**Classes and methods**

```python
class sage.combinat.designs.evenly_distributed_sets.EvenlyDistributedSetsBacktracker
```

Bases: object

Set of evenly distributed subsets in finite fields.

**Definition:** Let $K$ be a finite field of cardinality $q$ and $k$ an integer so that $k(k-1)$ divides $q-1$. Let $H = K^*$ be the multiplicative group of invertible elements in $K$. A $k$-evenly distributed set in $K$ is a set $B = \{b_1, b_2, \ldots, b_k\}$ of $k$ elements of $K$ so that the $k(k-1)$ differences $\Delta B = \{b_i - b_j; i \neq j\}$ hit each coset modulo $H^2(q-1)/(k(k-1))$ exactly twice.

Evenly distributed sets were introduced by Wilson [Wi72] (see also [BJL99-1], Chapter VII.6). He proved that for any $k$, and for any prime power $q$ large enough such that $k(k-1)$ divides $q$ there exists a $k$-evenly distributed set in the field of cardinality $q$. This existence result based on a counting argument (using Dirichlet theorem) does not provide a simple method to generate them.

From a $k$-evenly distributed set, it is straightforward to build a $(q,k,1)$-difference family (see `to_difference_family()`). Another approach to generate a difference family, somehow dual to this one, is via radical difference family (see in particular `radical_difference_family()` from the module `difference_family`).

By default, this backtracker only considers evenly distributed sets up to affine automorphisms, i.e. $B$ is considered equivalent to $sB + t$ for any invertible element $s$ and any element $t$ in the field $K$. Note that the set of differences is just multiplicatively translated by $s$ as $\Delta(sB + t) = s(\Delta B)$, and so that $B$ is an evenly distributed set if and only if $sB$ is one too. This behaviour can be modified via the argument `up_to_isomorphism` (see the input section and the examples below).

**INPUT:**

- $K$ – a finite field of cardinality $q$
- $k$ – a positive integer such that $k(k-1)$ divides $q-1$
- `up_to_isomorphism` - (boolean, default True) whether only consider evenly distributed sets up to automorphisms of the field of the form $x \mapsto ax + b$. If set to False then the iteration is over all evenly distributed sets that contain 0 and 1.
- `check` – boolean (default is False). Whether you want to check intermediate steps of the iterator. This is mainly intended for debugging purpose. Setting it to True will considerably slow the iteration.

**EXAMPLES:**

The main part of the code is contained in the iterator. To get one evenly distributed set just do:

```python
sage: from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(151), 6)
sage: B = E.an_element()
```
The class has a method to convert it to a difference family:

```
sage: E.to_difference_family(B)
[[0, 1, 69, 36, 57, 89],
 [0, 132, 48, 71, 125, 121],
 [0, 59, 145, 10, 41, 117],
 [0, 87, 114, 112, 127, 42],
 [0, 8, 99, 137, 3, 108]]
```

It is also possible to run over all evenly distributed sets:

```
sage: E = EvenlyDistributedSetsBacktracker(Zmod(13), 4, up_to_isomorphism=False)
sage: for B in E: print(B)
[0, 1, 11, 5]
[0, 1, 4, 6]
[0, 1, 9, 3]
[0, 1, 8, 10]
sage: E = EvenlyDistributedSetsBacktracker(Zmod(13), 4, up_to_isomorphism=True)
sage: for B in E: print(B)
[0, 1, 11, 5]
```

Or only count them:

```
sage: for k in range(13, 200, 12):
    ....:     if is_prime_power(k):
    ....:         K = GF(k, 'a')
    ....:         E1 = EvenlyDistributedSetsBacktracker(K, 4, False)
    ....:         E2 = EvenlyDistributedSetsBacktracker(K, 4, True)
    ....:         print("{:3} {:3} {:3}".format(k, E1.cardinality(), E2.cardinality()))
13  4   1
25 40   4
37 12   1
49 24   2
61 12   1
73 48   4
97 10   6
109 72   6
121 240  20
157 96   8
169 240  20
181 204  17
193 336  28
```

Note that by definition, the number of evenly distributed sets up to isomorphisms is at most \( k(k-1) \) times smaller than without isomorphisms. But it might not be exactly \( k(k-1) \) as some of them might have symmetries:

```
sage: B = EvenlyDistributedSetsBacktracker(Zmod(13), 4).an_element()
sage: B
[0, 1, 11, 5]
```
Combinatorics, Release 10.1

sage: [9^x + 5 for x in B]
[5, 1, 0, 11]
sage: [3^x + 11 for x in B]
[11, 1, 5, 0]

an_element()
Return an evenly distributed set.
If there is no such subset raise an EmptySetError.

EXAMPLES:
sage: from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(41), 5)
sage: E.an_element()
[0, 1, 13, 38, 31]
sage: E = EvenlyDistributedSetsBacktracker(Zmod(61), 6)
sage: E.an_element()
Traceback (most recent call last):
... EmptySetError: no 6-evenly distributed set in Ring of integers modulo 61

cardinality()
Return the number of evenly distributed sets.
Use with precaution as there can be a lot of such sets and this method might be very long to answer!

EXAMPLES:
sage: from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(GF(25,'a'), 4); E
to_difference_family(B, check=True)
Given an evenly distributed set B convert it to a difference family.
As for any \( x \in K^* = H \) we have \(|\Delta B \cap xH^{2(q-1)/(k(k-1))}| = 2 \) (see EvenlyDistributedSetsBacktracker), the difference family is produced as \( \{xB : x \in H^{2(q-1)/(k(k-1))}\} \).
This method is useful if you want to obtain the difference family from the output of the iterator.

INPUT:
• B – an evenly distributed set
• check – (boolean, default True) whether to check the result

EXAMPLES:

```python
sage: from sage.combinat.designs.evenly_distributed_sets import EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(41),5)
sage: B = E.an_element(); B
[0, 1, 13, 38, 31]
sage: D = E.to_difference_family(B); D
[[0, 1, 13, 38, 31], [0, 32, 6, 27, 8]]
sage: from sage.combinat.designs.difference_family import is_difference_family
sage: is_difference_family(Zmod(41),D,41,5,1)
```

Setting check to False is much faster:

```python
sage: timeit("df = E.to_difference_family(B, check=True)") # random
625 loops, best of 3: 117 µs per loop
sage: timeit("df = E.to_difference_family(B, check=False)") # random
625 loops, best of 3: 1.83 µs per loop
```

## 5.1.86 External Representations of Block Designs

The “ext_rep” module is an API to the abstract tree represented by an XML document containing the External Representation of a list of block designs. The module also provides the related I/O operations for reading/writing ext-rep files or data. The parsing is based on expat.

This is a modified form of the module ext_rep.py (version 0.8) written by Peter Dobcsanyi [Do2009] peter@designtheory.org.

**Todo:** The XML data from the designtheory.org database contains a wealth of information about things like automorphism groups, transitivity, cycle type representatives, etc, but none of this data is made available through the current implementation.

### Functions

**class** `sage.combinat.designs.ext_rep.XTree(node)`

Bases: object

A lazy class to wrap a rooted tree representing an XML document. The tree’s nodes are tuples of the structure:

- (name, {dictionary of attributes}, [list of children])

Methods and services of an XTree object t:

- `t.attribute` – attribute named
- `t.child` – first child named
- `t[i]` – i-th child
• for child in t: – iterate over t’s children
• len(t) – number of t’s children

If child is not an empty subtree, return the subtree as an XTree object. If child is an empty subtree, return _name of the subtree. Otherwise return the child itself.

The lazy tree idea originated from a utility class of the pyRXP 0.9 package by Robin Becker at ReportLab.

class sage.combinat.designs.ext_rep.XTreeProcessor
Bases: object

An incremental event-driven parser for ext-rep documents. The processing stages:
• <list_of_designs ...> opening element. call-back: list_of_designs_proc
• <list_definition> subtree. call-back: list_definition_proc
• <info> subtree. call-back: info_proc
• iterating over <designs> processing each <block_design> separately. call-back: block_design_proc
• finishing with closing </designs> and </list_of_designs>.

parse(xml_source)
The main parsing function. Given an XML source (either a file handle or a string), parse the entire XML source.

EXAMPLES:

```python
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: proc.save_designs = True
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)
sage: proc.list_of_designs[0]
(2, [[0, 1], [0, 1]])
```

sage.combinat.designs.ext_rep.check_dtrs_protocols(input_name, input_pv)
Check that the XML data is in a valid format. We can currently handle version 2.0. For more information see http://designtheory.org/library/extrep/

EXAMPLES:

```python
sage: from sage.combinat.designs import ext_rep
sage: ext_rep.check_dtrs_protocols('source', '2.0')
sage: ext_rep.check_dtrs_protocols('source', '3.0')
RuntimeError: Incompatible dtrs_protocols: program: 2.0 source: 3.0
```

sage.combinat.designs.ext_rep.designs_from_XML(fname)
Return a list of designs contained in an XML file fname. The list contains tuples of the form (v, bs) where v is the number of points of the design and bs is the list of blocks.

EXAMPLES:
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
(2, [[0, 1], [0, 1]])
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: from sage.combinat.designs.block_design import BlockDesign
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
(2, [[0, 1], [0, 1]])

sage: d = BlockDesign(v, blocks)

sage: d.blocks()
[[0, 1], [0, 1]]

sage: d.is_t_design(t=2)
True

sage: d.is_t_design(return_parameters=True)
(True, (2, 2, 2, 2))

sage.combinat.designs.ext_rep.designs_from_XML(url)

Return a list of designs contained in an XML file named by a URL. The list contains tuples of the form (v, bs) where v is the number of points of the design and bs is the list of blocks.

EXAMPLES:

sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
(2, [[0, 1], [0, 1]])

sage: ext_rep.designs_from_XML_url("file://" + file_loc)[0]
(2, [[0, 1], [0, 1]])

sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.icgsa.txt.bz2")
# optional - internet
[(3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 1], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [1, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]])]

sage.combinat.designs.ext_rep.dump_to_tmpfile(s)

Utility function to dump a string to a temporary file.

EXAMPLES:

sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile("boo")

sage: os.remove(file_loc)

sage.combinat.designs.ext_rep.open_extrep_file(fname)

Try to guess the compression type from extension and open the extrep file.

EXAMPLES:
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)

sage.combinat.designs.ext_rep.open_extrep_url(url)
Try to guess the compression type from extension and open the extrep file pointed to by the url. This function (unlike open_extrep_file) returns the uncompressed text contained in the file.

EXAMPLES:

sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
... proc = ext_rep.XTreeProcessor()
...
sage: s = ext_rep.open_extrep_url("file:///" + file_loc)
sage: proc.parse(s)
... os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: s = ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.icgsa.txt.bz2") # optional - internet

5.1.87 Database of generalised quadrangles with spread

This module implements some construction of generalised quadrangles with spread.

EXAMPLES:

sage: GQ, S = designs.generalised_quadrangle_with_spread(4, 16, check=False)
sage: GQ
Incidence structure with 325 points and 1105 blocks
sage: GQ2, O = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: GQ2
Incidence structure with 1105 points and 325 blocks
sage: GQ3 = GQ.dual()
sage: set(GQ3._points) == set(GQ2._points)
True
sage: GQ2.is_isomorphic(GQ3) # long time
True

REFERENCES:

• [PT2009]
• [TP1994]
• Wikipedia article Generalized_quadrangle

AUTHORS:

• Ivo Maffei (2020-07-26): initial version
sage.combinat.designs.gen_quadrangles_with_spread.dual_GQ_ovoid(GQ, O)

Compute the dual incidence structure of GQ and return the image of O under the dual map

INPUT:
- • GQ – IncidenceStructure; the generalised quadrangle we want the dual of
- • O – iterable; the iterable of blocks we want to compute the dual

OUTPUT:
A pair (D, S) where D is the dual of GQ and S is the dual of O

EXAMPLES:
```
sage: from sage.combinat.designs.gen_quadrangles_with_spread import \
    ....: dual_GQ_ovoid
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(3)
sage: t[0].is_generalized_quadrangle(parameters=True)
(9, 3)
sage: t = dual_GQ_ovoid(*t)
sage: t[0].is_generalized_quadrangle(parameters=True)
(3, 9)
sage: all([x in t[0] for x in t[1]])
True
```

sage.combinat.designs.gen_quadrangles_with_spread.generalised_quadrangle_hermitian_with_ovoid(q)

Construct the generalised quadrangle $H(3, q^2)$ with an ovoid.

The GQ has order $(q^2, q)$.

INPUT:
- • q – integer; a prime power

OUTPUT:
A pair (D, O) where D is an IncidenceStructure representing the generalised quadrangle and O is a list of points of D which constitute an ovoid of D

EXAMPLES:
```
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: t[0]
Incidence structure with 1105 points and 325 blocks
sage: len(t[1])
65
sage: G = t[0].intersection_graph([1]) # line graph
sage: G.is_strongly_regular(True)
(325, 68, 3, 17)
sage: set(t[0].block_sizes())
{17}
```

REFERENCES:
For more on $H(3, q^2)$ and the construction implemented here see [PT2009] or [TP1994].
Construct a generalised quadrangle GQ of order \((s, t)\) with a spread \(S\).

**INPUT:**
- \(s, t\) – integers; order of the generalised quadrangle
- existence – boolean;
- check – boolean; if True, then Sage checks that the object built is correct. (default: True)

**OUTPUT:**
A pair \((GQ, S)\) where \(GQ\) is a *IncidenceStructure* representing the generalised quadrangle and \(S\) is a list of blocks of \(GQ\) representing the spread of \(GQ\).

**EXAMPLES:**

```python
sage: t = designs.generalised_quadrangle_with_spread(3, 9)
sage: t[0]
Incidence structure with 112 points and 280 blocks
sage: designs.generalised_quadrangle_with_spread(5, 25, existence=True)
True
sage: (designs.generalised_quadrangle_with_spread(4, 16, check=False))[0]
Incidence structure with 325 points and 1105 blocks
sage: designs.generalised_quadrangle_with_spread(0, 2, existence=True)
False
```

**REFERENCES:**
For more on generalised quadrangles and their spread see [PT2009] or [TP1994].

sage.combinat.designs.gen_quadrangles_with_spread.is_GQ_with_spread(GQ, S, s=None, t=None)
Check if GQ is a generalised quadrangle of order \((s, t)\) and check that \(S\) is a spread of GQ

**INPUT:**
- GQ – *IncidenceStructure*; the incidence structure that is supposed to be a generalised quadrangle
- S – iterable; the spread of GQ as an iterable of the blocks of GQ
- s, t – integers (optional); if \((s, t)\) are given, then we check that GQ has order \((s, t)\)

**EXAMPLES:**

```python
sage: from sage.combinat.designs.gen_quadrangles_with_spread import *
sage: t = generalised_quadrangle_hermitian_with_ovoid(3)
sage: is_GQ_with_spread(t)
Traceback (most recent call last):
  ...TypeError: 'int' object is not iterable
sage: t = dual_GQ_ovoid(t)
sage: is_GQ_with_spread(t)
True
sage: is_GQ_with_spread(t, s=3)
True
```
5.1.88 Incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure is specified by a list of points, blocks, or an incidence matrix \((1, 2)\). `IncidenceStructure` instances have the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>automorphism_group()</code></td>
<td>Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.</td>
</tr>
<tr>
<td><code>block_sizes()</code></td>
<td>Return the set of block sizes.</td>
</tr>
<tr>
<td><code>blocks()</code></td>
<td>Return the list of blocks.</td>
</tr>
<tr>
<td><code>canonical_label()</code></td>
<td>Return a canonical label for the incidence structure.</td>
</tr>
<tr>
<td><code>coloring()</code></td>
<td>Compute a (weak) (k)-coloring of the hypergraph.</td>
</tr>
<tr>
<td><code>complement()</code></td>
<td>Return the complement of the incidence structure.</td>
</tr>
<tr>
<td><code>copy()</code></td>
<td>Return a copy of the incidence structure.</td>
</tr>
<tr>
<td><code>degree()</code></td>
<td>Return the degree of a point (p) (or a set of points).</td>
</tr>
<tr>
<td><code>degrees()</code></td>
<td>Return the degree of all sets of given size, or the degree of all points.</td>
</tr>
<tr>
<td><code>dual()</code></td>
<td>Return the dual of the incidence structure.</td>
</tr>
<tr>
<td><code>edge_coloring()</code></td>
<td>Compute a proper edge-coloring.</td>
</tr>
<tr>
<td><code>ground_set()</code></td>
<td>Return the ground set (i.e the list of points).</td>
</tr>
<tr>
<td><code>incidence_graph()</code></td>
<td>Return the incidence graph of the incidence structure.</td>
</tr>
<tr>
<td><code>incidence_matrix()</code></td>
<td>Return the incidence matrix (A) of the design. (A) is a ((v \times b)) matrix defined by: (A[i,j] = 1) if (i) is in block (B_j) and (0) otherwise.</td>
</tr>
<tr>
<td><code>induced_substructure()</code></td>
<td>Return the substructure induced by a set of points.</td>
</tr>
<tr>
<td><code>intersection_graph()</code></td>
<td>Return the intersection graph of the incidence structure.</td>
</tr>
<tr>
<td><code>is_berge_cyclic()</code></td>
<td>Check whether <code>self</code> is a Berge-Cyclic uniform hypergraph.</td>
</tr>
<tr>
<td><code>is_connected()</code></td>
<td>Test whether the design is connected.</td>
</tr>
<tr>
<td><code>is_generalized_quadrangle()</code></td>
<td>Test if the incidence structure is a generalized quadrangle.</td>
</tr>
<tr>
<td><code>is_isomorphic()</code></td>
<td>Return whether the two incidence structures are isomorphic.</td>
</tr>
<tr>
<td><code>is_regular()</code></td>
<td>Test whether the incidence structure is (r)-regular.</td>
</tr>
<tr>
<td><code>is_resolvable()</code></td>
<td>Test whether the hypergraph is resolvable.</td>
</tr>
<tr>
<td><code>is_simple()</code></td>
<td>Test whether this design is simple (i.e. no repeated block).</td>
</tr>
<tr>
<td><code>is_spread()</code></td>
<td>Check whether the input is a spread for <code>self</code>.</td>
</tr>
<tr>
<td><code>is_t_design()</code></td>
<td>Test whether <code>self</code> is a (t - (v, k, l)) design.</td>
</tr>
<tr>
<td><code>is_uniform()</code></td>
<td>Test whether the incidence structure is (k)-uniform</td>
</tr>
<tr>
<td><code>isomorphic_substructures_iterator()</code></td>
<td>Iterate over all copies of (H_2) contained in <code>self</code>.</td>
</tr>
<tr>
<td><code>num_blocks()</code></td>
<td>Return the number of blocks.</td>
</tr>
<tr>
<td><code>num_points()</code></td>
<td>Return the size of the ground set.</td>
</tr>
<tr>
<td><code>packing()</code></td>
<td>Return a maximum packing</td>
</tr>
<tr>
<td><code>rank()</code></td>
<td>Return the rank of the hypergraph (the maximum size of a block).</td>
</tr>
<tr>
<td><code>relabel()</code></td>
<td>Relabel the ground set</td>
</tr>
<tr>
<td><code>trace()</code></td>
<td>Return the trace of a set of points.</td>
</tr>
</tbody>
</table>

  This is a significantly modified form of part of the module block_design.py (version 0.6) written by Peter Dobcsanyi peter@designtheory.org.

- Vincent Delecroix (2014): major rewrite

1. Block designs and incidence structures from wikipedia. Wikipedia article Block_design Wikipedia article Incidence_structure
class sage.combinat.designs.incidence_structures.IncidenceStructure(points=None, blocks=None, incidence_matrix=None, name=None, check=True, copy=True)

Bases: object

A base class for incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure (i.e. hypergraph, i.e. set system) can be defined from a collection of blocks (i.e. sets, i.e. edges), optionally with an explicit ground set (i.e. point set, i.e. vertex set). Alternatively they can be defined from a binary incidence matrix.

INPUT:

• points – (i.e. ground set, i.e. vertex set) the underlying set. If points is an integer \( v \), then the set is considered to be \( \{0, \ldots, v - 1\} \).

Note: The following syntax, where points is omitted, automatically defines the ground set as the union of the blocks:

```
sage: H = IncidenceStructure([[\'a\', \'b\', \'c\'],[\'c\', \'d\', \'e\']])
sage: sorted(H.ground_set())
[\'a\', \'b\', \'c\', \'d\', \'e\']
```

• blocks – (i.e. edges, i.e. sets) the blocks defining the incidence structure. Can be any iterable.

• incidence_matrix – a binary incidence matrix. Each column represents a set.

• name (a string, such as “Fano plane”).

• check – whether to check the input

• copy – (use with caution) if set to False then blocks must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your blocks object will become the IncidenceStructure instance’s internal data.

EXAMPLES:

An incidence structure can be constructed by giving the number of points and the list of blocks:

```
sage: IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
Incidence structure with 7 points and 7 blocks
```

Only providing the set of blocks is sufficient. In this case, the ground set is defined as the union of the blocks:

```
sage: IncidenceStructure([[1,2,3],[2,3,4]])
Incidence structure with 4 points and 2 blocks
```

Or by its adjacency matrix (a \( \{0, 1\} \)-matrix in which rows are indexed by points and columns by blocks):

```
sage: m = matrix([[0,1,0],[0,0,1],[1,0,1],[1,1,1]])
# Needs sage.modules
sage: IncidenceStructure(m)
Incidence structure with 4 points and 3 blocks
```
The points can be any (hashable) object:

```
sage: V = [(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]
sage: B = [(V[0], V[1], V[2]), (V[1], V[2]), (V[0], V[2])]
sage: I = IncidenceStructure(V, B)
sage: I.ground_set()
[(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]
sage: I.blocks()
[[[0, 'a'), (0, 'b'), (1, 'a'), [0, 'a'), (1, 'a'), [(0, 'b'), (1, 'a')]]
```

The order of the points and blocks does not matter as they are sorted on input (see github issue #11333):

```
sage: A = IncidenceStructure([0,1,2], [[0],[0,2]])
sage: B = IncidenceStructure([1,0,2], [[0],[2,0]])
sage: B == A
True
sage: C = BlockDesign(2, [[0], [1,0]])
sage: D = BlockDesign(2, [[0,1], [0]])
sage: C == D
True
```

If you care for speed, you can set `copy=False`, but in that case, your input must be a list of lists and the ground set must be 0, ..., v − 1:

```
sage: blocks = [[0,1],[2,0],[1,2]]  # a list of lists of integers
sage: I = IncidenceStructure(3, blocks, copy=False)
sage: I._blocks is blocks
True
```

**automorphism_group()**

Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.

**EXAMPLES:**

```
sage: # needs sage.groups sage.rings.finite_rings
sage: P = designs.DesarguesianProjectivePlaneDesign(2); P
(7,3,1)-Balanced Incomplete Block Design
sage: G = P.automorphism_group()
True
sage: G
Permutation Group with generators [...]
sage: G.cardinality()
168
```

A non self-dual example:

```
sage: IS = IncidenceStructure(list(range(4)), [[0,1,2,3],[1,2,3]])
sage: IS.automorphism_group().cardinality()  # needs sage.groups
6
sage: IS.dual().automorphism_group().cardinality()  # needs sage.groups
(continues on next page)
Examples with non-integer points:

```python
sage: I = IncidenceStructure('abc', ('ab', 'ac', 'bc'))
sage: I.automorphism_group()  # needs sage.groups
Permutation Group with generators [('b', 'c'), ('a', 'b')]
sage: IncidenceStructure([[1,2],[3,4]]).automorphism_group()  # needs sage.groups
Permutation Group with generators [[(1,2),(3,4)]]
```

`block_sizes()`

Return the set of block sizes.

EXAMPLES:

```python
sage: BD = IncidenceStructure(8, [[0,1,3],[1,4,5,6],[1,2],[5,6,7]])
sage: BD.block_sizes()
[3, 2, 4, 3]
sage: BD = IncidenceStructure(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
```

`blocks()`

Return the list of blocks.

EXAMPLES:

```python
sage: BD = IncidenceStructure(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]])
sage: BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

`canonical_label()`

Return a canonical label for the incidence structure.

A canonical label is relabeling of the points into integers \( \{0, ..., n-1\} \) such that isomorphic incidence structures are relabelled to equal objects.

EXAMPLES:

```python
sage: # needs sage.schemes
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
sage: fano1 == fano2
False
sage: fano1.relabel(fano1.canonical_label())
sage: fano2.relabel(fano2.canonical_label())
sage: fano1 == fano2
True
```
**coloring**(*k*, *solver=None*, *verbose=None*, *integrality_tolerance=0*)

Compute a (weak) *k*-coloring of the hypergraph

A weak coloring of a hypergraph $\mathcal{H}$ is an assignment of colors to its vertices such that no set is monochromatic.

**INPUT:**

- *k* (integer) – compute a coloring with *k* colors if an integer is provided, otherwise returns an optimal coloring (i.e. with the minimum possible number of colors).
- *solver* – (default: *None*) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to *None*, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- *verbose* – non-negative integer (default: 0). Set the level of verbosity you want from the linear program solver. Since the problem is $NP$-complete, its solving may take some time depending on the graph. A value of 0 means that there will be no message printed by the solver.
- *integrality_tolerance* – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**EXAMPLES:**

The Fano plane has chromatic number 3:

```python
sage: len(designs.steiner_triple_system(7).coloring())
3
```

One admissible 3-coloring:

```python
sage: designs.steiner_triple_system(7).coloring() # not tested
[\[0, 2, 5, 1\], \[4, 3\], \[6\]]
```

The chromatic number of a graph is equal to the chromatic number of its 2-uniform corresponding hypergraph:

```python
sage: g = graphs.PetersenGraph()
sage: H = IncidenceStructure(g.edges(sort=True, labels=False))
sage: len(g.coloring())
3
sage: len(H.coloring())
3
```

**complement**(uniform=False)

Return the complement of the incidence structure.

Two different definitions of “complement” are made available, according to the value of uniform.

**INPUT:**

- *uniform* (boolean) –
  - if set to `False` (default), returns the incidence structure whose blocks are the complements of all blocks of the incidence structure.
  - If set to `True` and the incidence structure is *k*-uniform, returns the incidence structure whose blocks are all *k*-sets of the ground set that do not appear in `self`.  

5.1. Comprehensive Module List 717
EXAMPLES:

The complement of a BalancedIncompleteBlockDesign is also a 2-design:

```python
sage: bibd = designs.balanced_incomplete_block_design(13,4)  # needs sage.schemes
sage: bibd.is_t_design(return_parameters=True)  # needs sage.schemes
(True, (2, 13, 4, 1))

sage: bibd.complement().is_t_design(return_parameters=True)  # needs sage.schemes
(True, (2, 13, 9, 6))
```

The “uniform” complement of a graph is a graph:

```python
sage: g = graphs.PetersenGraph()
sage: G = IncidenceStructure(g.edges(sort=True, labels=False))
sage: H = G.complement(uniform=True)
sage: h = Graph(H.blocks())
sage: g == h
False
sage: g == h.complement()
True
```

copy()

Return a copy of the incidence structure.

EXAMPLES:

```python
sage: IS = IncidenceStructure([[[1,2,3,"e"],[name="Test")

sage: IS = IncidenceStructure([[[1,2,3,"e"],[name="Test")

sage: copy(IS)

sage: [1, 2, 3, 'e'] in copy(IS)
True

sage: copy(IS)._name
'Test'
```

degree(p=None, subset=False)

Return the degree of a point p (or a set of points).

The degree of a point (or set of points) is the number of blocks that contain it.

INPUT:

- p – a point (or a set of points) of the incidence structure.
- subset (boolean) – whether to interpret the argument as a set of point (subset=True) or as a point (subset=False, default).

EXAMPLES:

```python
sage: designs.steiner_triple_system(9).degree(3)
4
sage: designs.steiner_triple_system(9).degree([1,2],subset=True)
1
```
**degrees**(*size=None*)

Return the degree of all sets of given size, or the degree of all points.

The degree of a point (or set of point) is the number of blocks that contain it.

**INPUT:**

- *size* (integer) – return the degree of all subsets of points of cardinality *size*. When *size=None*, the function outputs the degree of all points.

**Note:** When *size=None* the output is indexed by the points. When *size=1* it is indexed by tuples of size 1. This is the same information, stored slightly differently.

**OUTPUT:**

A dictionary whose values are degrees and keys are either:

- the points of the incidence structure if *size=None* (default)
- the subsets of size *size* of the points stored as tuples

**EXAMPLES:**

```python
sage: IncidenceStructure([[1,2,3],[1,4]]).degrees(2)
{(1, 2): 1, (1, 3): 1, (1, 4): 1, (2, 3): 1, (2, 4): 0, (3, 4): 0}
```

In a Steiner triple system, all pairs have degree 1:

```python
sage: S13 = designs.steiner_triple_system(13)
sage: all(v == 1 for v in S13.degrees(2).values())
True
```

**dual**(*algorithm=None*)

Return the dual of the incidence structure.

**INPUT:**

- *algorithm* – whether to use Sage’s implementation (*algorithm=None*, default) or use GAP’s (*algorithm="gap"*).

**Note:** The *algorithm="gap"* option requires GAP’s Design package (included in the gap_packages Sage spkg).

**EXAMPLES:**

The dual of a projective plane is a projective plane:

```python
sage: PP = designs.DesarguesianProjectivePlaneDesign(4)
needs sage.rings.finite_rings
sage: PP.dual().is_t_design(return_parameters=True)
needs sage.modules sage.rings.finite_rings
(True, (2, 21, 5, 1))
```

**REFERENCE:**

edge_coloring()
Compute a proper edge-coloring.
A proper edge-coloring is an assignment of colors to the sets of the incidence structure such that two sets with non-empty intersection receive different colors. The coloring returned minimizes the number of colors.

OUTPUT:
A partition of the sets into color classes.

EXAMPLES:
```
sage: H = Hypergraph([{{1, 2, 3}, {2, 3, 4}, {3, 4, 5}, {4, 5, 6}}]; H
Incidence structure with 6 points and 4 blocks
sage: C = H.edge_coloring()
sage: C # random
[[[3, 4, 5]], [[2, 3, 4]], [[4, 5, 6], [1, 2, 3]]
```

ground_set()
Return the ground set (i.e the list of points).

EXAMPLES:
```
sage: IncidenceStructure(3, [[0, 1], [0, 2]]).ground_set()
[0, 1, 2]
```

incidence_graph(labels=False)
Return the incidence graph of the incidence structure
A point and a block are adjacent in this graph whenever they are incident.

INPUT:
• labels (boolean) – whether to return a graph whose vertices are integers, or labelled elements.
  – labels is False (default) – in this case the first vertices of the graphs are the elements of ground_set(), and appear in the same order. Similarly, the following vertices represent the elements of blocks(), and appear in the same order.
  – labels is True, the points keep their original labels, and the blocks are Set objects.

Note that the labelled incidence graph can be incorrect when blocks are repeated, and on some (rare) occasions when the elements of ground_set() mix Set() and non-Set objects.

EXAMPLES:
```
sage: BD = IncidenceStructure(7, [[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5],
....: [1, 4, 6], [2, 3, 6], [2, 4, 5]])
```
```
sage: BD.incidence_graph()
Bipartite graph on 14 vertices
```
```
sage: A = BD.incidence_matrix()
```
```
sage: Graph(block_matrix([[A*0, A],
....: [A.transpose(), A*0]])) == BD.incidence_graph()
True
```
**incidence_matrix()**

Return the incidence matrix \( A \) of the design. \( A \) is a \((v \times b)\) matrix defined by: \( A[i, j] = 1 \) if \( i \) is in block \( B_j \) and 0 otherwise.

**EXAMPLES:**

```python
sage: BD = IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],
                                 [1,4,6],[2,3,6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
sage: BD.incidence_matrix()  # needs sage.modules
[1 1 1 0 0 0 0]
[1 0 0 1 1 0 0]
[1 0 0 0 0 1 1]
[0 1 0 1 0 1 0]
[0 1 0 0 1 0 1]
[0 0 1 1 0 0 1]
[0 0 1 0 1 1 0]
```

**induced_substructure(points)**

Return the substructure induced by a set of points.

The substructure induced in \( \mathcal{H} \) by a set \( X \subseteq V(\mathcal{H}) \) of points is the incidence structure \( \mathcal{H}_X \) defined on \( X \) whose sets are all \( S \in \mathcal{H} \) such that \( S \subseteq X \).

**INPUT:**

- **points** – a set of points.

**Note:** This method goes over all sets of self before building a new `IncidenceStructure` (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

**EXAMPLES:**

A Fano plane with one point removed:

```python
sage: F = designs.steiner_triple_system(7)
sage: F.induced_substructure([0..5])
Incidence structure with 6 points and 4 blocks
```

**intersection_graph(sizes=None)**

Return the intersection graph of the incidence structure.

The vertices of this graph are the `blocks()` of the incidence structure. Two of them are adjacent if the size of their intersection belongs to the set `sizes`.

**INPUT:**

---

5.1. Comprehensive Module List 721
• sizes – a list/set of integers. For convenience, setting sizes to 5 has the same effect as sizes=[5].
   When set to None (default), behaves as sizes=PositiveIntegers().

EXAMPLES:
The intersection graph of a balanced_incomplete_block_design() is a strongly regular graph
(when it is not trivial):

```sage
sage: BIBD = designs.balanced_incomplete_block_design(19,3)
sage: G = BIBD.intersection_graph(1)
sage: G.is_strongly_regular(parameters=True)
(57, 24, 11, 9)
```

is_berge_cyclic()
Check whether self is a Berge-Cyclic uniform hypergraph.

A k-uniform Berge cycle (named after Claude Berge) of length ℓ is a cyclic list of distinct k-sets $F_1, \ldots, F_\ell$, $\ell > 1$, and distinct vertices $C = \{v_1, \ldots, v_\ell\}$ such that for each $1 \leq i \leq \ell$, $F_i$ contains $v_i$ and $v_{i+1}$ (where $v_{\ell+1} = v_1$).

A uniform hypergraph is Berge-cyclic if its incidence graph is cyclic. It is called “Berge-acyclic” otherwise.

For more information, see [Fag1983] and Wikipedia article Hypergraph.

EXAMPLES:

```sage
sage: Hypergraph(5, [[1, 2, 3], [2, 3, 4]]).is_berge_cyclic() # needs sage.modules
True
sage: Hypergraph(6, [[1, 2, 3], [3, 4, 5]]).is_berge_cyclic() # needs sage.modules
False
```

is_connected()
Test whether the design is connected.

EXAMPLES:

```sage
sage: IncidenceStructure(3, [[0,1],[0,2]]).is_connected()
True
sage: IncidenceStructure(4, [[0,1],[2,3]]).is_connected()
False
```

is_generalized_quadrangle(\texttt{verbose=False, parameters=False})
Test if the incidence structure is a generalized quadrangle.

An incidence structure is a generalized quadrangle iff (see [BH2012], section 9.6):

• two blocks intersect on at most one point.
• For every point $p$ not in a block $B$, there is a unique block $B'$ intersecting both $\{p\}$ and $B$

It is a regular generalized quadrangle if furthermore:

• it is $s + 1$-uniform for some positive integer $s$.
• it is $t + 1$-regular for some positive integer $t$.

For more information, see the Wikipedia article Generalized_quadrangle.
**Note:** Some references (e.g. [PT2009] or Wikipedia article Generalized_quadrangle) only allow regular generalized quadrangles. To use such a definition, see the parameters optional argument described below, or the methods `is_regular()` and `is_uniform()`.

**INPUT:**

- `verbose` (boolean) – whether to print an explanation when the instance is not a generalized quadrangle.
- `parameters` (boolean; False) – if set to `True`, the function returns a pair \((s, t)\) instead of `True` answers. In this case, \(s\) and \(t\) are the integers defined above if they exist (each can be set to `False` otherwise).

**EXAMPLES:**

```python
sage: h = designs.CremonaRichmondConfiguration()
    # needs networkx
sage: h.is_generalized_quadrangle()
    # needs networkx
True
```

This is actually a regular generalized quadrangle:

```python
sage: h.is_generalized_quadrangle(parameters=True)
    # needs networkx
(2, 2)
```

**`is_isomorphic()`**

Return whether the two incidence structures are isomorphic.

**INPUT:**

- `other` – an incidence structure.
- `certificate` (boolean) – whether to return an isomorphism from `self` to `other` instead of a boolean answer.

**EXAMPLES:**

```python
sage: # needs sage.schemes
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
```

```python
sage: fano1.is_isomorphic(fano2)
    # needs networkx
True
```

```python
sage: fano1.is_isomorphic(fano2,certificate=True)
    # needs networkx
{0: 0, 1: 1, 2: 2, 3: 6, 4: 4, 5: 3, 6: 5}
```

**`is_regular()`**

Test whether the incidence structure is \(r\)-regular.

An incidence structure is said to be \(r\)-regular if all its points are incident with exactly \(r\) blocks.

**INPUT:**

- `r` (integer)

**OUTPUT:**

If \(r\) is defined, a boolean is returned. If \(r\) is set to `None` (default), the method returns either `False` or the integer \(r\) such that the incidence structure is \(r\)-regular.
**Warning:** In case of 0-regular incidence structure, beware that if `not H.is_regular()` is a satisfied condition.

**EXAMPLES:**

```sage
dsage: designs.balanced_incomplete_block_design(7,3).is_regular()
# needs sage.schemes
3
```

```sage
dsage: designs.balanced_incomplete_block_design(7,3).is_regular(r=3)
# needs sage.schemes
True
```

```sage
dsage: designs.balanced_incomplete_block_design(7,3).is_regular(r=4)
# needs sage.schemes
False
```

**is_resolvable** *(certificate, solver=False, verbose=0, check=0, integrality_tolerance=True)*

Test whether the hypergraph is resolvable

A hypergraph is said to be resolvable if its sets can be partitioned into classes, each of which is a partition of the ground set.

**Note:** This problem is solved using an Integer Linear Program, and GLPK (the default LP solver) has been reported to be very slow on some instances. If you hit this wall, consider installing a more powerful MILP solver (CPLEX, Gurobi, ...).

**INPUT:**

- **certificate** (boolean) – whether to return the classes along with the binary answer (see examples below).
- **solver** – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- **verbose** – integer (default: 0). Sets the level of verbosity. Set to 0 by default, which means quiet.
- **check** (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- **integrality_tolerance** – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**EXAMPLES:**

Some resolvable designs:

```sage
dsage: TD = designs.transversal_design(2,2,resolvable=True)
dsage: TD.is_resolvable()
True
```

```sage
dsage: AG = designs.AffineGeometryDesign(3,1,GF(2))
# needs sage.rings.finite_rings
```

```sage
dsage: AG.is_resolvable()
# needs sage.rings.finite_rings
True
```
Their classes:

```python
sage: b, cls = TD.is_resolvable(True)
sage: b  
True
sage: cls # random
[[[0, 3], [1, 2]], [[1, 3], [0, 2]]]

sage: b, cls = AG.is_resolvable(True)  # needs sage.rings.finite_rings
sage: b  
True
sage: cls # random
[[[6, 7], [4, 5], [0, 1], [2, 3]],
 [[5, 7], [0, 4], [3, 6], [1, 2]],
 [[0, 2], [4, 7], [1, 3], [5, 6]],
 [[3, 4], [0, 7], [1, 5], [2, 6]],
 [[3, 7], [1, 6], [0, 5], [2, 4]],
 [[0, 6], [2, 7], [1, 4], [3, 5]],
 [[4, 6], [0, 3], [2, 5], [1, 7]]]
```

A non-resolvable design:

```python
sage: Fano = designs.balanced_incomplete_block_design(7,3)  # needs sage.schemes
sage: Fano.is_resolvable()  # needs sage.schemes
False
sage: Fano.is_resolvable(True)
(False, [])
```

**is_simple()**

Test whether this design is simple (i.e. no repeated block).

**EXAMPLES:**

```python
sage: IncidenceStructure(3, [[0,1],[1,2],[0,2]]).is_simple()
True
sage: IncidenceStructure(3, [[0],[0]]).is_simple()
False
```

**is_spread**

Check whether the input is a spread for self.

A spread of an incidence structure \((P, B)\) is a subset of \(B\) which forms a partition of \(P\).
INPUT:

- `spread` – iterable; defines the spread

EXAMPLES:

```python
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[1, 2, 3], [4, 5, 6]])
True
sage: E.is_spread([[1, 2, 3, 4, 5, 6]])
Traceback (most recent call last):
  ... TypeError: 'sage.rings.integer.Integer' object is not iterable
sage: E.is_spread([[1, 2, 3, 4], [5, 6]])
False
```

Order of blocks or of points within each block doesn’t matter:

```python
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[5, 6, 4], [3, 1, 2]])
True
```

`is_t_design(t=None, v=None, k=None, l=None, return_parameters=False)`

Test whether `self` is a \( t-(v,k,l) \) design.

A \( t-(v,k,\lambda) \) (sometimes called \( t \)-design for short) is a block design in which:

- the underlying set has cardinality \( v \)
- the blocks have size \( k \)
- each \( t \)-subset of points is covered by \( \lambda \) blocks

INPUT:

- \( t,v,k,l \) (integers) – their value is set to `None` by default. The function tests whether the design is a \( t-(v,k,l) \) design using the provided values and guesses the others. Note that \( l \) cannot be specified if \( t \) is not.
- `return_parameters` (boolean)– whether to return the parameters of the \( t \)-design. If set to `True`, the function returns a pair (boolean_answer, (\( t,v,k,l \))).

EXAMPLES:

```python
sage: fano_blocks = [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]]
sage: BD = IncidenceStructure(7, fano_blocks)
sage: BD.is_t_design()
True
sage: BD.is_t_design(return_parameters=True)
(True, (2, 7, 3, 1))
sage: BD.is_t_design(2, 7, 3, 1)
True
sage: BD.is_t_design(1, 7, 3, 3)
True
sage: BD.is_t_design(0, 7, 3, 7)
True
sage: BD.is_t_design(0, 6, 3, 7) or BD.is_t_design(0,7,4,7) or BD.is_t_design(0,7,
```

(continues on next page)
Steiner triple and quadruple systems are other names for $2 - (v, 3, 1)$ and $3 - (v, 4, 1)$ designs:

```
sage: S3_9 = designs.steiner_triple_system(9)
sage: S3_9.is_t_design(2,9,3,1)
True
sage: blocks = designs.steiner_quadruple_system(8)
sage: S4_8 = IncidenceStructure(8, blocks)
sage: S4_8.is_t_design(3,8,4,1)
True
sage: blocks = designs.steiner_quadruple_system(14)
sage: S4_14 = IncidenceStructure(14, blocks)
sage: S4_14.is_t_design(3,14,4,1)
True
```

Some examples of Witt designs that need the gap database:

```
sage: BD = designs.WittDesign(9)  # optional - gap_package_design
sage: BD.is_t_design(2,9,3,1)    # optional - gap_package_design
True
sage: W12 = designs.WittDesign(12)  # optional - gap_package_design
sage: W12.is_t_design(5,12,6,1)  # optional - gap_package_design
True
sage: W12.is_t_design(4)    # optional - gap_package_design
True
```

Further examples:

```
sage: D = IncidenceStructure(4, [[]], [[]])
sage: D.is_t_design(return_parameters=True)
(True, (0, 4, 0, 2))
sage: D = IncidenceStructure(4, [[0], [1], [0, 2], [0, 3]])
sage: D.is_t_design(return_parameters=True)
(True, (0, 4, 2, 3))
sage: D = IncidenceStructure(4, [[0, 1], [1, 2], [0, 3]])
sage: D.is_t_design(return_parameters=True)
(True, (1, 4, 1, 1))
sage: D = IncidenceStructure(4, [[0, 1], [2, 3]])
sage: D.is_t_design(return_parameters=True)
```

(continues on next page)
is_uniform($k=\text{None}$)
Test whether the incidence structure is $k$-uniform
An incidence structure is said to be $k$-uniform if all its blocks have size $k$.

**INPUT:**
- $k$ (integer)

**OUTPUT:**
If $k$ is defined, a boolean is returned. If $k$ is set to None (default), the method returns either False or the integer $k$ such that the incidence structure is $k$-uniform.

**Warning:** In case of 0-uniform incidence structure, beware that if not $H$.is_uniform() is a satisfied condition.

**EXAMPLES:**

```
sage: designs.balanced_incomplete_block_design(7,3).is_uniform()  # needs sage.schemes
3
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=3)  # needs sage.schemes
True
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=4)  # needs sage.schemes
False
```

isomorphic_substructures_iterator($H2$, induced=False)
Iterates over all copies of $H2$ contained in self.
A hypergraph $H_1$ contains an isomorphic copy of a hypergraph $H_2$ if there exists an injection $f : V(H_2) \rightarrow V(H_1)$ such that for any set $S_2 \in E(H_2)$ the set $S_1 = f(S2)$ belongs to $E(H_1)$.

It is an induced copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{S : S \in E(H_1) \text{ and } f(V(H_2))\}$.

This function lists all such injections. In particular, the number of copies of $H$ in itself is equal to the size of its automorphism group.

See subhypergraph_search for more information.

**INPUT:**
- $H2$ an IncidenceStructure object.
- induced (boolean) – whether to require the copies to be induced. Set to False by default.

**EXAMPLES:**
How many distinct $C_5$ in Petersen’s graph?
As the automorphism group of $C_5$ has size 10, the number of distinct unlabelled copies is 12. Let us check that all functions returned correspond to an actual $C_5$ subgraph:

```
sage: for f in IP.isomorphic_substructures_iterator(IC):
    ....:    assert all(P.has_edge(f[x],f[y]) for x,y in C.edges(sort=True, labels=False))
```

The number of induced copies, in this case, is the same:

```
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC, induced=True))
120
```

They begin to differ if we make one vertex universal:

```
sage: P.add_edges([[0,x] for x in P], loops=False)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
420
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC, induced=True))
60
```

The number of copies of $H$ in itself is the size of its automorphism group:

```
sage: H = designs.projective_plane(3)  # needs sage.schemes
sage: sum(1 for _ in H.isomorphic_substructures_iterator(H))  # needs sage.schemes
5616
sage: H.automorphism_group().cardinality()  # needs sage.groups sage.schemes
5616
```

**num_blocks()**

Return the number of blocks.

**EXAMPLES:**

```
sage: designs.DesarguesianProjectivePlaneDesign(2).num_blocks()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2],[1,2,3]])
sage: B.num_blocks()
5
```

**num_points()**

Return the size of the ground set.

**EXAMPLES:**
```python
sage: designs.DesarguesianProjectivePlaneDesign(2).num_points()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2],[1,2,3]])
sage: B.num_points()
4
```

packing(solver, verbose=None, integrality_tolerance=0)

Return a maximum packing

A maximum packing in a hypergraph is collection of disjoint sets/blocks of maximal cardinality. This problem is NP-complete in general, and in particular on 3-uniform hypergraphs. It is solved here with an Integer Linear Program.

For more information, see the Wikipedia article Packing_in_a_hypergraph.

INPUT:
- solver – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on LP solvers and which default solver is used, see the method solve of the class MixedIntegerLinearProgram.
- verbose – integer (default: 0). Sets the level of verbosity. Set to 0 by default, which means quiet.
- integrality_tolerance – parameter for use with MILP solvers over an inexact base ring: see MixedIntegerLinearProgram.get_values().

EXAMPLES:

```python
sage: P = IncidenceStructure([[1,2],[3,4],[2,3]]).packing() # needs sage.numerical.mip
sage: sorted(sorted(b) for b in P) # needs sage.numerical.mip
[[1, 2], [3, 4]]
sage: len(designs.steiner_triple_system(9).packing()) # needs sage.numerical.mip
3
```

rank()

Return the rank of the hypergraph (the maximum size of a block).

EXAMPLES:

```python
sage: h = Hypergraph(8, [[0,1,3],[1,4,5,6],[1,2]])
sage: h.rank()
4
```

relabel(perm=None, inplace=True)

Relabel the ground set

INPUT:
- perm – can be one of
  - a dictionary – then each point p (which should be a key of d) is relabeled to d[p]
  - a list or a tuple of length n – the first point returned by ground_set() is relabeled to 1[0], the second to 1[1],...
  - None – the incidence structure is relabeled to be on \{0, 1, ..., n − 1\} in the ordering given by ground_set().
• inplace – If True then return a relabeled graph and does not touch self (default is False).

EXAMPLES:

```
sage: # needs sage.schemes
doctest.sage
sage: TD = designs.transversal_design(5,5)
sage: TD.relabel({i: chr(97+i) for i in range(25)})

['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm', 
 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y']
```

Relabel to integer points:

```
sage: TD.relabel()  # needs sage.schemes
sage: TD.blocks()[:3]  # needs sage.schemes
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23]]
```

```
trace(points, min_size=1, multiset=True)
```

Return the trace of a set of points.

Given an hypergraph \( \mathcal{H} \), the trace of a set \( X \) of points in \( \mathcal{H} \) is the hypergraph whose blocks are all non-empty \( S \cap X \) where \( S \in \mathcal{H} \).

INPUT:

• points – a set of points.

• min_size (integer; default 1) – minimum size of the sets to keep. By default all empty sets are discarded, i.e. \( \text{min\_size}=1 \).

• multiset (boolean; default True) – whether to keep multiple copies of the same set.

**Note:** This method goes over all sets of self before building a new \( \text{IncidenceStructure} \) (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:

A Baer subplane of order 2 (i.e. a Fano plane) in a projective plane of order 4:

```
sage: # needs sage.schemes
sage: P4 = designs.projective_plane(4)
sage: F = designs.projective_plane(2)
sage: for x in Subsets(P4.ground_set(),7):
    ....:     if P4.trace(x,min_size=2).is_isomorphic(F):
    ....:         break
sage: subplane = P4.trace(x,min_size=2); subplane
```

Incidence structure with 7 points and 7 blocks

```
sage: subplane.is_isomorphic(F)
```

True
5.1.89 Mutually Orthogonal Latin Squares (MOLS)

The main function of this module is `mutually_orthogonal_latin_squares()` and can be used to generate MOLS (or check that they exist):

```python
sage: MOLS = designs.mutually_orthogonal_latin_squares(4,8)
```

For more information on MOLS, see the Wikipedia entry on MOLS. If you are only interested by latin squares, see `latin`.

The functions defined here are

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mutually_orthogonal_latin_squares()</code></td>
<td>Return $k$ Mutually Orthogonal $n \times n$ Latin Squares.</td>
</tr>
<tr>
<td><code>are_mutually_orthogonal_latin_squares()</code></td>
<td>Check if the list $l$ of matrices in $l$ are MOLS.</td>
</tr>
<tr>
<td><code>latin_square_product()</code></td>
<td>Return the product of two (or more) latin squares.</td>
</tr>
<tr>
<td><code>MOLS_table()</code></td>
<td>Prints the MOLS table.</td>
</tr>
</tbody>
</table>

Table of MOLS

Sage can produce a table of MOLS similar to the one from the Handbook of Combinatorial Designs [DesignHandbook] (available here).

```python
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(600) # long time
```

(continues on next page)
Comparison with the results from the Handbook of Combinatorial Designs (2ed) [DesignHandbook]:

<table>
<thead>
<tr>
<th>sage: MOLS_table(600, compare=True) # long time</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>0</td>
</tr>
<tr>
<td>20</td>
</tr>
<tr>
<td>40</td>
</tr>
<tr>

REFERENCES:
Functions

sage.combinat.designs.latin_squares.MOLS_table(start, stop=None, compare=False, width=None)

Prints the MOLS table that Sage can produce.

INPUT:

- start, stop (integers) – print the table of MOLS for value of \( n \) such that \( \text{start} \leq n \leq \text{stop} \). If only one integer is given as input, it is interpreted as the value of \( \text{stop} \) with \( \text{start}=0 \) (same behaviour as range).
- compare (boolean) – if sets to True the MOLS displays with + and – entries its difference with the table from the Handbook of Combinatorial Designs (2ed).
- width (integer) – the width of each column of the table. By default, it is computed from range of values determined by the parameters start and stop.

EXAMPLES:

```
sage: # needs sage.schemes
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(100)
```

```
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19
```

```
0| +oo +oo 1 2 3 4 1 6 7 8 2 10 5 12 4 4 15 16 5 18
20| 4 5 3 22 7 24 4 26 5 28 4 30 31 5 4 5 8 36 4 5
40| 7 40 5 42 5 6 4 46 8 48 6 5 5 52 5 6 7 7 5 58
60| 5 60 5 63 7 5 66 5 6 70 7 72 5 7 6 6 6 78
80| 9 80 8 82 6 6 6 7 8 88 6 7 6 6 6 7 96 6 8
```

```
sage: MOLS_table(100, width=4)
```

```
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14
```

```
0| +oo +oo 1 2 3 4 1 6 7 8 2 10 5 12 4 4 15 16 5 18
```

```
sage: MOLS_table(100, compare=True)
```

```
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19
```

```
0| + + + +
```

```
sage: MOLS_table(50, 100, compare=True)
```

(continues on next page)
sage.combinat.designs.latin_squares.are_mutually_orthogonal_latin_squares(l, verbose=False)

Check whether the list of matrices in l form mutually orthogonal latin squares.

INPUT:
- verbose - if True then print why the list of matrices provided are not mutually orthogonal latin squares

EXAMPLES:

sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_squares
sage: m1 = matrix([[0,1,2],[2,0,1],[1,2,0]])

sage: m2 = matrix([[0,1,2],[1,2,0],[2,0,1]])

sage: m3 = matrix([[0,1,2],[2,0,1],[1,2,0]])

sage: are_mutually_orthogonal_latin_squares([m1,m2])
True

sage: are_mutually_orthogonal_latin_squares([m1,m3])
False

sage: are_mutually_orthogonal_latin_squares([m2,m3])
True

sage: are_mutually_orthogonal_latin_squares([m1,m2,m3], verbose=True)
Squares 0 and 2 are not orthogonal
False

sage: m = designs.mutually_orthogonal_latin_squares(7,8)

sage: are_mutually_orthogonal_latin_squares(m)
True

sage.combinat.designs.latin_squares.latin_square_product(M, N, *others)

Return the product of two (or more) latin squares.

Given two Latin Squares M, N of respective sizes m, n, the direct product \( M \times N \) of size mn is defined by \((M \times N)((i_1, i_2), (j_1, j_2)) = (M(i_1, j_1), N(i_2, j_2))\) where \(i_1, j_1 \in [m], i_2, j_2 \in [n]\).

Each pair of values \((i, j) \in [m] \times [n]\) is then relabeled to \(in + j\).

This is Lemma 6.25 of [Stinson2004].

INPUT:
- An arbitrary number of latin squares (greater than 2).

EXAMPLES:

sage: from sage.combinat.designs.latin_squares import latin_square_product

sage: m = designs.mutually_orthogonal_latin_squares(3,4)[0]

sage: latin_square_product(m,m,m)
64 x 64 sparse matrix over Integer Ring (use the '.str()' method to see the entries)
Return \( k \) Mutually Orthogonal \( n \times n \) Latin Squares (MOLS).

For more information on Mutually Orthogonal Latin Squares, see \textit{latin_squares}.

INPUT:

- \( k \) (integer) – number of MOLS. If \( k=None \) it is set to the largest value available.
- \( n \) (integer) – size of the latin square.
- \texttt{partitions} (boolean) – a Latin Square can be seen as 3 partitions of the \( n^2 \) cells of the array into \( n \) sets of size \( n \), respectively:
  - The partition of rows
  - The partition of columns
  - The partition of number (cells numbered with 0, cells numbered with 1, ...)

These partitions have the additional property that any two sets from different partitions intersect on exactly one element.

When \texttt{partitions} is set to \texttt{True}, this function returns a list of \( k + 2 \) partitions satisfying this intersection property instead of the \( k + 2 \) MOLS (though the data is exactly the same in both cases).

- \texttt{check} – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to \texttt{True} by default.

EXAMPLES:

```python
sage: designs.mutually_orthogonal_latin_squares(4, 5)
[:,:]
[0 2 4 1 3] [0 3 1 4 2] [0 4 3 2 1] [0 1 3 4]
[4 1 3 0 2] [3 1 4 2 0] [2 1 0 4 3] [4 0 1 2 3]
[3 0 2 4 1] [1 4 2 0 3] [4 3 2 1 0] [3 4 0 1 2]
[2 4 1 3 0] [4 2 0 3 1] [1 0 4 3 2] [2 3 4 0 1]
[1 3 0 2 4],[2 0 3 1 4],[3 2 1 0 4],[1 2 3 4 0]
]
```

```python
sage: designs.mutually_orthogonal_latin_squares(3, 7)
[:,:]
[0 2 4 6 1 3 5] [0 3 6 2 5 1 4] [0 4 1 5 2 6 3]
[6 1 3 5 0 2 4] [5 1 4 0 3 6 2] [4 1 5 2 6 3 0]
[5 0 2 4 6 1 3] [3 6 2 5 1 4 0] [1 5 2 6 3 0 4]
[4 6 1 3 5 0 2] [1 4 0 3 6 2 5] [5 2 6 3 0 4 1]
[3 5 0 2 4 6 1] [6 2 5 1 4 0 3] [2 6 3 0 4 1 5]
[2 4 6 1 3 5 0] [4 0 3 6 2 5 1] [6 3 0 4 1 5 2]
[1 3 5 0 2 4 6], [2 5 1 4 0 3 6], [3 0 4 1 5 2 6]
]
```

```python
sage: designs.mutually_orthogonal_latin_squares(2, 5, partitions=True)
[:,:]
[[[0, 1, 2, 3, 4],
  [5, 6, 7, 8, 9],
[continues on next page]
What is the maximum number of MOLS of size 8 that Sage knows how to build?

```
sage: designs.orthogonal_arrays.largest_available_k(8)-2
# needs sage.schemes
7
```

If you only want to know if Sage is able to build a given set of MOLS, query the `orthogonal_arrays.*` functions:

```
sage: designs.orthogonal_arrays.is_available(5+2, 5)  # 5 MOLS of order 5
False
sage: designs.orthogonal_arrays.is_available(4+2,6)  # 4 MOLS of order 6
# needs sage.schemes
False
```

Sage, however, is not able to prove that the second MOLS do not exist:

```
sage: designs.orthogonal_arrays.exists(4+2,6)  # 4 MOLS of order 6
# needs sage.schemes
Unknown
```

If you ask for such a MOLS then you will respectively get an informative `EmptySetError` or `NotImplementedError`:

```
sage: designs.mutually_orthogonal_latin_squares(5, 5)
Traceback (most recent call last):
  ... EmptySetError: there exist at most n-1 MOLS of size n if n>=2
sage: designs.mutually_orthogonal_latin_squares(4,6)
# needs sage.schemes
Traceback (most recent call last):
  ... NotImplementedeError: I don't know how to build 4 MOLS of order 6
```
5.1.90 Orthogonal arrays (OA)

This module gathers some construction related to orthogonal arrays (or transversal designs). One can build an $OA(k, n)$ (or check that it can be built) from the Sage console with `designs.orthogonal_arrays.build`:

```sage
sage: OA = designs.orthogonal_arrays.build(4,8)
```

See also the modules `orthogonal_arrays_build_recursive` or `orthogonal_arrays_find_recursive` for recursive constructions.

This module defines the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>orthogonal_array()</code></td>
<td>Return an orthogonal array of parameters $k, n, t$.</td>
</tr>
<tr>
<td><code>transversal_design()</code></td>
<td>Return a transversal design of parameters $k, n$.</td>
</tr>
<tr>
<td><code>incomplete_orthogonal_array()</code></td>
<td>Return an $OA(k, n) - \sum_{1 \leq i \leq x} OA(k, s_i)$.</td>
</tr>
<tr>
<td><code>is_transversal_design()</code></td>
<td>Check that a given set of blocks $B$ is a transversal design.</td>
</tr>
<tr>
<td><code>is_orthogonal_array()</code></td>
<td>Check that the integer matrix $OA$ is an $OA(k, n, t)$.</td>
</tr>
<tr>
<td><code>wilson_construction()</code></td>
<td>Return a $OA(k, rm+u)$ from a truncated $OA(k+s, r)$ by Wilson’s construction.</td>

Functions

```python
class sage.combinat.designs.orthogonal_arrays.OAMainFunctions(*args, **kws)
    Bases: object

    Functions related to orthogonal arrays.

    An orthogonal array of parameters $k, n, t$ is a matrix with $k$ columns filled with integers from $[n]$ in such a way that for any $t$ columns, each of the $n^t$ possible rows occurs exactly once. In particular, the matrix has $n^t$ rows.

    For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

    From here you have access to:
    - `build(k, n, t=2)`: return an orthogonal array with the given parameters.
    - `is_available(k, n, t=2)`: answer whether there is a construction available in Sage for a given set of parameters.
    - `exists(k, n, t=2)`: answer whether an orthogonal array with these parameters exist.
    - `largest_available_k(n, t=2)`: return the largest integer $k$ such that Sage knows how to build an $OA(k, n)$.
```

738 Chapter 5. Comprehensive Module List
• `explain_construction(k,n,t=2)`: return a string that explains the construction that Sage uses to build an $OA(k,n)$.

EXAMPLES:

```python
sage: designs.orthogonal_arrays.build(3,2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]
```

```python
sage: designs.orthogonal_arrays.build(5,5)
[[0, 0, 0, 0, 0], [0, 1, 2, 3, 4], [0, 2, 4, 1, 3],
 [0, 3, 1, 4, 2], [0, 4, 3, 2, 1], [1, 0, 4, 3, 2],
 [1, 1, 1, 1, 1], [1, 2, 3, 4, 0], [1, 3, 0, 2, 4],
 [1, 4, 2, 0, 3], [2, 0, 3, 1, 4], [2, 1, 0, 4, 3],
 [2, 2, 2, 2, 2], [2, 3, 4, 0, 1], [2, 4, 1, 3, 0],
 [3, 0, 2, 4, 1], [3, 1, 4, 2, 0], [3, 2, 1, 0, 4],
 [3, 3, 3, 3, 3], [3, 4, 0, 1, 2], [4, 0, 1, 2, 3],
 [4, 1, 3, 0, 2], [4, 2, 0, 3, 1], [4, 3, 2, 1, 0],
 [4, 4, 4, 4, 4]]
```

What is the largest value of $k$ for which Sage knows how to compute a $OA(k,14,2)$?

```python
sage: designs.orthogonal_arrays.largest_available_k(14)
6
```

If you ask for an orthogonal array that does not exist, then you will either obtain an `EmptySetError` (if it knows that such an orthogonal array does not exist) or a `NotImplementedError`:

```python
sage: designs.orthogonal_arrays.build(4,2)
Traceback (most recent call last):
... EmptySetError: There exists no OA(4,2) as k(=4)>n+t-1=3
```

```python
sage: designs.orthogonal_arrays.build(12,20)
Traceback (most recent call last):
... NotImplementedException: I don't know how to build an OA(12,20)!
```

**static build**($k$, $n$, $t=2$, `resolvable=False`)

Return an $OA(k,n)$ of strength $t$

An orthogonal array of parameters $k$, $n$, $t$ is a matrix with $k$ columns filled with integers from $[n]$ in such a way that for any $t$ columns, each of the $n^t$ possible rows occurs exactly once. In particular, the matrix has $n^t$ rows.

More general definitions sometimes involve a $\lambda$ parameter, and we assume here that $\lambda = 1$.

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

**INPUT:**

- $k$, $n$, $t$ (integers) – parameters of the orthogonal array.
- `resolvable` (boolean) – set to `True` if you want the design to be resolvable. The $n$ classes of the resolvable design are obtained as the first $n$ blocks, then the next $n$ blocks, etc ... Set to `False` by default.

**EXAMPLES:**
```python
sage: designs.orthogonal_arrays.build(3,3,resolvable=True)  # indirect doctest
[[0, 0, 0],
 [1, 2, 1],
 [2, 1, 2],
 [0, 2, 2],
 [1, 1, 0],
 [2, 0, 1],
 [0, 1, 1],
 [1, 0, 2],
 [2, 2, 0]]
sage: OA_7_50 = designs.orthogonal_arrays.build(7,50)  # indirect doctest
```

### static `exists(k, n, t=2)`

Return the existence status of an $OA(k, n)$

**INPUT:**

- $k, n, t$ (integers) – parameters of the orthogonal array.

**Warning:** The function does not only return booleans, but `True`, `False`, or `Unknown`.

**See also:**

`is_available()`

**EXAMPLES:**

```python
sage: designs.orthogonal_arrays.exists(3,6)  # indirect doctest
True
sage: designs.orthogonal_arrays.exists(4,6)  # indirect doctest
Unknown
sage: designs.orthogonal_arrays.exists(7,6)  # indirect doctest
False
```

### static `explain_construction(k, n, t=2)`

Return a string describing how to builds an $OA(k, n)$

**INPUT:**

- $k, n, t$ (integers) – parameters of the orthogonal array.

**EXAMPLES:**

```python
sage: designs.orthogonal_arrays.explain_construction(9,565)
"Wilson's construction n=23.24+13 with master design OA(9+1,23)"
sage: designs.orthogonal_arrays.explain_construction(10,154)
"the database contains a (137,10;1,0;17)-quasi difference matrix'
```

### static `is_available(k, n, t=2)`

Return whether Sage can build an $OA(k, n)$.

**INPUT:**

- $k, n, t$ (integers) – parameters of the orthogonal array.
See also:

exists()

EXAMPLES:

```python
sage: designs.orthogonal_arrays.is_available(3,6) # indirect doctest
True
sage: designs.orthogonal_arrays.is_available(4,6) # indirect doctest
False
```

**static largest_available_k**(n, 𝑡=2)

Return the largest \( k \) such that Sage can build an \( OA(k, n) \).

**INPUT:**

- \( n \) (integer)
- \( t \) – (integer; default: 2) – strength of the array

**EXAMPLES:**

```python
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
  ... ValueError: n(=-1) was expected to be >=0
```

```python
sage.combinat.designs.orthogonal_arrays.OA_find_disjoint_blocks(OA, k, n, x, solver, integrality_tolerance)
```

Return \( x \) disjoint blocks contained in a given \( OA(k, n) \).

\( x \) blocks of an \( OA \) are said to be disjoint if they all have different values for a every given index, i.e. if they correspond to disjoint blocks in the \( TD \) associated with the \( OA \).

**INPUT:**

- \( OA \) – an orthogonal array
- \( k, n, x \) (integers)
- \( solver \) – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method solve of the class `MixedIntegerLinearProgram`.
- \( integrality_tolerance \) – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**See also:**

incomplete_orthogonal_array()
EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays import OA_find_disjoint_blocks
sage: k=3;n=4;x=3
sage: Bs = OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,x)
sage: assert len(Bs) == x
sage: for i in range(k):
....:   assert len(set([B[i] for B in Bs])) == x
sage: OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,5)
Traceback (most recent call last):
  ... ValueError: There does not exist 5 disjoint blocks in this OA(3,4)
```

sage.combinat.designs.orthogonal_arrays.OA_from_PBD(k, n, PBD, check=True)

Return an $OA(k,n)$ from a PBD

Construction

Let $B$ be a $(n, K, 1)$-PBD. If there exists for every $i \in K$ a $TD(k,i) - i \times TD(k,1)$ (i.e. if there exist $k$ idempotent MOLS), then one can obtain a $OA(k,n)$ by concatenating:

- A $TD(k,i) - i \times TD(k,1)$ defined over the elements of $B$ for every $B \in B$.
- The rows $(i, ..., i)$ of length $k$ for every $i \in [n]$.

Note: This function raises an exception when Sage is unable to build the necessary designs.

INPUT:

- $k,n$ (integers)
- $PBD$ – a PBD on $0,...,n-1$.

EXAMPLES:

We start from the example VI.1.2 from the [DesignHandbook] to build an $OA(3,10)$:

```python
sage: from sage.combinat.designs.orthogonal_arrays import OA_from_PBD
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage:
....: pbd = [[0,1,2,3],[0,4,5,6],[0,7,8,9],[1,4,7],[1,5,8],
....:    [1,6,9],[2,4,9],[2,5,7],[2,6,8],[3,4,8],[3,5,9],[3,6,7]]
sage: oa = OA_from_PBD(3,10,pbd)
sage: is_orthogonal_array(oa, 3, 10)
True
```

But we cannot build an $OA(4,10)$ for this PBD (although there exists an $OA(4,10)$):

```python
sage: OA_from_PBD(4,10,pbd)
Traceback (most recent call last):
  ... EmptySetError: There is no OA(n+1,n) - 3.OA(n+1,1) as all blocks intersect in a projective plane.
```

Or an $OA(3,6)$ (as the PBD has 10 points):

```python
sage: _ = OA_from_PBD(3,6,pbd)
Traceback (most recent call last):
  ... EmptySetError: There is no OA(n+1,n) - 3.OA(n+1,1) as all blocks intersect in a projective plane.
```
sage.combinat.designs.orthogonal_arrays.OA_from_Vmt(m, t, V)

Return an Orthogonal Array from a $V(m, t)$

INPUT:

- $m, t$ (integers)
- $V$ – the vector $V(m, t)$.

See also:

- QDM_from_Vmt()
- OA_from_quasi_difference_matrix()

EXAMPLES:

```sage
sage: _ = designs.orthogonal_arrays.build(6, 46) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.OA_from_quasi_difference_matrix(M, G, add_col=True, fill_hole=True)

Return an Orthogonal Array from a Quasi-Difference matrix

Difference Matrices

Let $G$ be a group of order $g$. A difference matrix $M$ is a $g \times k$ matrix with entries from $G$ such that for any $1 \leq i < j < k$ the set $\{d_{li} - d_{lj} : 1 \leq l \leq g\}$ is equal to $G$.

By concatenating the $g$ matrices $M + x$ (where $x \in G$), one obtains a matrix of size $g^2 \times x$ which is also an $OA(k, g)$.

Quasi-difference Matrices

A quasi-difference matrix is a difference matrix with missing entries. The construction above can be applied again in this case, where the missing entries in each column of $M$ are replaced by unique values on which $G$ has a trivial action.

This produces an incomplete orthogonal array with a “hole” (i.e. missing rows) of size ‘u’ (i.e. the number of missing values per column of $M$). If there exists an $OA(k, u)$, then adding the rows of this $OA(k, u)$ to the incomplete orthogonal array should lead to an $OA$…

Formal definition (from the Handbook of Combinatorial Designs [DesignHandbook])

Let $G$ be an abelian group of order $n$. A $(n, k; \lambda; \mu; u)$-quasi-difference matrix (QDM) is a matrix $Q = (q_{ij})$ with $\lambda(n - 1 + 2u) + \mu$ rows and $k$ columns, with each entry either empty or containing an element of $G$. Each column contains exactly $\lambda u$ entries, and each row contains at most one empty entry. Furthermore, for each $1 \leq i < j \leq k$ the multiset

$$\{q_{li} - q_{lj} : 1 \leq l \leq \lambda(n - 1 + 2u) + \mu, \text{ with } q_{li} \text{ and } q_{lj} \text{ not empty}\}$$

contains every nonzero element of $G$ exactly $\lambda$ times, and contains $0$ exactly $\mu$ times.

Construction

If a $(n, k; \lambda; \mu; u)$-QDM exists and $\mu \leq \lambda$, then an $ITD_\lambda(k, n + u; u)$ exists. Start with a $(n, k; \lambda; \mu; u)$-QDM $A$ over the group $G$. Append $\lambda - \mu$ rows of zeroes. Then select $u$ elements $\infty_1, \ldots, \infty_u$ not in $G$, and replace the empty entries, each by one of these infinite symbols, so that $\infty_i$ appears exactly once in each column. Develop
the resulting matrix over the group $G$ (leaving infinite symbols fixed), to obtain a $\lambda(n^2 + 2nu) \times k$ matrix $T$. Then $T$ is an orthogonal array with $k$ columns and index $\lambda$, having $n + u$ symbols and one hole of size $u$. Adding to $T$ an $OA(k, u)$ with elements $\infty_1, \ldots, \infty_u$ yields the $ITD_\lambda(k, n + u; u)$. For more information, see the Handbook of Combinatorial Designs [DesignHandbook] or http://web.cs.du.edu/~petr/milehigh/2013/Colbourn.pdf.

INPUT:

- $M$ – the difference matrix whose entries belong to $G$
- $G$ – a group
- `add_col` (boolean) – whether to add a column to the final OA equal to $(x_1, \ldots, x_g, x_1, \ldots, x_g, \ldots)$ where $G = \{x_1, \ldots, x_g\}$.
- `fill_hole` (boolean) – whether to return the incomplete orthogonal array, or complete it with the $OA(k, u)$ (default). When `fill_hole` is `None`, no block of the incomplete OA contains more than one value $\geq |G|$.

EXAMPLES:

```python
sage: _ = designs.orthogonal_arrays.build(6,20) # indirect doctest
```

```
from sage.combinat.designs.orthogonal_arrays import OA_from_wider_OA
sage: AO_from_wider_OA(designs.orthogonal_arrays.build(6,20,2),1)[:5]
[(19,), (19,), (19,), (19,), (19,)]
```

```python
sage: _ = designs.orthogonal_arrays.build(5,46) # indirect doctest
```

```
from sage.combinat.designs.orthogonal_arrays import OA_n_times_2_pow_c_from_matrix
sage: OA_n_times_2_pow_c_from_matrix(3,2,GF(2),GF(2)^2)
```

Return an $OA(k, 2^c)$ from a constrained $(G, k - 1, 2)$-difference matrix.

This construction appears in [AC1994] and [Ab1995].

Let $G$ be an additive Abelian group. We denote by $H$ a $GF(2)$-hyperplane in $GF(2^c)$. Let $A$ be a $(k - 1) \times 2|G|$ array with entries in $G \times GF(2^c)$ and $Y$ be a vector with $k - 1$ entries in $GF(2^c)$. Let $B$ and $C$ be respectively the part of the array that belong to $G$ and $GF(2^c)$.

The input $A$ and $Y$ must satisfy the following conditions. For any $i \neq j$ and $g \in G$:

- there are exactly two values of $s$ such that $B_{i,s} - B_{j,s} = g$ (i.e. $B$ is a $(G, k - 1, 2)$-difference matrix),
- let $s_1$ and $s_2$ denote the two values of $s$ given above, then exactly one of $C_{i,s_1} - C_{j,s_1}$ and $C_{i,s_2} - C_{j,s_2}$ belongs to the $GF(2)$-hyperplane $(Y_i - Y_j) \cdot H$ (we implicitly assumed that $Y_i \neq Y_j$).

Under these conditions, it is easy to check that the array whose $k - 1$ rows of length $|G| \cdot 2^c$ indexed by $1 \leq i \leq k - 1$ given by $A_{i,s} + (0, Y_i \cdot v)$ where $1 \leq s \leq 2|G|, v \in H$ is a $(G \times GF(2^c), k - 1, 1)$-difference matrix.

INPUT:
• \( k, c \) (integers) – integers
• \( G \) – an additive Abelian group
• \( A \) – a matrix with entries in \( G \times GF(2^c) \)
• \( Y \) – a vector with entries in \( GF(2^c) \)
• \( \text{check} \) – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

**Note:** By convention, a multiplicative generator \( w \) of \( GF(2^c)^* \) is fixed (inside the function). The hyperplane \( H \) is the one spanned by \( w^0, w^1, \ldots, w^{c-1} \). The \( GF(2^c) \) part of the input matrix \( A \) and vector \( Y \) are given in the following form: the integer \( i \) corresponds to the element \( w^i \) and \( \text{None} \) corresponds to \( 0 \).

**See also:**
Several examples use this construction:
• \( \text{OA}_9_40() \)
• \( \text{OA}_11_80() \)
• \( \text{OA}_15_112() \)
• \( \text{OA}_11_160() \)
• \( \text{OA}_16_176() \)
• \( \text{OA}_16_208() \)
• \( \text{OA}_15_224() \)
• \( \text{OA}_20_352() \)
• \( \text{OA}_20_416() \)
• \( \text{OA}_20_544() \)
• \( \text{OA}_11_640() \)
• \( \text{OA}_15_896() \)

**EXAMPLES:**

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_n_times_2_pow_c_from_matrix
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: A = [
    ....: [(0, None), (0, None), (0, None), (0, None), (0, None), (0, None), (0, None), (0, None), (0, None)]
    ....: [(0, None), (1, None), (2, 2), (3, 2), (4, 2), (2, None), (3, None), (4, None), (0, 2), (1, 2)],
    ....: [(0, None), (2, 5), (4, 5), (1, 2), (3, 6), (3, 4), (0, 0), (2, 1), (4, 1), (1, 6)],
    ....: [(0, None), (3, 4), (1, 4), (4, 0), (2, 5), (3, None), (1, 0), (4, 1), (2, 2), (0, 3)],
    ....: ]
sage: Y = [None, 0, 1, 6]
sage: OA = OA_n_times_2_pow_c_from_matrix(5, 3, GF(5), A, Y)
```

(continues on next page)
sage: is_orthogonal_array(OA, 5, 40, 2)
True

sage: A[0][0] = (1, None)
sage: OA_n_times_2_pow_c_from_matrix(5, 3, GF(5), A, Y)
Traceback (most recent call last):
...
ValueError: the first part of the matrix A must be a (G,k-1,2)-difference matrix

sage: A[0][0] = (0, 0)
sage: OA_n_times_2_pow_c_from_matrix(5, 3, GF(5), A, Y)
Traceback (most recent call last):
...
ValueError: B_2,0 - B_0,0 = B_2,6 - B_0,6 but the associated part of the matrix C does not satisfies the required condition

sage.combinat.designs.orthogonal_arrays.OA_relabel(OA, k, n, blocks=(), matrix=None)
Return a relabelled version of the OA.

INPUT:

- OA – an OA, or rather a list of blocks of length k, each of which contains integers from 0 to n - 1.
- k, n (integers)
- blocks (list of blocks) – relabels the integers of the OA from [0..n - 1] into [0..n - 1] in such a way that the i blocks from block are respectively relabeled as [n-i,...,n-i], ..., [n-1,...,n-1]. Thus, the blocks from this list are expected to have disjoint values for each coordinate. If set to the empty list (default) no such relabelling is performed.
- matrix – a matrix of dimensions k, n such that if the i coordinate of a block is x, this x will be relabelled with matrix[i][x]. This is not necessarily an integer between 0 and n - 1, and it is not necessarily an integer either. This is performed after the previous relabelling. If set to None (default) no such relabelling is performed.

Note: A None coordinate in one block remains a None coordinate in the final block.

EXAMPLES:

sage: from sage.combinat.designs.orthogonal_arrays import OA_relabel
sage: OA = designs.orthogonal_arrays.build(3, 2)
sage: OA_relabel(OA, 3, 2, matrix=[["A", "B"], ["C", "D"], ["E", "F"]])
[[['A', 'C', 'E'], ['A', 'D', 'F'], ['B', 'C', 'F'], ['B', 'D', 'E']]
sage: TD = OA_relabel(OA, 3, 2, matrix=[[0, 1], [2, 3], [4, 5]])
[[0, 2, 4], [0, 3, 5], [1, 2, 5], [1, 3, 4]]
sage: is_transversal_design(TD, 3, 2)
True

Making sure that [2, 2, 2, 2] is a block of OA(4, 3). We do this by relabelling block [0, 0, 0, 0] which belongs to the design:
sage: designs.orthogonal_arrays.build(4,3)
[[0, 0, 0, 0], [0, 1, 2, 1], [0, 2, 1, 2], [1, 0, 2, 2], [1, 1, 1, 0], [1, 2, 0, 1],
  [2, 0, 1, 1], [2, 1, 0, 2], [2, 2, 2, 0]]
sage: OA_relabel(designs.orthogonal_arrays.build(4,3),4,3,blocks=[[0,0,0,0]])
[[2, 2, 2, 2], [2, 0, 1, 0], [2, 1, 0, 1], [0, 2, 1, 1], [0, 0, 0, 2], [0, 1, 2, 0],
  [1, 2, 0, 0], [1, 0, 2, 1], [1, 1, 1, 2]]
sage.combinat.designs.orthogonal_arrays.QDM_from_Vmt(m, t, V)

Return a QDM from a $V(m,t)$

Definition
Let $q$ be a prime power and let $q = mt + 1$ for $m, t$ integers. Let $\omega$ be a primitive element of $F_q$. A $V(m,t)$ vector is a vector $(a_1, \ldots, a_{m+1})$ for which, for each $1 \leq k < m$, the differences

$$\{a_{i+k} - a_i : 1 \leq i \leq m + 1, i + k \neq m + 2\}$$

represent the $m$ cyclotomic classes of $F_{mt+1}$ (compute subscripts modulo $m + 2$). In other words, for fixed $k$, is $a_{i+k} - a_i = \omega^{mx+a}$ and $a_{j+k} - a_j = \omega^{ny+b}$ then $a \not\equiv b \mod m$.

Construction of a quasi-difference matrix from a $V(m,t)$ vector
Starting with a $V(m,t)$ vector $(a_1, \ldots, a_{m+1})$, form a single row of length $m + 2$ whose first entry is empty, and whose remaining entries are $(a_1, \ldots, a_{m+1})$. Form $t$ rows by multiplying this row by the $t$ th roots, i.e. the powers of $\omega^m$. From each of these $t$ rows, form $m + 2$ rows by taking the $m + 2$ cyclic shifts of the row. The result is a $(a, m + 2; 1, 0; t) - QDM$.

For more information, refer to the Handbook of Combinatorial Designs [DesignHandbook].

INPUT:
- $m, t$ (integers)
- $V$ – the vector $V(m,t)$.

See also:
OA_from_quasi_difference_matrix()

EXAMPLES:

sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest

sage.combinat.designs.orthogonal_arrays.TD_product(k, TD1, n1, TD2, n2, check=True)

Return the product of two transversal designs.

From a transversal design $TD_1$ of parameters $k, n_1$ and a transversal design $TD_2$ of parameters $k, n_2$, this function returns a transversal design of parameters $k, n$ where $n = n_1 \times n_2$.

Formally, if the groups of $TD_1$ are $V_1^1, \ldots, V_k^1$ and the groups of $TD_2$ are $V_1^2, \ldots, V_k^2$, the groups of the product design are $V_1^1 \times V_1^2, \ldots, V_k^1 \times V_k^2$ and its blocks are the $\{((x_1^1, x_1^2), \ldots, (x_k^1, x_k^2)) \}$ where $\{x_1^1, \ldots, x_k^1\}$ is a block of $TD_1$ and $\{x_1^2, \ldots, x_k^2\}$ is a block of $TD_2$.

INPUT:
- $TD1, TD2$ – transversal designs.
- $k, n1, n2$ (integers) – see above.
- $check$ (boolean) – Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
Note: This function uses transversal designs with $V_1 = \{0, \ldots, n-1\}, \ldots, V_k = \{(k-1)n, \ldots, kn-1\}$ both as input and output.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays import TD_product
sage: TD1 = designs.transversal_design(6,7)
sage: TD2 = designs.transversal_design(6,12)
sage: TD6_84 = TD_product(6,TD1,7,TD2,12)
```

```python
class sage.combinat.designs.orthogonal_arrays.TransversalDesign(blocks, k=None, n=None, check=True, **kwds)
```

Bases: `GroupDivisibleDesign`

Class for Transversal Designs

INPUT:

- `blocks` – collection of blocks
- `k, n` (integers) – parameters of the transversal design. They can be set to `None` (default) in which case their value is determined by the blocks.
- `check` (boolean) – whether to check that the design is indeed a transversal design with the right parameters. Set to `True` by default.

EXAMPLES:

```python
sage: designs.transversal_design(None,5)
Transversal Design TD(6,5)
sage: designs.transversal_design(None,30)
Transversal Design TD(6,30)
sage: designs.transversal_design(None,36)
Transversal Design TD(10,36)
```

```python
sage.combinat.designs.orthogonal_arrays.incomplete_orthogonal_array(k, n, holes, resolvable=False, existence=False)
```

Return an $OA(k,n) - \sum_{1 \leq i \leq x} OA(k,s_i)$. An $OA(k,n) - \sum_{1 \leq i \leq x} OA(k,s_i)$ is an orthogonal array from which have been removed disjoint $OA(k,s_1), \ldots, OA(k,s_x)$. If there exist $OA(k,s_1), \ldots, OA(k,s_x)$ they can be used to fill the holes and give rise to an $OA(k,n)$.

A very useful particular case (see e.g. the Wilson construction in `wilson_construction()`) is when all $s_i = 1$. In that case the incomplete design is a $OA(k,n) - x.OA(k,1)$. Such design is equivalent to transversal design $TD(k,n)$ from which has been removed $x$ disjoint blocks.

INPUT:

- `k, n` (integers)
- `holes` (list of integers) – respective sizes of the holes to be found.
- `resolvable` (boolean) – set to `True` if you want the design to be resolvable. The classes of the resolvable design are obtained as the first $n$ blocks, then the next $n$ blocks, etc ... Set to `False` by default.
- `existence` (boolean) – instead of building the design, return:
Combinatorics, Release 10.1

– True – meaning that Sage knows how to build the design
– Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see sage.misc.unknown).
– False – meaning that the design does not exist.

Note: By convention, the ground set is always $V = \{0, \ldots, n-1\}$.

If all holes have size 1, in the incomplete orthogonal array returned by this function the holes are
\[
\{n-1, \ldots, n-s_1\}^k, \{n-s_1-1, \ldots, n-s_1-s_2\}^k, \ldots
\]

More generally, if holes is equal to $u_1, \ldots, u_k$, the $i$-th hole is the set of points
\[
\{n - \sum_{j \geq i} u_j, \ldots, n - \sum_{j \geq i+1} u_j\}^k.
\]

See also:

OA_find_disjoint_blocks()

EXAMPLES:

```python
sage: IOA = designs.incomplete_orthogonal_array(3,3,[1,1,1])
```

```python
sage: IOA
[[0, 1, 2], [0, 2, 1], [1, 0, 2], [1, 2, 0], [2, 0, 1], [2, 1, 0]]
```

```python
sage: missing_blocks = [[0,0,0], [1,1,1], [2,2,2]]
```

```python
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
```

```python
sage: is_orthogonal_array(IOA + missing_blocks,3,3,2)
True
```

sage.combinat.designs.orthogonal_arrays.is_transversal_design(B, k, n, verbose=False)

Check that a given set of blocks B is a transversal design.

See transversal_design() for a definition.

INPUT:

• B – the list of blocks
• k, n – integers
• verbose (boolean) – whether to display information about what is going wrong.

Note: The transversal design must have \{0, \ldots, kn - 1\} as a ground set, partitioned as $k$ sets of size $n$:
\{0, \ldots, k-1\} $\sqcup$ \{k, \ldots, 2k-1\} $\sqcup$ \ldots $\sqcup$ \{k(n-1), \ldots, kn-1\}.

EXAMPLES:

```python
sage: TD = designs.transversal_design(5, 5, check=True) # indirect doctest
```

```python
sage: is_transversal_design(TD, 5, 5)
True
```

```python
sage: is_transversal_design(TD, 4, 4)
False
```

sage.combinat.designs.orthogonal_arrays.largest_available_k(n, t=2)

Return the largest $k$ such that Sage can build an OA($k,n$).

INPUT:
**Combinatorics, Release 10.1**

- **n** (integer)
- **t** – (integer; default: 2) – strength of the array

**EXAMPLES:**

```python
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
... ValueError: n(=-1) was expected to be >=0
```

```python
sage.combinat.designs.orthogonal_arrays.orthogonal_array(k, n, t=2, resolvable=False, check=True, existence=False, explain_construction=False)
```

Return an orthogonal array of parameters $k, n, t$.

An orthogonal array of parameters $k, n, t$ is a matrix with $k$ columns filled with integers from $[n]$ in such a way that for any $t$ columns, each of the $n^t$ possible rows occurs exactly once. In particular, the matrix has $n^t$ rows.

More general definitions sometimes involve a $\lambda$ parameter, and we assume here that $\lambda = 1$.

An orthogonal array is said to be *resolvable* if it corresponds to a resolvable transversal design (see `sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable()`).

For more information on orthogonal arrays, see Wikipedia article [Orthogonal_array](https://en.wikipedia.org/wiki/Orthogonal_array).

**INPUT:**

- **k** – (integer) number of columns. If $k=None$ it is set to the largest value available.
- **n** – (integer) number of symbols
- **t** – (integer; default: 2) – strength of the array
- **resolvable** (boolean) – set to `True` if you want the design to be resolvable. The $n$ classes of the resolvable design are obtained as the first $n$ blocks, then the next $n$ blocks, etc ... Set to `False` by default.
- **check** – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to `True` by default.
- **existence** (boolean) – instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`).
  - `False` – meaning that the design does not exist.
Note: When \( k=None \) and \( \text{existence}=\text{True} \) the function returns an integer, i.e. the largest \( k \) such that we can build a \( OA(k, n) \).

- **explain_construction** (boolean) – return a string describing the construction.

**OUTPUT:**

The kind of output depends on the input:

- if \( \text{existence}=\text{False} \) (the default) then the output is a list of lists that represent an orthogonal array with parameters \( k \) and \( n \)
- if \( \text{existence}=\text{True} \) and \( k \) is an integer, then the function returns a boolean: either True, Unknown or False
- if \( \text{existence}=\text{True} \) and \( k=None \) then the output is the largest value of \( k \) for which Sage knows how to compute a \( TD(k, n) \).

**Note:** This method implements theorems from [Stinson2004]. See the code’s documentation for details.

**See also:**

When \( t = 2 \) an orthogonal array is also a transversal design (see \texttt{transversal_design()} \) and a family of mutually orthogonal latin squares (see \texttt{mutually_orthogonal_latin_squares()}).

\[
\text{sage.combinat.designs.orthogonal_arrays.transversal_design}(k, n, \text{resolvable}=False, \text{check}=True, \\
\text{existence}=\text{False})
\]

Return a transversal design of parameters \( k, n \).

A transversal design of parameters \( k, n \) is a collection \( S \) of subsets of \( V = V_1 \cup \cdots \cup V_k \) (where the groups \( V_i \) are disjoint and have cardinality \( n \)) such that:

- Any \( S \in S \) has cardinality \( k \) and intersects each group on exactly one element.
- Any two elements from distincts groups are contained in exactly one element of \( S \).

More general definitions sometimes involve a \( \lambda \) parameter, and we assume here that \( \lambda = 1 \).

For more information on transversal designs, see [http://mathworld.wolfram.com/TransversalDesign.html](http://mathworld.wolfram.com/TransversalDesign.html).

**INPUT:**

- \( n, k \) – integers. If \( k \) is None it is set to the largest value available.
- **resolvable** (boolean) – set to True if you want the design to be resolvable (see \texttt{sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable()}). The \( n \) classes of the resolvable design are obtained as the first \( n \) blocks, then the next \( n \) blocks, etc ... Set to False by default.
- **check** – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.
- **existence** (boolean) – instead of building the design, return:
  - True – meaning that Sage knows how to build the design
  - Unknown – meaning that Sage does not know how to build the design, but that the design may exist (see \texttt{sage.misc.unknown}).
  - False – meaning that the design does not exist.
Note: When \( k=None \) and \( \text{existence=True} \) the function returns an integer, i.e. the largest \( k \) such that we can build a \( TD(k, n) \).

OUTPUT:
The kind of output depends on the input:

- if \( \text{existence=False} \) (the default) then the output is a list of lists that represent a \( TD(k, n) \) with \( V_1 = \{0, \ldots, n-1\}, \ldots, V_k = \{(k-1)n, \ldots, kn-1\} \)
- if \( \text{existence=True} \) and \( k \) is an integer, then the function returns a boolean: either True, Unknown or False
- if \( \text{existence=True} \) and \( k=None \) then the output is the largest value of \( k \) for which Sage knows how to compute a \( TD(k, n) \).

See also:

orthogonal_array() – a transversal design \( TD(k, n) \) is equivalent to an orthogonal array \( OA(k, n, 2) \).

EXAMPLES:

```python
sage: TD = designs.transversal_design(5,5); TD
Transversal Design TD(5,5)
sage: TD.blocks()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23], [0, 8, 11, 19, 22], [0, 9, 13, 17, 21], [1, 5, 14, 18, 22], [1, 6, 11, 16, 21], [1, 7, 13, 19, 20], [1, 8, 10, 17, 24], [1, 9, 12, 15, 23], [2, 5, 13, 16, 24], [2, 6, 10, 19, 23], [2, 7, 12, 17, 22], [2, 8, 14, 15, 21], [2, 9, 11, 18, 20], [3, 5, 12, 19, 21], [3, 6, 14, 17, 20], [3, 7, 11, 15, 24], [3, 8, 13, 18, 23], [3, 9, 10, 16, 22], [4, 5, 11, 17, 23], [4, 6, 13, 15, 22], [4, 7, 10, 18, 21], [4, 8, 12, 16, 20], [4, 9, 14, 19, 24]]
```

Some examples of the maximal number of transversal Sage is able to build:

```python
sage: TD_4_10 = designs.transversal_design(4,10)
sage: designs.transversal_design(5,10,existence=True)
Unknown
```

For prime powers, there is an explicit construction which gives a \( TD(n + 1, n) \):

```python
sage: designs.transversal_design(4, 3, existence=True)
True
sage: designs.transversal_design(674, 673, existence=True)
True
```

For other values of \( n \) it depends:

```python
sage: designs.transversal_design(7, 6, existence=True)
False
sage: designs.transversal_design(4, 6, existence=True)
Unknown
sage: designs.transversal_design(3, 6, existence=True)
True
```

(continues on next page)
If you ask for a transversal design that Sage is not able to build then an EmptySetError or a NotImplemented error is raised:

```
sage: designs.transversal_design(47, 100)
Traceback (most recent call last):
  ...  
NotImplementedError: I don't know how to build a TD(47,100)!
	sage: designs.transversal_design(55, 54)
Traceback (most recent call last):
  ...  
EmptySetError: There exists no TD(55,54)!
```

Those two errors correspond respectively to the cases where Sage answer Unknown or False when the parameter existence is set to True:

```
sage: designs.transversal_design(47, 100, existence=True)  
Unknown  
sage: designs.transversal_design(55, 54, existence=True)  
False  
```

If for a given \( n \) you want to know the largest \( k \) for which Sage is able to build a \( TD(k, n) \) just call the function with \( k \) set to None and existence set to True as follows:

```
sage: designs.transversal_design(None, 6, existence=True)  
3  
sage: designs.transversal_design(None, 20, existence=True)  
6  
sage: designs.transversal_design(None, 30, existence=True)  
6  
sage: designs.transversal_design(None, 120, existence=True)  
9  
```
sage.combinat.designs.orthogonal_arrays.wilson_construction(OA, k, r, m, u, check=True, 
explain_construction=False)

Returns a \( OA(k, rm + \sum_i u_i) \) from a truncated \( OA(k + s, r) \) by Wilson’s construction.

**Simple form:**
Let \( OA \) be a truncated \( OA(k + s, r) \) with \( s \) truncated columns of sizes \( u_1, ..., u_s \), whose blocks have sizes in \( \{k + b_1, ..., k + b_t\} \). If there exist:

- An \( OA(k, m + b_i) - b_i OA(k, 1) \) for every \( 1 \leq i \leq t \)
- An \( OA(k, u_i) \) for every \( 1 \leq i \leq s \)

Then there exists an \( OA(k, rm + \sum_i u_i) \). The construction is a generalization of Lemma 3.16 in [HananiBIBD].

**Brouwer-Van Rees form:**
Let \( OA \) be a truncated \( OA(k + s, r) \) with \( s \) truncated columns of sizes \( u_1, ..., u_s \). Let the set \( H_i \) of the \( u_i \) points of column \( k+i \) be partitioned into \( \sum_j H_{ij} \). Let \( m_{ij} \) be integers such that:

- For \( 0 \leq i < l \) there exists an \( OA(k, \sum_j m_{ij}|H_{ij}|) \)
- For any block \( B \in OA \) intersecting the sets \( H_{ij}(i) \) there exists an \( OA(k, m + \sum_i m_{ij}) - \sum_i OA(k, m_{ij(j)}) \).

Then there exists an \( OA(k, rm + \sum_i m_{ij}) \). This construction appears in [BvR1982].

**INPUT:**
- \( OA \) – an incomplete orthogonal array with \( k+s \) columns. The elements of a column of size \( c \) must belong to \( \{0, ..., c\} \). The missing entries of a block are represented by \( None \) values. If \( OA=None \), it is defined as a truncated orthogonal arrays with \( k+s \) columns.
- \( k, r, m \) (integers)
- \( u \) (list) – two cases depending on the form to use:
  - Simple form: a list of length \( s \) such that column \( k+i \) has size \( u[i] \). The untruncated points of column \( k+i \) are assumed to be \( \{0, ..., u[i]-1\} \).
  - Brouwer-Van Rees form: a list of length \( s \) such that \( u[i] \) is the list of pairs \( (m_{i0},|H_{i0}|), ..., (m_{ip_i},|H_{ip_i}|) \). The untruncated points of column \( k+i \) are assumed to be \( \{0, ..., u_i-1\} \) where \( u_i = \sum_j |H_{ij}| \). Besides, the first \( |H_{i0}| \) points represent \( H_{i0} \), the next \( |H_{i1}| \) points represent \( H_{i1} \), etc...
- \( explain_construction \) (boolean) – return a string describing the construction.
- \( check \) (boolean) – whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

**REFERENCE:**

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays_import wilson_construction
sage: from sage.combinat.designs.orthogonal_arrays_import OA_relabel
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive_import find_
˓→wilson_decomposition_with_one_truncated_group
sage: total = 0
sage: for k in range(3,8):
.....:    for n in range(1,30):
.....:        if find_wilson_decomposition_with_one_truncated_group(k,n):
.....:            total += 1
```
....:       f, args = find_wilson_decomposition_with_one_truncated_group(k,n)
....:       _ = f(*args)
sage: total

Brouwer-van Rees construction n=17.21+(9.4+1.1)+(9.9+1.1) with master design OA(71+2,17)

An example using the Brouwer-van Rees generalization:

sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.orthogonal_arrays import wilson_construction
sage: OA = designs.orthogonal_arrays.build(6,11)
sage: OA = [[x if (i<5 or x<5) else None for i,x in enumerate(R)] for R in OA]
sage: OAb = wilson_construction(OA,5,11,21,[(5,5)])
sage: is_orthogonal_array(OAb,5,256)
True

5.1.91 Orthogonal arrays (build recursive constructions)

This module implements several constructions of Orthogonal Arrays. As their input can be complex, they all have a counterpart in the orthogonal_arrays_find_recursive module that automatically computes it.

All these constructions are automatically queried when the orthogonal_array() function is called.

- **construction_3_3()**
  - Return an $OA(k, nm + i)$.
- **construction_3_4()**
  - Return a $OA(k, nm + rs)$.
- **construction_3_5()**
  - Return an $OA(k, nm + r + s + t)$.
- **construction_3_6()**
  - Return a $OA(k, nm + i)$.
- **construction_q_x()**
  - Return an $OA(k, (q - 1) * (q - x) + x + 2)$ using the $q - x$ construction.
- **OA_and_oval()**
  - Return a $OA(q + 1, q)$ whose blocks contains $\leq 2$ zeroes in the last $q$ columns.
- **thwartLemma_3_5()**
  - Returns an $OA(k, nm + a + b + c + d)$.
- **thwartLemma_4_1()**
  - Returns an $OA(k, nm + 4(n - 2))$.
- **three_factor_product()**
  - Returns an $OA(k + 1, n_1 n_2 n_3)$.
- **brouwer_separable_design()**
  - Returns a $OA(k, l(q^2 + q + 1) + x)$ using Brouwer's result on separable designs.
Functions

`sage.combinat.designs.orthogonal_arrays_build_recursive.OA_and_oval(q, solver, integrality_tolerance)`

Return a $OA(q+1, q)$ whose blocks contains $\leq 2$ zeroes in the last $q$ columns.

This $OA$ is build from a projective plane of order $q$, in which there exists an oval $O$ of size $q+1$ (i.e. a set of $q+1$ points no three of which are colinear/contained in a common set of the projective plane).

Removing an element $x \in O$ and all sets that contain it, we obtain a $TD(q+1, q)$ in which $O$ intersects all columns except one. As $O$ is an oval, no block of the $TD$ intersects it more than twice.

**INPUT:**

- $q$ – a prime power
- $\text{solver}$ – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- $\text{integrality_tolerance}$ – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**Note:** This function is called by `construction_3_6()`, an implementation of Construction 3.6 from [AC07].

**EXAMPLES:**

```python
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import OA_and_oval
sage: _ = OA_and_oval
```

`sage.combinat.designs.orthogonal_arrays_build_recursive.brouwer_separable_design(k, t, q, x, check=False, verbose=False, explain_construction=False)`

Returns a $OA(k, t(q^2 + q + 1) + x)$ using Brouwer’s result on separable designs.

This method is an implementation of Brouwer’s construction presented in [Brouwer80]. It consists in a systematic application of the usual transformation from PBD to OA, applied to a specific PBD.

**Baer subplanes**

When $q$ is a prime power, the projective plane $PG(2, q^2)$ can be partitioned into subplanes $PG(2, q)$ (called Baer subplanes), giving $PG(2, q^2) = B_1 \cup \cdots \cup B_{q^2-q+1}$. As a result, every line of the $PG(2, q^2)$ intersects one of the subplane on $q + 1$ points and all others on 1 point.

The $OA$ are built by considering $B_1 \cup \cdots \cup B_t$, for a total of $t(q^2 + q + 1)$ points (to which $x$ new points are then added). The blocks of this subdesign belong to two categories:

- The blocks of size $t$: they come from the lines which intersect a $B_i$ on $q + 1$ points for some $i > t$. The blocks of size $t$ can be partitioned into $q^2 - q + t - 1$ parallel classes according to their associated subplane $B_i$ with $i > t$.
- The blocks of size $q + t$: those blocks form a symmetric design, as every point is incident with $q + t$ of them.
Constructions

In the following, we write \( N = t(q^2 + q + 1) + x \). The code is also heavily commented, and will clear any doubt.

- **i) \( x = 0 \):** in that case we build a resolvable \( OA(k - 1, N) \) that will then be completed into an \( OA(k, N) \).
  - **Sets of size \( t \)**
    
    We take the product of each parallel class with the parallel classes of a resolvable \( OA(k - 1, t) - t.OA(k - 1, t) \), yielding new parallel classes.
  - **Sets of size \( q + t \)**
    
    A \( N \times (q + t) \) array is built whose rows are the sets of size \( q + t \) such that every value appears once per column. For each block of a \( OA(k - 1, q + t) - (q + t).OA(k - 1, t) \), the product with the rows of the matrix yields a parallel class.

- **ii) \( x = q + t \)**
  
  - **Sets of size \( t \)**
    
    Each set of size \( t \) gives a \( OA(k, t) - t.OA(k, 1) \), except if there is only one parallel class in which case a \( OA(k, t) \) is sufficient.
  
  - **Sets of size \( q + t \)**
    
    A \( (N - x) \times (q + t) \) array \( M \) is built whose \( N - x \) rows are the sets of size \( q + t \) such that every value appears once per column. For each of the new \( x = q + t \) points \( p_1, \ldots, p_{q+t} \) we build a matrix \( M_i \) obtained from \( M \) by adding a column equal to \( (p_i, p_i, \ldots) \). We add to the OA the product of all rows of the \( M_i \) with the block of the \( x = q + t \) parallel classes of a resolvable \( OA(k, t + q + 1) - (t + q + 1).OA(k, 1) \).
  
  - **Set of size \( x \)** An \( OA(k, x) \)

- **iii) \( x = q^2 - q + 1 - t \)**
  
  - **Sets of size \( t \)**
    
    All blocks of the \( i \)-th parallel class are extended with the \( i \)-th new point. The blocks are then replaced by a \( OA(k, t + 1) - (t + 1).OA(k, 1) \) or, if there is only one parallel class (i.e. \( x = 1 \)) by a \( OA(k, t + 1) - OA(k, 1) \).
  
  - **Set of size \( q + t \)**
    
    They are replaced by \( OA(k, q + t) - (q + t).OA(k, 1) \).
  
  - **Set of size \( x \)** An \( OA(k, x) \)

- **iv) \( x = q^2 + 1 \)**
  
  - **Sets of size \( t \)**
    
    All blocks of the \( i \)-th parallel class are extended with the \( i \)-th new point (the other \( x - q - t \) new points are not touched at this step). The blocks are then replaced by a \( OA(k, t + 1) - (t + 1).OA(k, 1) \) or, if there is only one parallel class (i.e. \( x = 1 \)) by a \( OA(k, t + 1) - OA(k, 1) \).
  
  - **Sets of size \( q + t \)** Same as for ii)
  
  - **Set of size \( x \)** An \( OA(k, x) \)

- **v) \( 0 < x < q^2 - q + 1 - t \)**
- **Sets of size** $t$
  The blocks of the first $x$ parallel class are extended with the $x$ new points, and replaced with $OA(k.t + 1) - (t + 1).OA(k, 1)$ or, if $x = 1$, by $OA(k.t + 1) - OA(k, 1)$
  The blocks of the other parallel classes are replaced by $OA(k, t) - t.OA(k, t)$ or, if there is only one class left, by $OA(k, t) - OA(k, t)$
- **Sets of size** $q + t$
  They are replaced with $OA(k, q + t) - (q + t).OA(k, 1)$.
- **Set of size** $x$) An $OA(k, x)$

  - vi) $t + q < x < q^2 + 1$

- **Sets of size** $t$) Same as in v) with an $x$ equal to $x - q + t$.
- **Sets of size** $t$) Same as in vii)
- **Set of size** $x$) An $OA(k, x)$

**INPUT:**
- **k, t, q, x** (integers)
- **check** – (boolean) Whether to check that output is correct before returning it. Set to False by default.
- **verbose** (boolean) – whether to print some information on the construction and parameters being used.
- **explain_construction** (boolean) – return a string describing the construction.

sage: print(designs.orthogonal_arrays.explain_construction(10,189))
Brouwer's separable design construction with t=9,q=4,x=0 from:
Andries E. Brouwer,
A series of separable designs with application to pairwise orthogonal Latin squares
Vol. 1, n. 1, pp. 39-41,
European Journal of Combinatorics, 1980

sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_3(k,n,m,i,explain_construction=False)

Return an $OA(k, nm + i)$. This is Wilson's construction with $i$ truncated columns of size 1 and such that a block $B_0$ of the incomplete OA intersects all truncated columns. As a consequence, all other blocks intersect only 0 or 1 of the last $i$ columns. This allow to consider the block $B_0$ only up to its first $k$ coordinates and then use a $OA(k, i)$ instead of a $OA(k, m + i) - i \cdot OA(k, 1)$. This is construction 3.3 from [AC07].

INPUT:

* k,n,m,i (integers) such that the following designs are available: $OA(k, n)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, r)$.
* explain_construction (boolean) – return a string describing the construction.

Julian R. Abel, Nicholas Cavenagh
Concerning eight mutually orthogonal latin squares,
Vol. 15, n.3, pp. 255-261,
Journal of Combinatorial Designs, 2007

sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_4(k, n, m, r, s, explain_construction=False)

Return a $OA(k, nm + rs)$.  
This is Wilson’s construction applied to a truncated $OA(k + r + 1, n)$ with $r$ columns of size 1 and one column of size $s$.  
The unique elements of the $r$ truncated columns are picked so that a block $B_0$ contains them all.  
- If there exists an $OA(k, m + r + 1)$ the column of size $s$ is truncated in order to intersect $B_0$.  
- Otherwise, if there exists an $OA(k, m + r)$, the last column must not intersect $B_0$

This is construction 3.4 from [AC07].

INPUT:  
- $k, n, m, r, s$ (integers) – we assume that $s < n$ and $1 \leq r, s$  
The following designs must be available: $OA(k, n), OA(k, m), OA(k, m + 1), OA(k, m + 2), OA(k, s)$.  
Additionally, it requires either a $OA(k, m + r)$ or a $OA(k, m + r + 1)$.
- explain_construction (boolean) – return a string describing the construction.

Journal of Combinatorial Designs, 2007

sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_5(k, n, m, r, s, t, explain_construction=False)

Return an $OA(k, nm + r + s + t)$.  
This is exactly Wilson’s construction with three truncated groups except we make sure that all blocks have size $> k$, so we don’t need a $OA(k, m + 0)$ but only $OA(k, m + 1), OA(k, m + 2), 'OA(k,m+3)'$.  

This is construction 3.5 from [AC07].

INPUT:

• \(k, n, m\) (integers)
• \(r, s, t\) (integers) – sizes of the three truncated groups, such that \(r \leq s\) and \((q - r - 1)(q - s) \geq (q - s - 1)(q - r)\).
• `explain_construction` (boolean) – return a string describing the construction.

The following designs must be available: \(OA(k, n), OA(k, r), OA(k, s), OA(k, t), OA(k, m + 1), OA(k, m + 2), OA(k, m + 3)\).

    Journal of Combinatorial Designs, 2007
```

sage.combinat.designs.orthogonal_arrays_build_recursive.construction_3_6(k, n, m, i, explain_construction=False)

Return a \(OA(k, nm + i)\)

This is Wilson's construction with \(r\) columns of order 1, in which each block intersects at most two truncated columns. Such a design exists when \(n\) is a prime power and is returned by \(OA\text{and} Oval()\).

INPUT:

• \(k, n, m, i\) (integers) – \(n\) must be a prime power. The following designs must be available: \(OA(k + r, q), OA(k, m), OA(k, m + 1), OA(k, m + 2)\).
• `explain_construction` (boolean) – return a string describing the construction.

This is construction 3.6 from [AC07].

See also:

• `find_construction_3_6()`
• `OA\text{and} Oval()`

EXAMPLES:
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_ ˓→construction_3_6

sage: k=8;n=95
sage: is_orthogonal_array(construction_3_6(*find_construction_3_6(k,n)[1]),k,n,2)
True
sage: print(designs.orthogonal_arrays.explain_construction(10,756))
Construction 3.6 with n=16,m=47,i=4 from:
    Julian R. Abel, Nicholas Cavenagh
    Concerning eight mutually orthogonal latin squares,
    Vol. 15, n.3, pp. 255-261,
    Journal of Combinatorial Designs, 2007

sage.combinat.designs.orthogonal_arrays_build_recursive.construction_q_x(k, q, x, check=True,
    explain_construction=False)

Return an $OA(k, (q - 1) \times (q - x) + x + 2)$ using the $q - x$ construction.

Let $v = (q - 1) \times (q - x) + x + 2$. If there exists a projective plane of order $q$ (e.g. when $q$ is a prime power) and $0 < x < q$ then there exists a $(v - 1, \{q - x - 1, q - x + 1\})$-GDD of type $(q - 1)^{q-x}(x + 1)^1$ (see [Greig99] or Theorem 2.50, section IV.2.3 of [DesignHandbook]). By adding to the ground set one point contained in all groups of the GDD, one obtains a $(v, \{q - x - 1, q - x + 1, q, x + 2\})$-PBD with exactly one set of size $x + 2$.

Thus, assuming that we have the following:

- $OA(k, q - x - 1) - (q - x - 1).OA(k, 1)$
- $OA(k, q - x + 1) - (q - x + 1).OA(k, 1)$
- $OA(k, q) - q.OA(k, 1)$
- $OA(k, x + 2)$

Then we can build from the PBD an $OA(k, v)$.

Construction of the PBD (shared by Julian R. Abel):

Start with a resolvable $(q^2, q, 1)$-BIBD and put the points into a $q \times q$ array so that rows form a parallel class and columns form another.

Now delete:

- All $x(q - 1)$ points from the first $x$ columns and not in the first row
- All $q - x$ points in the last $q - x$ columns AND the first row.

Then add a point $p_1$ to the blocks that are rows. Add a second point $p_2$ to the $q - x$ blocks that are columns of size $q - 1$, plus the first row of size $x + 1$.

INPUT:

- $k, q, x$ – integers such that $0 < x < q$ and such that Sage can build:
  - A projective plane of order $q$
  - $OA(k, q - x - 1) - (q - x - 1).OA(k, 1)$
  - $OA(k, q - x + 1) - (q - x + 1).OA(k, 1)$
  - $OA(k, q) - q.OA(k, 1)$
- \( OA(k, x + 2) \)

- **check** – (boolean) Whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed. Set to True by default.

- **explain_construction** (boolean) – return a string describing the construction.

```

**REFERENCES:**

```python
sage.combinat.designs.orthogonal_arrays_build_recursive.three_factor_product(k, n1, n2, n3, check=False, explain_construction=False)
```

Returns an \( OA(k + 1, n_1 n_2 n_3) \)

The three factor product construction from [DukesLing14] does the following:

If \( n_1 \leq n_2 \leq n_3 \) are such that there exists an \( OA(k, n_1) \), \( OA(k + 1, n_2) \) and \( OA(k + 1, n_3) \), then there exists a \( OA(k + 1, n_1 n_2 n_3) \).

It works with a modified product of orthogonal arrays ([Rees93], [Rees00]) which keeps track of parallel classes in the \( OA \) (the definition is given for transversal designs).

A subset of blocks in an \( TD(k, n) \) is called a \( c \)-parallel class if every point is covered exactly \( c \) times.
A 1-parallel class is a parallel class.

The modified product:

If there exists an \( OA(k, n_1) \), and if there exists an \( OA(k, n_2) \) whose blocks are partitionned into \( s \) \( n_1 \)-parallel classes and \( n_2 - sn_1 \) parallel classes, then there exists an \( OA(k, n_1 n_2) \) whose blocks can be partitionned into \( sn_1^2 \) parallel classes and \( (n_1 n_2 - sn_1^2)/n_1 = n_2 - sn_1 \) \( n_1 \)-parallel classes.

Proof:

- The product of the blocks of a parallel class with an \( OA(k, n_1) \) yields an \( n_1 \)-parallel class of an \( OA(k, n_1 n_2) \).
The product of the blocks of a $n_1$-parallel class of $OA(k, n_2)$ with an $OA(k, n_1)$ can be done in such a way that it yields $n_1n_2$ parallel classes of $OA(k, n_1n_2)$. Those classes cover exactly the pairs that would have been covered with the usual product.

This can be achieved by simple cyclic permutations. Let us build the product of the $n_1$-parallel class $\mathcal{P} \subseteq OA(k, n_2)$ with $OA(k, n_1)$: when computing the product of $P \in \mathcal{P}$ with $B_1 \in OA(k, n_1)$ the $i$-th coordinate should not be $(B_1^i, P_i)$ but $(B_1^i + r, P_i)$ (the sum is mod $n_1$) where $r$ is the number of blocks of $\mathcal{P}$ we have already processed whose $i$-th coordinate is equal to $P_i$ (note that $r < n_1$ as $\mathcal{P}$ is $n_1$-parallel).

With these tools, one can obtain the designs promised by the three factors construction applied to $k, n_1, n_2, n_3$ (thanks to Julian R. Abel’s help):

1) Let $s$ be the largest integer $\leq n_3/n_1$. Apply the product construction to $OA(k, n_1)$ and a resolvable $OA(k, n_3)$ whose blocks are partitioned into $s$ $n_1$-parallel classes and $n_3 - sn_1$ parallel classes. It results in a $OA(k, n_1n_3)$ partitionned into $sn_1^2$ parallel classes plus $(n_1n_3 - sn_1^2)/n_1 = n_3 - sn_1$ $n_1$-parallel classes.

2) Add $n_3 - n_1$ parallel classes to every $n_1$-parallel class to turn them into $n_3$-parallel classes. Apply the product construction to this partitionned $OA(k, n_1n_3)$ with a resolvable $OA(k, n_2)$.

3) As $OA(k, n_2)$ is resolvable, the $n_2$-parallel classes of $OA(k, n_1n_2n_3)$ are actually the union of $n_2$ parallel classes, thus the $OA(k, n_1n_2n_3)$ is resolvable and can be turned into an $OA(k + 1, n_1n_2n_3)$.

**INPUT:**

- $k, n_1, n_2, n_3$ (integers)
- `check` – (boolean) Whether to check that everything is going smoothly while the design is being built. It is disabled by default, as the constructor of orthogonal arrays checks the final design anyway.
- `explain_construction` (boolean) – return a string describing the construction.

sage: print(designed.orthogonal_arrays.explain_construction(10,648))
Three-factor product with n=8.9.9 from:
    Peter J. Dukes, Alan C.H. Ling,
    A three-factor product construction for mutually orthogonal latin squares,

REFERENCE:
sage.combinat.designs.orthogonal_arrays.build_recursive.thwart_lemma_3_5(k, n, m, a, b, c, d=0, complement=False, explain_construction=False)

Returns an \( OA(k, nm + a + b + c + d) \)

(When 'd=0')

According to [Thwarts] when \( n \) is a prime power and \( a + b + c \leq n + 1 \), one can build an \( OA(k + 3, n) \) with three truncated columns of sizes \( a, b, c \) in such a way that all blocks have size \( \leq k + 2 \).

(in order to build a \( OA(k, nm + a + b + c) \) the following designs must also exist: \( OA(k, a), OA(k, b), OA(k, c), OA(k, m + 0), OA(k, m + 1), OA(k, m + 2) \))

Considering the complement of each truncated column, it is also possible to build an \( OA(k + 3, n) \) with three truncated columns of sizes \( a, b, c \) in such a way that all blocks have size \( > k \) whenever \( (n-a)+(n-b)+(n-c) \leq n + 1 \).

(in order to build a \( OA(k, nm + a + b + c) \) the following designs must also exist: \( OA(k, a), OA(k, b), OA(k, c), OA(k, m + 1), OA(k, m + 2), OA(k, m + 3) \))

Here is the proof of Lemma 3.5 from [Thwarts] enriched with explanations from Julian R. Abel:

For any prime power \( n \) one can build \( k - 1 \) MOLS by associating to every nonzero \( x \in \mathbb{F}_n \) the latin square:

\[
M_x(i, j) = i + x * j \text{ where } i, j \in \mathbb{F}_n
\]

In particular \( M_1(i, j) = i + j \), whose \( n \) columns and lines are indexed by the elements of \( \mathbb{F}_n \). If we order the elements of \( \mathbb{F}_n \) as \( 0, 1, ..., n - 1, x + 0, ..., x + n - 1, x^2 + 0, ... \) and reorder the columns and lines of \( M_1 \) accordingly, the top-left \( a \times b \) squares contains at most \( a + b - 1 \) distinct symbols.

(When \( d \neq 0 \))

If there exists an \( OA(k + 3, n) \) with three truncated columns of sizes \( a, b, c \) in such a way that all blocks have size \( \leq k + 2 \), by truncating arbitrarily another column to size \( d \) one obtains an \( OA \) with 4 truncated columns whose blocks miss at least one value. Thus, following the proof again one can build an \( OA(k + 4) \) with four truncated columns of sizes \( a, b, c, d \) with blocks of size \( \leq k + 3 \).

(in order to build a \( OA(k, nm + a + b + c + d) \) the following designs must also exist: \( OA(k, a), OA(k, b), OA(k, c), OA(k, m + 0), OA(k, m + 1), OA(k, m + 2), OA(k, m + 3) \))

As before, this also shows that one can build an \( OA(k + 4, n) \) with four truncated columns of sizes \( a, b, c, d \) in such a way that all blocks have size \( > k \) whenever \( (n-a)+(n-b)+(n-c) \leq n + 1 \)

(in order to build a \( OA(k, nm + a + b + c + d) \) the following designs must also exist: \( OA(k, n-a), OA(k, n-b), OA(k, n-c), OA(k, m + 1), OA(k, m + 2), OA(k, m + 3), OA(k, m + 4) \))

INPUT:
• \(k, n, m, a, b, c, d\) – integers which must satisfy the constraints above. In particular, \(a + b + c \leq n + 1\) must hold. By default, \(d = 0\).

• complement (boolean) – whether to complement the sets, i.e. follow the \(n - a, n - b, n - c\) variant described above.

• explain_construction (boolean) – return a string describing the construction.

See also:

• find_thwart_lemma_3_5()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import thwart_lemma_3_5
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: OA = thwart_lemma_3_5(6, 23, 7, 5, 7, 8)
sage: is_orthogonal_array(OA, 6, 23*7+5+7+8, 2)
True
sage: print(designs.orthogonal_arrays.explain_construction(10, 408))
```

Lemma 4.1 with \(n=13, m=28\) from:

With sets of parameters from [Thwarts]:

```
sage: l = 
....:     [[11, 27, 78, 16, 17, 25, 0],
....:      [12, 19, 208, 11, 13, 16, 0],
....:      [12, 19, 208, 13, 13, 16, 0],
....:      [10, 13, 78, 9, 9, 13, 1],
....:      [10, 13, 79, 9, 9, 13, 1]]
sage: for k,n,m,a,b,c,d in l: # not tested --- too long
....:     OA = thwart_lemma_3_5(k,n,m,a,b,c,d,complement=True)
....:     assert is_orthogonal_array(OA,k,n*m+a+b+c+d,verbose=True)
```

Lemma 3.5 with \(n=13, m=79, a=9, b=1, c=0, d=9\) from:

REFERENCE:
sage.combinat.designs.orthogonal_arrays_build_recursive.thwart_lemma_4_1(k, n, m, explain_construction=False)

Returns an \(OA(k, nm + 4(n - 2))\).

Implements Lemma 4.1 from [Thwarts].

If \(n \equiv 0, 1 \pmod{3}\) is a prime power, then there exists a truncated \(OA(n + 1, n)\) whose last four columns have size \(n - 2\) and intersect every block on 1, 3 or 4 values. Consequently, if there exists an
\[ OA(k, m + 1), OA(k, m + 3), OA(k, m + 4) \text{ and } OA(k, n - 2) \] then there exists an \[ OA(k, nm + 4(n - 2) \]

Proof: form the transversal design by removing one point of the \( AG(2, 3) \) (Affine Geometry) contained in the Desarguesian Projective Plane \( PG(2, n) \).

The affine geometry on 9 points contained in the projective geometry \( PG(2, n) \) is given explicitly in [OS64] (Thanks to Julian R. Abel for finding the reference!).

INPUT:
- \( k, n, m \) (integers)
- \( \text{explain_construction} \) (boolean) – return a string describing the construction.

See also:
- \( \text{find_thwart_lemma_4_1()} \)

EXAMPLES:

```sage
sage: print(designs.orthogonal_arrays.explain_construction(10,408))
```

5.1.92 Orthogonal arrays (find recursive constructions)

This module implements several functions to find recursive constructions of **Orthogonal Arrays**.

The main function of this module, i.e. \( \text{find_recursive_construction()} \), queries all implemented recursive constructions of designs implemented in \( \text{orthogonal_arrays_build_recursive} \) in order to obtain an \( OA(k, n) \).

\( \text{find_recursive_construction()} \) is called by the \( \text{orthogonal_array()} \) function.

```python
find_recursive_construction() - Find a recursive construction of an \( OA(k, n) \) (calls all others find_* functions)
find_product_decomposition() - Find \( n_1n_2 = n \) to obtain an \( OA(k, n) \) by the product construction
find_wilson_decomposition() - Find \( r_m + u = n \) to obtain an \( OA(k, n) \) by Wilson's construction with one truncated column.
find_wilson_decomposition() - Find \( r_m + r_1 + r_2 = n \) to obtain an \( OA(k, n) \) by Wilson's construction with two truncated columns.
find_construction_3_3() - Find a decomposition for construction 3.3 from [AC07].
find_construction_3_4() - Find a decomposition for construction 3.4 from [AC07].
find_construction_3_5() - Find a decomposition for construction 3.5 from [AC07].
find_construction_3_6() - Find a decomposition for construction 3.6 from [AC07].
find_q_x() - Find integers \( q, x \) such that the \( q - x \) construction yields an \( OA(k, n) \).
find_thwart_lemma_3_5() - Find the values on which Lemma 3.5 from [Thwarts] applies.
find_thwart_lemma_4_1() - Find a decomposition for Lemma 4.1 from [Thwarts].
find_three_factor_product() - Find \( n_1n_2n_3 = n \) to obtain an \( OA(k, n) \) by the three-factor product from [DukesLing14].
find_brouwer_separable_design() - Find \( q^2 + q + 1 + x = n \) to obtain an \( OA(k, n) \) by Brouwer's separable design construction.
find_brouwer_van_rees_with_one_truncated_column() - Find \( n \) such that the Brouwer-van Rees constructions yields a \( OA(k, n) \).
```
REFERENCES:

Functions

sage.combinat.designs.orthogonal_arrays_find_recursive.find_brouwer_separable_design\((k, n)\)

Find \(t(q^2 + q + 1) + x = n\) to obtain an \(OA(k, n)\) by Brouwer’s separable design construction.

INPUT:

• \(k, n\) (integers)

The assumptions made on the parameters \(t, q, x\) are explained in the documentation of \texttt{brouwer_separable_design()}.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_brouwer_separable_design
sage: find_brouwer_separable_design(5, 13)\[1\]
\((5, 1, 3, 0)\)
sage: find_brouwer_separable_design(5, 14)
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.find_brouwer_van_rees_with_one_truncated_column\((k, n)\)

Find \(rm + x_1 + ... + x_c = n\) such that the Brouwer-van Rees constructions yields a \(OA(k, n)\).

Let \(n = rm + \sum_{1\leq i \leq c} u_i\) such that \(c \leq r\). The generalization of Wilson’s construction found by Brouwer and van Rees (with one truncated column) ensures that an \(OA(k, n)\) exists if the following designs exist: \(OA(k + 1, r), OA(k, m), OA(k, \sum_{1\leq i \leq c} u_i), OA(k, m + x_1) - OA(k, x_1), ..., OA(k, m + x_c) - OA(k, x_c)\).

For more information, see the documentation of \texttt{wilson_construction()}.

INPUT:

• \(k, n\) (integers)

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_brouwer_van_rees_with_one_truncated_column
sage: find_brouwer_van_rees_with_one_truncated_column(5, 53)\[1\]
\((None, 5, 7, 7, [[[2, 1], (2, 1)]])\)
sage: find_brouwer_van_rees_with_one_truncated_column(6, 96)\[1\]
\((None, 6, 7, 13, [[[3, 1], (1, 1), (1, 1)]])\)
```

sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_3\((k, n)\)

Find a decomposition for construction 3.3 from [AC07]

INPUT:

• \(k, n\) (integers)

See also:

\texttt{construction_3_3()}

OUTPUT:

A pair \(f, \text{args}\) such that \(f(*\text{args})\) returns the requested OA.
EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_construction_3_3
sage: find_construction_3_3(11,177)[1]
(11, 11, 16, 1)
sage: find_construction_3_3(12,11)
```

```python
sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_4(k, n)
Find a decomposition for construction 3.4 from [AC07]

INPUT:
• k,n (integers)

See also:
construction_3_4()

OUTPUT:
A pair f,args such that f(*args) returns the requested OA.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_construction_3_4
sage: find_construction_3_4(8,196)[1]
(8, 25, 7, 12, 9)
sage: find_construction_3_4(9,24)
```

```python
sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_5(k, n)
Find a decomposition for construction 3.5 from [AC07]

INPUT:
• k,n (integers)

See also:
construction_3_5()

OUTPUT:
A pair f,args such that f(*args) returns the requested OA.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_construction_3_5
sage: find_construction_3_5(8,111)[1]
(8, 13, 6, 9, 11, 13)
sage: find_construction_3_5(9,24)
```

```python
sage.combinat.designs.orthogonal_arrays_find_recursive.find_construction_3_6(k, n)
Find a decomposition for construction 3.6 from [AC07]

INPUT:
• k,n (integers)```
See also:

\textit{construction\_3\_6()}

OUTPUT:
A pair \(f,\text{args}\) such that \(f(*\text{args})\) returns the requested OA.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_ →construction\_3\_6
sage: find_construction\_3\_6(8,95)[1]
(8, 13, 7, 4)
sage: find_construction\_3\_6(8,98)
```

\texttt{sage.combinat.designs.orthogonal_arrays_find_recursive.find_product_decomposition}(k, n)
Find \(n_1n_2 = n\) to obtain an OA\((k, n)\) by the product construction.

If Sage can build a OA\((k, n_1)\) and a OA\((k, n_2)\) such that \(n = n_1 \times n_2\) then a OA\((k, n)\) can be built by a product construction (which correspond to Wilson's construction with no truncated column). This function look for a pair of integers \((n_1, n_2)\) with \(n_1 \leq n_2, n_1 \times n_2 = n\) and such that both an OA\((k, n_1)\) and an OA\((k, n_2)\) are available.

INPUT:

- \(k, n\) (integers) – see above.

OUTPUT:
A pair \(f,\text{args}\) such that \(f(*\text{args})\) is an OA\((k, n)\) or False if no product decomposition was found.

EXAMPLES:

```python
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_ →product_decomposition
sage: f, args = find_product_decomposition(6, 84)
sage: args
(\text{None}, 6, 7, 12, (), \text{False})
sage: _ = f(*args)
```

\texttt{sage.combinat.designs.orthogonal_arrays_find_recursive.find_q_x}(k, n)
Find integers \(q, x\) such that the \(q-x\) construction yields an OA\((k, n)\).

See the documentation of \textit{construction_q_x()} to find out what hypotheses the integers \(q, x\) must satisfy.

\textbf{Warning:} For efficiency reasons, this function checks that Sage can build an \(OA(k + 1, q - x - 1)\) and an \(OA(k + 1, q - x + 1)\), which is stronger than checking that Sage can build a \(OA(k, q - x - 1) - (q - x - 1)OA(k, 1)\) and a \(OA(k, q - x + 1) - (q - x + 1)OA(k, 1)\). The latter would trigger a lot of independent set computations in \texttt{sage.combinat.designs.orthogonal_arrays.incomplete_orthogonal_array()}. 

INPUT:

- \(k, n\) (integers)

\textbf{See also:}

\textit{construction_q_x()}

EXAMPLES:
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_q_x
sage: find_q_x(10,9)
False
sage: find_q_x(9,158)[1]
(9, 16, 6)

sage.combinat.designs.orthogonal_arrays_find_recursive.find_recursive_construction(n)
Find a recursive construction of an $OA(k, n)$ (calls all others find_* functions)
This determines whether an $OA(k, n)$ can be built through the following constructions:

- wilson_construction()
- construction_3_3()
- construction_3_4()
- construction_3_5()
- construction_3_6()
- construction_q_x()
- thwart_lemma_3_5()
- thwart_lemma_4_1()
- three_factor_product()
- brouwer_separable_design()

INPUT:
- k, n (integers)

OUTPUT:
Return a pair f, args such that f(*args) returns the requested OA if possible, and False otherwise.

EXAMPLES:

sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_recursive_construction
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: count = 0
sage: for n in range(10,150):
....:     k = designs.orthogonal_arrays.largest_available_k(n)
....:     if find_recursive_construction(k,n):
....:         count = count + 1
....:     f,args = find_recursive_construction(k,n)
....:     OA = f(*args)
....:     assert is_orthogonal_array(OA,k,n,2,verbose=True)
sage: count
56

sage.combinat.designs.orthogonal_arrays_find_recursive.find_three_factor_product(k, n)
Find $n_1 n_2 n_3$ to obtain an $OA(k, n)$ by the three-factor product from [DukesLing14]

INPUT:
- k, n (integers)
Combinatorics, Release 10.1

See also:

three_factor_product()

OUTPUT:

A pair \( f, \text{args} \) such that \( f(*\text{args}) \) returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_three_factor_product
sage: find_three_factor_product(10,648)[1]
(9, 8, 9, 9)
sage: find_three_factor_product(10,50)
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.find_thwart_lemma_3_5(k, N)

Find the values on which Lemma 3.5 from [Thwarts] applies.

OUTPUT:

A pair \( (f, \text{args}) \) such that \( f(*\text{args}) \) returns an OA\((k, n)\) or False if the construction is not available.

See also:

thwart_lemma_3_5()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_thwart_lemma_3_5
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: f, args = find_thwart_lemma_3_5(7, 66)
sage: args
(7, 9, 7, 1, 1, 0, False)
sage: OA = f(*args)
sage: is_orthogonal_array(OA, 7, 66, 2)
True
sage: f, args = find_thwart_lemma_3_5(6, 100)
sage: args
(6, 8, 10, 7, 5, 0, True)
sage: OA = f(*args)
sage: is_orthogonal_array(OA, 6, 100, 2)
True
```

Some values from [Thwarts]:

```
sage: kn = ((10,1046), (10,1048), (10,1059), (11,1524),
       ....: (11,2164), (12,3362), (12,3992), (12,3994))
sage: for k,n in kn:
    ....:     print("{} {} ".format(k,n,find_thwart_lemma_3_5(k,n)[1]))
10 1046 (10, 13, 79, 9, 1, 0, 9, False)
10 1048 (10, 13, 79, 9, 1, 0, 11, False)
10 1059 (10, 13, 80, 9, 1, 0, 9, False)
11 1524 (11, 19, 78, 16, 13, 13, 0, True)
```

(continues on next page)
sage: for k,n in kn:  # not tested -- too long
    ....: assert designs.orthogonal_array(k,n,existence=True) is True

sage.combinat.designs.orthogonal_arrays_find_recursive.find_thwart_lemma_4_1(k, n)

Find a decomposition for Lemma 4.1 from [Thwarts].

INPUT:
  • k, n (integers)

See also:
thwart_lemma_4_1()

OUTPUT:
A pair f, args such that f(*args) returns the requested OA.

EXAMPLES:

sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_  
     --thwart_lemma_4_1
sage: find_thwart_lemma_4_1(10, 408)[1]  
    (10, 13, 28)
sage: find_thwart_lemma_4_1(10, 50)  
    False

sage.combinat.designs.orthogonal_arrays_find_recursive.find_wilson_decomposition_with_one_truncated_group(k, n)

Find \( rm + u = n \) to obtain an \( OA(k, n) \) by Wilson's construction with one truncated column.

This function looks for possible integers \( m, t, u \) satisfying that \( mt + u = n \) and such that Sage knows how to build a \( OA(k, m) \), \( OA(k, m + 1) \), \( OA(k + 1, t) \) and a \( OA(k, u) \).

INPUT:
  • k, n (integers) – see above

OUTPUT:
A pair f, args such that f(*args) is an \( OA(k, n) \) or False if no decomposition with one truncated block was found.

EXAMPLES:

sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_  
     --wilson_decomposition_with_one_truncated_group
sage: f, args = find_wilson_decomposition_with_one_truncated_group(4, 38)  
    (None, 4, 5, 7, (3,), False)
sage: _ = f(*args)
sage: find_wilson_decomposition_with_one_truncated_group(4,20)
False

sage.combinat.designs.orthogonal_arrays_find_recursive.find_wilson_decomposition_with_two_truncated_groups(k,n)

Find \( rm + r_1 + r_2 = n \) to obtain an \( OA(k, n) \) by Wilson's construction with two truncated columns.

Look for integers \( r, m, r_1, r_2 \) satisfying \( n = rm + r_1 + r_2 \) and \( 1 \leq r_1, r_2 < r \) and such that the following designs exist: \( OA(k+2, r), OA(k, r_1), OA(k, r_2), OA(k, m), OA(k, m+1), OA(k, m+2) \).

INPUT:
- \( k, n \) (integers) – see above

OUTPUT:
A pair \( f, \text{args} \) such that \( f(*\text{args}) \) is an \( OA(k, n) \) or False if no decomposition with two truncated blocks was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_wilson_decomposition_with_two_truncated_groups
sage: f, args = find_wilson_decomposition_with_two_truncated_groups(5,58)
sage: args
(None, 5, 7, 7, (4, 5), False)
sage: _ = f(*args)
```

sage.combinat.designs.orthogonal_arrays_find_recursive.int_as_sum(value, S, k_max)

Return a tuple \( (s_1, s_2, \ldots, s_k) \) of less than \( k_{\text{max}} \) elements of \( S \) such that \( value = s_1 + s_2 + \ldots + s_k \). If there is no such tuples then the function returns None.

INPUT:
- \( value \) (integer)
- \( S \) – a list of integers
- \( k_{\text{max}} \) (integer)

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import int_as_sum
sage: D = int_as_sum(21,[5,12],100)
sage: for k in range(20,40):
....:     print("{} {}\n```
20 (5, 5, 5, 5)
21 None
22 (12, 5, 5)
23 None
24 (12, 12)
25 (5, 5, 5, 5, 5)
26 None
27 (12, 5, 5, 5)
28 None
29 (12, 12, 5)
30 (5, 5, 5, 5, 5)
```
5.1.93 Steiner Quadruple Systems

A Steiner Quadruple System on \( n \) points is a family \( SQS_n \subset \binom{[n]}{4} \) of 4-sets, such that any set \( S \subset [n] \) of size three is a subset of exactly one member of \( SQS_n \).

This module implements Haim Hanani’s constructive proof that a Steiner Quadruple System exists if and only if \( n \equiv 2, 4 \pmod{6} \). Hanani’s proof consists in 6 different constructions that build a large Steiner Quadruple System from a smaller one, and though it does not give a very clear understanding of why it works (to say the least)… it does!

The constructions have been implemented while reading two papers simultaneously, for one of them sometimes provides the informations that the other one does not. The first one is Haim Hanani’s original paper [Han1960], and the other one is a paper from Horan and Hurlbert which goes through all constructions [HH2012].

It can be used through the designs object:

```
sage: designs.steiner_quadruple_system(8)
```

Incidence structure with 8 points and 14 blocks

AUTHORS:

- Nathann Cohen (May 2013, while listening to “Le Blues Du Pauvre Delahaye”)

Index

This module’s main function is the following:

```
steiner_quadruple_system
```

Return a Steiner Quadruple System on \( n \) points

This function redistributes its work among 6 constructions:

5.1. Comprehensive Module List

775
It also defines two specific Steiner Quadruple Systems that the constructions require, i.e. $SQS_{14}$ and $SQS_{38}$ as well as the systems of pairs $P_\alpha(m)$ and $\overline{P_\alpha(m)}$ (see [Han1960]).

**Functions**

sage.combinat.designs.steiner_quadruple_systems.P(alpha, m)

Return the collection of pairs $P_\alpha(m)$

For more information on this system, see [Han1960].

**EXAMPLES:**

```
sage: from sage.combinat.designs.steiner_quadruple_systems import P
sage: P(3,4)
[(0, 5), (2, 7), (4, 1), (6, 3)]
```

sage.combinat.designs.steiner_quadruple_systems.barP(eps, m)

Return the collection of pairs $\overline{P_\alpha(m)}$

For more information on this system, see [Han1960].

**EXAMPLES:**

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP
sage: barP(3,4)
[(0, 4), (3, 5), (1, 2)]
```

sage.combinat.designs.steiner_quadruple_systems.barP_system()

Return the 1-factorization of $K_{2n}\overline{P(m)}$

For more information on this system, see [Han1960].

**EXAMPLES:**

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP_system
sage: barP_system(3)
[[(4, 3), (2, 5)],
 [(0, 5), (4, 1)],
 [(0, 2), (1, 3)],
 [(1, 5), (4, 2), (0, 3)],
 [(0, 4), (3, 5), (1, 2)],
 [(0, 1), (2, 3), (4, 5)]]
```

sage.combinat.designs.steiner_quadruple_systems.four_n_minus_six(B)

Return a Steiner Quadruple System on $4n - 6$ points.

**INPUT:**

- $B$ – A Steiner Quadruple System on $n$ points.

**EXAMPLES:**

```
sage: from sage.combinat.designs.steiner_quadruple_systems import four_n_minus_six
sage: for n in range(4, 20):
    ....:     if (n%6) in [2,4]:
    ....:         sqs = designs.steiner_quadruple_system_system(n)
```

(continues on next page)
Combinatorics, Release 10.1

(continued from previous page)

```python
....:     if not four_n_minus_six(sqs).is_t_design(3,4*n-6,4,1):
....:         print("Something is wrong!")
```

sage.combinat.designs.steiner_quadruple_systems.relabel_system(B)

Relabels the set so that \{n - 4, n - 3, n - 2, n - 1\} is in B.

INPUT:
- B – a list of 4-uples on 0, ..., n - 1.

EXAMPLES:

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import relabel_system
sage: SQS8 = designs.steiner_quadruple_system(8)
sage: relabel_system(SQS8)
```

sage.combinat.designs.steiner_quadruple_systems.steiner_quadruple_system(check=False)

Return a Steiner Quadruple System on n points.

INPUT:
- n – an integer such that \(n \equiv 2, 4 \pmod{6}\)
- check (boolean) – whether to check that the system is a Steiner Quadruple System before returning it (False by default)

EXAMPLES:

```python
sage: sqs4 = designs.steiner_quadruple_system(4)
sage: sqs4
Incidence structure with 4 points and 1 blocks
sage: sqs4.is_t_design(3,4,4,1)
True
```

sage.combinat.designs.steiner_quadruple_systems.three_n_minus_eight(B)

Return a Steiner Quadruple System on \(3n - 8\) points.

INPUT:
- B – A Steiner Quadruple System on n points.

EXAMPLES:

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_eight
sage: for n in range(4, 30):
....:     if (n%12) == 2:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not three_n_minus_eight(sqs).is_t_design(3,3*n-8,4,1):
....:             print("Something is wrong!")
```
sage.combinat.designs.steiner_quadruple_systems.three_n_minus_four(B)
Return a Steiner Quadruple System on $3n - 4$ points.

INPUT:
• B – A Steiner Quadruple System on $n$ points where $n \equiv 10 \pmod{12}$.

EXAMPLES:

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_four
sage: for n in range(4, 30):
    ....:     if n%12 == 10:
    ....:         sqs = designs.steiner_quadruple_system(n)
    ....:         if not three_n_minus_four(sqs).is_t_design(3,3*n-4,4,1):
    ....:             print("Something is wrong!")
```

sage.combinat.designs.steiner_quadruple_systems.three_n_minus_two(B)
Return a Steiner Quadruple System on $3n - 2$ points.

INPUT:
• B – A Steiner Quadruple System on $n$ points.

EXAMPLES:

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_two
sage: for n in range(4, 30):
    ....:     if (n%6) in [2,4]:
    ....:         sqs = designs.steiner_quadruple_system(n)
    ....:         if not three_n_minus_two(sqs).is_t_design(3,3*n-2,4,1):
    ....:             print("Something is wrong!")
```

sage.combinat.designs.steiner_quadruple_systems.twelve_n_minus_ten(B)
Return a Steiner Quadruple System on $12n - 6$ points.

INPUT:
• B – A Steiner Quadruple System on $n$ points.

EXAMPLES:

```python
sage: from sage.combinat.designs.steiner_quadruple_systems import twelve_n_minus_ten
sage: for n in range(4, 15):
    ....:     if (n%6) in [2,4]:
    ....:         sqs = designs.steiner_quadruple_system(n)
    ....:         if not twelve_n_minus_ten(sqs).is_t_design(3,12*n-10,4,1):
    ....:             print("Something is wrong!")
```

sage.combinat.designs.steiner_quadruple_systems.two_n(B)
Return a Steiner Quadruple System on $2n$ points.

INPUT:
• B – A Steiner Quadruple System on $n$ points.

EXAMPLES:
sage: from sage.combinat.designs.steiner_quadruple_systems import two_n
sage: for n in range(4, 30):
    ...:     if (n%6) in [2,4]:
    ...:         sqs = designs.steiner_quadruple_system(n)
    ...:         if not two_n(sqs).is_t_design(3,2*n,4,1):
    ...:             print("Something is wrong !")

5.1.94 Hypergraph isomorphic copy search

This module implements a code for the following problem:

**INPUT:** two hypergraphs $H_1, H_2$

**OUTPUT:** a copy of $H_2$ in $H_1$

It is also possible to enumerate all such copies, and to require that such copies be induced copies. More formally:

A copy of $H_2$ in $H_1$ is an injection $f : V(H_2) \rightarrow V(H_1)$ such that for any set $S_2 \in E(H_2)$ we have $f(S_2) \in E(H_1)$.

It is an *induced* copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{ S : S \in E(H_1) \text{ and } S \subseteq f(V(H_2)) \}$.

The functions implemented here lists all such injections. In particular, the number of copies of $H$ in itself is equal to $|\text{Aut}(H)|$.

The feature is available through `IncidenceStructure.isomorphic_substructures_iterator()`.

**Implementation**

A hypergraph is stored as a list of edges, each of which is a “dense” bitset over $|V(H_1)|$ points. In particular, two sets of distinct cardinalities require the same memory space. A hypergraph is a C struct with the following fields:

- `n,m` (int) – number of points and edges.
- `limbs` (int) – number of 64-bits blocks per set.
- `set_space` (uint64_t *) – address of the memory used to store the sets.
- `sets` (uint64_t **) – `sets[i]` points toward the `limbs` blocks encoding set $i$. Note also that `sets[i][limbs]` is equal to the cardinality of `set[i]`, so that `sets` has length $m*(\text{limbs+1})*\text{sizeof(uint64_t)}$.
- `names` (int *) – associates an integer ‘name’ to each of the n points.

The operations used on this data structure are:

- `void permute(hypergraph * h, int n1, int n2)` – exchanges points $n1$ and $n2$ in the data structure. Note that their names are also exchanged so that we still know which is which.
- `int induced_hypergraph(hypergraph * h1, int n, hypergraph * tmp1)` – stores in `tmp1` the hypergraph induced by the first $n$ points, i.e. all sets $S$ such that $S \subseteq \{0,\ldots,n-1\}$. The function returns the number of such sets.
- `void trace_hypergraph64(hypergraph * h, int n, hypergraph * tmp)` – stores in `tmp` the trace of $h$ on the first $n$ points, i.e. all sets of the form $S \cap \{0,\ldots,n-1\}$.
Algorithm

We try all possible assignments of a representant \( r_i \in H_1 \) for every \( i \in H_2 \). When we have picked a representant for the first \( n < n_1 \) points \( \{0, \ldots, n-1\} \subseteq V(H_2) \), we check that:

- The hypergraph induced by the (ordered) list \( 0, \ldots, n-1 \) in \( H_2 \) is equal to the one induced by \( r_0, \ldots, r_{n-1} \) in \( H_1 \).
- If \( S \subseteq \{0, \ldots, n-1\} \) is contained in \( c \) sets of size \( k \) in \( H_2 \), then \( \{ r_i : i \in S \} \) is contained in \( \geq c \) sets of size \( k \) in \( H_1 \). This is done by comparing the trace of the hypergraphs while remembering the original size of each set.

As we very often need to build the hypergraph obtained by the trace of the first \( n \) points (for all possible \( n \)), those hypergraphs are cached. The hypergraphs induced by the same points are handled similarly.

Limitations

**Number of points** For efficiency reason the implementation assumes that \( H_2 \) has \( \leq 64 \) points. Making this work for larger values means that calls to \texttt{qsort} have to be replaced by calls to \texttt{qsort_r} (i.e. to sort the edges you need to know the number of limbs per edge) and that induces a big slowdown for small cases (~50% when this code was implemented). Also, 64 points for \( H_2 \) is already very very big considering the problem at hand. Even \( |V(H_1)| > 64 \) seems too much.

**Vertex ordering** The order of vertices in \( H_2 \) has a huge influence on the performance of the algorithm. If no set of \( H_2 \) contains more that one of the first \( k < n \) points, then almost all partial assignments of representants are possible for the first \( k \) points (though the degree of the vertices is taken into account). For this reason it is best to pick an ordering such that the first vertices are contained in as many sets as possible together. A heuristic is implemented at \texttt{relabel_heuristic}.

AUTHORS:

- Nathann Cohen (November 2014, written in various airports between Nice and Chennai).

Methods

**class** \texttt{sage.combinat.designs.subhypergraph_search.SubHypergraphSearch}  

\texttt{Bases: object}

\texttt{relabel_heuristic}()

Relabels \( H_2 \) in order to make the algorithm faster.

Objective: we try to pick an ordering \( p_1, \ldots, p_k \) of the points of \( H_2 \) that maximizes the number of sets involving the first points in the ordering. One way to formalize the problems indicates that it may be NP-Hard (generalizes the max clique problem for graphs) so we do not try to solve it exactly: we just need a sufficiently good heuristic.

Assuming that the first points are \( p_1, \ldots, p_k \), we determine \( p_{k+1} \) as the point \( x \) such that the number of sets \( S \) with \( x \in S \) and \( S \cap \{ p_1, \ldots, p_k \} \neq \emptyset \) is maximal. In case of ties, we take a point with maximum degree.

This function is called when an instance of \texttt{SubHypergraphSearch} is created.

EXAMPLES:

```
sage: d = designs.projective_plane(3)  # needs sage.schemes
sage: d.isomorphic_substructures_iterator(d).relabel_heuristic()  # needs sage.schemes
```
5.1.95 Two-graphs

A two-graph on \( n \) points is a family \( T \subset \binom{[n]}{3} \) of 3-sets, such that any 4-set \( S \subset [n] \) of size four contains an even number of elements of \( T \). Any graph \( ([n], E) \) gives rise to a two-graph \( T(E) = \{ t \in \binom{[n]}{3} : |(t) \cap E| \text{ odd} \} \), and any two graphs with the same two-graph can be obtained one from the other by Seidel switching. This defines an equivalence relation on the graphs on \( [n] \), called Seidel switching equivalence. Conversely, given a two-graph \( T \), one can construct a graph \( \Gamma \) in the corresponding Seidel switching class with an isolated vertex \( w \). The graph \( \Gamma \setminus w \) is called the descendant of \( T \) w.r.t. \( v \).

\( T \) is called regular if each two-subset of \( [n] \) is contained in the same number \( \alpha \) of triples of \( T \).

This module implements a direct construction of a two-graph from a list of triples, construction of descendant graphs, regularity checking, and other things such as constructing the complement two-graph, cf. [BH2012].

AUTHORS:
- Dima Pasechnik (Aug 2015)

Index

This module’s methods are the following:

- `is_regular_twograph()`: tests if \( self \) is a regular two-graph, i.e. a 2-design
- `complement()`: returns the complement of \( self \)
- `descendant()`: returns the descendant graph at \( w \)

This module’s functions are the following:

- `taylor_twograph()`: constructs Taylor’s two-graph for \( U_3(q) \)
- `is_twograph()`: checks that the incidence system is a two-graph
- `twograph_descendant()`: returns the descendant graph w.r.t. a given vertex of the two-graph of a given graph

Methods

**class** `sage.combinat.designs.twographs.TwoGraph(points=None, blocks=None, incidence_matrix=None, name=None, check=False, copy=True)`

**Bases:** `IncidenceStructure`

Two-graphs class.

A two-graph on \( n \) points is a 3-uniform hypergraph, i.e. a family \( T \subset \binom{[n]}{3} \) of 3-sets, such that any 4-set \( S \subset [n] \) of size four contains an even number of elements of \( T \). For more information, see the documentation of the `twographs` module.

- `complement()`: The two-graph which is the complement of \( self \).
  That is, the two-graph consisting exactly of triples not in \( self \). Note that this is different from `complement` of the `parent class`.

EXAMPLES:
descendant($v$)

The descendant graph at $v$

The *switching class of graphs* corresponding to self contains a graph $D$ with $v$ its own connected component: removing $v$ from $D$, one obtains the descendant graph of self at $v$, which is constructed by this method.

**INPUT:**

- $v$ – an element of ground_set()

**EXAMPLES:**

```
sage: p = graphs.PetersenGraph().twograph().descendant(0)  # needs sage.modules
```

```
sage: p.is_strongly_regular(parameters=True)  # needs sage.modules
(9, 4, 1, 2)
```

\[
\text{sage.combinat.designs.twographs.is_twograph($T$)}
\]

Checks that the incidence system $T$ is a two-graph

**INPUT:**

- $T$ – an incidence structure

**EXAMPLES:**

```
a two-graph from a graph:
```

```

```
```
a non-regular 2-uniform hypergraph which is a two-graph:

```
sage: is_twograph(TwoGraph([[1,2,3],[1,2,4]]))
True
```

construcitng Taylor’s two-graph for $U_3(q)$, $q$ odd prime power

The Taylor’s two-graph $T$ has the $q^3 + 1$ points of the projective plane over $F_{q^2}$ singular w.r.t. the non-degenerate Hermitean form $S$ preserved by $U_3(q)$ as its ground set; the triples are $\{x, y, z\}$ satisfying the condition that $S(x, y) S(y, z) S(z, x)$ is square (respectively non-square) if $q \equiv 1 \mod 4$ (respectively if $q \equiv 3 \mod 4$). See §7E of [BL1984].

There is also a $2 - (q^3 + 1, q + 1, 1)$-design on these $q^3 + 1$ points, known as the unital of order $q$, also invariant under $U_3(q)$.

INPUT:

- $q$ – a power of an odd prime

EXAMPLES:

```
sage: from sage.combinat.designs.twographs import taylor_twograph
sage: T = taylor_twograph(3); T
Incidence structure with 28 points and 1260 blocks
```

Return the descendant graph w.r.t. vertex $v$ of the two-graph of $G$

In the switching class of $G$, construct a graph $\Delta$ with $v$ an isolated vertex, and return the subgraph $\Delta \setminus v$. It is equivalent to, although much faster than, computing the `TwoGraph.descendant()` of two-graph of $G$, as the intermediate two-graph is not constructed.

INPUT:

- $G$ – a graph
- $v$ – a vertex of $G$
- $name$ – (optional) None - no name, otherwise derive from the construction

EXAMPLES:

one of s.r.g.’s from the database:

```
sage: A = graphs.strongly_regular_graph(280,135,70)  # optional - gap_package_design internet
sage: twograph_descendant(A, 0).is_strongly_regular(parameters=True)  # optional - gap_package_design internet
(279, 150, 85, 75)
```
A combinatorial diagram is a collection of cells \((i, j)\) indexed by pairs of natural numbers. For arbitrary diagrams, see \texttt{Diagram}. There are also two other specific types of diagrams implemented here. They are northwest diagrams (\texttt{NorthwestDiagram}) and Rothe diagrams (\texttt{RotheDiagram()}, a special kind of northwest diagram).

AUTHORS:
- Trevor K. Karn (2022-08-01): initial version

class \texttt{sage.combinat.diagram.Diagram}(parent, cells, n_rows=None, n_cols=None, check=True)

   Bases: \texttt{ClonableArray}

   Combinatorial diagrams with positions indexed by rows and columns.

   The positions are indexed by rows and columns as in a matrix. For example, a Ferrers diagram is a diagram obtained from a partition \(\lambda = (\lambda_0, \lambda_1, \ldots, \lambda_\ell)\), where the cells are in rows \(i\) for \(0 \leq i \leq \ell\) and the cells in row \(i\) consist of \((i, j)\) for \(0 \leq j < \lambda_i\). In English notation, the indices are read from top left to bottom right as in a matrix.

   Indexing conventions are the same as \texttt{Partition}. Printing the diagram of a partition, however, will always be in English notation.

EXAMPLES:
To create an arbitrary diagram, pass a list of all cells:

\begin{verbatim}
sage: from sage.combinat.diagram import Diagram
sage: cells = [(0,0), (0,1), (1,0), (1,1), (4,4), (4,5), (4,6), (5,4), (7, 6)]
sage: D = Diagram(cells); D
\[(0, 0), (0, 1), (1, 0), (1, 1), (4, 4), (4, 5), (4, 6), (5, 4), (7, 6)\]
\end{verbatim}

We can visualize the diagram by printing 0’s and .’s. 0’s are present in the cells which are present in the diagram and a . represents the absence of a cell in the diagram:

\begin{verbatim}
sage: D.pp()
  0 0 . . . . .
  0 0 . . . . .
  . . . . . .  .
  . . . . . .  .
  . . . 0 0 0
  . . . 0 . .
  . . . . . .  .
  . . . . . .  .
  . . . . . .  .
\end{verbatim}

We can also check if certain cells are contained in a given diagram:

\begin{verbatim}
sage: (1, 0) in D
True
sage: (2, 2) in D
False
\end{verbatim}

If you know that there are entire empty rows or columns at the end of the diagram, you can manually pass them with keyword arguments \texttt{n_rows=} or \texttt{n_cols=}:
sage: Diagram([(0,0), (0,3), (2,2), (2,4)]).pp()
O . . O
. . . . .
. . O . O

sage: Diagram([(0,0), (0,3), (2,2), (2,4)], n_rows=6, n_cols=6).pp()
O . . O . .
. . . . . .
. . . . . .
. . . . . .
. . . . . .
. . . . . .

cells()

Return a list of the cells contained in the diagram self.

EXAMPLES:

sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])

sage: D1.cells()
[(0, 2), (0, 3), (1, 1), (3, 2)]

check()

Check that this is a valid diagram.

EXAMPLES:

sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (0,3), (2,2), (2,4)])

sage: D.check()

In the next two examples, a bad diagram is passed. The first example fails because one cell is indexed by negative integers:

sage: D = Diagram([(0,0), (0,-3), (2,2), (2,4)])
Traceback (most recent call last):
...
ValueError: diagrams must be indexed by non-negative integers

The next example fails because one cell is indexed by rational numbers:

sage: D = Diagram([(0,0), (0,3), (2/3,2), (2,4)])
Traceback (most recent call last):
...
ValueError: diagrams must be indexed by non-negative integers

n_cells()

Return the total number of cells contained in the diagram self.

EXAMPLES:

sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])

sage: D1.number_of_cells()
ncols()

Return the total number of rows of self.

EXAMPLES:
The following example has three columns which are filled, but they are contained in rows 0 to 3 (for a total of four):

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D.number_of_cols()
4
sage: D.ncols()
4
```

We can also include empty columns at the end:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_cols=6)
sage: D.number_of_cols()
6
sage: D.pp()
 . . O O . .
 . O . . . .
 . . . . . .
 . . O . . .
```

nrows()

Return the total number of rows of self.

EXAMPLES:
The following example has three rows which are filled, but they are contained in rows 0 to 3 (for a total of four):

```
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_rows()
4
sage: D1.nrows()
4
```

The total number of rows includes including those which are empty. We can also include empty rows at the end:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_rows=6)
sage: D.number_of_rows()
6
sage: D.pp()
```

(continues on next page)
number_of_cells()

Return the total number of cells contained in the diagram self.

EXAMPLES:

```python
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
```

```python
sage: D1.number_of_cells()
4
```

```python
sage: D1.n_cells()
4
```

number_of_cols()

Return the total number of rows of self.

EXAMPLES:

The following example has three columns which are filled, but they are contained in rows 0 to 3 (for a total of four):

```python
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)])
```

```python
sage: D.number_of_cols()
4
```

```python
sage: D.ncols()
4
```

We can also include empty columns at the end:

```python
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_cols=6)
```

```python
sage: D.number_of_cols()
6
```

```python
sage: D.pp()
.. 0 0 ..
. 0 . . .
. . . . .
. . 0 . ..
```

number_of_rows()

Return the total number of rows of self.

EXAMPLES:

The following example has three rows which are filled, but they are contained in rows 0 to 3 (for a total of four):
```python
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_rows()
4
sage: D1.nrows()
4
```

The total number of rows includes including those which are empty. We can also include empty rows at the end:

```python
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,2),(0,3),(1,1),(3,2)], n_rows=6)
sage: D.number_of_rows()
6
sage: D.pp()
.. O O
.. O ..
.. . .
.. O .
.. O .
.. . .
```

**pp()**

Return a visualization of the diagram.

Cells which are present in the diagram are filled with a O. Cells which are not present in the diagram are filled with a ..

**EXAMPLES:**

```python
sage: from sage.combinat.diagram import Diagram
sage: Diagram([(0,0), (0,3), (2,2), (2,4)]).pp()
O . . O .
.. . . .
.. O . O
sage: Diagram([(0,0), (0,3), (2,2), (2,4)], n_rows=6, n_cols=6).pp()
O . . O .
.. . . .
.. O . O.
.. . . .
.. . . .
```

**size()**

Return the total number of cells contained in the diagram self.

**EXAMPLES:**

```python
sage: from sage.combinat.diagram import Diagram
sage: D1 = Diagram([(0,2),(0,3),(1,1),(3,2)])
sage: D1.number_of_cells()
4
```

(continues on next page)
sage: D1.n_cells()
4

**specht_module**(base\_ring=None)

Return the Specht module corresponding to \texttt{self}.

**EXAMPLES:**

```ruby
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (2,3)])
sage: SM = D.specht_module(QQ)  # needs sage.modules
sage: s = SymmetricFunctions(QQ).s()
# needs sage.modules
sage: s(SM.frobenius_image())
# needs sage.modules
```

**specht_module\_dimension**(base\_ring=None)

Return the dimension of the Specht module corresponding to \texttt{self}.

**INPUT:**

• \texttt{base\_ring} – (default: Q) the base ring

**EXAMPLES:**

```ruby
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (2,3)])
# needs sage.modules
sage: D.specht_module(QQ).dimension()  # needs sage.modules
12
```

**class** \texttt{sage.combinat.diagram\_Diagrams}\texttt{(category=None)}

**Bases:** \texttt{UniqueRepresentation}, \texttt{Parent}

The class of combinatorial diagrams.

A **combinatorial diagram** is a set of cells indexed by pairs of natural numbers. Calling an instance of \texttt{Diagrams} is one way to construct diagrams.

**EXAMPLES:**

```ruby
sage: from sage.combinat.diagram import Diagrams
sage: Dgms = Diagrams()
sage: D = Dgms([(0,0), (0,3), (2,2), (2,4)])
sage: D.parent()
Combinatorial diagrams
```

**Element**

alias of \texttt{Diagram}
**from_composition**(*alpha*)

Create the diagram corresponding to a weak composition \( \alpha \vdash n \).

**EXAMPLES:**

```
sage: alpha = Composition([3,0,2,1,4,4])
sage: from sage.combinat.diagram import Diagrams
sage: Diagrams()(alpha).pp()
  0  0  0
  . . .
  0  0 .
  0  .
  0  0  0
  0  0  0
sage: Diagrams().from_composition(alpha).pp()
  0  0  0
  . . .
  0  0 .
  0  .
  0  0  0
  0  0  0
```

**from_polyomino**(*p*)

Create the diagram corresponding to a 2d Polyomino

**EXAMPLES:**

```
sage: from sage.combinat.tiling import Polyomino
# needs sage.modules
sage: p = Polyomino(((0,0),(1,0),(1,1),(1,2)])
# needs sage.modules
sage: from sage.combinat.diagram import Diagrams
sage: Diagrams()(p).pp() # needs sage.modules
  0  .
  0  0
sage: Diagrams().from_polyomino(p) # needs sage.modules
Traceback (most recent call last):
  ...
ValueError: the polyomino must be 2 dimensional
```

**from_zero_one_matrix**(*M*, **check**=True)

This works for a 2d Polyomino:

```
sage: p = Polyomino(((0,0,0), (0,1,0), (1,1,0), (1,1,1)), color='blue') # needs sage.modules
sage: Diagrams().from_polyomino(p) # needs sage.modules
Traceback (most recent call last):
  ...
ValueError: the polyomino must be 2 dimensional
```

**from_zero_one_matrix**(*M*, **check**=True)
Get a diagram from a matrix with entries in \{0, 1\}, where positions of cells are indicated by the 1’s.

**EXAMPLES:**

```python
sage: M = matrix([[1,0,1,1],[0,1,1,0]])
# needs sage.modules
sage: from sage.combinat.diagram import Diagrams
sage: Diagrams()(M).pp()  # needs sage.modules
O . O O
. O O .
```

```python
sage: M = matrix([[1, 0, 0], [1, 0, 0], [0, 0, 0]])
# needs sage.modules
sage: Diagrams()(M).pp()  # needs sage.modules
O . .
O . .
. . .
```

**class** `sage.combinat.diagram.NorthwestDiagram` *(parent, cells, n_rows=None, n_cols=None, check=True)*

**Bases:** `Diagram`  

Diagrams with the northwest property.

A diagram is a set of cells indexed by natural numbers. Such a diagram has the northwestern property if the presence of cells \((i_1, j_1)\) and \((i_2, j_2)\) implies the presence of the cell \((\min(i_1, i_2), \min(j_1, j_2))\). Diagrams with the northwestern property are called northwestern diagrams.

For general diagrams see `Diagram`.

**EXAMPLES:**

```python
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0,3), (3,0)])
```

To visualize them, use the `.pp()` method:

```python
sage: N.pp()
0 . 0
. . .
0 . .
```

**check()**

A diagram has the northwestern property if the presence of cells \((i_1, j_1)\) and \((i_2, j_2)\) implies the presence of the cell \((\min(i_1, i_2), \min(j_1, j_2))\). This method checks if the northwestern property is satisfied for `self`.

**EXAMPLES:**

```python
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0,3), (3,0)])
sage: N.check()
```
Here is a non-example:

```python
sage: notN = NorthwestDiagram([(0,1), (1,0)]) #.check() is implicit
Traceback (most recent call last):
...
ValueError: diagram is not northwest
```

**peelable_tableaux()**

Return the set of peelable tableaux whose diagram is `self`.

For a fixed northwest diagram $D$, we say that a Young tableau $T$ is $D$-peelable if:

1. the row indices of the cells in the first column of $D$ are the entries in an initial segment in the first column of $T$, and
2. the tableau $Q$ obtained by removing those cells from $T$ and playing jeu de taquin is $(D - C)$-peelable, where $D - C$ is the diagram formed by forgetting the first column of $D$.

Reiner and Shimozono [RS1995] showed that the number $\text{red}(w)$ of reduced words of a permutation $w$ may be computed using the peelable tableaux of the Rothe diagram $D(w)$. Explicitly,

$$
\text{red}(w) = \sum_{T} f_{\lambda(T)},
$$

where the sum runs over the $D(w)$-peelable tableaux $T$ and $f_\lambda$ is the number of standard Young tableaux of shape $\lambda$ (which may be computed using the hook-length formula).

**EXAMPLES:**

We can compute the $D$-peelable diagrams for a northwest diagram $D$:

```python
sage: from sage.combinat.diagram import NorthwestDiagram
sage: cells = [(0,0), (0,1), (0,2), (1,0), (2,0), (2,2), (2,4), ....
          (4,0), (4,2)]

sage: D = NorthwestDiagram(cells); D.pp()
O O O . .
O . . . .
O . O . O
. . . . .
O . O . .

sage: D.peelable_tableaux()

{{[1, 1, 1], [2, 3, 3], [3, 5], [5]},
 [{[1, 1, 1, 3], [2, 3], [3, 5], [5]}}
```

**EXAMPLES:**

If the diagram is only one column, there is only one peelable tableau:

```python
sage: from sage.combinat.diagram import NorthwestDiagram

sage: NWD = NorthwestDiagram([(0,0), (2,0)])

sage: NWD.peelable_tableaux()

{{[1], [3]}}
```

From [RS1995], we know that there is only one peelable tableau for the Rothe diagram of the permutation (in one line notation) 251643:

```python
sage: D = NorthwestDiagram([(1, 2), (1, 3), (3, 2), (3, 3), (4, 2)])

sage: D.pp()
(continues on next page)
Here are all the intermediate steps to compute the peelables for the Rothe diagram of (in one-line notation) 64817235. They are listed from deepest in the recursion to the final step. The recursion has depth five in this case so we will label the intermediate tableaux by $D_i$ where $i$ is the step in the recursion at which they appear.

Start with the one that has a single column:

```python
sage: D5 = NorthwestDiagram([(2,0)]); D5.pp()

O

sage: D5.peelable_tableaux()
{{[3]}}
```

Now we know all of the $D_5$ peelables, so we can compute the $D_4$ peelables:

```python
sage: D4 = NorthwestDiagram([(0,0), (2,0), (4,0), (2, 2)])

sage: D4.pp()
O . .
. . .
0 . 0
. . .
0 . .

sage: D4.peelable_tableaux()
{{[1, 3], [3], [5]}}
```

There is only one $D_4$ peelable, so we can compute the $D_3$ peelables:

```python
sage: D3 = NorthwestDiagram([(0,0), (0,1), (2,1), (2, 3), (4,1)])

sage: D3.pp()
0 0 . .
. . . .
. 0 . 0
. . . .
0 . . .

sage: D3.peelable_tableaux()
{{[1, 1], [3, 3], [5]}, [[1, 1, 3], [3], [5]]}
```

Now compute the $D_2$ peelables:

```python
sage: cells = [(0,0), (0,1), (0,2), (1,0), (2,0), (2,2), (2,4),.....
          (4,0), (4,2)]
```

(continues on next page)
```
sage: D2 = NorthwestDiagram(cells); D2.pp()
0 0 0 ...
0 . . .
0 . 0 . 0
. . .
0 . 0 .
sage: D2.peelable_tableaux()
{[[1, 1, 1], [2, 3, 3], [3, 5], [5]],
 [[1, 1, 1, 3], [2, 3], [3, 5], [5]]}
```

And the $D_1$ peelables:
```
sage: cells = [(0,0), (0,1), (0,2), (0,3), (1,0), (1,1), (2,0),
........
(2,1), (2,3), (2,5), (4,0), (4,1), (4,3)]
sage: D1 = NorthwestDiagram(cells); D1.pp()
0 0 0 0 .
0 0 . . .
0 0 . 0 .
. . . .
0 0 .
sage: D1.peelable_tableaux()
{[[1, 1, 1, 1], [2, 2, 3, 3], [3, 3, 5], [5, 5]],
 [[1, 1, 1, 1], [2, 2, 3], [3, 3, 5], [5, 5]],
 [[1, 1, 1, 1, 3], [2, 2, 3], [3, 3, 5], [5, 5]]}
```

Which we can use to get the $D$ peelables:
```
sage: cells = [(0,0), (0,1), (0,2), (0,3), (0,4),
........
(1,0), (1,1), (1,2),
........
(2,0), (2,1), (2,2), (2,4), (2,6),
........
(4,1), (4,2), (4,4)]
sage: D = NorthwestDiagram(cells); D.pp()
0 0 0 0 0 .
0 0 0 . .
0 0 . 0 .
. . . .
. 0 . .
sage: D.peelable_tableaux()
{[[1, 1, 1, 1, 1], [2, 2, 2, 3, 3], [3, 3, 3], [5, 5, 5]],
 [[1, 1, 1, 1, 1], [2, 2, 2, 3, 3], [3, 3, 3, 5], [5, 5]],
 [[1, 1, 1, 1, 1, 3], [2, 2, 2, 3], [3, 3, 3], [5, 5, 5]],
 [[1, 1, 1, 1, 1, 3], [2, 2, 2, 3], [3, 3, 3, 5], [5, 5]]}
```

**ALGORITHM:**

This implementation uses the algorithm suggested in Remark 25 of [RS1995].

```python
class sage.combinat.diagram.NorthwestDiagrams(category=None)
Bases: Diagrams

Diagrams satisfying the northwest property.

A diagram $D$ is a northwest diagram if for every two cells $(i_1,j_1)$ and $(i_2,j_2)$ in $D$ then there exists the cell $(\min(i_1,i_2),\min(j_1,j_2)) \in D$.
```
EXAMPLES:

```python
sage: from sage.combinat.diagram import NorthwestDiagram
sage: N = NorthwestDiagram([(0,0), (0, 10), (5,0)]); N.pp()
O . . . . . . . . . O
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
O . . . . . . . . . .
Note that checking whether or not the northwest property is satisfied is automatically checked. The diagram
found by adding the cell (1, 1) to the diagram above is *not* a northwest diagram. The cell (1, 0) should be present
due to the presence of (5, 0) and (1, 1):

```python
sage: from sage.combinat.diagram import Diagram
sage: Diagram([(0, 0), (0, 10), (5, 0), (1, 1)]).pp()
O . . . . . . . . . O
. O . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
O . . . . . . . . . .
sage: NorthwestDiagram([(0, 0), (0, 10), (5, 0), (1, 1)])
Traceback (most recent call last):
... ValueError: diagram is not northwest
```

However, this behavior can be turned off if you are confident that you are providing a northwest diagram:

```python
sage: N = NorthwestDiagram([(0, 0), (0, 10), (5, 0),
...: (1, 1), (0, 1), (1, 0)],
...: check=False)
sage: N.pp()
O O . . . . . . . . O
O O . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
O . . . . . . . . . .
```

Note that arbitrary diagrams which happen to be northwest diagrams only live in the parent of `Diagrams`:

```python
sage: D = Diagram([(0, 0), (0, 10), (5, 0), (1, 1), (0, 1), (1, 0)])
sage: D.pp()
0 0 . . . . . . . . 0
0 0 . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
. . . . . . . . . . .
0 . . . . . . . . . .
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: D in NorthwestDiagrams()
sage: D in NorthwestDiagrams()
False
```
Here are some more examples:

```python
sage: from sage.combinat.diagram import NorthwestDiagram, NorthwestDiagrams
sage: D = NorthwestDiagram([(0,1), (0,2), (1,1)]); D.pp()
 . 0 0
 . 0 .

sage: NWDgms = NorthwestDiagrams()

sage: D = NWDgms([(1,1), (1,2), (2,1)]); D.pp()
 . . .
 . O O
 . O .

sage: D.parent()
Combinatorial northwest diagrams
```

Additionally, there are natural constructions of a northwest diagram given the data of a permutation (Rothe diagrams are the prototypical example of northwest diagrams), or the data of a partition of an integer, or a skew partition.

The Rothe diagram $D(\omega)$ of a permutation $\omega$ is specified by the cells

$$D(\omega) = \{(\omega_j, i) : i < j, \omega_i > \omega_j\}.$$

We can construct one by calling `rothe_diagram()` method on the set of all `NorthwestDiagrams`:

```python
sage: w = Permutations(4)([4,3,2,1])
sage: NorthwestDiagrams().rothe_diagram(w).pp()
O O O .
O O . .
O . . .
. . . .
```

To turn a Ferrers diagram into a northwest diagram, we may call `from_partition()`. This will return a Ferrer’s diagram in the set of all northwest diagrams. For many use-cases it is probably better to get Ferrer’s diagrams by the corresponding method on partitions, namely `sage.combinat.partitions.Partitions.ferrers_diagram()`:

```python
sage: mu = Partition([7,3,1,1])
sage: mu.pp()
******
 *** *
 **

sage: NorthwestDiagrams().from_partition(mu).pp()
0 0 0 0 0 0
0 0 0 . . .
0 . . . . .
0 . . . . .
```

It is also possible to turn a Ferrers diagram of a skew partition into a northwest diagram, although it is more subtle than just using the skew diagram itself. One must first reflect the partition about a vertical axis so that the skew partition looks “backwards”:

```python
sage: mu, nu = Partition([5,4,3,2,1]), Partition([3,2,1])
sage: s = mu/nu; s.pp()
```

(continues on next page)
sage: NorthwestDiagrams().from_skew_partition(s).pp()
O O . . .
. O O . .
. . O O .
. . . O O
. . . . O

Element
alias of NorthwestDiagram

from_parallelogram_polyomino(p)
Create the diagram corresponding to a ParallelogramPolyomino.
EXAMPLES:

sage: p = ParallelogramPolyomino([[0, 0, 1, 0, 0, 0, 1, 1],
                                 [1, 1, 0, 1, 0, 0, 0, 0]])

sage: from sage.combinat.diagram import NorthwestDiagrams
sage: NorthwestDiagrams().from_parallelogram_polyomino(p).pp()  # needs sage.modules
O O . . .
. O O . .
. . O O .
. . . O O
. . . . O

from_partition(mu)
Return the Ferrer’s diagram of mu as a northwest diagram.
EXAMPLES:

sage: mu = Partition([5,2,1]); mu.pp()  # needs sage.modules
*****
**
*

sage: mu.parent()
Partitions

sage: from sage.combinat.diagram import NorthwestDiagrams
sage: D = NorthwestDiagrams().from_partition(mu)
sage: D.pp()
0 0 0 0 0
0 0 . . .
0 . . . .
sage: D.parent()
Combinatorial northwest diagrams

This will print in English notation even if the notation is set to French for the partition:
We construct a northwest diagram from a permutation by constructing its Rothe diagram. Formally, if \( \omega \) is a permutation then the Rothe diagram \( D(\omega) \) is the diagram whose cells are

\[
D(\omega) = \{(\omega_j, i) : i < j, \omega_i > \omega_j\}.
\]

Informally, one can construct the Rothe diagram by starting with all \( n^2 \) possible cells, and then deleting the cells \( (i, \omega(i)) \) as well as all cells to the right and below. (These are sometimes called “death rays”.)

See also:

RotheDiagram()

EXAMPLES:

```python
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: w = Permutations(3)((2,1,3))
```

```text
sage: NorthwestDiagrams().rothe_diagram(w).pp()
O . .
. . .
. . .
```

```text
sage: w = Permutations(8)((2,5,4,1,3,6,7,8))
```

```text
sage: NorthwestDiagrams().rothe_diagram(w).pp()
O . . . . . . .
0 . . . . . . .
0 . 0 . . . . .
0 . 0 . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
. . . . . . . .
```

from_skew_partition(s)

Get the northwest diagram found by reflecting a skew shape across a vertical plane.

EXAMPLES:
rothe_diagram(w)

Return the Rothe diagram of w.

We construct a northwest diagram from a permutation by constructing its Rothe diagram. Formally, if \( \omega \) is a Permutation then the Rothe diagram \( D(\omega) \) is the diagram whose cells are

\[
D(\omega) = \{ (\omega_j, i) : i < j, \, \omega_i > \omega_j \}.
\]

Informally, one can construct the Rothe diagram by starting with all \( n^2 \) possible cells, and then deleting the cells \((i, \omega(i))\) as well as all cells to the right and below. (These are sometimes called “death rays”.)

See also:

RotheDiagram()

EXAMPLES:

```python
sage: from sage.combinat.diagram import NorthwestDiagrams
sage: w = Permutations(3)([2,1,3])
```

```python
sage: NorthwestDiagrams().rothe_diagram(w).pp()
```

```python
0 . .
. . .
. . .
```

```python
sage: w = Permutations(8)([2,5,4,1,3,6,7,8])
```

```python
sage: NorthwestDiagrams().rothe_diagram(w).pp()
```

```python
0 . . . . . .
0 . 0 . . .
0 . 0 . . .
```

(continues on next page)
The Rothe diagram of a permutation \( w \).

**EXAMPLES:**

```
sage: w = Permutations(9)([1, 7, 4, 5, 9, 3, 2, 8, 6])
sage: from sage.combinat.diagram import RotheDiagram
sage: D = RotheDiagram(w); D.pp()
...
```

The Rothe diagram is a northwest diagram:

```
sage: D.parent()
Combinatorial northwest diagrams
```

Some other examples:

```
sage: RotheDiagram([2, 1, 4, 3]).pp()
0 . .
 0 .
 0 .
 0 .
```

```
sage: RotheDiagram([4, 1, 3, 2]).pp()
0 0 0
 0 .
 0 .
 0 .
```

Currently, only elements of the set of `sage.combinat.permutations.Permutations` are supported. In particular, elements of permutation groups are not supported:

```
sage: w = SymmetricGroup(9).an_element()
# needs sage.groups
sage: RotheDiagram(w)
# needs sage.groups
Traceback (most recent call last):
...
ValueError: w must be a permutation
```
5.1.97 Diagram and Partition Algebras

AUTHORS:

• Mike Hansen (2007): Initial version
• Mike Zabrocki (2018): Implementation of individual element diagram classes
• Aaron Lauve, Mike Zabrocki (2018): Implementation of orbit basis for Partition algebra.

class sage.combinat.diagram_algebras.AbstractPartitionDiagram(parent, d, check=True)
Bases: AbstractSetPartition
Abstract base class for partition diagrams.

This class represents a single partition diagram, that is used as a basis key for a diagram algebra element. A partition diagram should be a partition of the set \{1, \ldots, k, -1, \ldots, -k\}. Each such set partition is regarded as a graph on nodes \{1, \ldots, k, -1, \ldots, -k\} arranged in two rows, with nodes 1, \ldots, k in the top row from left to right and with nodes -1, \ldots, -k in the bottom row from left to right, and an edge connecting two nodes if and only if the nodes lie in the same subset of the set partition.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd1 = da.AbstractPartitionDiagram(pd, [[1,2],[-1,-2]])
sage: pd2 = da.AbstractPartitionDiagram(pd, [[1,2],[-1,-2]])
sage: pd1
{{-2, -1}, {1, 2}}
sage: pd1 == pd2
True
sage: pd1 == [[1,2],[-1,-2]]
True
sage: pd1 == ((-2,-1),(2,1))
True
sage: pd1 == SetPartition([[1,2],[-1,-2]])
True
sage: pd3 = da.AbstractPartitionDiagram(pd, [[1,-2],[-1,2]])
sage: pd1 == pd3
False
sage: pd4 = da.AbstractPartitionDiagram(pd, [[1,2],[3,4]])
Traceback (most recent call last):
...
ValueError: {{1, 2}, {3, 4}} does not represent two rows of vertices of order 2
```

base_diagram()

Return the underlying implementation of the diagram.

OUTPUT:

• tuple of tuples of integers

EXAMPLES:
check()

Check the validity of the input for the diagram.

compose(other, check=True)

Compose self with other.

The composition of two diagrams $X$ and $Y$ is given by placing $X$ on top of $Y$ and removing all loops.

OUTPUT:

A tuple where the first entry is the composite diagram and the second entry is how many loop were removed.

Note: This is not really meant to be called directly, but it works to call it this way if desired.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).compose(pd([[1,2],[-1,-2]]))
({{-2, -1}, {1, 2}}, 1)
```

count_blocks_of_size(n)

Count the number of blocks of a given size.

INPUT:

* n – a positive integer

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: pd = PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]])
sage: pd.count_blocks_of_size(1)
2
sage: pd.count_blocks_of_size(2)
1
sage: pd.count_blocks_of_size(3)
2
```

diagram()

Return the underlying implementation of the diagram.

OUTPUT:

* tuple of tuples of integers

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.AbstractPartitionDiagrams(2)
sage: pd([[1,2],[-1,-2]]).base_diagram() == ((-2,-1),(1,2))
True
```
dual()

Return the dual diagram of self by flipping it top-to-bottom.

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import PartitionDiagram
sage: D = PartitionDiagram([[1,-1],[2,-2,-3],[3]])
```

```python
sage: D.dual()
{{-3}, {-2, 2, 3}, {-1, 1}}
```

is_planar()

Test if the diagram self is planar.

A diagram element is planar if the graph of the nodes is planar.

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import BrauerDiagram
```

```python
sage: BrauerDiagram([[1,-2],[2,-1]]).is_planar()  # False
sage: BrauerDiagram([[1,-1],[2,-2]]).is_planar()  # True
```

order()

Return the maximum entry in the diagram element.

A diagram element will be a partition of the set \{-1, -2, \ldots, -k, 1, 2, \ldots, k\}. The order of the diagram element is the value $k$.

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import PartitionDiagram
```

```python
sage: PartitionDiagram([[1,-1],[2,-2,-3],[3]]).order()  # 3
```

```python
sage: PartitionDiagram([[1,-1]]).order()  # 1
```

```python
sage: PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]]).order()  # 5
```

propagating_number()

Return the propagating number of the diagram.

The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
```

```python
sage: pd = da.AbstractPartitionDiagrams(2)
```

```python
sage: d1 = pd([[1,-2],[2,-1]])
```

```python
sage: d1.propagating_number()  # 2
```

```python
sage: d2 = pd([[1,2],[-2,-1]])
```

```python
sage: d2.propagating_number()  # 0
```

set_partition()

Return the underlying implementation of the diagram as a set of sets.
class sage.combinat.diagram_algebras.AbstractPartitionDiagrams(order, category=None)

Bases: Parent, UniqueRepresentation

This is an abstract base class for partition diagrams.

The primary use of this class is to serve as basis keys for diagram algebras, but diagrams also have properties in their own right. Furthermore, this class is meant to be extended to create more efficient contains methods.

INPUT:

• order – integer or integer +1/2; the order of the diagrams
• category – (default: FiniteEnumeratedSets()); the category

All concrete classes should implement attributes

• _name – the name of the class
• _diagram_func – an iterator function that takes the order as its only input

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(2)
sage: pd
Partition diagrams of order 2
sage: pd.an_element() in pd
True
sage: elm = pd([[1,2],[-1,-2]])
sage: elm in pd
True
```

Element

alias of AbstractPartitionDiagram

class sage.combinat.diagram_algebras.BrauerAlgebra(k, q, base_ring, prefix)

Bases: SubPartitionAlgebra, UnitDiagramMixin

A Brauer algebra.

The Brauer algebra of rank \( k \) is an algebra with basis indexed by the collection of set partitions of \( \{1, \ldots, k, -1, \ldots, -k\} \) with block size 2.

This algebra is a subalgebra of the partition algebra. For more information, see PartitionAlgebra.

INPUT:

• k – rank of the algebra
• q – the deformation parameter \( q \)

OPTIONAL ARGUMENTS:

• base_ring – (default None) a ring containing \( q \); if None then just takes the parent of \( q \)
• prefix – (default "B") a label for the basis elements

EXAMPLES:

We now define the Brauer algebra of rank 2 with parameter \( x \) over \( \mathbb{Z} \):

```python
sage: R.<x> = ZZ[]
sage: B = BrauerAlgebra(2, x, R)
sage: B
Brauer Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Integer Ring
sage: B.basis()
Lazy family (Term map from Brauer diagrams of order 2 to Brauer Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Integer Ring(i))_{i in Brauer diagrams of order 2}
sage: B.basis().keys()
Brauer diagrams of order 2
sage: B.basis().keys()([[-2, 1], [2, -1]])
{{-2, 1}, {-1, 2}}
sage: b = B.basis().list(); b
[B{{-2, -1}, {1, 2}}, B{{-2, 1}, {-1, 2}}, B{{-2, 2}, {-1, 1}}]
sage: b[0]
B{{-2, -1}, {1, 2}}
sage: b[0]^2
x*B{{-2, -1}, {1, 2}}
sage: b[0]^5
x^4*B{{-2, -1}, {1, 2}}
```

Note, also that since the symmetric group algebra is contained in the Brauer algebra, there is also a conversion between the two.

```python
sage: R.<x> = ZZ[]
sage: B = BrauerAlgebra(2, x, R)
sage: S = SymmetricGroupAlgebra(R, 2)
sage: S([2,1])*B([[-1,-1],[2,-2]])
B{{-2, 1}, {-1, 2}}
```

\texttt{jucys\_murphy(\textit{j})}

Return the \( j \)-th generalized Jucys-Murphy element of \textit{self}.

The \( j \)-th Jucys-Murphy element of a Brauer algebra is simply the \( j \)-th Jucys-Murphy element of the symmetric group algebra with an extra \( (z - 1)/2 \) term, where \( z \) is the parameter of the Brauer algebra.

REFERENCES:

EXAMPLES:

```python
sage: z = var('z')
# optional - sage.symbolic
sage: B = BrauerAlgebra(3,z)
# optional - sage.symbolic
sage: B.jucys_murphy(1)
(1/2*z-1/2)*B{{-3, 3}, {-2, 2}, {-1, 1}}
sage: B.jucys_murphy(3)
```

(continues on next page)
-B\{-3, -2\}, \{-1, 1\}, \{2, 3\} - B\{-3, -1\}, \{-2, 2\}, \{1, 3\}
+ B\{-3, 1\}, \{-2, 2\}, \{-1, 3\} + B\{-3, 2\}, \{-2, 3\}, \{-1, 1\}
+ (1/2*z-1/2)*B\{-3, 3\}, \{-2, 2\}, \{-1, 1\}

options = Current options for Brauer diagram - display: normal

class sage.combinat.diagram_algebras.BrauerDiagram(parent, d, check=True)
    Bases: AbstractPartitionDiagram

A Brauer diagram.
A Brauer diagram for an integer $k$ is a partition of the set $\{1, \ldots, k, -1, \ldots, -k\}$ with block size 2.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(2)
sage: bd1 = bd([[1,2],[-1,-2]])
sage: bd2 = bd([[1,2,-1,-2]])
Traceback (most recent call last):
...
ValueError: all blocks of \{-2, -1, 1, 2\} must be of size 2
```

bijection_on_free_nodes(two_line=False)

Return the induced bijection - as a list of $(x, f(x))$ values - from the free nodes on the top at the Brauer diagram to the free nodes at the bottom of self.

OUTPUT:

If two_line is True, then the output is the induced bijection as a two-row list (inputs, outputs).

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
```

check()

Check the validity of the input for self.

involution_permutation_triple(curtn=True)

Return the involution permutation triple of self.

From Graham-Lehrer (see BrauerDiagrams), a Brauer diagram is a triple $(D_1, D_2, \pi)$, where:

- $D_1$ is a partition of the top nodes;
- $D_2$ is a partition of the bottom nodes;
- $\pi$ is the induced permutation on the free nodes.

INPUT:
• curt – (default: True) if True, then return bijection on free nodes as a one-line notation (standardized to look like a permutation), else, return the honest mapping, a list of pairs \((i, -j)\) describing the bijection on free nodes

**EXAMPLES:**

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.involution_permutation_triple()
([(1, 2)], [(-3, -2)], [1])
sage: elm.involution_permutation_triple(curt=False)
([(1, 2)], [(-3, -2)], [[3, -1]])
```

**is_elementary_symmetric()**

Check if is elementary symmetric.

Let \((D_1, D_2, \pi)\) be the Graham-Lehrer representation of the Brauer diagram \(d\). We say \(d\) is elementary symmetric if \(D_1 = D_2\) and \(\pi\) is the identity.

**EXAMPLES:**

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-1,-2],[3,-3]])
sage: elm.is_elementary_symmetric()
True
sage: elm2 = bd([[1,2],[-1, -3],[3,-2]])
sage: elm2.is_elementary_symmetric()
False
```

**options = Current options for Brauer diagram – display: normal**

**perm()**

Return the induced bijection on the free nodes of self in one-line notation, re-indexed and treated as a permutation.

See also:

`bijection_on_free_nodes()`

**EXAMPLES:**

```
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: elm = bd([[1,2],[-2,-3],[3,-1]])
sage: elm.perm()
[1]
```

**class** `sage.combinat.diagram_algebras.BrauerDiagrams(order, category=None)`

Bases: `AbstractPartitionDiagrams`

This class represents all Brauer diagrams of integer or integer +1/2 order. For more information on Brauer diagrams, see `BrauerAlgebra`.

**EXAMPLES:**

5.1. Comprehensive Module List 807
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(2); bd
Brauer diagrams of order 2
sage: bd.list()
[{{-2, -1}, {1, 2}}, {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]

sage: bd = da.BrauerDiagrams(5/2); bd
Brauer diagrams of order 5/2
sage: bd.list()
[{{-3, 3}, {-2, -1}, {1, 2}},
  {{-3, 3}, {-2, 1}, {-1, 2}},
  {{-3, 3}, {-2, 2}, {-1, 1}}]

Element
alias of BrauerDiagram
cardinality()
Return the cardinality of self.
The number of Brauer diagrams of integer order \( k \) is \((2^k - 1)!!\).

EXAMPLES:

```sage
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(3)
sage: bd.cardinality()
15
sage: bd = da.BrauerDiagrams(7/2)
sage: bd.cardinality()
15
```

from_involution_permutation_triple(D1_D2_pi)
Construct a Brauer diagram of self from an involution permutation triple.

A Brauer diagram can be represented as a triple where the first entry is a list of arcs on the top row of the diagram, the second entry is a list of arcs on the bottom row of the diagram, and the third entry is a permutation on the remaining nodes. This triple is called the involution permutation triple. For more information, see [GL1996].

INPUT:

- D1_D2_pi– a list or tuple where the first entry is a list of arcs on the top of the diagram, the second entry is a list of arcs on the bottom of the diagram, and the third entry is a permutation on the free nodes.

REFERENCES:

EXAMPLES:

```sage
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(4)
sage: bd.from_involution_permutation_triple([[[1,2]],[[3,4],[2,1]]])

options = Current options for Brauer diagram - display: normal
**symmetric_diagrams**(l=None, perm=None)

Return the list of Brauer diagrams with symmetric placement of \( l \) arcs, and with free nodes permuted according to \( perm \).

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: bd = da.BrauerDiagrams(4)
sage: bd.symmetric_diagrams(l=1, perm=[2,1])
[{{-4, -2}, {-3, 1}, {-1, 3}, {2, 4}},
 {{-4, -3}, {-2, 1}, {-1, 2}, {3, 4}},
 {{-4, -1}, {-3, 2}, {-2, 3}, {1, 4}},
 {{-4, 2}, {-3, -1}, {-2, 4}, {1, 3}},
 {{-4, 3}, {-3, 4}, {-2, -1}, {1, 2}},
 {{-4, 1}, {-3, -2}, {-1, 4}, {2, 3}}]
```

class sage.combinat.diagram_algebras.DiagramAlgebra(k, q, base_ring, prefix, diagrams, category=None)

Bases: CombinatorialFreeModule

Abstract class for diagram algebras and is not designed to be used directly.

class Element

Bases: IndexedFreeModuleElement

An element of a diagram algebra.

This subclass provides a few additional methods for partition algebra elements. Most element methods are already implemented elsewhere.

diagram()

Return the underlying diagram of `self` if `self` is a basis element. Raises an error if `self` is not a basis element.

**EXAMPLES:**

```python
sage: R.<x> = ZZ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = 3*P([[1,2],[-2,-1]])
sage: elt.diagram()
{{-2, -1}, {1, 2}}
```

diagrams()

Return the diagrams in the support of `self`.

**EXAMPLES:**

```python
sage: R.<x> = ZZ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = 3*P([[1,2],[-2,-1]]) + P([[1,2],[-2], [-1]])
sage: sorted(elt.diagrams(), key=str)
[{{-2, -1}, {1, 2}}, {{-2}, {-1}, {1, 2}}]
```

order()

Return the order of `self`.

The order of a partition algebra is defined as half of the number of nodes in the diagrams.
EXAMPLES:

```python
sage: q = var('q')  # optional - sage.symbolic
sage: PA = PartitionAlgebra(2, q)  # optional - sage.symbolic
sage: PA.order()  # optional - sage.symbolic
2
```

**set_partitions()**

Return the collection of underlying set partitions indexing the basis elements of a given diagram algebra.

**Todo**: Is this really necessary? deprecate?

---

class sage.combinat.diagram_algebras.DiagramBasis(k, q, base_ring, prefix, diagrams, category=None)

Bases: DiagramAlgebra

Abstract base class for diagram algebras in the diagram basis.

**product_on_basis(d1, d2)**

Return the product $D_{d_1} D_{d_2}$ by two basis diagrams.

class sage.combinat.diagram_algebras.IdealDiagram(parent, d, check=True)

Bases: AbstractPartitionDiagram

The element class for a ideal diagram.

An ideal diagram for an integer $k$ is a partition of the set $\{1, \ldots, k, -1, \ldots, -k\}$ where the propagating number is strictly smaller than the order.

**EXAMPLES:**

```python
sage: from sage.combinat.diagram_algebras import IdealDiagrams as IDs
sage: IDs(2)
Ideal diagrams of order 2
sage: IDs(2).list()
[[{-2, -1, 1, 2}],
 {{-2, 1, 2}, {-1}},
 {{-2}, {-1, 1, 2}},
 {{-2, -1}, {1, 2}},
 {{-2}, {-1}, {1, 2}},
 {{-2, -1, 1}, {2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, -1, 2}, {1}},
 {{-2, 2}, {-1}, {1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2}, {-1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}},
 {{-2}, {-1}, {1}, {2}}]

sage: from sage.combinat.diagram_algebras import PartitionDiagrams as PDs
sage: PDs(4).cardinality() == factorial(4) + IDs(4).cardinality()
True
```
check()

Check the validity of the input for self.

class sage.combinat.diagram_algebras.IdealDiagrams(order, category=None)

Bases: AbstractPartitionDiagrams

All “ideal” diagrams of integer or integer +1/2 order.

If \( k \) is an integer then an ideal diagram of order \( k \) is a partition diagram of order \( k \) with propagating number less than \( k \).

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
dsage: id = da.IdealDiagrams(3)
sage: id.an_element() in id
True
sage: id.cardinality() == len(id.list())
True
sage: da.IdealDiagrams(3/2).list()
[[-2, -1, 1, 2],
 [-2, 1, 2], [-1],
 [-2, -1, 2], [1],
 [-2, 2], [-1], [1]]
```

Element

alias of IdealDiagram

class sage.combinat.diagram_algebras.OrbitBasis(alg)

Bases: DiagramAlgebra

The orbit basis of the partition algebra.

Let \( D_\pi \) represent the diagram basis element indexed by the partition \( \pi \), then (see equations (2.14), (2.17) and (2.18) of [BH2017])

\[
D_\pi = \sum_{\tau \geq \pi} O_\tau,
\]

where the sum is over all partitions \( \tau \) which are coarser than \( \pi \) and \( O_\tau \) is the orbit basis element indexed by the partition \( \tau \).

If \( \mu_{2k}(\pi, \tau) \) represents the Moebius function of the partition lattice, then

\[
O_\pi = \sum_{\tau \geq \pi} \mu_{2k}(\pi, \tau)D_\tau.
\]

If \( \tau \) is a partition of \( \ell \) blocks and the \( i^{th} \) block of \( \tau \) is a union of \( b_i \) blocks of \( \pi \), then

\[
\mu_{2k}(\pi, \tau) = \prod_{i=1}^{\ell} (-1)^{b_i - 1}(b_i - 1)!. 
\]

EXAMPLES:

```python
sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis(); O2
```

(continues on next page)
Orbit basis of Partition Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Rational Field

```
sage: oa = O2([[1], [-1], [2, -2]]); ob = O2([[[-1, -2, 2], [1]]]); oa, ob
(O{{-2, 2}, {-1}, {1}}, O{{-2, -1, 2}, {1}})
sage: oa * ob
(x-2)*O{{-2, -1, 2}, {1}}
```

We can convert between the two bases:

```
sage: pa = P2(oa); pa
2*P{{-2, -1, 1, 2}} - P{{-2, -1, 2}, {1}} - P{{-2, 1, 2}, {-1}}
+ P{{-2, 2}, {-1}, {1}} - P{{-2, 2}, {-1, 1}}
sage: pa * ob
(-x+2)*P{{-2, -1, 1, 2}} + (x-2)*P{{-2, -1, 2}, {1}}
sage: _ == pa * P2(ob)
True
sage: ob * pa
(x-2)*O{{-2, -1, 2}, {1}}
```

Note that the unit in the orbit basis is not a single diagram, in contrast to the natural diagram basis:

```
sage: P2.one()
P{{-2, 2}, {-1, 1}}
sage: O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}
sage: O2.one() == P2.one()
True
```

class Element

```
Bases: Element

```
sage: R.<x> = QQ[]
sage: O2 = PartitionAlgebra(2, x, R).orbit_basis()
sage: P2 = O2.diagram_basis(); P2
Partition Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Rational Field
sage: o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: P2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}

one()

Return the element 1 of the partition algebra in the orbit basis.

EXAMPLES:

sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis()
sage: O2.one()
O{{-2, -1, 1, 2}} + O{{-2, 2}, {-1, 1}}

product_on_basis(d1, d2)

Return the product \(O_{d_1}O_{d_2}\) of two elements in the orbit basis self.

EXAMPLES:

sage: R.<x> = QQ[]
sage: OP = PartitionAlgebra(2, x, R).orbit_basis()
sage: SP = OP.basis().keys(); sp = SP([-2, -1, 1, 2])
sage: OP.product_on_basis(sp, sp)
O{{-2, -1, 1, 2}}
sage: o1 = OP.one(); o2 = OP([]); o3 = OP.an_element()
sage: o2 == o1
False
sage: o1 * o1 == o1
True
sage: o3 * o1 == o3 * o1 == o3
True
sage: o4 = (3*OP([[[-2, -1, 1], [2]]) + 2*OP([[[-2, -1, 1, 2]])

We compute Examples 4.5 in [BH2017]:
+ (x^2-9*x+20)*O{{-4}, {-3, -1, 2, 3}, {-2, 4}, {1}}
+ (x^2-9*x+20)*O{{-4, 1}, {-3, -1}, {-2, 4}, {2, 3}}
+ (x^2-7*x+12)*O{{-4, 1}, {-3, -1}, {-2, 4}, {2, 3}}
+ (x^2-9*x+20)*O{{-4, 2, 3}, {-3, -1}, {-2, 4}, {1}}
+ (x^2-7*x+12)*O{{-4, 2, 3}, {-3, -1, 1}, {-2, 4}}

sage: O[1,-1],[2,-2],[3],[4,-3],[-4] * O[1,-2],[2],[3,-1],[4],[5,-3],[-4] * (x-6)*O{{-4}, {-3}, {-2, 1}, {-1, 4}, {2}, {3}}
+ (x-5)*O{{-4}, {-3, 3}, {-2, 1}, {-1, 4}, {2}}
+ (x-5)*O{{-4, 3}, {-3}, {-2, 1}, {-1, 4}, {2}}

sage: P = PartitionAlgebra(6,x); O = P.orbit_basis()
sage: (O[1,-2,-3],[2,4],[3,5,-6],[6,-1],[-4,-5])
+ (O[1,-2],[2,3],[4],[5],[6,-4,-5,-6],[-1,-3])

0

sage: (O[1,-2],[2,-3],[3,5],[4,-5],[6,-4],[-1],[-6])
+ (O[1,-2],[2,-1],[3,-4],[4,-6],[5,-3],[6,-5])
O{{-6, 6}, {-5}, {-4, 2}, {-3, 4}, {-2}, {-1, 1}, {3, 5}}

REFERENCES:

• [BH2017]

class sage.combinat.diagram_algebras.PartitionAlgebra(k, q, base_ring, prefix)

Bases: DiagramBasis, UnitDiagramMixin

A partition algebra.

A partition algebra of rank $k$ over a given ground ring $R$ is an algebra with ($R$-module) basis indexed by the collection of set partitions of $\{1, \ldots, k, -1, \ldots, -k\}$. Each such set partition can be represented by a graph on nodes $\{1, \ldots, k, -1, \ldots, -k\}$ arranged in two rows, with nodes $1, \ldots, k$ in the top row from left to right and with nodes $-1, \ldots, -k$ in the bottom row from left to right, and edges drawn such that the connected components of the graph are precisely the parts of the set partition. (This choice of edges is often not unique, and so there are often many graphs representing one and the same set partition; the representation nevertheless is useful and vivid. We often speak of “diagrams” to mean graphs up to such equivalence of choices of edges; of course, we could just as well speak of set partitions.)

There is not just one partition algebra of given rank over a given ground ring, but rather a whole family of them, indexed by the elements of $R$. More precisely, for every $q \in R$, the partition algebra of rank $k$ over $R$ with parameter $q$ is defined to be the $R$-algebra with basis the collection of all set partitions of $\{1, \ldots, k, -1, \ldots, -k\}$, where the product of two basis elements is given by the rule

$$a \cdot b = q^N(a \circ b),$$

where $a \circ b$ is the composite set partition obtained by placing the diagram (i.e., graph) of $a$ above the diagram of $b$, identifying the bottom row nodes of $a$ with the top row nodes of $b$, and omitting any closed “loops” in the middle. The number $N$ is the number of connected components formed by the omitted loops.

The parameter $q$ is a deformation parameter. Taking $q = 1$ produces the semigroup algebra (over the base ring) of the partition monoid, in which the product of two set partitions is simply given by their composition.

The partition algebra is regarded as an example of a “diagram algebra” due to the fact that its natural basis is given by certain graphs often called diagrams.
contains the blocks \(\{r + 1\}\) and \(\{-r - 1\}\) and if \(i \in \mathbb{Z}\), then \(e_i\) contains the block \(\{-i, -i - 1, i, i + 1\}\), with all other blocks being \(\{-j, j\}\). So we have:

\[
\begin{align*}
sage: & P = PartitionAlgebra(4, 0) \\
&sage: P.a(2) \\
&P\{\{-4, 4\}, \{-3, -2\}, \{-1, 1\}, \{2, 3\}\} \\
&sage: P.e(3/2) \\
&P\{\{-4, 4\}, \{-3, 3\}, \{-2\}, \{-1, 1\}, \{2\}\} \\
&sage: P.e(2) \\
&P\{\{-4, 4\}, \{-3, -2, 2, 3\}, \{-1, 1\}\} \\
&sage: P.e(5/2) \\
&P\{\{-4, 4\}, \{-3\}, \{-2, 2\}, \{-1, 1\}, \{3\}\} \\
&sage: P.s(2) \\
&P\{\{-4, 4\}, \{-3, 2\}, \{-2, 3\}, \{-1, 1\}\}
\end{align*}
\]

An excellent reference for partition algebras and their various subalgebras (Brauer algebra, Temperley–Lieb algebra, etc) is the paper [HR2005].

**INPUT:**

- \(k\) – rank of the algebra
- \(q\) – the deformation parameter \(q\)

**OPTIONAL ARGUMENTS:**

- \(\texttt{base\_ring}\) – (default \(\texttt{None}\)) a ring containing \(q\); if \(\texttt{None}\), then Sage automatically chooses the parent of \(q\)
- \(\texttt{prefix}\) – (default \(\texttt{"P"}\)) a label for the basis elements

**EXAMPLES:**

The following shorthand simultaneously defines the univariate polynomial ring over the rationals as well as the variable \(x\):

\[
\begin{align*}
&sage: R.<x> = PolynomialRing(QQ) \\
&sage: R \\
Univariate Polynomial Ring in x over Rational Field \\
&sage: x \\
x \\
&sage: x.parent() \texttt{is} R \\
True
\end{align*}
\]

We now define the partition algebra of rank 2 with parameter \(x\) over \(\mathbb{Z}\) in the usual (diagram) basis:

\[
\begin{align*}
&sage: R.<x> = ZZ[] \\
&sage: A2 = PartitionAlgebra(2, x, R) \\
&sage: A2 \\
Partition Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Integer Ring \\
&sage: A2.basis().keys() \\
Partition diagrams of order 2 \\
&sage: A2.basis().keys()([[\{-2, 1\}, \{-1\}])] \\
\{{\{-2, 1\}, \{-1\}}\} \\
&sage: A2.basis().list() \\
\\{P\{-2, -1, 1, 2\}, P\{-2, 1, 2\}, \{-1\}\}, \\
P\{-2, -1, 1, 2\}, P\{-2, -1\}, \{1, 2\}\}, \\
P\{-2, -1, 1, 2\}, P\{-2, -1\}, \{2\}\}, \}
\end{align*}
\]
Combinatorics, Release 10.1

\[
P\{\{-2, 1\}, \{-1, 2\}\}, P\{\{-2, 1\}, \{-1\}, \{2\}\},
P\{\{-2, 2\}, \{-1, 1\}\}, P\{\{-2, -1, 1\}, \{2\}\},
P\{\{-2, 2\}, \{-1\}, \{1\}\}, P\{\{-2, 2\}, \{-1, 1\}, \{2\}\},
P\{\{-2\}, \{-1, 2\}, \{1\}\}, P\{\{-2\}, \{-1\}, \{1\}, \{2\}\}
\]

\textbf{sage: } E = A2([[1,2],[2,-1]]); E
P\{\{-2, 2\}, \{-1\}, \{1\}\}
\textbf{sage: } E \text{ in } A2.basis().list()
True
\textbf{sage: } E^2
x*P\{\{-2, 2\}, \{-1\}, \{1\}\}
\textbf{sage: } E^5
x^4*P\{\{-2, 2\}, \{-1\}, \{1\}\}
\textbf{sage: } \left( A2([[-2,-2],[1,2]]) - 2*A2([[1,2],[1,-2]]) \right)^2
(4*x-4)*P\{\{-2, 2\}, \{-1\}, \{1\}\}
\textbf{sage: } A2.an_element(); a2
3*P\{\{-2\}, \{-1, 1, 2\}\} + 2*P\{\{-2, -1, 2\}, \{-1\}\}
\textbf{sage: } A4\{\[]\}
P\{\{-4, 4\}, \{-3, 3\}, \{-2, 2\}, \{-1, 1\}\}
\textbf{sage: } A4(5)
5*P\{\{-4, 4\}, \{-3, 3\}, \{-2, 2\}, \{-1, 1\}\}
\textbf{sage: } A3 = SymmetricGroupAlgebra(ZZ, 3)
\textbf{sage: } s3 = A3.an_element(); s3
[1, 2, 3] + 2*[1, 3, 2] + 3*[2, 1, 3] + [3, 1, 2]
\textbf{sage: } A4\{s3\}
P\{\{-4, 4\}, \{-3, 1\}, \{-2, 3\}, \{-1, 2\}\}
\textbf{sage: } A4([2,1])
P\{\{-4, 4\}, \{-3, 3\}, \{-2, 1\}, \{-1, 2\}\}
\]

Next, we construct an element:

\[
\textbf{sage: } a2 = A2.an_element(); a2
3*P\{\{-2\}, \{-1, 1, 2\}\} + 2*P\{\{-2, -1, 2\}, \{-1\}\} + 2*P\{\{-2, 1, 2\}, \{-1\}\}
\]

There is a natural embedding into partition algebras on more elements, by adding identity strands:

\[
\textbf{sage: } A4 = PartitionAlgebra(4, x, R)
\textbf{sage: } A4(a2)
3*P\{\{-4, 4\}, \{-3, 3\}, \{-2, 2\}, \{-1, 1\}\}
\]

Thus, the empty partition corresponds to the identity:

\[
\textbf{sage: } A4([[]])
P\{\{-4, 4\}, \{-3, 3\}, \{-2, 2\}, \{-1, 1\}\}
\]

The group algebra of the symmetric group is a subalgebra:

\[
\textbf{sage: } S3 = SymmetricGroupAlgebra(ZZ, 3)
\textbf{sage: } s3 = S3.an_element(); s3
[1, 2, 3] + 2*[1, 3, 2] + 3*[2, 1, 3] + [3, 1, 2]
\textbf{sage: } A4(s3)
P\{\{-4, 4\}, \{-3, 1\}, \{-2, 3\}, \{-1, 2\}\}
\]

Be careful not to confuse the embedding of the group algebra of the symmetric group with the embedding of partial set partitions. The latter are embedded by adding the parts \(\{i, -i\}\) if possible, and singletons sets for the remaining parts:
Another subalgebra is the Brauer algebra, which has perfect matchings as basis elements. The group algebra of the symmetric group is in fact a subalgebra of the Brauer algebra:

```
sage: B3 = BrauerAlgebra(3, x, R)
sage: b3 = B3(s3); b3
B{{-3, 1}, {-2, 3}, {-1, 2}} + 2*B{{-3, 2}, {-2, 3}, {-1, 1}}
+ 3*B{{-3, 3}, {-2, 1}, {-1, 2}} + B{{-3, 3}, {-2, 2}, {-1, 1}}
```

An important basis of the partition algebra is the orbit basis:

```
sage: O2 = A2.orbit_basis()
sage: o2 = O2([[1,2],[-1,-2]]); o2
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}
```

The diagram basis element corresponds to the sum of all orbit basis elements indexed by coarser set partitions:

```
sage: A2(o2)
P{{-2, -1}, {1, 2}}
```

We can convert back from the orbit basis to the diagram basis:

```
sage: o2 = O2.an_element(); o2
3*O{{-2}, {-1, 1, 2}} + 2*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
sage: A2(o2)
3*P{{-2}, {-1, 1, 2}} - 3*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
```

One can work with partition algebras using a symbol for the parameter, leaving the base ring unspecified. This implies that the underlying base ring is Sage’s symbolic ring.

```
sage: q = var('q')
sage: PA = PartitionAlgebra(2, q); PA
Partition Algebra of rank 2 with parameter q over Symbolic Ring
sage: PA([[1,2],[-2,-1]])^2 == q*PA([[1,2],[-2,-1]])
True
```

The identity element of the partition algebra is the set partition \{\{1, -1\}, \{2, -2\}, \ldots, \{k, -k\}):

```
sage: P = PA.basis().list()  # optional - sage.symbolic
sage: PA.one()  # optional - sage.symbolic
P{{-2, 2}, {-1, 1}}
```
We now give some further examples of the use of the other arguments. One may wish to "specialize" the parameter to a chosen element of the base ring:

```sage
sage: R.<q> = RR[]
sage: PA = PartitionAlgebra(2, q, R, prefix='B')
sage: PA
Partition Algebra of rank 2 with parameter q over Univariate Polynomial Ring in q over Real Field with 53 bits of precision
sage: PA([[1,2],[1,-1]])
1.00000000000000*B{{-2, -1}, {1, 2}}
```

Symmetric group algebra elements and elements from other subalgebras of the partition algebra (e.g., BrauerAlgebra and TemperleyLiebAlgebra) can also be coerced into the partition algebra:

```sage
sage: S = SymmetricGroupAlgebra(SR, 2)  #...
sage: B = BrauerAlgebra(2, x, SR)  #...
sage: A = PartitionAlgebra(2, x, SR)  #...
sage: S([[2,1]]) * A([[1,-1],[2,-2]])
P{{-2, 1}, {-1, 2}}
sage: B([[1,-1],[2,1]]) * A([[1,-1],[2,-2]])
P{{-2, -1}, {1, 2}}
sage: A([[1,-1],[2,-2]]) * B([[1,-1],[2,1]])
P{{-2, -1}, {1, 2}}
```

The same is true if the elements come from a subalgebra of a partition algebra of smaller order, or if they are defined over a different base ring:

```sage
sage: R = FractionField(ZZ['q']); q = R.gen()
sage: S = SymmetricGroupAlgebra(ZZ, 2)
sage: B = BrauerAlgebra(2, q, ZZ[q])
sage: A = PartitionAlgebra(3, q, R)
sage: S([[2,1]]) * A([[1,-1],[2,-3],[3,-2]])
P{{-3, 1}, {-2, 3}, {-1, 2}}
```

(continues on next page)
class Element
Bases: Element
dual()

Return the dual of self.

The dual of an element in the partition algebra is formed by taking the dual of each diagram in the support.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: elt = P.an_element(); elt
3*P{{-2}, {-1, 1, 2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, 1, 2}, {-1}}
sage: elt.dual()
3*P{{-2, -1, 1}, {2}} + 2*P{{-2, -1, 1, 2}} + 2*P{{-2, -1, 2}, {1}}
```

to_orbit_basis()

Return self in the orbit basis of the associated partition algebra.

EXAMPLES:

```
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: pp = P.an_element();
sage: pp.to_orbit_basis()
3*O{{-2}, {-1, 1, 2}} + 7*O{{-2, -1, 1, 2}} + 2*O{{-2, 1, 2}, {-1}}
```

\( L(i) \)

Return the \( i \)-th Jucys-Murphy element \( L_i \) from [Eny2012].

INPUT:

- \( i \) – a half integer between 1/2 and \( k \)

ALGORITHM:

We use the recursive definition for \( L_{2i} \) given in [Cre2020]. See also [Eny2012] and [Eny2013].

Note: \( L_{1/2} \) and \( L_1 \) differs from [HR2005].

EXAMPLES:

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.jucys_murphy_element(1/2)
```
We test the relations in Lemma 2.2.3(2) in [Cre2020] (v1):

\[
\text{sage: } k = 4 \\
\text{sage: } R.<n> = QQ[] \\
\text{sage: } P = PartitionAlgebra(k, n) \\
\text{sage: } L = [P.L(i/2) \text{ for } i \text{ in range}(1,2*k+1)] \\
\text{sage: } \text{all}(x.dual() == x \text{ for } x \text{ in } L) \\
\text{True} \\
\text{sage: } \text{all}(x * y == y * x \text{ for } x \text{ in } L \text{ for } y \text{ in } L) \quad \# \text{long time} \\
\text{True} \\
\text{sage: } Lsum = \text{sum}(L) \\
\text{sage: } \text{gens} = [P.s(i) \text{ for } i \text{ in range}(1,k)] \\
\text{sage: } \text{gens} += [P.e(i/2) \text{ for } i \text{ in range}(1,2*k)] \\
\text{sage: } \text{all}(x * Lsum == Lsum * x \text{ for } x \text{ in } \text{gens}) \\
\text{True}
\]

Also the relations in Lemma 2.2.3(3) in [Cre2020] (v1):

\[
\text{sage: } \text{all}(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2) \\
\quad \text{== (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range}(1,k)) \\
\text{True} \\
\text{sage: } \text{all}(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2)) \\
\quad \text{== (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2) \\
\quad \text{== n * P.e(i/2) for i in range}(1,2*k)) \\
\text{True} \\
\text{sage: } \text{all}(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2) \\
\quad \text{== P.L(2*i/2) * P.e(2*i/2) for i in range}(1,k)) \\
\text{True} \\
\text{sage: } \text{all}(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2) \\
\quad \text{== P.e(2*i/2) * P.L(2*i/2) for i in range}(1,k)) \\
\text{True} \\
\text{sage: } \text{all}(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2) \\
\quad \text{== P.L(2*i/2) * P.e(2*i/2) for i in range}(1,k)) \\
\text{True} \\
\text{sage: } \text{all}(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2) \\
\quad \text{== P.e(2*i/2) * P.L(2*i/2) for i in range}(1,k)) \\
\text{True}
\]

The same tests for a half integer partition algebra:
sage: k = 9/2
sage: R.<n> = QQ[]
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L)
True
sage: all(x * y == y * x for x in L for y in L)  # long time
True
sage: Lsum = sum(L)
sage: gens = [P.s(i) for i in range(1,k-1/2)]
sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2) == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,floor(k)))
True
sage: all(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2) == P.L(2*i/2) * P.e(2*i/2) for i in range(1,ceil(k)))
True

a(i)

Return the element $a_i$ in self.

The element $a_i$ is the cap and cup at $(i, i + 1)$, so it contains the blocks $\{i, i + 1\}, \{-i, -i - 1\}$. Other blocks are of the form $\{-j, j\}$.

INPUT:

- $i$ – an integer between 1 and $k - 1$

EXAMPLES:

sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1}, {1, 2}}
sage: P3.a(2)
P{{-3, -2}, {-1, 1}, {2, 3}}

sage: P3 = PartitionAlgebra(5/2, n)
sage: P3.a(1)
P{{-3, 3}, {-2, -1}, {1, 2}}
Combinatorics, Release 10.1

\textbf{sage}: P3.a(2)

Traceback (most recent call last):
...
ValueError: i must be an integer between 1 and 1

\textbf{e}(i)

Return the element \( e_i \) in \textit{self}.

If \( i = (2r + 1)/2 \), then \( e_i \) contains the blocks \( \{r + 1\} \) and \( \{-r - 1\} \). If \( i \in \mathbb{Z} \), then \( e_i \) contains the block \( \{-i, -i - 1, i, i + 1\} \). Other blocks are of the form \( \{-j, j\} \).

**INPUT:**

\begin{itemize}
  \item \textit{i} – a half integer between 1/2 and \( k - 1/2 \)
\end{itemize}

**EXAMPLES:**

\begin{verbatim}
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.e(1)
P{-3, 3}, {-2, -1, 1, 2}
sage: P3.e(2)
P{-3, -2, 2, 3}, {-1, 1}
sage: P3.e(1/2)
P{-3, 3}, {-2, 2}, {-1, 1, 1}
sage: P3.e(5/2)
P{-3}, {-2, 2}, {-1, 1, 3}
sage: P3.e(0)
Traceback (most recent call last):
...
ValueError: i must be an (half) integer between 1/2 and 5/2
\end{verbatim}

\textbf{generator_a}(i)

Return the element \( a_i \) in \textit{self}.

The element \( a_i \) is the cap and cup at \( (i, i + 1) \), so it contains the blocks \( \{i, i + 1\}, \{-i, -i - 1\} \). Other blocks are of the form \( \{-j, j\} \).

**INPUT:**

\begin{itemize}
  \item \textit{i} – an integer between 1 and \( k - 1 \)
\end{itemize}

**EXAMPLES:**

\begin{verbatim}
sage: P2h = PartitionAlgebra(5/2,n)
sage: [P2h.e(k/2) for k in range(1,5)]
[P{-3, 3}, {-2, 2}, {-1}, {1}],
P{-3, 3}, {-2, -1, 1, 2}],
P{-3, 3}, {-2}, {-1, 1}, {2}],
P{-3, -2, 2, 3}, {-1, 1}]
\end{verbatim}

822 Chapter 5. Comprehensive Module List
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.a(1)
P{-3, 3}, {-2, -1}, {1, 2}
sage: P3.a(2)
P{-3, -2}, {-1, 1}, {2, 3}

sage: P3 = PartitionAlgebra(5/2, n)
sage: P3.a(1)
P{-3, 3}, {-2, -1}, {1, 2}
sage: P3.a(2)
Traceback (most recent call last):
... ValueError: i must be an integer between 1 and 1

generator_e(i)
Return the element $e_i$ in self.

If $i = (2r + 1)/2$, then $e_i$ contains the blocks \{r + 1\} and \{-r - 1\}. If $i \in \mathbb{Z}$, then $e_i$ contains the block \{-i, -i - 1, i, i + 1\}. Other blocks are of the form \{-j, j\}.

INPUT:

• i – a half integer between 1/2 and $k - 1/2$

EXAMPLES:

sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.e(1)
P{-3, 3}, {-2, -1, 1, 2}
sage: P3.e(2)
P{-3, -2, 2, 3}, {-1, 1}
sage: P3.e(1/2)
P{-3, 3}, {-2, 2}, {-1}, {1}
sage: P3.e(5/2)
P{-3}, {-2, 2}, {-1, 1}, {3}
sage: P3.e(0)
Traceback (most recent call last):
... ValueError: i must be an (half) integer between 1/2 and 5/2

sage: P3.e(3)
Traceback (most recent call last):
... ValueError: i must be an (half) integer between 1/2 and 5/2

sage: P2h = PartitionAlgebra(5/2, n)
sage: [P2h.e(k/2) for k in range(1,5)]
[P{-3, 3}, {-2, -1, 1, 2},
P{-3, 3}, {-2, -1, 1, 2},
P{-3, 3}, {-2, -1, 1, 2},
P{-3, -2, 2, 3}, {-1, 1}]

generator_s(i)
Return the i-th simple transposition $s_i$ in self.
Borrowing the notation from the symmetric group, the $i$-th simple transposition $s_i$ has blocks of the form $\{-i, i+1\}, \{-i, i\}$. Other blocks are of the form $\{-j, j\}$.

**INPUT:**
- $i$ – an integer between 1 and $k - 1$

**EXAMPLES:**

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.s(1)
P\{-3, 3\}, \{-2, 1\}, \{-1, 2\}
sage: P3.s(2)
P\{-3, 2\}, \{-2, 3\}, \{-1, 1\}
```

**jucys_murphy_element($i$)**

Return the $i$-th Jucys-Murphy element $L_i$ from [Eny2012].

**INPUT:**
- $i$ – a half integer between 1/2 and $k$

**ALGORITHM:**
We use the recursive definition for $L_2i$ given in [Cre2020]. See also [Eny2012] and [Eny2013].

**Note:** $L_{1/2}$ and $L_1$ differs from [HR2005].

**EXAMPLES:**

```
sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.jucys_murphy_element(1/2)
0
sage: P3.jucys_murphy_element(1)
P\{-3, 3\}, \{-2, 2\}, \{-1\}, \{1\}
sage: P3.jucys_murphy_element(2)
P\{-3, 3\}, \{-2\}, \{-1, 1\}, \{2\} - P\{-3, 3\}, \{-2\}, \{-1, 1, 2\}
+ P\{-3, 3\}, \{-2, -1\}, \{1, 2\} - P\{-3, 3\}, \{-2, -1, 1\}, \{2\}
+ P\{-3, 3\}, \{-2, 1\}, \{-1, 2\}
sage: P3.jucys_murphy_element(3/2)
n*P\{-3, 3\}, \{-2, -1, 1, 2\} - P\{-3, 3\}, \{-2, -1, 2\}, \{1\}
- P\{-3, 3\}, \{-2, 1, 2\}, \{-1\} + P\{-3, 3\}, \{-2, 2\}, \{-1, 1\}
True
```

We test the relations in Lemma 2.2.3(2) in [Cre2020] (v1):
sage: P = PartitionAlgebra(k, n)
sage: L = [P.L(i/2) for i in range(1,2*k+1)]
sage: all(x.dual() == x for x in L) # long time
True
sage: all(x * y == y * x for x in L for y in L) # long time
True
sage: Lsum = sum(L)

sage: gens += [P.e(i/2) for i in range(1,2*k)]
sage: all(x * Lsum == Lsum * x for x in gens)
True
sage: all(P.e((2*i+1)/2) * P.sigma(2*i/2) * P.e((2*i+1)/2) == (n - P.L((2*i-1)/2)) * P.e((2*i+1)/2) for i in range(1,floor(k)))
True

(continues on next page)
sage: all(P.e(i/2) * (P.L(i/2) + P.L((i+1)/2)) == (P.L(i/2) + P.L((i+1)/2)) * P.e(i/2) for i in range(1,2*k))
True
sage: all(P.sigma(2*i/2) * P.e((2*i-1)/2) * P.e(2*i/2) == P.L(2*i/2) * P.e(2*i/2) for i in range(1,ceil(k)))
True
sage: all(P.e(2*i/2) * P.e((2*i-1)/2) * P.sigma(2*i/2) == P.e(2*i/2) * P.L(2*i/2) for i in range(1,ceil(k)))
True
sage: all(P.sigma((2*i+1)/2) * P.e((2*i+1)/2) * P.e(2*i/2) == P.L(2*i/2) * P.e(2*i/2) for i in range(1,floor(k)))
True
sage: all(P.e(2*i/2) * P.e((2*i+1)/2) * P.sigma((2*i+1)/2) == P.e(2*i/2) * P.L(2*i/2) for i in range(1,floor(k)))
True

orbit_basis()

Return the orbit basis of self.

EXAMPLES:

sage: R.<x> = QQ[]
sage: P2 = PartitionAlgebra(2, x, R)
sage: O2 = P2.orbit_basis(); O2
Orbit basis of Partition Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Rational Field
sage: pp = 7 * P2[{-1}, {-2, 1, 2}] - 2 * P2[{-2}, {-1, 1}, {2}]; pp
-2*P{{-2}, {-1, 1}, {2}} + 7*P{{-2, 1, 2}, {-1}}

sage: op = pp.to_orbit_basis(); op
-2*O{{-2}, {-1, 1}, {2}} - 2*O{{-2, -1, 1}, {2}}
- 2*O{{-2, -1, 1}, {2}} + 5*O{{-2, -1, 1, 2}}
+ 7*O{{-2, 1, 2}, {-1}} - 2*O{{-2, 2}, {-1, 1}}
sage: op == O2(op)
True
sage: pp * op.leading_term()
4*P{{-2}, {-1, 1}, {2}} - 4*P{{-2, -1, 1}, {2}}
+ 14*P{{-2, -1, 1, 2}} - 14*P{{-2, 1, 2}, {-1}}

s()

Return the i-th simple transposition s_i in self.

Borrowing the notation from the symmetric group, the i-th simple transposition s_i has blocks of the form \{-i, i+1\}, \{-i-1, i\}. Other blocks are of the form \{-j, j\}.

INPUT:

• i – an integer between 1 and k – 1

EXAMPLES:

sage: R.<n> = QQ[]
sage: P3 = PartitionAlgebra(3, n)
sage: P3.s(1)

(continues on next page)
P\{\{-3, 3\}, \{-2, 1\}, \{-1, 2\}\}
\text{sage:} \ P3.s(2)
P\{\{-3, 2\}, \{-2, 3\}, \{-1, 1\}\}

\text{sage:} \ R.<n> = ZZ[]
\text{sage:} \ P2h = PartitionAlgebra(5/2,n)
\text{sage:} \ P2h.s(1)
P\{\{-3, 3\}, \{-2, 1\}, \{-1, 2\}\}

\textbf{sigma}(i)

Return the element \(\sigma_i\) from [Eny2012] of \texttt{self}.

\textbf{INPUT:}

- \(i\) – a half integer between 1/2 and \(k - 1/2\)

\textbf{Note:} In [Cre2020] and [Eny2013], these are the elements \(\sigma_{2i}\).

\textbf{EXAMPLES:}

\text{sage:} \ R.<n> = QQ[]
\text{sage:} \ P3 = PartitionAlgebra(3, n)
\text{sage:} \ P3.sigma(1)
P\{\{-3, 3\}, \{-2, 2\}, \{-1, 1\}\}
\text{sage:} \ P3.sigma(3/2)
P\{\{-3, 3\}, \{-2, 1\}, \{-1, 2\}\}
\text{sage:} \ P3.sigma(2)
-P\{\{-3, -1, 1, 3\}, \{-2, 2\}\} + P\{\{-3, -1, 3\}, \{-2, 1, 2\}\}
+ P\{\{-3, 1, 3\}, \{-2, -1, 2\}\} - P\{\{-3, 3\}, \{-2, -1, 1, 2\}\}
+ P\{\{-3, 3\}, \{-2, 2\}, \{-1, 1\}\}
\text{sage:} \ P3.sigma(5/2)
-P\{\{-3, -1, 1, 2\}, \{-2, 3\}\} + P\{\{-3, -1, 2\}, \{-2, 1, 3\}\}
+ P\{\{-3, 1, 2\}, \{-2, -1, 3\}\} - P\{\{-3, 2\}, \{-2, -1, 1, 3\}\}
+ P\{\{-3, 2\}, \{-2, 3\}, \{-1, 1\}\}

We test the relations in Lemma 2.2.3(1) in [Cre2020] (v1):

\text{sage:} \ k = 4
\text{sage:} \ R.<x> = QQ[]
\text{sage:} \ P = PartitionAlgebra(k, x)
\text{sage:} \ all(P.sigma(i/2).dual() == P.sigma(i/2) \text{ for } i \text{ in range}(1,2*k))
True
\text{sage:} \ all(P.sigma(i)*P.e(i) == P.e(i)*P.sigma(i) == P.e(i) \text{ for } i \text{ in range}(1,floor(k)))
True
\text{sage:} \ all(P.sigma(i+1/2)*P.e(i) == P.e(i)*P.sigma(i+1/2) == P.e(i) \text{ for } i \text{ in range}(1,floor(k)))
True

(continues on next page)
sage: k = 9/2
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(k, x)
sage: all(P.sigma(i/2).dual() == P.sigma(i/2)
....:     for i in range(1,2*k-1))
True
sage: all(P.sigma(i)*P.sigma(i+1/2) == P.sigma(i+1/2)*P.sigma(i) == P.s(i)
....:     for i in range(1,k-1/2))
True
sage: all(P.sigma(i)*P.e(i) == P.e(i)*P.sigma(i) == P.e(i)
....:     for i in range(1,floor(k)))
True
sage: all(P.sigma(i+1/2)*P.e(i) == P.e(i)*P.sigma(i+1/2) == P.e(i)
....:     for i in range(1,floor(k)))
True

class sage.combinat.diagram_algebras.PartitionDiagram(parent, d, check=True)

Bases: AbstractPartitionDiagram

The element class for a partition diagram.

A partition diagram for an integer $k$ is a partition of the set $\{1, \ldots, k, -1, \ldots, -k\}$

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import PartitionDiagram, PartitionDiagrams
sage: PartitionDiagrams(1)
Partition diagrams of order 1
sage: PartitionDiagrams(1).list()
[{{-1, 1}}, {{-1}, {1}}]
sage: PartitionDiagram(((1,-2),(2,-1))).parent()
Partition diagrams of order 2
```

class sage.combinat.diagram_algebras.PartitionDiagrams(order, category=None)

Bases: AbstractPartitionDiagrams

This class represents all partition diagrams of integer or integer $+1/2$ order.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(1); pd
Partition diagrams of order 1
sage: pd.list()
[{{-1, 1}}, {{-1}, {1}}]
sage: pd = da.PartitionDiagrams(3/2); pd
Partition diagrams of order 3/2
sage: pd.list()
[{{-2, -1, 1, 2}},
 {(-2, 1, 2), {1}},
```
Element

alias of PartitionDiagram

cardinality()

The cardinality of partition diagrams of half-integer order \( n \) is the \( 2n \)-th Bell number.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pd = da.PartitionDiagrams(3)
sage: pd.cardinality()
203
sage: pd = da.PartitionDiagrams(7/2)
sage: pd.cardinality()
877
```

class sage.combinat.diagram_algebras.PlanarAlgebra(k, q, base_ring, prefix)

Bases: SubPartitionAlgebra, UnitDiagramMixin

A planar algebra.

The planar algebra of rank \( k \) is an algebra with basis indexed by the collection of all planar set partitions of \( \{1, \ldots, k, -1, \ldots, -k\} \).

This algebra is thus a subalgebra of the partition algebra. For more information, see PartitionAlgebra.

INPUT:

- \( k \) – rank of the algebra
- \( q \) – the deformation parameter \( q \)

OPTIONAL ARGUMENTS:

- `base_ring` – (default `None`) a ring containing \( q \); if `None` then just takes the parent of \( q \)
- `prefix` – (default "Pl") a label for the basis elements

EXAMPLES:

We define the planar algebra of rank 2 with parameter \( x \) over \( \mathbb{Z} \):

```python
sage: R.<x> = ZZ[]
sage: Pl = PlanarAlgebra(2, x, R); Pl
Planar Algebra of rank 2 with parameter x over Univariate Polynomial Ring in x over Integer Ring
sage: Pl.basis().keys()
Planar diagrams of order 2
sage: Pl.basis().keys()([[[-1, 1], [2, -2]]])
{{-2, 2}, {-1, 1}}
sage: Pl.basis().list()
[Pl{{{2}, {-1}, {1}}, Pl{{{2}, {-1}, {1}, {2}}},
```
class sage.combinat.diagram_algebras.PlanarDiagram

The element class for a planar diagram.

A planar diagram for an integer $k$ is a partition of the set \{1, \ldots, k, -1, \ldots, -k\} so that the diagram is non-crossing.

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import PlanarDiagrams
sage: PlanarDiagrams(2)
Planar diagrams of order 2
sage: PlanarDiagrams(2).list()

[[{-2}, {-1}, {1, 2}],
 {{-2}, {-1}, {1}, {2}},
 {{-2, 1}, {-1}, {2}},
 {{-2, 2}, {-1}, {1}},
 {{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1, 1}},
 {{-2}, {-1, 1}, {2}},
 {{-2}, {-1, 2}, {1}},
 {{-2}, {-1, 1, 2}}]
```

check()

Check the validity of the input for self.
EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pld = da.PlanarDiagrams(1); pld
Planar diagrams of order 1
sage: pld.list()
[{{-1, 1}}, {{-1}, {1}}]
```

```python
sage: pld = da.PlanarDiagrams(3/2); pld
Planar diagrams of order 3/2
sage: pld.list()
[{{-2, 1, 2}, {-1}},
 {{-2, 2}, {-1}, {1}},
 {{-2, 2}, {-1, 1}},
 {{-2, -1, 2}, {1}},
 {{-2, -1, 1, 2}}]
```

**Element**

alias of `PlanarDiagram`

**cardinality()**

Return the cardinality of self.

The number of all planar diagrams of order $k$ is the $2k$-th Catalan number.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: pld = da.PlanarDiagrams(3)
sage: pld.cardinality()
132
```

class `sage.combinat.diagram_algebras.PropagatingIdeal`

A propagating ideal.

The propagating ideal of rank $k$ is a non-unital algebra with basis indexed by the collection of ideal set partitions of $\{1, \ldots, k, -1, \ldots, -k\}$. We say a set partition is *ideal* if its propagating number is less than $k$.

This algebra is a non-unital subalgebra and an ideal of the partition algebra. For more information, see `PartitionAlgebra`.

EXAMPLES:

We now define the propagating ideal of rank 2 with parameter $x$ over $\mathbb{Z}$:

```python
sage: R.<x> = QQ[]
sage: I = PropagatingIdeal(2, x, R); I
Propagating Ideal of rank 2 with parameter x over Univariate Polynomial Ring in x over Rational Field
sage: I.basis().keys()
Ideal diagrams of order 2
sage: I.basis().list()
[I{{-2, -1, 1, 2}},
 I{{-2, 1, 2}, {-1}},
 I{{-2}, {-1, 1, 2}},
 I{{-2}, {-1, 1, 2}}]
```
class Element

Bases: Element

An element of a propagating ideal.

We need to take care of exponents since we are not unital.

class sage.combinat.diagram_algebras.SubPartitionAlgebra(k, q, base_ring, prefix, diagrams, category=None)

Bases: DiagramBasis

A subalgebra of the partition algebra in the diagram basis indexed by a subset of the diagrams.

class Element

Bases: Element

to_orbit_basis()

Return self in the orbit basis of the associated ambient partition algebra.

EXAMPLES:

```sage
R.<x> = QQ[]
sage: B = BrauerAlgebra(2, x, R)
sage: bb = B([-2, -1], [1, 2]); bb
B{{-2, -1}, {1, 2}}
sage: bb.to_orbit_basis()
O{{-2, -1}, {1, 2}} + O{{-2, -1, 1, 2}}
```

ambient()

Return the partition algebra self is a sub-algebra of.

EXAMPLES:

```sage
x = var('x')
# optional - sage.symbolic
sage: BA = BrauerAlgebra(2, x)
# optional - sage.symbolic
sage: BA.ambient()
Partition Algebra of rank 2 with parameter x over Symbolic Ring
```
lift()
Return the lift map from diagram subalgebra to the ambient space.

EXAMPLES:

```python
sage: R.<x> = QQ[]
sage: BA = BrauerAlgebra(2, x, R)
sage: E = BA([[1,2],[1,-2]])
sage: lifted = BA.lift(E); lifted
B{{-2, -1}, {1, 2}}
sage: lifted.parent() is BA.ambient()
```

retract(x)
Retract an appropriate partition algebra element to the corresponding element in the partition subalgebra.

EXAMPLES:

```python
sage: R.<x> = QQ[]
sage: BA = BrauerAlgebra(2, x, R)
sage: PA = BA.ambient()
sage: E = PA([[1,2], [-1,-2]])
```

sage.combinat.diagram_algebras.TL_diagram_ascii_art(diagram, use_unicode=False, blobs=[])
Return ascii art for a Temperley-Lieb diagram `diagram`.

**INPUT:**

- `diagram` – a list of pairs of matchings of the set \{-1, \ldots, -n, 1, \ldots, n\}
- `use_unicode` – (default: False): whether or not to use unicode art instead of ascii art
- `blobs` – (optional) a list of matchings with blobs on them

**EXAMPLES:**

```python
sage: from sage.combinat.diagram_algebras import TL_diagram_ascii_art
sage: TL = [(15,-12), (14,-13), (11,15), (10,14), (9,-6),
        (8,-4), (3,1), (2,-1), (2,3), (4,5),
        (6,11), (7, 8), (9,10), (12,13)]
```

---

(continues on next page)
class sage.combinat.diagram_algebras.TemperleyLiebAlgebra($k, q, base\_ring, prefix$)

Bases: SubPartitionAlgebra, UnitDiagramMixin

A Temperley–Lieb algebra.

The Temperley–Lieb algebra of rank $k$ is an algebra with basis indexed by the collection of planar set partitions of $\{1, \ldots, k, -1, \ldots, -k\}$ with block size 2.

This algebra is thus a subalgebra of the partition algebra. For more information, see PartitionAlgebra.

INPUT:

- $k$ – rank of the algebra
- $q$ – the deformation parameter $q$

OPTIONAL ARGUMENTS:

- $base\_ring$ – (default None) a ring containing $q$; if None then just takes the parent of $q$
- $prefix$ – (default "T") a label for the basis elements

EXAMPLES:

We define the Temperley–Lieb algebra of rank 2 with parameter $x$ over $\mathbb{Z}$:
```python
sage: R.<x> = ZZ[]
sage: T = TemperleyLiebAlgebra(2, x, R); T
Temperley-Lieb Algebra of rank 2 with parameter x
over Univariate Polynomial Ring in x over Integer Ring
sage: T.basis()
Lazy family (Term map from Temperley Lieb diagrams of order 2
to Temperley-Lieb Algebra of rank 2 with parameter x over
Univariate Polynomial Ring in x over Integer
Ring(i))_{i in Temperley Lieb diagrams of order 2}
sage: T.basis().keys()
Temperley Lieb diagrams of order 2
sage: T.basis().keys()([-1, 1], [2, -2])
{{-2, 2}, {-1, 1}}
sage: b = T.basis().list(); b
[T{{-2, -1}, {1, 2}}, T{{-2, 2}, {-1, 1}}]
sage: b[0]
T{{-2, -1}, {1, 2}}
sage: b[0]^2 == x*b[0]
True
sage: b[0]^5 == x^4*b[0]
True
```

```
class sage.combinat.diagram_algebras.TemperleyLiebDiagram(parent, d, check=True)
    Bases: AbstractPartitionDiagram
    The element class for a Temperley-Lieb diagram.
    A Temperley-Lieb diagram for an integer k is a partition of the set {1, ..., k, -1, ..., -k} so that the blocks are all of size 2 and the diagram is planar.
    EXAMPLES:
    sage: from sage.combinat.diagram_algebras import TemperleyLiebDiagrams
    sage: TemperleyLiebDiagrams(2)
    Temperley Lieb diagrams of order 2
    sage: TemperleyLiebDiagrams(2).list()
    [{{-2, -1}, {1, 2}}, {{-2, 2}, {-1, 1}}]
    check()
    Check the validity of the input for self.

class sage.combinat.diagram_algebras.TemperleyLiebDiagrams(order, category=None)
    Bases: AbstractPartitionDiagrams
    All Temperley-Lieb diagrams of integer or integer +1/2 order.
    For more information on Temperley-Lieb diagrams, see TemperleyLiebAlgebra.
    EXAMPLES:
    sage: import sage.combinat.diagram_algebras as da
    sage: td = da.TemperleyLiebDiagrams(3); td
    Temperley Lieb diagrams of order 3
    sage: td.list()
    [{{-3, 3}, {-2, -1}, {1, 2}},
     {{-3, 1}, {-2, -1}, {2, 3}}]
```
{{{−3, −2}, {−1, 1}, {2, 3}},
{−3, −2}, {−1, 3}, {1, 2}},
{−3, 3}, {−2, 2}, {−1, 1}}

**sage:** td = da.TemperleyLiebDiagrams(5/2); td
Temperley Lieb diagrams of order 5/2
**sage:** td.list()
[[{-3, 3}, {-2, -1}, {1, 2}], {{-3, 3}, {-2, 2}, {-1, 1}}]

**Element**

alias of *TemperleyLiebDiagram*

**cardinality()**

Return the cardinality of self.

The number of Temperley–Lieb diagrams of integer order \( k \) is the \( k \)-th Catalan number.

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: td = da.TemperleyLiebDiagrams(3)
sage: td.cardinality()
5
```

**class sage.combinat.diagram_algebras.UnitDiagramMixin**

Bases: object

Mixin class for diagram algebras that have the unit indexed by the `identity_set_partition()`.

**one_basis()**

The following constructs the identity element of self.

It is not called directly; instead one should use DA.one() if DA is a defined diagram algebra.

**EXAMPLES:**

```python
sage: R.<x> = QQ[]
sage: P = PartitionAlgebra(2, x, R)
sage: P.one_basis()
{{-2, 2}, {-1, 1}}
```

**sage.combinat.diagram_algebras.brauer_diagrams\( (k)\)**

Return a generator of all Brauer diagrams of order \( k \).

A Brauer diagram of order \( k \) is a partition diagram of order \( k \) with block size 2.

**INPUT:**

- \( k \) – the order of the Brauer diagrams

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.brauer_diagrams(2)]
[[{-2, -1}, {1, 2}], {{-2, 1}, {-1, 2}}, {{-2, 2}, {-1, 1}}]
sage: [SetPartition(p) for p in da.brauer_diagrams(5/2)]
[[{-3, 3}, {-2, -1}, {1, 2}], {{-3, 3}, {-2, 2}, {-1, 1}}]
```
sage.combinat.diagram_algebras.diagram_latex(diagram, fill=False, edge_options=None, edge_additions=None)

Return latex code for the diagram diagram using tikz.

EXAMPLES:

```python
sage: from sage.combinat.diagram_algebras import PartitionDiagrams, diagram_latex
e
sage: P = PartitionDiagrams(2)
e
sage: D = P([[1,2],[-2,-1]])
e
sage: print(diagram_latex(D)) # indirect doctest
\begin{tikzpicture}[scale = 0.5,thick, baseline={(0,-1ex/2)}]
\tikzstyle{vertex} = [shape = circle, minimum size = 7pt, inner sep = 1pt]
\node[vertex] (G--2) at (1.5, -1) [shape = circle, draw] {};
\node[vertex] (G--1) at (0.0, -1) [shape = circle, draw] {};
\node[vertex] (G-1) at (0.0, 1) [shape = circle, draw] {};
\node[vertex] (G-2) at (1.5, 1) [shape = circle, draw] {};
\draw (G--2) .. controls +(-0.5, 0.5) and +(0.5, 0.5) .. (G--1);
\draw (G-1) .. controls +(0.5, -0.5) and +(-0.5, -0.5) .. (G-2);
\end{tikzpicture}
```

sage.combinat.diagram_algebras.ideal_diagrams(k)

Return a generator of all “ideal” diagrams of order k.

An ideal diagram of order k is a partition diagram of order k with propagating number less than k.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
e
sage: all_diagrams = da.partition_diagrams(2)
e
sage: [SetPartition(p) for p in all_diagrams if p not in da.ideal_diagrams(2)]
[[{-2, 1}, {-1, 2}], {{-2, 2}, {-1, 1}}]
e
sage: all_diagrams = da.partition_diagrams(3/2)
e
sage: [SetPartition(p) for p in all_diagrams if p not in da.ideal_diagrams(3/2)]
[[{-2, 2}, {-1, 1}]]
```

sage.combinat.diagram_algebras.identity_set_partition(k)

Return the identity set partition \{\{1, -1\}, \ldots, \{k, -k\}\}.

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
e
sage: SetPartition(da.identity_set_partition(2))
{{-2, 2}, {-1, 1}}
```

sage.combinat.diagram_algebras.is_planar(sp)

Return True if the diagram corresponding to the set partition sp is planar; otherwise, return False.

EXAMPLES:
```python
sage: import sage.combinat.diagram_algebras as da
sage: da.is_planar( da.to_set_partition([[1,-2],[2,-1]]))
False
sage: da.is_planar( da.to_set_partition([[1,-1],[2,-2]]))
True
```

`sage.combinat.diagram_algebras.pair_to_graph(sp1, sp2)`

Return a graph consisting of the disjoint union of the graphs of set partitions `sp1` and `sp2` along with edges joining the bottom row (negative numbers) of `sp1` to the top row (positive numbers) of `sp2`.

The vertices of the graph `sp1` appear in the result as pairs `(k, 1)`, whereas the vertices of the graph `sp2` appear as pairs `(k, 2).

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: sp1 = da.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = da.to_set_partition([[1,-2],[2,-1]])
sage: g = da.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices
sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
[((-2, 1), (1, 1), None), ((-2, 1), (2, 2), None),
 ((-1, 1), (1, 1), None), ((-1, 1), (2, 2), None),
 ((-1, 2), (2, 1), None), ((-1, 2), (2, 2), None)]
```

Another example which used to be wrong until [github issue #15958]:

```python
sage: sp3 = da.to_set_partition([[1,-1],[2],[-2]])
sage: sp4 = da.to_set_partition([[1,-1],[2],[-2]])
sage: g = da.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices
sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
[((-2, 1), (1, 1), None), ((-2, 1), (2, 2), None),
 ((-1, 1), (1, 2), None),
 ((-1, 1), (1, 2), None),
 ((-1, 2), (2, 1), None), ((-1, 2), (2, 2), None)]
```

`sage.combinat.diagram_algebras.partition_diagrams(k)`

Return a generator of all partition diagrams of order `k`.

A partition diagram of order `k ∈ Z` to is a set partition of `{1, ..., k, -1, ..., -k}`. If we have `k - 1/2 ∈ ZZ`, then a partition diagram of order `k ∈ 1/2ZZ` is a set partition of `{1, ..., k + 1/2, -1, ..., -(k + 1/2)}` with `k + 1/2` and `-(k + 1/2)` in the same block. See [HR2005].

**INPUT:**

- `k` – the order of the partition diagrams

**EXAMPLES:**

```python
sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.partition_diagrams(2)]
```
\[\{\{-2, -1, 1, 2\}\}, \{\{-2, 1, 2\}, \{-1\}\}, \{\{-2, -1, 1, 2\}\}, \{\{-2\}, \{-1, 1, 2\}\}, \{\{-2, -1, 1\}, \{2\}\}, \{\{-2, 1\}, \{-1, 2\}\}, \{\{-2, 1\}, \{-1\}, \{2\}\}, \{\{-2, 2\}, \{-1, 2\}\}, \{\{-2, 2\}, \{-1\}, \{1\}\}, \{\{-2\}, \{-1, 2\}\}, \{\{-2, -1, 2\}, \{1\}\}, \{\{-2, -1, 2\}, \{1\}, \{2\}\}, \{\{-2\}, \{-1\}, \{1\}, \{2\}\}\]

sage: [SetPartition(p) for p in da.partition_diagrams(3/2)]
\[\{\{-2, -1, 1, 2\}\}, \{\{-2, 1, 2\}, \{-1\}\}, \{\{-2, 2\}, \{-1, 1\}\}, \{\{-2\}, \{-1, 1\}, \{2\}\}, \{\{-2\}, \{-1, 2\}, \{1\}\}, \{\{-2, -1\}, \{1\}, \{2\}\}, \{\{-2\}, \{-1\}, \{1\}, \{2\}\}\]

sage.combinat.diagram_algebras.planar_diagrams(k)

Return a generator of all planar diagrams of order \(k\).

A planar diagram of order \(k\) is a partition diagram of order \(k\) that has no crossings.

EXAMPLES:

sage: from sage.combinat.diagram_algebras import planar_diagrams
sage: all_diagrams = [SetPartition(p) for p in da.partition_diagrams(2)]
sage: da2 = [SetPartition(p) for p in da.planar_diagrams(2)]
sage: [p for p in all_diagrams if p not in da2]
\[\{\{-2, -1, 1, 2\}\}, \{\{-2, 1, 2\}, \{-1\}\}, \{\{-2, 2\}, \{-1, 1\}\}, \{\{-2\}, \{-1, 1\}, \{2\}\}, \{\{-2\}, \{-1, 2\}, \{1\}\}, \{\{-2, -1\}, \{1\}, \{2\}\}, \{\{-2\}, \{-1\}, \{1\}, \{2\}\}\]

sage.combinat.diagram_algebras.planar_partitions_rec(X)

Iterate over all planar set partitions of \(X\) by using a recursive algorithm.

ALGORITHM:
To construct the set partition \(\rho = \{\rho_1, \ldots, \rho_k\}\) of \([n]\), we remove the part of the set partition containing the last
element of \( X \), which we consider to be \( \rho_k = \{i_1, \ldots, i_m\} \) without loss of generality. The remaining parts come from the planar set partitions of \( \{1, \ldots, i_1 - 1\}, \{i_1 + 1, \ldots, i_2 - 1\}, \ldots, \{i_m + 1, \ldots, n\} \).

EXAMPILES:

```
sage: import sage.combinat.diagram_algebras as da
sage: list(da.planar_partitions_rec([1,2,3]))
[[[1, 2], [3]], [[1], [2], [3]], [[2], [1, 3]], [[1], [2, 3]], [[1, 2, 3]]]
```

sage.combinat.diagram_algebras.propagating_number\((sp)\)

Return the propagating number of the set partition \( sp \).

The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: sp1 = da.to_set_partition([[1,-2], [2,-1]])
sage: sp2 = da.to_set_partition([[1,2], [-2,-1]])
sage: da.propagating_number(sp1)
2
sage: da.propagating_number(sp2)
0
```

sage.combinat.diagram_algebras.temperley_lieb_diagrams\((k)\)

Return a generator of all Temperley–Lieb diagrams of order \( k \).

A Temperley–Lieb diagram of order \( k \) is a partition diagram of order \( k \) with block size 2 and is planar.

INPUT:

- \( k \) – the order of the Temperley–Lieb diagrams

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: [SetPartition(p) for p in da.temperley_lieb_diagrams(2)]
[[{-2, -1}, {1, 2}], {{-2, 2}, {-1, 1}}]
sage: [SetPartition(p) for p in da.temperley_lieb_diagrams(5/2)]
[[{-3, 3}, {-2, -1}, {1, 2}], {{-3, 3}, {-2, 2}, {-1, 1}}]
```

sage.combinat.diagram_algebras.to_Brauer_partition\((l, k=None)\)

Same as to_set_partition() but assumes omitted elements are connected straight through.

EXAMPLES:

```
sage: import sage.combinat.diagram_algebras as da
sage: f = lambda sp: SetPartition(da.to_Brauer_partition(sp))
sage: f([[1,2],[-1,-2]]) == SetPartition([[1,2],[-1,-2]])
True
sage: f([[1,3],[-1,-3]]) == SetPartition([[1,3],[-3,-1],[2,-2]])
True
sage: f([[1,4],[-3,-1],[3,4]]) == SetPartition([[-3,-1],[2,-2],[1,-4],[3,4]])
True
sage: p = SetPartition([[1,2],[-1,-2],[3,-3],[4,-4]])
sage: SetPartition(da.to_Brauer_partition([[1,2],[-1,-2]], k=4)) == p
True
```
Return a graph representing the set partition \(sp\).

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: g = da.to_graph( da.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices
sage: g.vertices(sort=True)
[-2, -1, 1, 2]
```

```python
sage: g.edges(sort=True)
[(-2, 1, None), (-1, 2, None)]
```

Convert input to a set partition of \(\{1,\ldots,k,-1,\ldots,-k\}\)

Convert a list of a list of numbers to a set partitions. Each list of numbers in the outer list specifies the numbers contained in one of the blocks in the set partition.

If \(k\) is specified, then the set partition will be a set partition of \(\{1,\ldots,k,-1,\ldots,-k\}\). Otherwise, \(k\) will default to the minimum number needed to contain all of the specified numbers.

INPUT:

- \(l\) - a list of lists of integers
- \(k\) - integer (optional, default \(None\))

OUTPUT:

- a list of sets

EXAMPLES:

```python
sage: import sage.combinat.diagram_algebras as da
sage: f = lambda sp: SetPartition(da.to_set_partition(sp))
```

```python
sage: f([[1,-1],[2,-2]]) == SetPartition(da.identity_set_partition(2))
True
```

```python
sage: da.to_set_partition([[1]])
[\{1\}, \{-1\}]
```

```python
sage: da.to_set_partition([[1,-1],[-2,3]],9/2)
[\{-1, 1\}, \{-2, 3\}, \{2\}, \{-4, 4\}, \{-5, 5\}, \{-3\}]
```

5.1.98 Exact Cover Problem via Dancing Links

Use A. Ajanki’s DLXMatrix class to solve the exact cover problem on the matrix \(M\) (treated as a dense binary matrix).

EXAMPLES:

```python
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  # no exact covers
  # optional - sage.modules
sage: for cover in AllExactCovers(M):
  # optional - sage.modules
  ....: print(cover)
```

(continues on next page)
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) # two exact covers
˓→optional - sage.modules
sage: for cover in AllExactCovers(M):
˓→optional - sage.modules
....:
print(cover)
[(1, 1, 0), (0, 0, 1)]
[(1, 0, 1), (0, 1, 0)]

class sage.combinat.dlx.DLXMatrix(ones, initialsolution=None)

Bases: object

Solve the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix M with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1's.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form:
(note the 1-index!):

\[
\begin{bmatrix}
[1, [i_{11}, i_{12}, ..., i_{1r}]] \\
... \\
[m, [i_{m1}, i_{m2}, ..., i_{ms}]]
\end{bmatrix}
\]

where M[j][i_jk] = 1.

The first example below corresponds to the matrix:

\[
\begin{bmatrix}
1 & 1 & 1 & 0 \\
1 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

which is exactly covered by:

\[
\begin{bmatrix}
1 & 1 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

and

\[
\begin{bmatrix}
1 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

EXAMPLES:

sage: from sage.combinat.dlx import *
sage: ones = [[1,[1,2,3]]]
sage: ones+= [[2,[1,3]]]
sage: ones+= [[3,[2]]]
sage: ones+= [[4,[4]]]
sage: DLXM = DLXMatrix(ones,[4])
sage: for C in DLXM:
....:
print(C)

(continues on next page)
Note: The 0 entry is reserved internally for headers in the sparse representation, so rows and columns begin their indexing with 1. Apologies for any heartache this causes. Blame the original author, or fix it yourself.

next()

Search for the first solution we can find, and return it.

Knuth describes the Dancing Links algorithm recursively, though actually implementing it as a recursive algorithm is permissible only for highly restricted problems. (for example, the original author implemented this for Sudoku, and it works beautifully there)

What follows is an iterative description of DLX:

```python
stack <- [(NULL)]
level <- 0
while level >= 0:
    cur <- stack[level]
    if cur = NULL:
        if R[h] = h:
            level <- level - 1
            yield solution
        else:
            cover(best_column)
            stack[level] = best_column
    else if D[cur] != C[cur]:
        if cur != C[cur]:
            delete solution[level]
            for j in L[cur], L[L[cur]], ... , while j != cur:
                uncover(C[j])
            cur <- D[cur]
            solution[level] <- cur
            stack[level] <- cur
            for j in R[cur], R[R[cur]], ... , while j != cur:
                cover(C[j])
            level <- level + 1
            stack[level] <- (NULL)
        else:
            if C[cur] != cur:
                delete solution[level]
                for j in L[cur], L[L[cur]], ... , while j != cur:
                    uncover(C[j])
                uncover(cur)
            level <- level - 1
```

sage.combinat.dlx.**OneExactCover**(M)

Use A. Ajanki’s DLXMatrix class to solve the exact cover problem on the matrix M (treated as a dense binary matrix).

**EXAMPLES:**
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  # no exact covers
˓→optional - sage.modules
sage: OneExactCover(M)
˓→optional - sage.modules

sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])  # two exact covers
˓→optional - sage.modules
sage: OneExactCover(M)
˓→optional - sage.modules
[(1, 1, 0), (0, 0, 1)]

5.1.99 Dyck Words

A class of an object enumerated by the Catalan numbers, see [Sta-EC2], [StaCat98] for details.

AUTHORS:

• Mike Hansen
• Dan Drake (2008-05-30): DyckWordBacktracker support
• Florent Hivert (2009-02-01): Bijections with NonDecreasingParkingFunctions
• Christian Stump (2011-12): added combinatorial maps and statistics
• Mike Zabrocki:
  – (2012-10): added pretty print, characteristic function, more functions
  – (2013-01): added inverse of area/div, bounce/area map
• Jean–Baptiste Priez, Travis Scrimshaw (2013-05-17): Added ASCII art
• Travis Scrimshaw (2013-07-09): Removed CombinatorialClass and added global options.

REFERENCES:

class sage.combinat.dyck_word.CompleteDyckWords
Bases: DyckWords

Abstract base class for all complete Dyck words.

Element

alias of DyckWord_complete

from_Catalan_code(code)

Return the Dyck word associated to the given Catalan code.

A Catalan code of length \( n \) is a sequence \((a_1, a_2, \ldots, a_n)\) of \( n \) integers \( a_i \) such that:

• \( 0 \leq a_i \leq n - i \) for every \( i \);
• if \( i < j \) and \( a_i > 0 \) and \( a_j > 0 \) and \( a_{i+1} = a_{i+2} = \ldots = a_{j-1} = 0 \), then \( a_i - a_j < j - i \).

It turns out that the Catalan codes of length \( n \) are in bijection with Dyck words.

The Catalan code of a Dyck word is example (x) in Richard Stanley’s exercises on combinatorial interpretations for Catalan objects. The code in this example is the reverse of the description provided there. See [Sta-EC2] and [StaCat98].

EXAMPLES:
from_area_sequence(code)

Return the Dyck word associated to the given area sequence code.

See to_area_sequence() for a definition of the area sequence of a Dyck word.

See also:
area(), to_area_sequence().

INPUT:

• code – a list of integers satisfying code[0] == 0 and 0 <= code[i+1] <= code[i]+1.

EXAMPLES:

sage: DyckWords().from_area_sequence([])
[]
sage: DyckWords().from_area_sequence([0])
[1, 0]
sage: DyckWords().from_area_sequence([0, 1])
[1, 1, 0, 0]
sage: DyckWords().from_area_sequence([0, 0])
[1, 0, 1, 0]

from_non_decreasing_parking_function(pf)

Bijection from non-decreasing parking functions.

See there the method to_dyck_word() for more information.

EXAMPLES:

sage: D = DyckWords()
sage: D.from_non_decreasing_parking_function([])
[]
sage: D.from_non_decreasing_parking_function([1])
[1, 0]
sage: D.from_non_decreasing_parking_function([1,1])
[1, 1, 0, 0]
sage: D.from_non_decreasing_parking_function([1,2])
[1, 0, 1, 0]
sage: D.from_non_decreasing_parking_function([1,1,1])
[1, 1, 0, 0, 0]
sage: D.from_non_decreasing_parking_function([1,2,3])
[1, 0, 1, 0, 1, 0]
from_noncrossing_partition(ncp)

Convert a noncrossing partition ncp to a Dyck word.

EXAMPLES:

```sage
sage: DyckWord(noncrossing_partition=[[1,2]])  # indirect doctest
[1, 1, 0, 0]
sage: DyckWord(noncrossing_partition=[[1],[2]])
[1, 0, 1, 0]
sage: dws = DyckWords(5).list()
sage: ncps = [x.to_noncrossing_partition() for x in dws]
sage: dws2 = [DyckWord(noncrossing_partition=x) for x in ncps]
sage: dws == dws2
True
```

class sage.combinat.dyck_word.CompleteDyckWords_all

Bases: CompleteDyckWords, DyckWords_all

All complete Dyck words.

class height_poset

Bases: UniqueRepresentation, Parent

The poset of complete Dyck words compared componentwise by heights.

This is, D is smaller than or equal to D' if it is weakly below D'.

This is implemented by comparison of area sequences.

def le(dw1, dw2)

Compare two Dyck words of equal size, and return True if all of the heights of dw1 are less than or equal to the respective heights of dw2.

See also:

to_area_sequence()

EXAMPLES:

```sage
sage: poset = DyckWords().height_poset()
sage: poset.le(DyckWord([]), DyckWord([]))
True
sage: poset.le(DyckWord([1,0]), DyckWord([1,0]))
True
sage: poset.le(DyckWord([1,0,1,0]), DyckWord([1,1,0,0]))
True
sage: poset.le(DyckWord([1,1,0,0]), DyckWord([1,0,1,0]))
False
sage: [poset.le(dw1, dw2)
....:  for dw1 in DyckWords(3) for dw2 in DyckWords(3)]
[True, True, True, True, True, False, True, False, True, False, True, False, True, False, False, True, True, False, False, False, False, False, True]
```

class sage.combinat.dyck_word.CompleteDyckWords_size(k)

Bases: CompleteDyckWords, DyckWords_size

All complete Dyck words of a given size.
cardinality()

Return the number of complete Dyck words of semilength \( n \), i.e. the \( n \)-th Catalan number.

**EXAMPLES:**

```python
sage: DyckWords(4).cardinality()
14
sage: ns = list(range(9))
sage: dws = [DyckWords(n) for n in ns]
sage: all(dw.cardinality() == len(dw.list()) for dw in dws)
True
```

random_element()

Return a random complete Dyck word of semilength \( n \).

The algorithm is based on a classical combinatorial fact. One chooses at random a word with \( n \) 0’s and \( n + 1 \) 1’s. One then considers every 1 as an ascending step and every 0 as a descending step, and one finds the lowest point of the path (with respect to a slightly tilted slope). One then cuts the path at this point and builds a Dyck word by exchanging the two parts of the word and removing the initial step.

Todo: extend this to m-Dyck words

**EXAMPLES:**

```python
sage: dw = DyckWords(8)
sage: dw.random_element()  # random
[1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 1, 0, 1, 0, 1, 0]
sage: D = DyckWords(8)
sage: D.random_element() in D
True
```

class sage.combinat.dyck_word.DyckWord(parent, l, latex_options={})

Bases: CombinatorialElement

A Dyck word.

A Dyck word is a sequence of open and close symbols such that every close symbol has a corresponding open symbol preceding it. That is to say, a Dyck word of length \( n \) is a list with \( k \) entries 1 and \( n - k \) entries 0 such that the first \( i \) entries always have at least as many 1s among them as 0s. (Here, the 1 serves as the open symbol and the 0 as the close symbol.) Alternatively, the alphabet 1 and 0 can be replaced by other characters such as ‘(’ and ‘)’.

A Dyck word is complete if every open symbol moreover has a corresponding close symbol.

A Dyck word may also be specified by either a noncrossing partition or by an area sequence or the sequence of heights.

A Dyck word may also be thought of as a lattice path in the \( \mathbb{Z}^2 \) grid, starting at the origin \((0,0)\), and with steps in the North \( N = (0,1) \) and east \( E = (1,0) \) directions such that it does not pass below the \( x = y \) diagonal. The diagonal is referred to as the “main diagonal” in the documentation. A North step is represented by a 1 in the list and an East step is represented by a 0.

Equivalently, the path may be represented with steps in the \( NE = (1,1) \) and the \( SE = (1,-1) \) direction such that it does not pass below the horizontal axis.

A path representing a Dyck word (either using \( N \) and \( E \) steps, or using \( NE \) and \( SE \) steps) is called a Dyck path.
EXAMPLES:

sage: dw = DyckWord([1, 0, 1, 0]); dw
[1, 0, 1, 0]
sage: print(dw)
()()
sage: dw.height()
1
sage: dw.to_noncrossing_partition()
{{1}, {2}}

sage: DyckWord('()()')
[1, 0, 1, 0]
sage: DyckWord('(())')
[1, 1, 0, 0]
sage: DyckWord('(()')
[1, 1]
sage: DyckWord('')
[]

sage: DyckWord(noncrossing_partition=[[1],[2]])
[1, 0, 1, 0]
sage: DyckWord(noncrossing_partition=[[1,2]])
[1, 1, 0, 0]
sage: DyckWord(noncrossing_partition=[])  # Empty list
[]

sage: DyckWord(area_sequence=[0,0])
[1, 0, 1, 0]
sage: DyckWord(area_sequence=[0,1])
[1, 1, 0, 0]
sage: DyckWord(area_sequence=[0,1,2,2,0,1,1,2])

(continues on next page)

/\  
sage: DyckWord([1,0,1,1,0,0]).pretty_print()  
___  
| x  
|x| .  
| . .

**ascent_prime_decomposition()**

Decompose this Dyck word into a sequence of ascents and prime Dyck paths.

A Dyck word is *prime* if it is complete and has precisely one return - the final step. In particular, the empty Dyck path is not prime. Thus, the factorization is unique.

This decomposition yields a sequence of odd length: the words with even indices consist of up steps only, the words with odd indices are prime Dyck paths. The concatenation of the result is the original word.

**EXAMPLES:**

sage: D = DyckWord([1,1,0,1,1,0,0,1,1,1,0,1])
sage: D.ascent_prime_decomposition()  
[[1, 1], [1, 0], [], [1, 0], [1, 1, 1], [1, 0], [1]]

sage: DyckWord([]).ascent_prime_decomposition()  
[]

sage: DyckWord([1,1]).ascent_prime_decomposition()  
[[1, 1]]

sage: DyckWord([1,0,1,0]).ascent_prime_decomposition()  
[[], [1, 0], [], [1, 0], []]

**associated_parenthesis(pos)**

Report the position for the parenthesis in `self` that matches the one at position `pos`.

The positions in `self` are counted from 0.

**INPUT:**

- `pos` – the index of the parenthesis in the list

**OUTPUT:**

- Integer representing the index of the matching parenthesis. If no parenthesis matches, return `None`.

---

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: DyckWord([1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(0)
1
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(1)
0
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(2)
3
sage: DyckWord([1, 0, 1, 0]).associated_parenthesis(3)
2
sage: DyckWord([1, 1, 0, 0]).associated_parenthesis(0)
3
sage: DyckWord([1, 1, 0, 0]).associated_parenthesis(2)
1
sage: DyckWord([1, 1]).associated_parenthesis(0)
2
```

catalan_factorization()

Decompose this Dyck word into a sequence of complete Dyck words.

Each element of the list returned is a (possibly empty) complete Dyck word. The original word is obtained by placing an up step between each of these complete Dyck words. Thus, the number of words returned is one more than the final height.

See Section 1.2 of [CC1982] or Lemma 9.1.1 of [Lot2005].

EXAMPLES:

```python
sage: D = DyckWord([1,1,1,0,1,0,1,1,1,1,0,1])
sage: D.catalan_factorization()
[[], [], [1, 0, 1, 0], [], [], [1, 0], []]
sage: DyckWord([]).catalan_factorization()
[[[]]]
sage: DyckWord([1,1]).catalan_factorization()
[[], [], []]
sage: DyckWord([1,0,1,0]).catalan_factorization()
[[[1, 0, 1, 0]]]
```

height()

Return the height of self.

We view the Dyck word as a Dyck path from \((0, 0)\) to \((2n, 0)\) in the first quadrant by letting 1’s represent steps in the direction \((1, 1)\) and 0’s represent steps in the direction \((1, -1)\).

The height is the maximum \(y\)-coordinate reached.

See also:

heights()

EXAMPLES:
heights()

Return the heights of self.

We view the Dyck word as a Dyck path from \((0,0)\) to \((2n,0)\) in the first quadrant by letting 1’s represent steps in the direction \((1,1)\) and 0’s represent steps in the direction \((1,-1)\).

The heights is the sequence of the \(y\)-coordinates of all \(2n + 1\) lattice points along the path.

See also:

from_heights(), min_from_heights()

EXAMPLES:

```python
sage: DyckWord([]).heights()
(0,)
sage: DyckWord([1,0]).heights()
(0, 1, 0)
sage: DyckWord([1, 1, 0, 0]).heights()
(0, 1, 2, 1, 0)
sage: DyckWord([1, 1, 0, 1, 0]).heights()
(0, 1, 2, 1, 2, 1)
sage: DyckWord([1, 1, 0, 0, 1, 0]).heights()
(0, 1, 2, 1, 0, 1, 0)
sage: DyckWord([1, 0, 1, 0]).heights()
(0, 1, 0, 1, 0)
sage: DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]).heights()
(0, 1, 2, 1, 0, 1, 2, 3, 2, 1, 0)
```

is_complete()

Return True if self is complete.

A Dyck word \(d\) is complete if \(d\) contains as many closers as openers.

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).is_complete()
True
sage: DyckWord([1, 0, 1, 1, 0]).is_complete()
False
```
latex_options()

Return the latex options for use in the _latex_ function as a dictionary.

The default values are set using the options.

- **tikz_scale** – (default: 1) scale for use with the tikz package.
- **diagonal** – (default: False) boolean value to draw the diagonal or not.
- **line_width** – (default: 2*``tikz_scale``) value representing the line width.
- **color** – (default: black) the line color.
- **bounce_path** – (default: False) boolean value to indicate if the bounce path should be drawn.
- **peaks** – (default: False) boolean value to indicate if the peaks should be displayed.
- **valleys** – (default: False) boolean value to indicate if the valleys should be displayed.

EXAMPLES:

```sage
sage: D = DyckWord([1,0,1,0,1,0])
sage: D.latex_options()
{'bounce_path': False,
 'color': 'black',
 'diagonal': False,
 'line width': 2,
 'peaks': False,
 'tikz_scale': 1,
 'valleys': False}
```

**Todo**: This should probably be merged into DyckWord.options.

length()

Return the length of self.

EXAMPLES:

```sage
sage: DyckWord([1, 0, 1, 0]).length()
4
sage: DyckWord([1, 0, 1, 1, 0]).length()
5
```

number_of_close_symbols()

Return the number of close symbols in self.

EXAMPLES:

```sage
sage: DyckWord([1, 0, 1, 0]).number_of_close_symbols()
2
sage: DyckWord([1, 0, 1, 1, 0]).number_of_close_symbols()
2
```

number_of_double_rises()

Return the number of positions in self where there are two consecutive 1’s.

EXAMPLES:
number_of_initial_rises()

Return the length of the initial run of self.

OUTPUT:

• a non–negative integer indicating the length of the initial rise

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).number_of_initial_rises()
1
sage: DyckWord([1, 1, 0, 0]).number_of_initial_rises()
2
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_initial_rises()
2
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_initial_rises()
1
```

number_of_open_symbols()

Return the number of open symbols in self.

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).number_of_open_symbols()
2
sage: DyckWord([1, 0, 1, 1, 0]).number_of_open_symbols()
3
```

number_of_peaks()

Return the number of peaks of the Dyck path associated to self.

See also:

peaks(), number_of_valleys()

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).number_of_peaks()
2
sage: DyckWord([1, 1, 0, 0]).number_of_peaks()
1
sage: DyckWord([1,1,0,1,0,1,0,0]).number_of_peaks()
3
sage: DyckWord([]).number_of_peaks()
0
```

number_of_touch_points()

Return the number of touches of self at the main diagonal.
OUTPUT:

- a non-negative integer

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_touch_points()
2
sage: DyckWord([1, 1, 0, 0]).number_of_touch_points()
1
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_touch_points()
2
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_touch_points()
2
```

**number_of_valleys()**

Return the number of valleys of `self`.

See also:

`number_of_peaks()`, `valleys()`

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).number_of_valleys()
1
sage: DyckWord([1, 1, 0, 0]).number_of_valleys()
0
sage: DyckWord([1, 1, 0, 0, 1, 0]).number_of_valleys()
1
sage: DyckWord([1, 0, 1, 1, 0, 0]).number_of_valleys()
1
```

**peaks()**

Return a list of the positions of the peaks of a Dyck word.

A peak is 1 followed by a 0. Note that this does not agree with the definition given in [Hag2008].

See also:

`valleys()`, `number_of_peaks()`

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).peaks()
[0, 2]
sage: DyckWord([1, 1, 0, 0]).peaks()
[1]
sage: DyckWord([1, 1, 0, 1, 0, 1, 0, 0]).peaks()  # Haglund's def gives 2
[1, 3, 5]
```

**plot(****kwds**)**

Plot a Dyck word as a continuous path.

EXAMPLES:

```
sage: w = DyckWords(100).random_element()
sage: w.plot()
```

(continues on next page)
position_of_first_return()

Return the number of vertical steps before the Dyck path returns to the main diagonal.

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).position_of_first_return()
1
sage: DyckWord([1, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0, 0]).position_of_first_return()
7
sage: DyckWord([1, 1, 0, 0]).position_of_first_return()
2
sage: DyckWord([1, 0, 1, 0]).position_of_first_return()
1
sage: DyckWord([]).position_of_first_return()
0
```

positions_of_double_rises()

Return a list of positions in self where there are two consecutive 1’s.

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 1, 0]).positions_of_double_rises()
[2, 5]
sage: DyckWord([1, 1, 0, 0]).positions_of_double_rises()
[0]
sage: DyckWord([1, 0, 1, 0]).positions_of_double_rises()
[]
```

pp(type=None, labelling=None, underpath=True)

Display a DyckWord as a lattice path in the \( \mathbb{Z}^2 \) grid.

If the type is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

If the type is “NE-SE”, then the path is simply printed as up steps and down steps.

INPUT:

- type – (default: None) can either be:
  - None to use the option default
  - “N-E” to show self as a path of north and east steps, or
  - “NE-SE” to show self as a path of north-east and south-east steps.
- labelling – (if type is “N-E”) a list of labels assigned to the up steps in self.
- underpath – (if type is “N-E”, default:True) If True, the labelling is shown under the path; otherwise, it is shown to the right of the path.
EXAMPLES:

```python
sage: for D in DyckWords(3): D.pretty_print()

_   |   _
|   | .
| .
___|   x
|   | .
| .
___|   x

   ______
  | x x x 16
 ___| x x . 15
| x x x .. 14

(continues on next page)
pretty_print(type=None, labelling=None, underpath=True)

Display a DyckWord as a lattice path in the $\mathbb{Z}^2$ grid.

If the type is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

If the type is “NE-SE”, then the path is simply printed as up steps and down steps.

INPUT:

- **type** – (default: None) can either be:
  - None to use the option default
  - “N-E” to show self as a path of north and east steps, or
  - “NE-SE” to show self as a path of north-east and south-east steps.

- **labelling** – (if type is “N-E”) a list of labels assigned to the up steps in self.

- **underpath** – (if type is “N-E”, default: True) If True, the labelling is shown under the path; otherwise, it is shown to the right of the path.

EXAMPLES:

sage: for D in DyckWords(3): D.pretty_print()
sage: for D in DyckWords(3): D.pretty_print(type="NE-SE")

sage: D = DyckWord([1,1,1,0,1,0,0,1,1])
sage: D.pretty_print()

sage: D = DyckWord([1,1,1,0,1,0,0,1,1,0])
sage: D.pretty_print()

sage: D = DyckWord([1,1,1,0,1,0,0,1,1,0,0])
sage: D.pretty_print()

sage: DyckWord(area_sequence=[0,1,0]).pretty_print(labelling=[1,3,2])
sage: DyckWord(area_sequence=[0,1,1,2,3,2,3,3,2,0,1,1,2,3,4,2,3]).pretty_print(labelling=list(range(17)),underpath=False)

| x x x 16

| x . . . . . . . . . . . 1
| . . . . . . . . . . . . 0
Combinatorics, Release 10.1

```
sage: DyckWord([]).pretty_print()
```

`returns_to_zero()`

Return a list of positions where `self` has height 0, excluding the position 0.

EXAMPLES:

```
sage: DyckWord([]).returns_to_zero()
[]
sage: DyckWord([1, 0]).returns_to_zero()
[2]
sage: DyckWord([1, 0, 1, 0]).returns_to_zero()
[2, 4]
sage: DyckWord([1, 1, 0, 0]).returns_to_zero()
[4]
```

`rise_composition()`

The sequences of lengths of runs of 1’s in `self`. Also equal to the sequence of lengths of vertical segments in the Dyck path.

EXAMPLES:

```
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).pretty_print()
   ___
   | x
   |_______| .
   | x x x . .
   | x x . . .
   |__| x . . .
   |  | x . . .
   |   | . . .

sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).rise_composition()
[2, 3, 2]
sage: DyckWord([1,1,0,0]).rise_composition()
[2]
sage: DyckWord([1,0,1,0]).rise_composition()
[1, 1]
```

`set_latex_options(D)`

Set the latex options for use in the `_latex_` function.

The default values are set in the `__init__` function.

- `tikz_scale` – (default: 1) scale for use with the tikz package.
- `diagonal` – (default: `False`) boolean value to draw the diagonal or not.
- `line_width` – (default: `2*``tikz_scale``") value representing the line width.
- `color` – (default: black) the line color.
- `bounce path` – (default: `False`) boolean value to indicate if the bounce path should be drawn.
- `peaks` – (default: `False`) boolean value to indicate if the peaks should be displayed.
- `valleys` – (default: `False`) boolean value to indicate if the valleys should be displayed.
**INPUT:**

- $D$ – a dictionary with a list of latex parameters to change

**EXAMPLES:**

```python
sage: D = DyckWord([1,0,1,0,1,0])
sage: D.set_latex_options({"tikz_scale":2})
sage: D.set_latex_options({"valleys":True, "color":"blue"})
```

**Todo:** This should probably be merged into DyckWord.options.

**tamari_interval(other)**

Return the Tamari interval between `self` and `other` as a `TamariIntervalPoset`.

A “Tamari interval” means an interval in the Tamari order. The Tamari order on the set of Dyck words of size $n$ is the partial order obtained from the Tamari order on the set of binary trees of size $n$ (see `tamari_lequal()`) by means of the Tamari bijection between Dyck words and binary trees (`to_dyck_word_tamari()`).

**INPUT:**

- `other` – a Dyck word greater or equal to `self` in the Tamari order

**EXAMPLES:**

```python
sage: dw = DyckWord([1, 1, 0, 1, 0, 0, 1, 0])
sage: ip = dw.tamari_interval(DyckWord([1, 1, 1, 0, 0, 1, 0, 0])); ip
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, ___)]
sage: ip.lower_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]
sage: ip.upper_dyck_word()
[1, 1, 1, 0, 0, 1, 0, 0]
sage: ip.interval_cardinality()
4
sage: ip.number_of_tamari_inversions()
2
sage: list(ip.dyck_words())
[[1, 1, 1, 0, 0, 1, 0, 0],
 [1, 1, 1, 0, 0, 0, 1, 0],
 [1, 1, 0, 1, 0, 1, 0, 0],
 [1, 1, 0, 1, 0, 0, 1, 0]]
sage: dw.tamari_interval(DyckWord([1,1,0,0,1,1,0,0]))
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice
```

**to_area_sequence()**

Return the area sequence of the Dyck word `self`.

The area sequence of a Dyck word $w$ is defined as follows: Representing the Dyck word $w$ as a Dyck path from $(0, 0)$ to $(n, n)$ using $N$ and $E$ steps (this involves padding $w$ by $E$ steps until $w$ reaches the main diagonal if $w$ is not already a complete Dyck path), the area sequence of $w$ is the sequence $(a_1, a_2, \ldots, a_n)$, where $a_i$ is the number of full cells in the $i$-th row of the rectangle $[0, n] \times [0, n]$ which lie completely above the diagonal. (The cells are the regions into which the rectangle is subdivided by the lines $x = i$ with $i$
integer and the lines $y = j$ with $j$ integer. The $i$-th row consists of all the cells between the lines $y = i - 1$ and $y = i$.)

An alternative definition: Representing the Dyck word $w$ as a Dyck path consisting of $NE$ and $SE$ steps, the area sequence is the sequence of ordinates of all lattice points on the path which are starting points of $NE$ steps.

A list of integers $l$ is the area sequence of some Dyck path if and only if it satisfies $l_0 = 0$ and $0 \leq l_{i+1} \leq l_i + 1$ for $i > 0$.

**EXAMPLES:**

```python
sage: DyckWord([]).to_area_sequence()
[]
sage: DyckWord([1, 0]).to_area_sequence()
[0]
sage: DyckWord([1, 1, 0, 0]).to_area_sequence()
[0, 1]
sage: DyckWord([1, 0, 1, 0]).to_area_sequence()
[0, 0]
sage: all(dw == DyckWords().from_area_sequence(dw.to_area_sequence())
....:     for i in range(6) for dw in DyckWords(i))
True
sage: DyckWord([1,0,1,0,1,0,1,0,1,0,1,0]).to_area_sequence()
[0, 0, 0, 0, 0]
```

**to_binary_tree**(usemap='1L0R')

Return a binary tree recursively constructed from the Dyck path `self` by the map `usemap`. The default `usemap` is '1L0R' which means:

- an empty Dyck word is a leaf,
- a non empty Dyck word reads 1L0R where $L$ and $R$ correspond to respectively its left and right subtrees.

**INPUT:**

- `usemap` – a string, either '1L0R', '1R0L', 'L1R0', 'R1L0'

Other valid `usemap` are '1R0L', 'L1R0', and 'R1L0'. These correspond to different maps from Dyck paths to binary trees, whose recursive definitions are hopefully clear from the names.

**EXAMPLES:**

```python
sage: dw = DyckWord([1,0])
sage: dw.to_binary_tree()
[., .]
sage: dw = DyckWord([])
sage: dw.to_binary_tree()
.
sage: dw = DyckWord([1,0,1,1,0,0])

(continues on next page)```
sage: dw.to_binary_tree()
[., [[., .], .]]
sage: dw.to_binary_tree("L1R0")
[[., .], [., .]]
sage: dw = DyckWord([1,0,1,0,1,0,1,0,0])
sage: dw.to_binary_tree() == dw.to_binary_tree("1R0L").left_right_symmetry()
True
sage: dw.to_binary_tree() == dw.to_binary_tree("L1R0").left_border_symmetry()
False
sage: dw.to_binary_tree("1R0L") == dw.to_binary_tree("L1R0").left_right_symmetry()
True
sage: dw.to_binary_tree("R1L0") == dw.to_binary_tree("L1R0").left_right_symmetry()
True
sage: dw.to_binary_tree("R10L")
Traceback (most recent call last):
  ...:
ValueError: R10L is not a correct map

**to_binary_tree_tamari()**

Return the binary tree corresponding to self in a way which is consistent with the Tamari orders on the set of Dyck paths and on the set of binary trees.

This is the 'L1R0' map documented in to_binary_tree().

**EXAMPLES:**

```python
sage: DyckWord([1,0]).to_binary_tree_tamari()
[., .]
sage: DyckWord([1,0,1,1,0,0]).to_binary_tree_tamari()
[[., .], [., .]]
sage: DyckWord([1,0,1,0,1,0]).to_binary_tree_tamari()
[[[., .], .], .]
```

**to_path_string(unicode=False)**

Return a path representation of the Dyck word consisting of steps / and \.

**INPUT:**

- unicode – boolean (default False) whether to use unicode

**EXAMPLES:**

```python
sage: print(DyckWord([1, 0, 1, 0]).to_path_string())  
/\/

sage: print(DyckWord([1, 1, 0, 0]).to_path_string())  
/\  
/\  \  
```

(continued from previous page)
to_standard_tableau()

Return a standard tableau of shape \((a, b)\) where \(a\) is the number of open symbols and \(b\) is the number of close symbols in \texttt{self}.

EXAMPLES:

```
sage: DyckWord([]).to_standard_tableau()
[]
sage: DyckWord([1, 0]).to_standard_tableau()
[[1], [2]]
sage: DyckWord([1, 1, 0, 0]).to_standard_tableau()
[[1, 2], [3, 4]]
sage: DyckWord([1, 0, 1, 0]).to_standard_tableau()
[[1, 3], [2, 4]]
sage: DyckWord([1, 0, 1]).to_standard_tableau()
[[1, 3], [2]]
```

to_tamari_sorting_tuple()

Convert a Dyck word to a Tamari sorting tuple.

The result is a list of integers, one for every up-step from left to right. To each up-step is associated the distance to the corresponding down step in the Dyck word.

This is useful for a faster conversion to binary trees.

EXAMPLES:

```
sage: DyckWord([]).to_tamari_sorting_tuple()
[]
sage: DyckWord([1, 0]).to_tamari_sorting_tuple()
[0]
sage: DyckWord([1, 1, 0, 0]).to_tamari_sorting_tuple()
[1, 0]
sage: DyckWord([1, 0, 1, 0]).to_tamari_sorting_tuple()
[0, 0]
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_tamari_sorting_tuple()
[2, 0, 0]
```

See also:

to_Catalan_code()

touch_composition()

Return a composition which indicates the positions where \texttt{self} returns to the diagonal.

This assumes \texttt{self} to be a complete Dyck word.

OUTPUT:

- a composition of length equal to the length of the Dyck word.

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).touch_composition()
[1, 1]
sage: DyckWord([1, 1, 0, 0]).touch_composition()
[1, 1]
```

(continues on next page)
touch_points()

Return the abscissae (or, equivalently, ordinates) of the points where the Dyck path corresponding to self (comprising NE and SE steps) touches the main diagonal. This includes the last point (if it is on the main diagonal) but excludes the beginning point.

Note that these abscissae are precisely the entries of returns_to_zero() divided by 2.

OUTPUT:
• a list of integers indicating where the path touches the diagonal

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).touch_points()
[1, 2]
sage: DyckWord([1, 1, 0, 0]).touch_points()
[2]
sage: DyckWord([1, 1, 0, 1, 0, 0]).touch_points()
[2, 3]
sage: DyckWord([1, 0, 1, 1, 0, 0]).touch_points()
[1, 3]
```

valleys()

Return a list of the positions of the valleys of a Dyck word.

A valley is 0 followed by a 1.

See also:
`peaks()`, `number_of_valleys()`

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).valleys()
[1]
sage: DyckWord([1, 1, 0, 0]).valleys()
[]
sage: DyckWord([1, 1, 0, 1, 0, 1, 0, 0]).valleys()
[2, 4]
```

class sage.combinat.dyck_word.DyckWordBacktracker(k1, k2)

Bases: GenericBacktracker

This class is an iterator for all Dyck words with \( n \) opening parentheses and \( n - k \) closing parentheses using the backtracker class. It is used by the DyckWords_size class.

This is not really meant to be called directly, partially because it fails in a couple corner cases: \( \text{DWB}(0) \) yields \([0]\), not the empty word, and \( \text{DWB}(k, k+1) \) yields something (it shouldn't yield anything). This could be fixed with a sanity check in \_rec(), but then we'd be doing the sanity check \emph{every time} we generate new objects; instead, we do \emph{one} sanity check in DyckWords and assume here that the sanity check has already been made.
AUTHOR:

- Dan Drake (2008-05-30)

class sage.combinat.dyck_word.DyckWord_complete(parent, l, latex_options={})

Bases: DyckWord

The class of complete Dyck words. A Dyck word is complete, if it contains as many closers as openers.

For further information on Dyck words, see DyckWords_class.

area()

Return the area for self corresponding to the area of the Dyck path.

One can view a balanced Dyck word as a lattice path from (0, 0) to (n, n) in the first quadrant by letting ‘1’s represent steps in the direction (1, 0) and ‘0’s represent steps in the direction (0, 1). The resulting path will remain weakly above the diagonal y = x.

The area statistic is the number of complete squares in the integer lattice which are below the path and above the line y = x. The ‘half-squares’ directly above the line y = x do not contribute to this statistic.

EXAMPLES:

sage: dw = DyckWord([1,0,1,0])
sage: dw.area() # 2 half-squares, 0 complete squares
0

sage: dw = DyckWord([1,1,1,0,1,1,0,0,1,0,1,0,0])
sage: dw.area()
19

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 5 complete squares
5

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 4 complete squares
4

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 3 complete squares
3

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 2 complete squares
2

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 1 complete square
1

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 1 complete square
1

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 2 complete squares
2

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 3 complete squares
3

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 4 complete squares
4

sage: DyckWord([1,1,1,0,1,0,0,0]).area() # 5 complete squares
5

(continues on next page)
area_dinv_to_bounce_area_map()

Return the image of self under the map which sends a Dyck word with area equal to \( r \) and dinv equal to \( s \) to a Dyck word with bounce equal to \( r \) and area equal to \( s \).

The inverse of this map is bounce_area_to_area_dinv_map().

For a definition of this map, see [Hag2008] p. 50 where it is called \( \zeta \). However, this map differs from Haglund’s map by an application of reverse() (as does the definition of the bounce() statistic).

EXAMPLES:

```python
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area_dinv_to_bounce_area_map()
[1, 0, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0]
```

bounce()

Return the bounce statistic of self due to J. Haglund, see [Hag2008].

One can view a balanced Dyck word as a lattice path from \((0, 0)\) to \((n, n)\) in the first quadrant by letting \('1's represent steps in the direction \((0, 1)\) and \('0's represent steps in the direction \((1, 0)\). The resulting path will remain weakly above the diagonal \(y = x\).

We describe the bounce statistic of such a path in terms of what is known as the “bounce path”.

We can think of our bounce path as describing the trail of a billiard ball shot West from \((n, n)\), which “bounces” down whenever it encounters a vertical step and “bounces” left when it encounters the line \(y = x\).

The bouncing ball will strike the diagonal at the places

\[(0, 0), (j_1, j_1), (j_2, j_2), \ldots, (j_r - 1, j_r - 1), (j_r, j_r) = (n, n)\].

We define the bounce to be the sum \(\sum_{i=1}^{r-1} j_i\).

EXAMPLES:

```python
sage: DyckWord([1,1,1,0,1,1,0,0,0,1,1,0,0,1,0,0,0]).bounce()
7
sage: DyckWord([1,1,1,1,0,0,0,0]).bounce()
(continues on next page)```
sage: DyckWord([1,1,1,0,1,0,0,0]).bounce()
1
sage: DyckWord([1,1,1,0,1,0,0,0]).bounce()
2
sage: DyckWord([1,1,1,1,0,0,1,0]).bounce()
3
sage: DyckWord([1,0,1,1,0,1,0,0]).bounce()
3
sage: DyckWord([1,1,0,1,1,0,0,0]).bounce()
1
sage: DyckWord([1,1,0,0,1,1,0,0]).bounce()
2
sage: DyckWord([1,0,1,1,1,0,0,0]).bounce()
1
sage: DyckWord([1,0,1,1,1,0,0,0]).bounce()
4
sage: DyckWord([1,0,1,1,1,0,0,0]).bounce()
3
sage: DyckWord([1,1,0,0,1,0,1,0]).bounce()
5
sage: DyckWord([1,1,0,0,1,0,1,0]).bounce()
4
sage: DyckWord([1,1,0,1,0,1,0,0]).bounce()
2
sage: DyckWord([1,0,1,0,1,0,1,0]).bounce()
6

**bounce_area_to_area_dinv_map()**

Return the image of the Dyck word under the map which sends a Dyck word with bounce equal to \( r \) and area equal to \( s \) to a Dyck word with area equal to \( r \) and dinv equal to \( s \).

This implementation uses a recursive method by saying that the last entry in the area sequence of the Dyck word \( \text{self} \) is equal to the number of touch points of the Dyck path minus 1 of the image of this map.

The inverse of this map is **area_dinv_to_bounce_area_map()**.

For a definition of this map, see [Hag2008] p. 50 where it is called \( \zeta^{-1} \). However, this map differs from Haglund’s map by an application of reverse() (as does the definition of the bounce() statistic).

**EXAMPLES:**

```python
sage: DyckWord([1,1,0,1,0,1,0,0,1,1,0,1,0,0]).bounce_area_to_area_dinv_map() [1, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 0]
sage: DyckWord([1,1,0,1,0,1,0,0,1,1,0,1,0,0]).area() 5
sage: DyckWord([1,1,0,1,0,1,0,0,1,1,0,1,0,0]).bounce() 9
sage: DyckWord([1,1,0,1,0,1,0,0,1,1,0,1,0,0]).area() 9
sage: DyckWord([1,1,0,1,0,1,0,0,1,1,0,1,0,0]).dinv() 5
sage: all(D==D.bounce_area_to_area_dinv_map().area_dinv_to_bounce_area_map() for D in DyckWords(6))
True
```
Combinatorics, Release 10.1

(continued from previous page)

True
sage: DyckWord([1,1,0,0]).bounce_area_to_area_dinv_map()
[1, 0, 1, 0]
sage: DyckWord([1,0,1,0]).bounce_area_to_area_dinv_map()
[1, 1, 0, 0]

bounce_path()

Return the bounce path of self formed by starting at \((n, n)\) and traveling West until encountering the first vertical step of self, then South until encountering the diagonal, then West again to hit the path, etc. until the \((0, 0)\) point is reached. The path followed by this walk is the bounce path.

See also:

bounce()

EXAMPLES:

sage: DyckWord([1,1,0,1,0,0]).bounce_path()
[1, 0, 1, 1, 0, 0]
sage: DyckWord([1,1,1,0,0,0]).bounce_path()
[1, 1, 1, 0, 0, 0]
sage: DyckWord([1,0,1,0,1,0]).bounce_path()
[1, 0, 1, 0, 1, 0]
sage: DyckWord([1,1,1,1,0,0,1,0,0,0]).bounce_path()
[1, 1, 0, 0, 1, 1, 1, 0, 0, 0]

characteristic_symmetric_function(q=None, R=Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field)

The characteristic function of self is the sum of \(q^{\text{dinv}(D,F)}Q_{\text{ides}(\text{read}(D,F))}\) over all permutation fillings of the Dyck path representing self, where \(\text{ides}(\text{read}(D, F))\) is the descent composition of the inverse of the reading word of the filling.

INPUT:

• q – (default: \(q = R('q')\)) a parameter for the generating function power

• R – (default : \(R = QQ['q', 't'].fraction_field()\)) the base ring to do the calculations over

OUTPUT:

• an element of the symmetric functions over the ring \(R\) (in the Schur basis).

EXAMPLES:

sage: R = QQ['q','t'].fraction_field()
sage: (q,t) = R.gens()
sage: f = sum(t**D.area()*D.characteristic_symmetric_function() for D in DyckWords(3)); f
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: f.nabla(power=-1)
s[1, 1, 1]

decomposition_reverse()

Return the involution of self with a recursive definition.

If a Dyck word \(D\) decomposes as \(1D_10D_2\) where \(D_1\) and \(D_2\) are complete Dyck words then the decomposition reverse is \(1\phi(D_2)0\phi(D_1)\).
EXAMPLES:

```python
sage: DyckWord([1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]).decomposition_reverse()
[1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]
```

```python
sage: DyckWord([1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]).decomposition_reverse()
[1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]
```

```python
sage: DyckWord([1,1,0,0]).decomposition_reverse()
[1, 0, 1, 0]
```

```python
sage: DyckWord([1,0,1,0]).decomposition_reverse()
[1, 1, 0, 0]
```

```python
dinv(labeling=None)
Return the dinv statistic of self due to M. Haiman, see [Hag2008].
If a labeling is provided then this function returns the dinv of the labeled Dyck word.

INPUT:
- labeling – an optional argument to be viewed as the labelings of the vertical edges of the Dyck path

OUTPUT:
- an integer representing the dinv statistic of the Dyck path or the labelled Dyck path.

EXAMPLES:

```python
sage: DyckWord([1,0,1,0,1,0,1,0,1,0]).dinv()
10
sage: DyckWord([1,1,1,1,1,0,0,0,0,0]).dinv()
0
sage: DyckWord([1,1,1,1,0,1,0,0,0,0]).dinv()
1
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv()
13
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv([1,2,3,4,5,6,7])
11
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).dinv([6,7,5,3,4,2,1])
2
```

```python
first_return_decomposition()
Decompose a Dyck word into a pair of Dyck words (potentially empty) where the first word consists of the word after the first up step and the corresponding matching closing parenthesis.

EXAMPLES:

```python
sage: DyckWord([1,0,1,0,1,0,1,0,1,0,1,0,0]).first_return_decomposition()
([1, 0, 1, 0], [1, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0])
```

```python
sage: DyckWord([1,1,0,0]).first_return_decomposition()
([], [1, 0])
```

```python
list_parking_functions()
Return all parking functions whose supporting Dyck path is self.

EXAMPLES:

```python
sage: DyckWord([1,0,1,0,1,0,1,0,1,0,1,0,0]).list_parking_functions()
```
```
major_index()

Return the major index of self.

The major index of a Dyck word $D$ is the sum of the positions of the valleys of $D$ (when started counting at position 1).

EXAMPLES:

```
sage: DyckWord([1, 0, 1, 0]).major_index()
2
sage: DyckWord([1, 0, 0, 0]).major_index()
0
sage: DyckWord([1, 1, 0, 1, 0]).major_index()
4
sage: DyckWord([1, 0, 1, 0, 0]).major_index()
2
```

number_of_parking_functions()

Return the number of parking functions with self as the supporting Dyck path.

One representation of a parking function is as a pair consisting of a Dyck path and a permutation $\pi$ such that if $[a_0, a_1, \ldots, a_{n-1}]$ is the area_sequence of the Dyck path (see to_area_sequence) then the permutation $\pi$ satisfies $\pi_i < \pi_{i+1}$ whenever $a_i < a_{i+1}$. This function counts the number of permutations $\pi$ which satisfy this condition.

EXAMPLES:

```
sage: DyckWord(area_sequence=[0,1,2]).number_of_parking_functions()
1
sage: DyckWord(area_sequence=[0,1,1]).number_of_parking_functions()
3
sage: DyckWord(area_sequence=[0,1,0]).number_of_parking_functions()
3
sage: DyckWord(area_sequence=[0,0,0]).number_of_parking_functions()
6
```

number_of_tunnels(tunnel_type='centered')

Return the number of tunnels of self of type tunnel_type.

A tunnel is a pair $(a, b)$ where $a$ is the position of an open parenthesis and $b$ is the position of the matching close parenthesis. If $a + b = n$ then the tunnel is called centered. If $a + b < n$ then the tunnel is called left and if $a + b > n$, then the tunnel is called right.

INPUT:

- tunnel_type – (default: 'centered') can be one of the following: 'left', 'right', 'centered', or 'all'.

EXAMPLES:
pyramid_weight()

Return the pyramid weight of self.

A pyramid of self is a subsequence of the form $1^h0^h$. A pyramid is maximal if it is neither preceded by a 1 nor followed by a 0.

The pyramid weight of a Dyck path is the sum of the lengths of the maximal pyramids and was defined in [DS1992].

EXAMPLES:

```python
sage: DyckWord([1,1,0,1,1,1,0,0,1,0,0,0,1,1,0,0]).pyramid_weight()
6
sage: DyckWord([1,1,0,1,0,0,0]).pyramid_weight()
3
sage: DyckWord([1,0,1,0,1,0]).pyramid_weight()
3
sage: DyckWord([1,1,0,1,0,0]).pyramid_weight()
2
```

reading_permutation()

Return the reading permutation of self.

This is the permutation formed by taking the reading word of the Dyck path representing self (with $N$ and $E$ steps) if the vertical edges of the Dyck path are labeled from bottom to top with 1 through $n$ and the diagonals are read from top to bottom starting with the diagonal furthest from the main diagonal.

EXAMPLES:

```python
sage: DyckWord([1,0,1,0]).reading_permutation()
[2, 1]
sage: DyckWord([1,1,0,0]).reading_permutation()
[2, 1]
sage: DyckWord([1,1,0,1,0,0]).reading_permutation()
[3, 2, 1]
sage: DyckWord([1,1,0,0,1,0]).reading_permutation()
[2, 3, 1]
sage: DyckWord([1,0,1,0,0,1,0,1,0]).reading_permutation()
[3, 4, 2, 1]
```

reverse()

Return the reverse and complement of self.
This operation corresponds to flipping the Dyck path across the $y = -x$ line.

EXAMPLES:

```python
sage: DyckWord([1,1,0,0,1,0]).reverse()
[1, 0, 1, 1, 0, 0]
sage: DyckWord([1,1,1,0,0,0]).reverse()
[1, 1, 1, 0, 0, 0]
sage: len([D for D in DyckWords(5) if D.reverse() == D])
10
```

**semilength()**

Return the semilength of self.

The semilength of a complete Dyck word $d$ is the number of openers and the number of closers.

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).semilength()
2
```

**to_132_avoiding_permutation()**

Use the bijection by C. Krattenthaler in [Kra2001] to send self to a 132-avoiding permutation.

EXAMPLES:

```python
sage: DyckWord([1,1,0,0]).to_132_avoiding_permutation()
[1, 2]
sage: DyckWord([1,0,1,0]).to_132_avoiding_permutation()
[2, 1]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_132_avoiding_permutation()
[6, 5, 4, 7, 2, 1, 3]
```

**to_312_avoiding_permutation()**

Convert self to a 312-avoiding permutation using the bijection by Bandlow and Killpatrick in [BK2001]. This sends the area to the inversion number.

EXAMPLES:

```python
sage: DyckWord([1,1,0,0]).to_312_avoiding_permutation()
[1, 2]
sage: DyckWord([1,0,1,0]).to_312_avoiding_permutation()
[2, 1]
sage: p = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_312_avoiding_permutation();
    p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: p.length()
5
```

**to_321_avoiding_permutation()**

Use the bijection (pp. 60-61 of [Knu1973] or section 3.1 of [CK2008]) to send self to a 321-avoiding permutation.
It is shown in [EP2004] that it sends the number of centered tunnels to the number of fixed points, the number of right tunnels to the number of excedences, and the semilength plus the height of the middle point to 2 times the length of the longest increasing subsequence.

**EXAMPLES:**

```python
sage: DyckWord([1,0,1,0]).to_321_avoiding_permutation()
[2, 1]
sage: DyckWord([1,1,0,0]).to_321_avoiding_permutation()
[1, 2]
sage: D = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0])
sage: p = D.to_321_avoiding_permutation()
sage: p
[3, 5, 1, 6, 2, 7, 4]
sage: D.number_of_tunnels() 0
sage: p.number_of_fixed_points() 0
sage: D.number_of_tunnels('right') 4
sage: len(p.weak_excedences())-p.number_of_fixed_points() 4
sage: n = D.semilength()
sage: D.heights()[n] + n 8
sage: 2*p.longest_increasing_subsequence_length() 8
```

### `to_Catalan_code()`

Return the Catalan code associated to self.

A Catalan code of length $n$ is a sequence $(a_1, a_2, \ldots, a_n)$ of $n$ integers $a_i$ such that:

- $0 \leq a_i \leq n - i$ for every $i$;
- if $i < j$ and $a_i > 0$ and $a_j > 0$ and $a_{i+1} = a_{i+2} = \cdots = a_{j-1} = 0$, then $a_i - a_j < j - i$.

It turns out that the Catalan codes of length $n$ are in bijection with Dyck words.

The Catalan code of a Dyck word is example (x) in Richard Stanley’s exercises on combinatorial interpretations for Catalan objects. The code in this example is the reverse of the description provided there. See [Sta-EC2] and [StaCat98].

**EXAMPLES:**

```python
sage: DyckWord([]).to_Catalan_code() []
sage: DyckWord([1, 0]).to_Catalan_code() [0]
sage: DyckWord([1, 1, 0, 0]).to_Catalan_code() [0, 1]
sage: DyckWord([1, 0, 1, 0]).to_Catalan_code() [0, 0]
sage: all(dw == DyckWords().from_Catalan_code(dw.to_Catalan_code())
....:   for i in range(6) for dw in DyckWords(i))
True
```
See also:

to_tamari_sorting_tuple()

to_alternating_sign_matrix()

Return self as an alternating sign matrix.

This is an inclusion map from Dyck words of length $2n$ to certain $n \times n$ alternating sign matrices.

EXAMPLES:

```python
sage: DyckWord([1,1,1,0,1,0,0,0]).to_alternating_sign_matrix()
[ 0 0 1 0]
[ 1 0 -1 1]
[ 0 1 0 0]
[ 0 0 1 0]
sage: DyckWord([1,0,1,0,1,1,0,0]).to_alternating_sign_matrix()
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
[0 0 1 0]
```

to_non_decreasing_parking_function()

Bijection to non-decreasing parking functions.

See there the method to_dyck_word() for more information.

EXAMPLES:

```python
sage: DyckWord([]).to_non_decreasing_parking_function()
[]
sage: DyckWord([1,0]).to_non_decreasing_parking_function()
[1]
sage: DyckWord([1,1,0,0]).to_non_decreasing_parking_function()
[1, 1]
sage: DyckWord([1,0,1,0]).to_non_decreasing_parking_function()
[1, 2]
sage: DyckWord([1,0,1,0,1,0,0,1,0]).to_non_decreasing_parking_function()
[1, 2, 2, 3, 5]
```

to_noncrossing_partition(bijection=None)

Bijection of Biane from self to a noncrossing partition.

There is an optional parameter bijection that indicates if a different bijection from Dyck words to noncrossing partitions should be used (since there are potentially many).

If the parameter bijection is “Stump” then the bijection used is from [Stu2008], see also the method to_noncrossing_permutation().

Thanks to Mathieu Dutour for describing the bijection. See also from_noncrossing_partition().

EXAMPLES:

```python
sage: DyckWord([]).to_noncrossing_partition()
{}
sage: DyckWord([1, 0]).to_noncrossing_partition()
{{1}}
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition()
```
Combinatorics, Release 10.1

(continued from previous page)

{{1, 2}}
sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition()
{{1, 2, 3}}
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition()
{{1}, {2}, {3}}
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition()
{{1, 3}, {2}}
sage: DyckWord([]).to_noncrossing_partition("Stump")
{}
sage: DyckWord([1, 0]).to_noncrossing_partition("Stump")
{{1}}
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition("Stump")
{{1, 2}}
sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition("Stump")
{{1, 3}, {2}}
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition("Stump")
{{1}, {2}, {3}}
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition("Stump")
{{1, 2, 3}}

to_noncrossing_partition()

Use the bijection by C. Stump in [Stu2008] to send self to a non-crossing permutation.

A non-crossing permutation when written in cyclic notation has cycles which are strictly increasing. Sends the area to the inversion number and self.major_index() to \( n(n-1) - \text{maj}(\sigma) - \text{maj}(\sigma^{-1}) \). Uses the function \( \text{pealing()} \)

EXAMPLES:

sage: DyckWord([1,1,0,0]).to_noncrossing_permutation()
[2, 1]
sage: DyckWord([1,0,1,0]).to_noncrossing_permutation()
[1, 2]
sage: p = DyckWord([1,1,0,1,0,0,1,1,0,1,0,0]).to_noncrossing_permutation();
˓→p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,0]).area()
5
sage: p.length()
5

to_ordered_tree()

Return the ordered tree corresponding to self where the depth of the tree is the maximal height of self.

EXAMPLES:

sage: D = DyckWord([1,1,0,0])
sage: D.to_ordered_tree()
[[[]]]
sage: D = DyckWord([1,0,1,0])
sage: D.to_ordered_tree()
[[[]], [[]]]
sage: D = DyckWord([1, 0, 1, 1, 0, 0])

(continues on next page)
Combinatorics, Release 10.1

(continued from previous page)

\begin{verbatim}
\texttt{sage: D.to_ordered_tree()}
[[[]], [[]]]
\texttt{sage: D = DyckWord([1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 0])}
\texttt{sage: D.to_ordered_tree()}
[[[], [[]], [[]]], [[]]]]
\end{verbatim}

\textbf{to_pair_of_standard_tableaux()}

Convert \texttt{self} to a pair of standard tableaux of the same shape and of length less than or equal to two.

\textbf{EXAMPLES:}

\begin{verbatim}
\texttt{sage: DyckWord([1,0,1,0]).to_pair_of_standard_tableaux()}
(([1], [2]), ([1], [2]))
\texttt{sage: DyckWord([1,1,0,0]).to_pair_of_standard_tableaux()}
(([1], [2]), ([1], [2]))
\texttt{sage: DyckWord([1,1,1,0,0,1,1,0,1,0,0]).to_pair_of_standard_tableaux()}
(([1, 2, 4, 7], [3, 5, 6]), ([1, 2, 4, 6], [3, 5, 7]))
\end{verbatim}

\textbf{to_partition()}

Return the partition associated to \texttt{self}.

This partition is determined by thinking of \texttt{self} as a lattice path and considering the cells which are above the path but within the $n \times n$ grid and the partition is formed by reading the sequence of the number of cells in this collection in each row.

\textbf{OUTPUT:}

- a partition representing the rows of cells in the square lattice and above the path

\textbf{EXAMPLES:}

\begin{verbatim}
\texttt{sage: DyckWord([]).to_partition()}
[]
\texttt{sage: DyckWord([1,0]).to_partition()}
[]
\texttt{sage: DyckWord([1,1,0,0]).to_partition()}
[]
\texttt{sage: DyckWord([1,0,1,0]).to_partition()}
[1]
\texttt{sage: DyckWord([1,0,1,0,1,0]).to_partition()}
[2, 1]
\texttt{sage: DyckWord([1,1,0,1,0]).to_partition()}
[2]
\texttt{sage: DyckWord([1,0,1,1,0,0]).to_partition()}
[1, 1]
\end{verbatim}

\textbf{to_permutation(map)}

This is simply a method collecting all implemented maps from Dyck words to permutations.

\textbf{INPUT:}

- map – defines the map from Dyck words to permutations. These are currently:
  - Bandlow-Killpatrick: \texttt{to_312_avoiding_permutation()}
  - Knuth: \texttt{to_321_avoiding_permutation()}
- Krattenthaler: `to_132_avoiding_permutation()`
- Stump: `to_noncrossing_permutation()`

**EXAMPLES:**

```python
sage: D = DyckWord([1,1,0,1,0,0,0])
sage: D.pretty_print()
_____
  | x x
  | x x.
  | x .
  | . .

sage: D.to_permutation(map="Bandlow-Killpatrick")
[3, 4, 2, 1]
sage: D.to_permutation(map="Stump")
[4, 2, 3, 1]
sage: D.to_permutation(map="Knuth")
[1, 2, 4, 3]
sage: D.to_permutation(map="Krattenthaler")
[2, 1, 3, 4]
```

to_triangulation()

Map `self` to a triangulation.

The map from complete Dyck words of length $2n$ to triangulations of $n+2$-gon given by this function is a bijection that can be described as follows.

Consider the Dyck word as a path from $(0, 0)$ to $(n, n)$ staying above the diagonal, where 1 is an up step and 0 is a right step. Then each horizontal step has a co-height (0 at the top and $n-1$ at most at the bottom). One reads the Dyck word from left to right. At the beginning, all vertices from 0 to $n+1$ are available. For each horizontal step, one creates an edge from the vertex indexed by the co-height to the next available vertex. This chops out a triangle from the polygon and one removes the middle vertex of this triangle from the list of available vertices.

This bijection has the property that the set of smallest vertices of the edges in a triangulation is an encoding of the co-heights, from which the Dyck word can be easily recovered.

**OUTPUT:**

a list of pairs $(i, j)$ that are the edges of the triangulations.

**EXAMPLES:**

```python
sage: DyckWord([1, 1, 0, 0]).to_triangulation()
[(0, 2)]
sage: [t.to_triangulation() for t in DyckWords(3)]
[[[2, 4), (1, 4)],
 [[2, 4), (0, 2)],
 [[1, 3), (1, 4)],
 [[1, 3), (0, 3)],
 [[0, 2), (0, 3)]]
```

**REFERENCES:**

- [Cha2005]
to_triangulation_as_graph()
Map self to a triangulation and return the result as a graph.
See to_triangulation() for the bijection used to map complete Dyck words to triangulations.
OUTPUT:
• a graph containing both the perimeter edges and the inner edges of a triangulation of a regular polygon.
EXAMPLES:

```python
sage: g = DyckWord([1, 1, 0, 0, 1, 0]).to_triangulation_as_graph()
sage: g
Graph on 5 vertices
sage: g.edges(sort=True, labels=False)
[(0, 1), (0, 4), (1, 2), (1, 3), (1, 4), (2, 3), (3, 4)]
sage: g.show()  # not tested
```

tunnels()
Return an iterator of ranges of the matching parentheses in the Dyck word self.
That is, if (a,b) is in self.tunnels(), then the matching parenthesis to self[a] is self[b-1].
EXAMPLES:

```python
sage: list(DyckWord([1, 1, 0, 1, 1, 0, 0, 1, 0, 0]).tunnels())
[(0, 10), (1, 3), (3, 7), (4, 6), (7, 9)]
```
class sage.combinat.dyck_word.DyckWords
Bases: UniqueRepresentation, Parent
Dyck words.
A Dyck word is a sequence $(w_1, \ldots, w_n)$ consisting of 1s and 0s, with the property that for any $i$ with $1 \leq i \leq n$, the sequence $(w_1, \ldots, w_i)$ contains at least as many 1s as 0s.
A Dyck word is balanced if the total number of 1s is equal to the total number of 0s. The number of balanced Dyck words of length $2k$ is given by the Catalan number $C_k$.
EXAMPLES:
This class can be called with three keyword parameters k1, k2 and complete.
If neither k1 nor k2 are specified, then DyckWords returns the combinatorial class of all balanced (=complete) Dyck words, unless the keyword complete is set to False (in which case it returns the class of all Dyck words).

```python
sage: DW = DyckWords(); DW
Complete Dyck words
sage: [] in DW
True
sage: [1, 0, 1, 0] in DW
True
sage: [1, 1, 0] in DW
False
sage: ADW = DyckWords(complete=False); ADW
Dyck words
sage: [] in ADW
True
sage: [1, 0, 1, 0] in ADW
```
(continues on next page)
If just $k_1$ is specified, then it returns the balanced Dyck words with $k_1$ opening parentheses and $k_1$ closing parentheses.

```
sage: DW = DyckWords(2); DW
Dyck words with 2 opening parentheses and 2 closing parentheses
sage: DW.first()
[1, 0, 1, 0]
sage: DW.last()
[1, 1, 0, 0]
sage: DW.cardinality()
2
sage: DyckWords(100).cardinality() == catalan_number(100)
True
```

If $k_2$ is specified in addition to $k_1$, then it returns the Dyck words with $k_1$ opening parentheses and $k_2$ closing parentheses.

```
sage: DW32 = DyckWords(3,2); DW32
Dyck words with 3 opening parentheses and 2 closing parentheses
sage: DW32.list()
[[[1, 0, 1, 0, 1],
  [1, 0, 1, 1, 0],
  [1, 1, 0, 0, 1],
  [1, 1, 0, 1, 0],
  [1, 1, 1, 0, 0]]
```

**Element**

alias of *DyckWord*

**from_heights(heights)**

Compute a Dyck word knowing its heights.

We view the Dyck word as a Dyck path from $(0, 0)$ to $(2n, 0)$ in the first quadrant by letting 1’s represent steps in the direction $(1, 1)$ and 0’s represent steps in the direction $(1, -1)$.

The *heights()* is the sequence of the $y$-coordinates of the $2n + 1$ lattice points along this path.

**EXAMPLES:**

```
sage: from sage.combinat.dyck_word import DyckWord
sage: D = DyckWords(complete=False)
sage: D.from_heights((0,))
[]
sage: D.from_heights((0, 1, 0))
[1, 0]
sage: D.from_heights((0, 1, 2, 1, 0))
[1, 1, 0, 0]
```

This also works for incomplete Dyck words:
min_from_heights(heights)
Compute the smallest Dyck word which achieves or surpasses a given sequence of heights.

INPUT:
• heights – a nonempty list or iterable consisting of nonnegative integers, the first of which is 0

OUTPUT:
• The smallest Dyck word whose sequence of heights is componentwise higher-or-equal to heights. Here, “smaller” can be understood both in the sense of lexicographic order on the Dyck words, and in the sense of every vertex of the path having the smallest possible height.

See also:
• heights()
• from_heights()

EXAMPLES:

```python
def min_from_heights(heights):
    heights = [0] + heights
    heights += [0] * 100
    D = DyckWords(complete=False)
    return D.min_from_heights(heights)
```
**cardinality()**

Return the number of Dyck words with \(k_1\) openers and \(k_2\) closers.

This number is

\[
\frac{k_1 - k_2 + 1}{k_1 + 1} \binom{k_1 + k_2}{k_2} = \binom{k_1 + k_2}{k_2} - \binom{k_1 + k_2}{k_2 - 1}
\]

if \(k_2 \leq k_1 + 1\), and 0 if \(k_2 > k_1\) (these numbers are the same if \(k_2 = k_1 + 1\)).

**EXAMPLES:**

```sage
sage: DyckWords(3, 2).cardinality()
5
sage: all(all(DyckWords(p, q).cardinality() == len(DyckWords(p, q).list()) for q in range(p + 1)) for p in range(7))
True
```

**sage.combinat.dyck_word.is_a(obj, k1=None, k2=None)**

Test if \(obj\) is a Dyck word with exactly \(k_1\) open symbols and exactly \(k_2\) close symbols.

If \(k_1\) is not specified, then the number of open symbols can be arbitrary. If \(k_1\) is specified but \(k_2\) is not, then \(k_2\) is set to be \(k_1\).

**EXAMPLES:**

```sage
sage: from sage.combinat.dyck_word import is_a
sage: is_a([1,1,0,0])
True
sage: is_a([1,0,1,0])
True
sage: is_a([1,1,0,0], 2)
True
sage: is_a([1,1,0,0], 3)
False
sage: is_a([1,1,0,0], 3, 2)
False
sage: is_a([1,1,0])
True
sage: is_a([1,0,1])
False
sage: is_a([1,0,0])
False
sage: is_a([1,1,0],2,1)
True
sage: is_a([1,1,0],2)
False
sage: is_a([1,1,0],1,1)
False
```

**sage.combinat.dyck_word.is_area_sequence(seq)**

Test if a sequence \(l\) of integers satisfies \(l_0 = 0\) and \(0 \leq l_{i+1} \leq l_i + 1\) for \(i > 0\).

**EXAMPLES:**
sage: from sage.combinat.dyck_word import is_area_sequence
sage: is_area_sequence([0,2,0])
False
sage: is_area_sequence([1,2,3])
False
sage: is_area_sequence([0,1,0])
True
sage: is_area_sequence([0,1,2])
True
sage: is_area_sequence([])
True

sage.combinat.dyck_word.pealing(D, return_touches=False)
A helper function for computing the bijection from a Dyck word to a 231-avoiding permutation using the bijection “Stump”. For details see [Stu2008].

See also:

to_noncrossing_partition()

EXAMPLES:

sage: from sage.combinat.dyck_word import pealing
sage: pealing(DyckWord([1,1,0,0]))
[1, 0, 1, 0]
sage: pealing(DyckWord([1,0,1,0]))
[1, 0, 1, 0]
sage: pealing(DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]), return_touches=True)
([1, 0, 1, 0, 1, 0, 1, 0, 1, 0], [[1, 2], [3, 5]])

sage.combinat.dyck_word.replace_parens(x)
A map sending '(' to open_symbol and ')' to close_symbol, and raising an error on any input other than '(' and ')'. The values of the constants open_symbol and close_symbol are subject to change.

This is the inverse map of replace_symbols().

INPUT:
• x – either an opening or closing parenthesis

OUTPUT:
• If x is an opening parenthesis, replace x with the constant open_symbol.
• If x is a closing parenthesis, replace x with the constant close_symbol.
• Raise a ValueError if x is neither an opening nor a closing parenthesis.

See also:

replace_symbols()

EXAMPLES:
sage: from sage.combinat.dyck_word import replace_parens
sage: replace_parens('(')
1
sage: replace_parens(')')
0
sage: replace_parens(1)
Traceback (most recent call last):
  ... ValueError

sage.combinat.dyck_word.replace_symbols(x)
A map sending open_symbol to '(' and close_symbol to ')', and raising an error on any input other than open_symbol and close_symbol. The values of the constants open_symbol and close_symbol are subject to change.

This is the inverse map of replace_parens().

INPUT:
• x – either open_symbol or close_symbol.

OUTPUT:
• If x is open_symbol, replace x with '('.
• If x is close_symbol, replace x with ')'.
• If x is neither open_symbol nor close_symbol, a ValueError is raised.

See also:
replace_parens()

EXAMPLES:

sage: from sage.combinat.dyck_word import replace_symbols
sage: replace_symbols(1)
'(1
sage: replace_symbols(0)
')
sage: replace_symbols(3)
Traceback (most recent call last):
  ... ValueError

5.1.100 Substitutions over unit cube faces (Rauzy fractals)

This module implements the $E_1^* (\sigma)$ substitution associated with a one-dimensional substitution $\sigma$, that acts on unit faces of dimension $(d - 1)$ in $R^d$.

This module defines the following classes and functions:
• Face - a class to model a face
• Patch - a class to model a finite set of faces
• E1Star - a class to model the $E_1^* (\sigma)$ application defined by the substitution sigma
Combinatorics, Release 10.1

See the documentation of these objects for more information.

The convention for the choice of the unit faces and the definition of $E^*_1(\sigma)$ varies from article to article. Here, unit faces are defined by

\[
[x, 1]^* = \{x + \lambda e_2 + \mu e_3 : \lambda, \mu \in [0, 1]\}
\]
\[
[x, 2]^* = \{x + \lambda e_1 + \mu e_3 : \lambda, \mu \in [0, 1]\}
\]
\[
[x, 3]^* = \{x + \lambda e_1 + \mu e_2 : \lambda, \mu \in [0, 1]\}
\]

and the dual substitution $E^*_1(\sigma)$ is defined by

\[
E^*_1(\sigma)([x, i]^*) = \bigcup_{k=1,2,3} \bigcup_{s|\sigma(k) = p_i} [M^{-1}(x + \ell(s)), k]^*,
\]

where $\ell(s)$ is the abelianized of $s$, and $M$ is the matrix of $\sigma$.

- Timo Jolivet (2010-08, 2010-09, 2011): redesign

REFERENCES:

EXAMPLES:

We start by drawing a simple three-face patch:

```
sage: from sage.combinat.e_one_star import ElStar, Face, Patch
game: x = [Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)]
sage: P = Patch(x)
sage: P
Patch: [[(0, 0, 0), 1]^*, [(0, 0, 0), 2]^*, [(0, 0, 0), 3]^*]
sage: P.plot()  #not tested
```

We apply a substitution to this patch, and draw the result:

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = ElStar(sigma)
sage: E(P)
Patch: [[(0, 0, 0), 1]^*, [(0, 0, 0), 2]^*, [(0, 0, 0), 3]^*, [(0, 1, -1), 2]^*, [(1, 0, -1), 1]^*]
sage: E(P).plot()  #not tested
```

Note:

- The type of a face is given by an integer in $[1, \ldots, d]$ where $d$ is the length of the vector of the face.
- The alphabet of the domain and the codomain of $\sigma$ must be equal, and they must be of the form $[1, \ldots, d]$, where $d$ is a positive integer corresponding to the length of the vectors of the faces on which $E^*_1(\sigma)$ will act.
The application of an E1Star substitution assigns to each new face the color of its preimage. The repaint method allows us to repaint the faces of a patch. A single color can also be assigned to every face, by specifying a list of a single color:

```python
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.repaint(['green'])
sage: P.plot()  #not tested
```

A list of colors allows us to color the faces sequentially:

```python
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: P = E(P)
sage: P.repaint(['red', 'yellow', 'green', 'blue', 'black'])
sage: P = E(P, 3)
sage: P.plot()  #not tested
```

All the color schemes from `list(matplotlib.cm.datad)` can be used:

```python
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: P.repaint(cmap='summer')
sage: P = E(P, 3)
sage: P.plot()  #not tested
sage: P.repaint(cmap='hsv')
sage: P = E(P, 2)
sage: P.plot()  #not tested
```

It is also possible to specify a dictionary to color the faces according to their type:

```python
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: P = E(P, 5)
```

```python
sage: P.repaint({1:(0.7, 0.7, 0.7), 2:(0.5,0.5,0.5), 3:(0.3,0.3,0.3)})
```

Let us look at a nice big patch in 3D:

```python
sage: sigma = WordMorphism({1:[1,2], 2:[3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: P = P + P.translate([-1,1,0])
sage: P = E(P, 11)
sage: P.plot3d()  #not tested
```

Plotting with TikZ pictures is possible:

```python
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: s = P.plot_tikz()
sage: print(s)  #not tested
```

\begin{tikzpicture}
\[x={(-0.216506cm,-0.125000cm)}, y={(0.216506cm,-0.125000cm)}, z={(0.000000cm,0.250000cm)}\]
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
```

(continues on next page)
Plotting patches made of unit segments instead of unit faces:

```python
sage: P = Patch([Face([0,0]), 1], Face([0,0], 2))
```

```python
sage: E = E1Star(WordMorphism({1:[1,2], 2:[1]}))
```

```python
sage: F = E1Star(WordMorphism({1:[1,1,2], 2:[2,1]}))
```

```python
sage: E(P,5).plot()  # optional - sage.plot
```

Graphics object consisting of 21 graphics primitives

```python
sage: F(P,3).plot()  # optional - sage.plot
```

Graphics object consisting of 34 graphics primitives

Everything works in any dimension (except for the plotting features which only work in dimension two or three):

```python
sage: P = Patch([Face((0,0,0,0),1), Face((0,0,0,0),4)])
```

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1]})
```

```python
sage: E = E1Star(sigma)
```

```python
sage: E(P)
```

Patch: 

\[

(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, -1), 4]^*, \\
(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, -1), 3]^*, \\
(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, -1), 2]^*,
\end{align*}
\]

(continues on next page)
class sage.combinat.e_one_star.E1Star(sigma, method='suffix')

Bases: sageObject

A class to model the $E_1^\ast(\sigma)$ map associated with a unimodular substitution $\sigma$.

INPUT:

- sigma - unimodular WordMorphism, i.e. such that its incidence matrix has determinant $\pm 1$.
- method - 'prefix' or 'suffix' (optional, default: 'suffix') Enables to use an alternative definition $E_1^\ast(\sigma)$ substitutions, where the abelianized of the prefix is used instead of the suffix.

Note: The alphabet of the domain and the codomain of $\sigma$ must be equal, and they must be of the form $[1, \ldots, d]$, where $d$ is a positive integer corresponding to the length of the vectors of the faces on which $E_1^\ast(\sigma)$ will act.

EXAMPLES:

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
```

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
```

```python
sage: E = E1Star(sigma)
```

```python
sage: E(P)
Patch: [[[0, 0, 0], 1]*, [[0, 0, 0], 2]*, [[0, 0, 0], 3]*, [[0, 1, -1], 2]*, [[1, 0, -1], 1]*]
```

```python
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
```

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
```

```python
sage: E = E1Star(sigma, method='prefix')
```

```python
sage: E(P)
Patch: [[[0, 0, 0], 1]*, [[0, 0, 0], 2]*, [[0, 0, 0], 3]*, [[0, 0, 1], 1]*, [[0, 0, -1], 2]*]
```

```python
sage: x = [Face((0,0,0,0),1), Face((0,0,0,0),4)]
```

```python
sage: P = Patch(x)
```

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1], 4:[1]})
```

```python
sage: E = E1Star(sigma)
```

```python
sage: E(P)
Patch: [[[0, 0, 0, 0], 3]*, [[0, 0, 0, 0], 4]*, [[0, 0, 1, -1], 3]*, [[0, 1, 0, -1], -2]*, [[1, 0, 0, -1], 1]*]
```

inverse_matrix()

Return the inverse of the matrix associated with self.

EXAMPLES:

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
```

```python
sage: E = E1Star(sigma)
```

```python
sage: E.inverse_matrix()
[ 0 1 0]
```
matrix()

Return the matrix associated with self.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.matrix()
[1 1 1]
[1 0 0]
[0 1 0]
```

sigma()

Return the WordMorphism associated with self.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.sigma()
WordMorphism: 1->12, 2->13, 3->1
```

class sage.combinat.e_one_star.Face(v, t, color=None)

A class to model a unit face of arbitrary dimension.

A unit face in dimension $d$ is represented by a $d$-dimensional vector $v$ and a type $t$ in $\{1,\ldots,d\}$. The type of the face corresponds to the canonical unit vector to which the face is orthogonal. The optional color argument is used in plotting functions.

INPUT:

- $v$ - tuple of integers
- $t$ - integer in $[1, \ldots, \text{len}(v)]$, type of the face. The face of type $i$ is orthogonal to the canonical vector $e_i$.
- $\text{color}$ - color (optional, default: None) color of the face, used for plotting only. If None, its value is guessed from the face type.

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.vector()
(0, 2, 0)
sage: f.type()
3
```
Combinatorics, Release 10.1

```
sage: f = Face((0,2,0), 3, color=(0.5, 0.5, 0.5))
sage: f.color()
RGB color (0.5, 0.5, 0.5)

color(color=None)
Return or change the color of the face.

INPUT:
• color - string, rgb tuple, color (optional, default: None) the new color to assign to the face. If None, it returns the color of the face.

OUTPUT:
color or None

EXAMPLES:
```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.color()
RGB color (0.0, 0.0, 1.0)
sage: f.color('red')
sage: f.color()
RGB color (1.0, 0.0, 0.0)
```

type()
Return the type of the face.

EXAMPLES:
```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.type()
3
sage: f = Face((0,2,0), 3)
sage: f.type()
3
```

vector()
Return the vector of the face.

EXAMPLES:
```
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.vector()
(0, 2, 0)
```

class sage.combinat.e_one_star.Patch(faces, face_contour=None)
Bases: SageObject
A class to model a collection of faces. A patch is represented by an immutable set of Faces.
**Note:** The dimension of a patch is the length of the vectors of the faces in the patch, which is assumed to be the same for every face in the patch.

**Note:** Since version 4.7.1, Patches are immutable, except for the colors of the faces, which are not taken into account for equality tests and hash functions.

**INPUT:**

- **faces** - finite iterable of faces
- **face_contour** - dict (optional, default: None) maps the face type to vectors describing the contour of unit faces. If None, defaults contour are assumed for faces of type 1, 2, 3 or 1, 2, 3. Used in plotting methods only.

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P
Patch: [[[0, 0, 0], 1]*, [[0, 0, 0], 2]*, [[0, 0, 0], 3]*]

sage: face_contour = {}
sage: face_contour[1] = map(vector, [(0,0,0),(0,1,0),(0,1,1),(0,0,1)])
sage: face_contour[2] = map(vector, [(0,0,0),(0,0,1),(1,0,1),(1,0,0)])
sage: face_contour[3] = map(vector, [(0,0,0),(1,0,0),(1,1,0),(0,1,0)])
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]], face_contour=face_contour)

sage: P
Patch: [[[0, 0, 0], 1]*, [[0, 0, 0], 2]*, [[0, 0, 0], 3]*]
```

**difference**(other)

Return the difference of self and other.

**INPUT:**

- **other** - a finite iterable of faces or a single face

**EXAMPLES:**

```python
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.difference(Face([0,0,0],2))
Patch: [[[0, 0, 0], 1]*, [[0, 0, 0], 3]*]
sage: P.difference(P)
Patch: []
```

**dimension()**

Return the dimension of the vectors of the faces of self

It returns *None* if self is the empty patch.

The dimension of a patch is the length of the vectors of the faces in the patch, which is assumed to be the same for every face in the patch.

**EXAMPLES:**
```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([[Face((0,0,0),t) for t in [1,2,3]]])
sage: P.dimension()
3
```

**faces_of_color**(color)

Return a list of the faces that have the given color.

**INPUT:**

- *color* - color

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1, 'red'), Face((1,2,0),3, 'blue'), Face((1,2,0), -1, 'red')])
sage: sorted(P.faces_of_color('red'))
[[[0, 0, 0], 1]*, [[1, 2, 0], 1]*]
```

**faces_of_type**(t)

Return a list of the faces that have type t.

**INPUT:**

- *t* - integer or any other type

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: sorted(P.faces_of_type(1))
[[[0, 0, 0], 1]*, [[1, 2, 0], 1]*]
```

**faces_of_vector**(v)

Return a list of the faces whose vector is v.

**INPUT:**

- *v* - a vector

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: sorted(P.faces_of_vector([1,2,0]))
[[[1, 2, 0], 1]*, [[1, 2, 0], 3]*]
```

**occurrences_of**(other)

Return all positions at which other appears in self, that is, all vectors v such that set(other.translate(v)) <= set(self).

**INPUT:**

- *other* - a Patch

**OUTPUT:**

a list of vectors
EXAMPLES:

```python
sage: from sage.combinat.e_one_star import Face, Patch, E1Star
sage: P = Patch([[Face([0,0,0], 1), Face([0,0,0], 2), Face([0,0,0], 3)])
sage: Q = Patch([[Face([0,0,0], 1), Face([0,0,0], 2)])
```

```python
sage: P.occurrences_of(Q)
[(0, 0, 0)]
```

```python
sage: Q = Q.translate([1,2,3])
```

```python
sage: P.occurrences_of(Q)
[(-1, -2, -3)]
```

```python
sage: E = E1Star(WordMorphism({1:[1,2], 2:[1,3], 3:[1]}))
```

```python
sage: P = Patch([[Face([0,0,0], 1), Face([0,0,0], 2), Face([0,0,0], 3)])
```

```python
sage: P = E(P,4)
```

```python
sage: Q = Patch([[Face([0,0,0], 1), Face([0,0,0], 2)])
```

```python
sage: L = P.occurrences_of(Q)
```

```python
sage: sorted(L)
[(0, 0, 0), (0, 0, 1), (0, 1, -1), (1, 0, -1), (1, 1, -3), (1, 1, -2)]
```

```python
plot(projmat=None, opacity=0.75)
```

Return a 2D graphic object depicting the patch.

INPUT:

- `projmat` - matrix (optional, default: None) the projection matrix. Its number of lines must be two. Its number of columns must equal the dimension of the ambient space of the faces. If None, the isometric projection is used by default.

- `opacity` - float between 0 and 1 (optional, default: 0.75) opacity of the face

**Warning:** Plotting is implemented only for patches in two or three dimensions.

EXAMPLES:

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([[Face((0,0,0), t) for t in [1,2,3]])
```

```python
sage: P.plot()  # optional - sage.plot
```

Graphics object consisting of 3 graphics primitives

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
```

```python
sage: E = E1Star(sigma)
```

```python
sage: P = Patch([[Face((0,0,0), t) for t in [1,2,3]])
```

```python
sage: P = E(P, 5)
```

```python
sage: P.plot()  # optional - sage.plot
```

Graphics object consisting of 57 graphics primitives

Plot with a different projection matrix:

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
```

```python
sage: E = E1Star(sigma)
```

```python
sage: P = Patch([[Face((0,0,0), t) for t in [1,2,3]])
```

(continues on next page)
Plot patches made of unit segments:

```python
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
```

```python
sage: P.plot()  #optional - sage.plot
Graphics object consisting of 17 graphics primitives
```

```python
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.repaint()
sage: P.plot3d()  #not tested
```

```python
plot_tikz(projmat=None, print_tikz_env=True, edgelcolor='black', scale=0.25, drawzero=False,
extra_code_before='', extra_code_after='')
```

Return a 3D graphics object depicting the patch.

**Warning:** 3D plotting is implemented only for patches in three dimensions.

EXAMPLES:

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
```

```python
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
```

```python
sage: P.plot3d()  #not tested
```

```python
sage: P = E1Star(WordMorphism({1:[1,2], 2:[1]}))
```

```python
sage: E(P,5).plot()  #optional - sage.plot
Graphics object consisting of 21 graphics primitives
```

```python
sage: F = E1Star(WordMorphism({1:[1,1,2], 2:[2,1]}))
```

```python
sage: F(P,3).plot()  #optional - sage.plot
Graphics object consisting of 34 graphics primitives
```

```python
plot_tikz()  #optional - sage.plot
graphics object consisting of 17 graphics primitives
```

```
```

5.1. Comprehensive Module List
• `edgecolor` - string (optional, default: 'black') either 'black' or 'facecolor' (color of unit face edges)
• `scale` - real number (optional, default: 0.25) scaling constant for the whole figure
• `drawzero` - bool (optional, default: False) if True, mark the origin by a black dot
• `extra_code_before` - string (optional, default: '') extra code to include in the tikz picture
• `extra_code_after` - string (optional, default: '') extra code to include in the tikz picture

EXAMPLES:

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: s = P.plot_tikz()
sage: len(s)
602
sage: print(s)  # not tested
\begin{tikzpicture}
\begin{tikzpicture}
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\end{tikzpicture}
```

Plot using shades of gray (useful for article figures):

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 4)
sage: from sage.misc.latex import latex  # not tested
sage: latex.add_to_preamble('\\usepackage{tikz}')  # not tested
sage: view(P)  # not tested
```

Plotting with various options:

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: M = matrix(2,3,[float(u) for u in [1.0,0.7071,0,0,1.0,-0.7071]])
```
Adding X, Y, Z axes using the extra code feature:

```python
sage: length = 1.5
sage: space = 0.3
sage: axes = ''
sage: axes += "\draw[->, thick, black] (0,0,0) -- (%s, 0, 0);\n" % length
sage: axes += "\draw[->, thick, black] (0,0,0) -- (0, %s, 0);\n" % length
sage: axes += "\node at (%s,0,0) \{$x$};\n" % (length + space)
```

```python
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
```

```python
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\end{tikzpicture}
```

```
repaint(cmap='Set1')
```

Repaint all the faces of self from the given color map.

This only changes the colors of the faces of self.

**INPUT:**

- cmap - color map (default: 'Set1'). It can be one of the following:
  - string – A coloring map. For available coloring map names type: sorted(colormaps)
  - list – a list of colors to assign cyclically to the faces. A list of a single color colors all the faces
with the same color.

- `dict` – a dict of face types mapped to colors, to color the faces according to their type.

- `{}`, the empty dict - shortcut for `{1: 'red', 2: 'green', 3: 'blue'}`.

**EXAMPLES:**

Using a color map:

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: color = (0, 0, 0)
sage: P = Patch([Face((0,0,0),t,color) for t in [1,2,3]])
sage: for f in P: f.color()
RGB color (0.0, 0.0, 0.0)
RGB color (0.0, 0.0, 0.0)
RGB color (0.0, 0.0, 0.0)
sage: P.repaint()
sage: next(iter(P)).color()  #random
RGB color (0.498..., 0.432..., 0.522...)
```

Using a list of colors:

```python
sage: P = Patch([Face((0,0,0),t,color) for t in [1,2,3]])
sage: P.repaint([(0.9, 0.9, 0.9), (0.65,0.65,0.65), (0.4,0.4,0.4)])
sage: for f in P: f.color()
RGB color (0.9, 0.9, 0.9)
RGB color (0.65, 0.65, 0.65)
RGB color (0.4, 0.4, 0.4)
```

Using a dictionary to color faces according to their type:

```python
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.repaint({1: 'black', 2: 'yellow', 3: 'green'})
sage: P.plot()  #not tested
sage: P.repaint({})  #not tested
```

**translate**(v)

Return a translated copy of self by vector v.

**INPUT:**

- v - vector or tuple

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: P.translate([-1,-2,0])
Patch: [((-1, -2, 0), 1)*, ([0, 0, 0], 1)*, ([0, 0, 0], 3)*]
```

**union**(other)

Return a Patch consisting of the union of self and other.

**INPUT:**

- other - a Patch or a Face or a finite iterable of faces
EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((0,0,0),2)])
```

```
sage: P.union(Face((1,2,3), 3))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*]
```

```
sage: P.union([Face((1,2,3), 3), Face((2,3,3), 2)])
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*, [(2, 3, 3), 2]*]
```

5.1.102 Tools for enumeration modulo the action of a permutation group

sage.combinat.enumeration_mod_permgroup.all_children(v, max_part)

Returns all the children of an integer vector (ClonableIntArray) v in the tree of enumeration by lexicographic order. The children of an integer vector v whose entries have the sum n are all integer vectors of sum n + 1 which follow v in the lexicographic order.

That means this function adds 1 on the last non-zero entries and the following ones. For an integer vector v such that

\[ v = [..., a, 0, 0] \] with \( a \neq 0 \),

then, the list of children is

\[ [..., a + 1, 0, 0], [..., a, 1, 0], [..., a, 0, 1] \].

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import all_children
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: v = IncreasingIntArrays([1,2,3,4])
sage: all_children(v, -1)
[[1, 2, 3, 5]]
```

sage.combinat.enumeration_mod_permgroup.canonical_children(sgs, v, max_part)

Returns the canonical children of the integer vector v. This function computes all children of the integer vector v via the function all_children() and returns from this list only those which are canonicals identified via the function is_canonical().

EXAMPLES:

```
sage: from sage.combinat.enumeration_mod_permgroup import canonical_children
sage: G = PermutationGroup([[1,2,3,4]])
sage: sgs = G.strong_generating_system()
sage: IA = IncreasingIntArrays()
sage: canonical_children(sgs, IA([1,2,3,5]), -1)
[]
```
sage.combinat.enumeration_mod_permgroup.canonical_representative_of_orbit_of(sgs, v)

Returns the maximal vector for the lexicographic order living in the orbit of \( v \) under the action of the permutation group whose strong generating system is \( sgs \). The maximal vector is also called “canonical”. Hence, this method returns the canonical vector inside the orbit of \( v \). If \( v \) is already canonical, the method returns \( v \).

Let \( G \) to be the permutation group which admits \( sgs \) as a strong generating system. An integer vector \( v \) is said to be canonical under the action of \( G \) if and only if:

\[
v = \max_{\text{lex order}} \{ g \cdot v | g \in G \}
\]

EXAMPLES:

```python
sage: from sage.combinat.enumeration_mod_permgroup import canonical_representative_of_orbit_of
sage: G = PermutationGroup([[1,2,3,4]])
sage: sgs = G.strong_generating_system()
sage: IA = IncreasingIntArrays()
sage: canonical_representative_of_orbit_of(sgs, IA([1,2,3,5]))
[5, 1, 2, 3]
```

sage.combinat.enumeration_mod_permgroup.is_canonical(sgs, v)

Returns True if the integer vector \( v \) is maximal with respect to the lexicographic order in its orbit under the action of the permutation group whose strong generating system is \( sgs \). Such vectors are said to be canonical.

Let \( G \) to be the permutation group which admit \( sgs \) as a strong generating system. An integer vector \( v \) is said to be canonical under the action of \( G \) if and only if:

\[
v = \max_{\text{lex order}} \{ g \cdot v | g \in G \}
\]

EXAMPLES:

```python
sage: from sage.combinat.enumeration_mod_permgroup import is_canonical
sage: G = PermutationGroup([[1,2,3,4]])
sage: sgs = G.strong_generating_system()
sage: IA = IncreasingIntArrays()
sage: is_canonical(sgs, IA([1,2,3,6]))
False
```

sage.combinat.enumeration_mod_permgroup.lex_cmp(v1, v2)

Lexicographic comparison of ClonableIntArray.

INPUT:

Two instances \( v_1, v_2 \) of ClonableIntArray

OUTPUT:

-1, 0, 1, depending on whether \( v_1 \) is lexicographically smaller, equal, or greater than \( v_2 \).

EXAMPLES:

```python
sage: I = IntegerVectorsModPermutationGroup(SymmetricGroup(5),5)
sage: v1 = I([2,3,1,2,3], check=False)```
sage: v2 = I([2,3,2,3,2], check=False)
sage: v3 = J([2,3,1,2,3,1], check=False)
sage: from sage.combinat.enumeration_mod_permgroup import lex_cmp
sage: lex_cmp(v1, v1)
0
sage: lex_cmp(v1, v2)
-1
sage: lex_cmp(v2, v1)
1
sage: lex_cmp(v1, v3)
-1
sage: lex_cmp(v3, v1)
1

sage.combinat.enumeration_mod_permgroup.lex_cmp_partial(v1, v2, step)

Partial comparison of the two lists according the lexicographic order. It compares the step-th first entries.

EXAMPLES:

sage: from sage.combinat.enumeration_mod_permgroup import lex_cmp_partial
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: lex_cmp_partial(IA([0,1,2,3]),IA([0,1,2,4]),3)
0
sage: lex_cmp_partial(IA([0,1,2,3]),IA([0,1,2,4]),4)
-1

sage.combinat.enumeration_mod_permgroup.orbit(sgs, v)

Returns the orbit of the integer vector v under the action of the permutation group whose strong generating system is sgs.

NOTE:

The returned orbit is a set. In the doctests, we convert it into a sorted list.

EXAMPLES:

sage: from sage.combinat.enumeration_mod_permgroup import orbit
sage: G = PermutationGroup([(1,2,3,4)])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: sorted(orbit(sgs, IA([1,2,3,4])))
[[1, 2, 3, 4], [2, 3, 4, 1], [3, 4, 1, 2], [4, 1, 2, 3]]
5.1.103 Compute Bell and Uppuluri-Carpenter numbers

AUTHORS:
• Nick Alexander

\texttt{sage.combinat.expnums.expnums(n, aa)}

Compute the first \( n \) exponential numbers around \( aa \), starting with the zero-th.

INPUT:
• \( n \) - C machine int
• \( aa \) - C machine int

OUTPUT: A list of length \( n \).

ALGORITHM: We use the same integer addition algorithm as GAP. This is an extension of Bell’s triangle to the general case of exponential numbers. The recursion performs \( O(n^2) \) additions, but the running time is dominated by the cost of the last integer addition, because the growth of the integer results of partial computations is exponential in \( n \). The algorithm stores \( O(n) \) integers, but each is exponential in \( n \).

EXAMPLES:

\begin{verbatim}
\texttt{sage: expnums(10, 1)}
\[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]\n\end{verbatim}

\begin{verbatim}
\texttt{sage: expnums(10, -1)}
\[1, -1, 3, 1, 1, -2, -9, -9, 50, 267]\n\end{verbatim}

\begin{verbatim}
\texttt{sage: expnums(1, 1)}
\[1]\n\texttt{sage: expnums(0, 1)}
\[\]
\texttt{sage: expnums(-1, 0)}
\[\]
\end{verbatim}

AUTHORS:
• Nick Alexander

\texttt{sage.combinat.expnums.expnums2(n, aa)}

A vanilla python (but compiled via Cython) implementation of \texttt{expnums}.

We Compute the first \( n \) exponential numbers around \( aa \), starting with the zero-th.

EXAMPLES:

\begin{verbatim}
\texttt{sage: from sage.combinat.expnums import expnums2}
\texttt{sage: expnums2(10, 1)}
\[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]\n\end{verbatim}
5.1.104 Families

This is a backward compatibility stub. Use `sage.sets.family` instead.

5.1.105 Brent Yorgey’s fast algorithm for integer vector (multiset) partitions.

ALGORITHM:

https://wiki.haskell.org/The_Monad.Reader/Previous_issues

AUTHORS:

• D. K. Sunko (2020-02-19): initial version
• F. Chapoton (2020-02-22): conversion to iterators and shorter doctests and doc tweaks
• T. Scrimshaw (2020-03-06): Cython optimizations and doc tweaks

```
sage.combinat.fast_vector_partitions.fast_vector_partitions(v, min_vals=None)
```

Brent Yorgey’s fast algorithm for integer vector (multiset) partitions.

INPUT:

• `v` – list of non-negative integers, understood as the vector to be partitioned

• `min_vals` – optional list of non-negative integers, of same length as `v`

OUTPUT:

A list of lists, each representing a vector partition of `v`.

If `min_vals` is given, only partitions with parts `p >= min_vals` in the lexicographic ordering will appear.

If `min_vals` is given and `len(min_vals) != len(v)`, an error is raised.

EXAMPLES:

The older the computer, the more impressive the comparison:

```
sage: from sage.combinat.fast_vector_partitions import fast_vector_partitions
sage: fastvparts = list(fast_vector_partitions([3, 3, 3]))
sage: vparts = list(VectorPartitions([3, 3, 3]))
sage: vparts == fastvparts[::-1]
True
sage: len(fastvparts)
686
sage: list(fast_vector_partitions([1, 2, 3], min_vals=[0, 1, 1]))
[[[1, 2, 3]],
 [[0, 2, 3], [1, 0, 0]],
 [[0, 2, 2], [1, 0, 1]],
 [[0, 2, 1], [1, 0, 2]],
 [[0, 2, 0], [1, 0, 3]],
 [[0, 1, 3], [1, 1, 0]],
 [[0, 1, 2], [1, 1, 1]],
 [[0, 1, 1], [1, 1, 2]],
 [[0, 1, 1], [0, 1, 2], [1, 0, 0]],
 [[0, 1, 1], [0, 1, 1], [1, 0, 1]]]
sage: L1 = list(fast_vector_partitions([5, 7, 6], min_vals=[1, 3, 2]))
```

(continues on next page)
sage: L1 == list(VectorPartitions([5, 7, 6], min=[1, 3, 2]))[::-1]
True

Note: The partitions are returned as an iterator.

In this documentation, $a <|= b$ means $a[i] \leq b[i]$ for all $i$ (notation following B. Yorgey’s paper). It is the monomial partial ordering in Dickson’s lemma: $a <|= b$ iff $x^a$ divides $x^b$ as monomials.

Warning: The ordering of the partitions is reversed with respect to the output of Sage class VectorPartitions.

sage.combinat.fast_vector_partitions.recursive_vector_partitions(v, vL)
Iterate over a lexicographically ordered list of lists, each list representing a vector partition of v, such that no part of any partition is lexicographically smaller than vL.

Internal part of fast_vector_partitions().

INPUT:
• v – list of non-negative integers, understood as a vector
• vL – list of non-negative integers, understood as a vector

EXAMPLES:

sage: from sage.combinat.fast_vector_partitions import recursive_vector_partitions
sage: list(recursive_vector_partitions([2, 2, 2],[1, 1, 1]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]]]

sage: list(recursive_vector_partitions([2, 2, 2],[1, 1, 0]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]], [[1, 1, 0], [1, 1, 2]]]

sage: list(recursive_vector_partitions([2, 2, 2],[1, 0, 1]))
[[[2, 2, 2]],
 [[1, 1, 1], [1, 1, 1]],
 [[1, 1, 0], [1, 1, 2]],
 [[1, 0, 2], [1, 2, 0]],
 [[1, 0, 1], [1, 2, 1]]]

sage.combinat.fast_vector_partitions.recursive_within_from_to(m, s, e, useS, useE)
Iterate over a lexicographically ordered list of lists v satisfying e <= v <= s and v <|= m as vectors.

Internal part of fast_vector_partitions().

INPUT:
• m – list of non-negative integers, understood as a vector
• s – list of non-negative integers, understood as a vector
• e – list of non-negative integers, understood as a vector
• useS – boolean
• useE – boolean

EXAMPLES:
sage: from sage.combinat.fast_vector_partitions import recursive_within_from_to
sage: list(recursive_within_from_to([1, 2, 3],[1, 2, 2],[1, 1, 1],True,True))
[[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]

Note: The flags useS and useE are used to implement the condition efficiently. Because testing it loops over
the vector, re-testing at each step as the vector is parsed is inefficient: all but the last comparison have been
done cumulatively already. This code tests only for the last one, using the flags to accumulate information from
previous calls.

Warning: Expects to be called with s <= m.
Expects to be called first with useS == useE == True.

sage.combinat.fast_vector_partitions.within_from_to(m, s, e)
Iterate over a lexicographically ordered list of lists v satisfying e <= v <= s and v <|= m as vectors.
Internal part of fast_vector_partitions().

INPUT:
• m – list of non-negative integers, understood as a vector
• s – list of non-negative integers, understood as a vector
• e – list of non-negative integers, understood as a vector

EXAMPLES:
sage: from sage.combinat.fast_vector_partitions import within_from_to
sage: list(within_from_to([1, 2, 3], [1, 2, 2], [1, 1, 1]))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]

Note: The input s will be “clipped” internally if it does not satisfy the condition s <|= m.
To understand the input check, some line art is helpful. Assume that (a,b) are the two least significant coordi-
nates of some vector. Say:

\[
e = (2,3), \quad s = (7,6), \quad m = (9,8).
\]

In the figure, these values are denoted by E, S, and M, while the letter X stands for all other allowed values of v = (a,b):

\[
\begin{array}{c|c|c|c|c|c|c|c|c}
& & & & & & & & \\
8 & ---X---X---X---X---X---X---X---M \\
| & | & | & | & | & | & \\
7 - & X & X & X & X & X & | & | \\
| & | & | & | & | & | & \\
6 - & X & X & X & X & X & S & | & \\
| & | & | & | & | & | & \\
5 - & X & X & X & X & X & | & | \\
| & | & | & | & | & | & \\
4 - & X & X & X & X & X & | & | \\
\end{array}
\]
If $S$ moves horizontally, the full-height columns fill the box in until $S$ reaches $M$, at which point it remains the limit in the $b$-direction as it moves out of the box, while $M$ takes over as the limit in the $a$-direction, so the $M$-column remains filled only up to $S$, no matter how much $S$ moves further to the right.

If $S$ moves vertically, its column will be filled to the top of the box, but it remains the relevant limit in the $a$-direction, while $M$ takes over in the $b$-direction as $S$ goes out of the box upwards.

Both behaviors are captured by using the smaller coordinate of $S$ and $M$, whenever $S$ is outside the box defined by $M$. The input will be “clipped” accordingly in that case.

### Warning
The “clipping” behavior is transparent to the user, but may be puzzling when comparing outputs with the function `recursive_within_from_to()` which has no input protection.

#### 5.1.106 Fully commutative elements of Coxeter groups

An element $w$ in a Coxeter system $(W,S)$ is fully commutative (FC) if every two reduced words of $w$ can be related by a sequence of only commutation relations, i.e., relations of the form $st = ts$ where $s, t$ are commuting generators in $S$. See [Ste1996].

Authors:
- Chase Meadors, Tianyuan Xu (2020): Initial version

### Acknowledgements

A draft of this code was written during an REU project at University of Colorado Boulder. We thank Rachel Castro, Joel Courtney, Thomas Magnuson and Natalie Schoenhals for their contribution to the project and the code.
check()
Called automatically when an element is created.

EXAMPLES:

```
sage: CoxeterGroup(['A', 3]).fully_commutative_elements()(1, 2) # indirect doctest
[1, 2]
sage: CoxeterGroup(['A', 3]).fully_commutative_elements()(1, 2, 1) # indirect doctest
Traceback (most recent call last):
... ValueError: the input is not a reduced word of a fully commutative element
```

coset_decomposition(J, side='left')
Return the coset decomposition of self with respect to the parabolic subgroup generated by J.

INPUT:
- J – subset of the generating set $S$ of the Coxeter system
- side – string (default: 'left'); if the value is set to 'right', then the function returns the tuple $(w'_J, w'_J)$ from the coset decomposition $w = w'_J \cdot w'_J$ of $w$ with respect to $J$

OUTPUT:
The tuple of elements $(w_J, w^J)$ such that $w = w_J \cdot w^J$, $w_J$ is generated by the elements in $J$, and $w^J$ has no left descent from $J$. This tuple is unique and satisfies the equation $\ell(w) = \ell(w_J) + \ell(w^J)$, where $\ell$ denotes Coxeter length, by general theory; see Proposition 2.4.4 of [BB2005].

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 6]).fully_commutative_elements()
sage: w = FC([1, 6, 2, 5, 4, 6, 5])
sage: w.coset_decomposition({1})
([1, 6, 2, 5, 4, 6, 5], [1])
sage: w.coset_decomposition({1}, side = 'right')
([1, 6, 2, 5, 4, 6, 5], [])
sage: w.coset_decomposition({5, 6})
([6, 5, 6], [1, 2, 4, 5])
sage: w.coset_decomposition({5, 6}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

Note: The factor $w_J$ of the coset decomposition $w = w_J \cdot w^J$ can be obtained by greedily "pulling left descents of $w$ that are in $J$ to the left"; see the proof of [BB2005]. This greedy algorithm works for all elements in Coxeter group, but it becomes especially simple for FC elements because descents are easier to find for FC elements.

descents(side='left')
Obtain the set of descents on the appropriate side of self.

INPUT:
- side – string (default: 'left'); if set to 'right', find the right descents

A generator $s$ is called a left or right descent of an element $w$ if $l(sw)$ or $l(ws)$ is smaller than $l(w)$, respectively. If $w$ is FC, then $s$ is a left descent of $w$ if and only if $s$ appears to in the word and every
generator to the left of the leftmost $s$ in the word commutes with $s$. A similar characterization exists for right descents of FC elements.

EXAMPLES:

```python
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: sorted(w.descents())
[1, 4]
sage: w.descents(side='right')
{3}
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: sorted(FC([1, 4, 3, 5, 2, 4, 3]).descents())
[1, 4]
```

See also:

`find_descent()`

`find_descent(s, side='left')`

Check if $s$ is a descent of `self` and find its position if so.

A generator $s$ is called a left or right descent of an element $w$ if $l(sw)$ or $l(ws)$ is smaller than $l(w)$, respectively. If $w$ is FC, then $s$ is a left descent of $w$ if and only if $s$ appears to in the word and every generator to the left of the leftmost $s$ in the word commutes with $s$. A similar characterization exists for right descents of FC elements.

INPUT:

- `s` – integer representing a generator of the Coxeter system
- `side` – string (default: 'left'); if the argument is set to 'right', the function checks if $s$ is a right descent of `self` and finds the index of the rightmost occurrence of $s$ if so

OUTPUT:

Determine if the generator $s$ is a left descent of `self`; return the index of the leftmost occurrence of $s$ in `self` if so and return `None` if not.

EXAMPLES:

```python
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: w.find_descent(1)
0
sage: w.find_descent(1, side='right')

sage: w.find_descent(4)
1
sage: w.find_descent(4, side='right')

sage: w.find_descent(3)
```

`group_element()`

Get the actual element of the Coxeter group associated with `self.parent()` corresponding to `self`.

EXAMPLES:
sage: W = CoxeterGroup(['A', 3])
sage: FC = W.fully_commutative_elements()
sage: x = FC([1, 2])
sage: x.group_element()
\[
\begin{bmatrix}
0 & -1 & 1 \\
1 & -1 & 1 \\
0 & 0 & 1
\end{bmatrix}
\]
sage: x.group_element() in W
True

**has_descent** (*s*, *side='left'*)

Determine if *s* is a descent on the appropriate side of *self*.

**INPUT:**

- *side* – string (default: 'left'); if set to 'right', determine if *self* has *s* as a right descent

**OUTPUT:** a boolean value

**EXAMPLES:**

sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: w.has_descent(1)
True
sage: w.has_descent(1, side='right')
False
sage: w.has_descent(4)
True
sage: w.has_descent(4, side='right')
False

**See also:**

*find_descent()*

**heap**(\**kargs\*)

Create the heap poset of *self*.

The heap of an FC element *w* is a labeled poset that can be defined from any reduced word of *w*. Different reduced words yield isomorphic labeled posets, so the heap is well defined.

Heaps are very useful for visualizing and studying FC elements; see, for example, [Ste1996] and [GX2020].

**INPUT:**

- *self* – list, a reduced word *w* = \(s_0...s_{k-1}\) of an FC element
- *one_index* – boolean (default: False). Setting the value to True will change the underlying set of the poset to \(\{1, 2, \ldots, n\}\)
- *display_labeling* – boolean (default: False). Setting the value to True will display the label \(s_i\) for each element *i* of the poset

**OUTPUT:**

A labeled poset where the underlying set is \(\{0, 1, \ldots, k-1\}\) and where each element *i* carries \(s_i\) as its label. The partial order \(\prec\) on the poset is defined by declaring \(i \prec j\) if \(i < j\) and \(m(s_i, s_j) \neq 2\).

**EXAMPLES:**
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: FC([1, 4, 3, 5, 2, 4]).heap().cover_relations()
[[[1, 2], [1, 3], [2, 5], [2, 4], [3, 5], [0, 4]]
sage: FC([1, 4, 3, 5, 4, 2]).heap(one_index=True).cover_relations()
[[2, 3], [2, 4], [3, 6], [3, 5], [4, 6], [1, 5]]

is_fully_commutative()
Check if self is the reduced word of an FC element.

To check if self is FC, we use the well-known characterization that an element \( w \) in a Coxeter system \((W, S)\) is FC if and only if for every pair of generators \( s, t \in S \) for which \( m(s, t) > 2 \), no reduced word of \( w \) contains the `braid` word \( stst... \) of length \( m(s, t) \) as a contiguous subword. See [Ste1996].

check() is an alias of this method, and is called automatically when an element is created.

EXAMPLES:

```sage
c = CoxeterGroup(['A', 3]).fully_commutative_elements()
x = c([1, 2]); x.is_fully_commutative()
True
x = c.element_class(c, [1, 2, 1], check=False); x.is_fully_commutative()
False
```

n_value()
Calculate the n-value of self.

The n-value of a fully commutative element is the width (length of any longest antichain) of its heap. The n-value is important as it coincides with Lusztig's a-value for FC elements in all Weyl and affine Weyl groups as well as so-called star-reducible groups; see [GX2020].

EXAMPLES:

```sage
c = CoxeterGroup(['A', 5]).fully_commutative_elements()
c.n_value()
2
c([1, 2, 3]).n_value()
1
c([1, 3, 2]).n_value()
2
c([1, 3, 2, 5]).n_value()
3
```

normalize()
Mutate self into Cartier-Foata normal form.

EXAMPLES:

The following reduced words express the same FC elements in \( B_5 \):

```sage
c = CoxeterGroup(['B', 5]).fully_commutative_elements()
c([1, 4, 3, 5, 2, 4, 3])
[1, 4, 3, 5, 2, 4, 3]
c([4, 1, 3, 5, 2, 4, 3])
[1, 4, 3, 5, 2, 4, 3]
c([4, 3, 1, 5, 4, 2, 3])
[1, 4, 3, 5, 2, 4, 3]
```
Note: The Cartier–Foata form of a reduced word of an FC element $w$ can be found recursively by repeatedly moving left descents of elements to the left and ordering the left descents from small to large. In the above example, the left descents of the element are 4 and 1, therefore the Cartier–Foata form of the element is the concatenation of [1,4] with the Cartier–Foata form of the remaining part of the word. See [Gre2006].

See also:

descents()

plot_heap()

Display the Hasse diagram of the heap of self.

The Hasse diagram is rendered in the lattice $S \times \mathbb{N}$, with every element $i$ in the poset drawn as a point labelled by its label $s_i$. Every point is placed in the column for its label at a certain level. The levels start at 0 and the level $k$ of an element $i$ is the maximal number $k$ such that the heap contains a chain $i_0 \prec i_1 \prec ... \prec i_k$ where $i_k = i$. See [Ste1996] and [GX2020].

OUTPUT: GraphicsObject

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: FC([3,2,4,3,1]).plot_heap()     #optional - sage.plot
Graphics object consisting of 15 graphics primitives
```

star_operation($J$, direction, side='left')

Apply a star operation on self relative to two noncommuting generators.

Star operations were first defined on elements of Coxeter groups by Kazhdan and Lusztig in [KL1979] with respect to pair of generators $s, t$ such that $m(s, t) = 3$. Later, Lusztig generalized the definition in [Lus1985], via coset decompositions, to allow star operations with respect to any pair of generators $s, t$ such that $m(s, t) \geq 3$. Given such a pair, we can potentially perform four types of star operations corresponding to all combinations of a ‘direction’ and a ‘side’: upper left, lower left, upper right and lower right; see [Gre2006].
Let \( w \) be an element in \( W \) and let \( J \) be any pair \( \{s, t\} \) of noncommuting generators in \( S \). Consider the coset decomposition \( w = w J \cdot wJ \) of \( w \) relative to \( J \). Then an upper left star operation is defined on \( w \) if and only if \( 1 \leq l(w J) \leq m(s, t) - 2 \); when this is the case, the operation returns \( x \cdot w J \cdot wJ \) where \( x \) is the letter \( J \) different from the leftmost letter of \( wJ \). A lower left star operation is defined on \( w \) if and only if \( 2 \leq l(w J) \leq m(s, t) - 1 \); when this is the case, the operation removes the leftmost letter of \( wJ \) from \( w \). Similar facts hold for right star operations. See [Gre2006].

The facts of the previous paragraph hold in general, even if \( w \) is not FC. Note that if \( f \) is a star operation of any kind, then for every element \( w \in W \), the elements \( w \) and \( f(w) \) are either both FC or both not FC.

**INPUT:**
- \( J \) – a set of two integers representing two noncommuting generators of the Coxeter system
- \( \text{direction} \) – string, ‘upper’ or ‘lower’; the function performs an upper or lower star operation according to \( \text{direction} \)
- \( \text{side} \) – string (default: ‘left’); if this is set to ‘right’, the function performs a right star operation

**OUTPUT:**

The Cartier–Foata form of the result of the star operation if the operation is defined on \( \text{self} \), None otherwise.

**EXAMPLES:**

We will compute all star operations on the following FC element in type \( B_6 \) relative to \( J = \{5, 6\} \):

```python
sage: FC = CoxeterGroup(['B', 6]).fully_commutative_elements()
sage: w = FC([1, 6, 2, 5, 4, 6, 5])
```

Whether and how a left star operations can be applied depend on the coset decomposition \( w = w J \cdot wJ \):

```python
sage: w.coset_decomposition({5, 6})
([], [6, 5, 6])
```

Only the lower star operation is defined on the left on \( w \):

```python
sage: w.star_operation({5, 6}, 'upper')
sage: w.star_operation({5, 6}, 'lower')
[1, 5, 2, 4, 6, 5]
```

Whether and how a right star operations can be applied depend on the coset decomposition \( w = w^J \cdot wJ \):

```python
sage: w.coset_decomposition({5, 6}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

Both types of right star operations on defined for this example:

```python
sage: w.star_operation({5, 6}, 'upper', side='right')
sage: w.star_operation({5, 6}, 'lower', side='right')
[1, 6, 2, 5, 4, 6, 5, 6]
```

**class** `sage.combinat.fully_commutative_elements.FullyCommutativeElements(coxeter_group)`

**Bases:** `UniqueRepresentation, Parent`

Class for the set of fully commutative (FC) elements of a Coxeter system.
Combinatorics, Release 10.1

Coxeter systems with finitely many FC elements, or *FC-finite* Coxeter systems, are classified by Stembridge in [Ste1996]. They fall into seven families, namely the groups of types $A_n, B_n, D_n, E_n, F_n, H_n$ and $I_2(m)$.

**INPUT:**
- `data` – CoxeterMatrix, CartanType, or the usual datum that can is taken in the constructors for these classes (see `sage.combinat.root_system.coxeter_group.CoxeterGroup()`)

**OUTPUT:**

The class of fully commutative elements in the Coxeter group constructed from `data`. This will belong to the category of enumerated sets. If the Coxeter data corresponds to a Cartan type, the category is further refined to either finite enumerated sets or infinite enumerated sets depending on whether the Coxeter group is FC-finite; the refinement is not carried out if `data` is a Coxeter matrix not corresponding to a Cartan type.

**Todo:** It would be ideal to implement the aforementioned refinement to finite and infinite enumerated sets for all possible `data`, regardless of whether it corresponds to a Cartan type. Doing so requires determining if an arbitrary Coxeter matrix corresponds to a Cartan type. It may be best to address this issue in `sage.combinat.root_system`. On the other hand, the refinement in the general case may be unnecessary in light of the fact that Stembridge’s classification of FC-finite groups contains a very small number of easily-recognizable families.

**EXAMPLES:**

Create the enumerate set of fully commutative elements in $B_3$:

```python
sage: FC = CoxeterGroup(['B', 3]).fully_commutative_elements(); FC
Fully commutative elements of Finite Coxeter group over Number Field in a with defining polynomial x^2 - 2 with a = 1.414213562373095? with Coxeter matrix:
[1 3 2]
[3 1 4]
[2 4 1]
```

Construct elements:

```python
sage: FC([])
[]
sage: FC([1,2])
[1, 2]
sage: FC([2,3,2])
[2, 3, 2]
sage: FC([3,2,3])
[3, 2, 3]
```

Elements are normalized to Cartier–Foata normal form upon construction:

```python
sage: FC([3,1])
[1, 3]
sage: FC([2,3,1])
[2, 1, 3]
sage: FC([1,3]) == FC([3,1])
True
```

Attempting to create an element from an input that is not the reduced word of a fully commutative element throws a `ValueError`:
Enumerate the FC elements in $A_3$:

```python
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: FCA3.category()
Category of finite enumerated sets
sage: FCA3.list()
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3], [3, 2, 1], [2, 1, 3], [1, 3, 2], [1, 2, 3], [2, 1, 3, 2]]
```

Count the FC elements in $B_8$:

```python
sage: FCB8 = CoxeterGroup(['B', 8]).fully_commutative_elements()
sage: len(FCB8)  # long time (7 seconds)
14299
```

Iterate through the FC elements of length up to 2 in the non-FC-finite group affine $A_2$:

```python
sage: FCAffineA2 = CoxeterGroup(['A', 2, 1]).fully_commutative_elements()
sage: FCAffineA2.category()
Category of infinite enumerated sets
sage: list(FCAffineA2.iterate_to_length(2))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2], [1, 2]]
```

The cardinality of the set is determined from the classification of FC-finite Coxeter groups:

```python
sage: CoxeterGroup('A2').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('B7').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('A3~').fully_commutative_elements().category()
Category of infinite enumerated sets
sage: CoxeterGroup('F4~').fully_commutative_elements().category()
```

(continues on next page)
Combinatorics, Release 10.1

Category of finite enumerated sets

sage: CoxeterGroup('E8~').fully_commutative_elements().category()
Category of finite enumerated sets

sage: CoxeterGroup('F4~xE8~').fully_commutative_elements().category()
Category of finite enumerated sets

sage: CoxeterGroup('B4~xE8~').fully_commutative_elements().category()
Category of infinite enumerated sets

Element

alias of FullyCommutativeElement

coxeter_group()

Obtain the Coxeter group associated with self.

EXAMPLES:

```python
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: FCA3.coxeter_group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2]
[3 1 3]
[2 3 1]
```

iterate_to_length(length)

Iterate through the elements of this class up to a maximum length.

INPUT:

- length – integer; maximum length of element to generate

OUTPUT: generator for elements of self of length up to length

EXAMPLES:

The following example produces all FC elements of length up to 2 in the group $A_3$:

```python
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: list(FCA3.iterate_to_length(2))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3]]
```

The lists for length 4 and 5 are the same since 4 is the maximum length of an FC element in $A_3$:

```python
sage: list(FCA3.iterate_to_length(4)) == list(FCA3)
True
```

The following example produces all FC elements of length up to 4 in the affine Weyl group $\tilde{A}_2$:

```python
sage: FCAffineA2 = CoxeterGroup(['A', 2, 1]).fully_commutative_elements()
sage: FCAffineA2.category()
```

(continues on next page)

\begin{verbatim}
\textbf{sage: list(FCAffineA2.iterate_to_length(4))}
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2],
 [1, 2], [2, 1, 0], [1, 2, 0], [2, 0, 1], [0, 2, 1], [1, 0, 2],
 [0, 1, 2], [0, 2, 1, 0], [0, 1, 2, 0], [1, 2, 0, 1],
 [1, 0, 2, 1], [2, 1, 0, 2], [2, 0, 1, 2]]
\end{verbatim}

5.1.107 Finite state machines, automata, transducers

This module adds support for finite state machines, automata and transducers.

For creating automata and transducers you can use classes

- \texttt{Automaton} and \texttt{Transducer} (or the more general class \texttt{FiniteStateMachine})

or the generators

- \texttt{automata} and \texttt{transducers}

which contain \texttt{preconstructed and commonly used automata and transducers}. See also the examples below.

Examples

We start with a general `FiniteStateMachine`. Later there will be also an `Automaton` and a `Transducer`.

A simple finite state machine

We can easily create a finite state machine by

```
sage: fsm = FiniteStateMachine()
sage: fsm
Empty finite state machine
```

By default this is the empty finite state machine, so not very interesting. Let’s create and add some states and transitions:

```
sage: day = fsm.add_state('day')
sage: night = fsm.add_state('night')
sage: sunrise = fsm.add_transition(night, day)
sage: sunset = fsm.add_transition(day, night)
```

Let us look at sunset more closely:

```
sage: sunset
Transition from 'day' to 'night': -|-|
```

Note that could also have created and added the transitions directly by:

```
sage: fsm.add_transition('day', 'night')
Transition from 'day' to 'night': -|-|
```

This would have had added the states automatically, since they are present in the transitions.

Anyhow, we got the following finite state machine:

```
sage: fsm
Finite state machine with 2 states
```

We can also obtain the underlying **directed graph** by
To visualize a finite state machine, we can use \texttt{latex()} and run the result through LaTeX, see the section on \texttt{LaTeX output} below.

Alternatively, we could have created the finite state machine above simply by

\begin{lstlisting}[language=sage]
\texttt{sage: FiniteStateMachine([(['night', 'day'], ['day', 'night'])])}
Finite state machine with 2 states
\end{lstlisting}

See \texttt{FiniteStateMachine} for a lot of possibilities to create finite state machines.

\section*{A simple Automaton (recognizing NAFs)}

We want to build an automaton which recognizes non-adjacent forms (NAFs), i.e., sequences which have no adjacent non-zeros. We use 0, 1, and \(-1\) as digits:

\begin{lstlisting}[language=sage]
\texttt{sage: NAF = Automaton(....:
   ...:   {'A': [('A', 0), ('B', 1), ('B', -1)], 'B': [('A', 0)])}
\texttt{sage: NAF.state('A').is_initial = True}
\texttt{sage: NAF.state('A').is_final = True}
\texttt{sage: NAF.state('B').is_final = True}
\texttt{sage: NAF}
Automaton with 2 states
\end{lstlisting}

Of course, we could have specified the initial and final states directly in the definition of \texttt{NAF} by \texttt{initial_states=['A']} and \texttt{final_states=['A', 'B']}.

So let’s test the automaton with some input:

\begin{lstlisting}[language=sage]
\texttt{sage: NAF([0])}
True
\texttt{sage: NAF([0, 1])}
True
\texttt{sage: NAF([1, -1])}
False
\texttt{sage: NAF([0, -1, 0, 1])}
True
\texttt{sage: NAF([0, -1, -1, -1, 0])}
False
\texttt{sage: NAF([-1, 0, 0, 1, 1])}
False
\end{lstlisting}

Alternatively, we could call that by

\begin{lstlisting}[language=sage]
\texttt{sage: NAF.process([0, -1, 0, 1])}
(True, 'B')
\end{lstlisting}

which gives additionally the state in which we arrived.

We can also let an automaton act on a word:

\begin{lstlisting}[language=sage]
\end{lstlisting}
Recognizing NAFs via Automata Operations

Alternatively, we can use automata operations to recognize NAFs; for simplicity, we only use the input alphabet \([0, 1]\). On the one hand, we can construct such an automaton by forbidding the word 11:

```python
sage: forbidden = automata.ContainsWord([1, 1], input_alphabet=[0, 1])
sage: NAF_negative = forbidden.complement()
sage: NAF_negative([1, 1, 0, 1])
False
sage: NAF_negative([1, 0, 1, 0, 1])
True
```

On the other hand, we can write this as a regular expression and translate that into automata operations:

```python
sage: zero = automata.Word([0])
sage: one = automata.Word([1])
sage: epsilon = automata.EmptyWord(input_alphabet=[0, 1])
sage: NAF_positive = (zero + one*zero).kleene_star() * (epsilon + one)
```

We check that the two approaches are equivalent:

```python
sage: NAF_negative.is_equivalent(NAF_positive)
True
```

See also:
- `ContainsWord()`
- `Word()`
- `complement()`
- `kleene_star()`
- `EmptyWord()`
- `is_equivalent()`

**LaTeX output**

We can visualize a finite state machine by converting it to \LaTeX{} by using the usual function `latex()`. Within \LaTeX{}, TikZ is used for typesetting the graphics, see the Wikipedia article PGF/TikZ.

```python
sage: print(latex(NAF))  # abs tol 1e-3
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state, accepting, initial] (v0) at (3.000000, 0.000000) {$\texttt{A}$};
\node[state, accepting] (v1) at (-3.000000, 0.000000) {$\texttt{B}$};
\path[->] (v0) edge[loop above] node {$0$} (v0);
\path[->] (v0) edge node[rotate=360.00, anchor=north] {$\texttt{B}$} (v1);
\path[->] (v1) edge node[rotate=0.00, anchor=south] {$\texttt{A}$} (v0);
\end{tikzpicture}
```

We can turn this into a graphical representation.
To actually see this, use the live documentation in the Sage notebook and execute the cells in this and the previous section.

Several options can be set to customize the output, see `latex_options()` for details. In particular, we use `format_letter_negative()` to format $-1$ as $1$.

```python
sage: NAF.latex_options(
    ...:     coordinates={'A': (0, 0),
    ...:                    'B': (6, 0),
    ...:     initial_where={'A': 'below'},
    ...:     format_letter=NAF.format_letter_negative,
    ...:     format_state_label=lambda x:
    ...:         r'$\mathcal{%s} % x.label()$
    ...: )
sage: print(latex(NAF))
\begin{tikzpicture}
[auto, initial text=, >=latex]
\node[state, accepting, initial, initial where=below] (v0) at (0.000000, 0.000000) {$\rightarrow \mathcal{A}$};
\node[state, accepting] (v1) at (6.000000, 0.000000) {$\mathcal{B}$};
\path[->] (v0) edge[loop above] node {$0$} ();
\path[->] (v0.5.00) edge node[rotate=0.00, anchor=south] {$1, \overline{1}$} (v1.175.00);
\path[->] (v1.185.00) edge node[rotate=360.00, anchor=north] {$0$} (v0.355.00);
\end{tikzpicture}
```

To use the output of `latex()` in your own \LaTeX{} file, you have to include

\begin{verbatim}
\usepackage{tikz}
\usetikzlibrary{automata}
\end{verbatim}

into the preamble of your file.

### A simple transducer (binary inverter)

Let’s build a simple transducer, which rewrites a binary word by inverting each bit:

```python
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
    ...:     initial_states=['A'], final_states=['A'])
```

We can look at the states and transitions:

```python
sage: inverter.states()
['A']
sage: for t in inverter.transitions():
    ...:     print(t)
Transition from 'A' to 'A': 0|1
Transition from 'A' to 'A': 1|0
```

Now we apply a word to it and see what the transducer does:

```python
sage: inverter([0, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 1])
[1, 0, 1, 1, 0, 0, 1, 1, 1, 0, 0, 0]
```
True means, that we landed in a final state, that state is labeled 'A', and we also got an output.

**Transducers and (in)finite Words**

A transducer can also act on everything iterable, in particular, on Sage’s *words*.

```python
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
```

Let us take the inverter from the previous section and feed some finite word into it:

```python
sage: w = W([1, 1, 0, 1]); w
word: 1101
sage: inverter(w)
word: 0010
```

We see that the output is again a word (this is a consequence of calling `process()` with `automatic_output_type`). We can even input something infinite like an infinite word:

```python
sage: tm = words.ThueMorseWord(); tm
word: 0110100110010110100110100110110100110010110...

sage: inverter(tm)
word: 1001011001101001011010011001011001101001...
```

**A transducer which performs division by 3 in binary**

Now we build a transducer, which divides a binary number by 3. The labels of the states are the remainder of the division. The transition function is

```python
sage: def f(state_from, read):
....:     if state_from + read <= 1:
....:         state_to = 2*state_from + read
....:         write = 0
....:     else:
....:         state_to = 2*state_from + read - 3
....:         write = 1
....:     return (state_to, write)
```

which assumes reading a binary number from left to right. We get the transducer with

```python
sage: D = Transducer(f, initial_states=[0], final_states=[0],
....:                  input_alphabet=[0, 1])
```

Let us try to divide 12 by 3:

```python
sage: D([1, 1, 0, 0])
[0, 1, 0, 0]
```

Now we want to divide 13 by 3:
The raised `ValueError` means 13 is not divisible by 3.

**Gray Code**

The Gray code is a binary numeral system where two successive values differ in only one bit, cf. the Wikipedia article `Gray_code`. The Gray code of an integer $n$ is obtained by a bitwise xor between the binary expansion of $n$ and the binary expansion of $\lfloor n/2 \rfloor$; the latter corresponds to a shift by one position in binary.

The purpose of this example is to construct a transducer converting the standard binary expansion to the Gray code by translating this construction into operations with transducers.

For this construction, the least significant digit is at the left-most position. Note that it is easier to shift everything to the right first, i.e., multiply by 2 instead of building $\lfloor n/2 \rfloor$. Then, we take the input xor with the right shift of the input and forget the first letter.

We first construct a transducer shifting the binary expansion to the right. This requires storing the previously read digit in a state.
Next, we construct the transducer performing the xor operation. We also have to take None into account as our shift_right_transducer waits one iteration until it starts writing output. This corresponds with our intention to forget the first letter.

```python
sage: def xor_transition(state, digits):
    ....:     if digits[0] is None or digits[1] is None:
    ....:         return (0, None)
    ....:     else:
    ....:         return (0, digits[0].__xor__(digits[1]))

sage: xor_transducer = Transducer(
    ....:     xor_transition,
    ....:     initial_states=[0],
    ....:     final_states=[0],
    ....:     input_alphabet=list(product([None, 0, 1], [0, 1])))

sage: xor_transducer.transitions()
[Transition from 0 to 0: (None, 0)|-,
 Transition from 0 to 0: (None, 1)|-,
 Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|0]

sage: xor_transducer([(None, 0), (None, 1), (0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 0]

sage: xor_transducer([(0, None)])
Traceback (most recent call last):
  ... ValueError: Invalid input sequence.
```

The transducer computing the Gray code is then constructed as a Cartesian product between the shifted version and the original input (represented here by the shift_right_transducer and the identity transducer, respectively). This Cartesian product is then fed into the xor_transducer as a composition of transducers.

```python
sage: product_transducer = shift_right_transducer.cartesian_product(transducers.Identity([0, 1]))
sage: Gray_transducer = xor_transducer(product_transducer)

We use construct_final_word_out() to make sure that all output is written; otherwise, we would have to make sure that a sufficient number of trailing zeros is read.

```python
sage: Gray_transducer.construct_final_word_out([0])
sage: Gray_transducer.transitions()
[Transition from ('I', 0, 0) to (0, 0, 0): 0|-,
 Transition from ('I', 0, 0) to (1, 0, 0): 1|-,
 Transition from (0, 0, 0) to (0, 0, 0): 0|0,
 Transition from (0, 0, 0) to (1, 0, 0): 1|0,
 Transition from (1, 0, 0) to (0, 0, 0): 0|1,
 Transition from (1, 0, 0) to (1, 0, 0): 1|1]
```

There is a prepackaged transducer for Gray code, let’s see whether they agree. We have to use relabeled() to relabel our states with integers.

```python
sage: constructed = Gray_transducer.relabeled()
sage: packaged = transducers.GrayCode()
```

(continues on next page)
Finally, we check that this indeed computes the Gray code of the first 10 non-negative integers.

```
sage: for n in srange(10):
    ....:     Gray_transducer(n.bits())
[[]]
[1]
[1, 1]
[0, 1]
[0, 1, 1]
[1, 1, 1]
[1, 0, 1]
[0, 0, 1]
[0, 0, 1, 1]
[1, 0, 1, 1]
```

**Using the hook-functions**

Let’s use the previous example “division by 3” to demonstrate the optional state and transition parameters hook.

First, we define what those functions should do. In our case, this is just saying in which state we are and which transition we take.

```
sage: def state_hook(process, state, output):
    ....:     print("We are now in State %s.\n" % (state.label(),))

def transition_hook(transition, process):
    ....:     print("Currently we go from %s to %s, \n" % (transition.from_state, transition.to_state),
    ....:         "reading %s and writing %s." % (FSMWordSymbol(transition.word_in),
    ....:         FSMWordSymbol(transition.word_out)))
```

Now, let’s add these hook-functions to the existing transducer:

```
sage: for s in D.iter_states():
    ....:     s.hook = state_hook

def transition_hook(transition, process):
    ....:     print("Currently we go from %s to %s, \n" % (transition.from_state, transition.to_state),
    ....:         "reading %s and writing %s." % (FSMWordSymbol(transition.word_in),
    ....:         FSMWordSymbol(transition.word_out)))
```

Rerunning the process again now gives the following output:

```
sage: D.process([1, 1, 0, 1], check_epsilon_transitions=False)
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
Currently we go from 1 to 0, reading 1 and writing 1.
We are now in State 0.
Currently we go from 0 to 0, reading 0 and writing 0.
We are now in State 0.
```

(continues on next page)
Currently we go from 0 to 1, reading 1 and writing 0. We are now in State 1.
(False, 1, [0, 1, 0, 0])

The example above just explains the basic idea of using hook-functions. In the following, we will use those hooks more seriously.

**Warning:** The hooks of the states are also called while exploring the epsilon successors of a state (during processing). In the example above, we used `check_epsilon_transitions=False` to avoid this (and also therefore got a cleaner output).

**Warning:** The arguments used when calling a hook have changed in github issue #16538 from `hook(state, process)` to `hook(process, state, output)`.

### Detecting sequences with same number of 0 and 1

Suppose we have a binary input and want to accept all sequences with the same number of 0 and 1. This cannot be done with a finite automaton. Anyhow, we can make usage of the hook functions to extend our finite automaton by a counter:

```python
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: C = FiniteStateMachine()

sage: def update_counter(process, state, output):
...:    try:
...:        l = process.preview_word()
...:    except RuntimeError:
...:        raise StopIteration
...:    if l == 1:
...:        process.fsm.counter += 1
...:    elif process.fsm.counter < 0:
...:        process.fsm.counter = 0
...:    else:
...:        process.fsm.counter -= 1
...:
...:    next_state = 'zero'
...:    return FSMTransition(state, process.fsm.state(next_state),
...:                          l, process.fsm.counter)

sage: C.add_state(FSMState('zero', hook=update_counter, is_initial=True, is_final=True))
'state zero'

sage: C.add_state(FSMState('positive', hook=update_counter))
'positive'

sage: C.add_state(FSMState('negative', hook=update_counter))
'negative'
```

Now, let’s input some sequence:

```python
sage: C.counter = 0; C([1, 1, 1, 1, 0, 0])
(False, 'positive', [1, 2, 3, 4, 3, 2])
```
The result is False, since there are four 1 but only two 0. We land in the state positive and we can also see the values of the counter in each step.

Let’s try some other examples:

```
sage: C.counter = 0; C([1, 1, 0, 0])
(True, 'zero', [1, 2, 1, 0])
sage: C.counter = 0; C([0, 1, 0, 0])
(False, 'negative', [-1, 0, -1, -2])
```

See also methods Automaton.process() and Transducer.process() (or even FiniteStateMachine.process()), the explanation of the parameter hook and the examples in FSMState and FSMTransition, and the description and examples in FSMProcessIterator for more information on processing and hooks.

Methods

class sage.combinat.finite_state_machine.Automaton(*args, **kwargs)

Bases: FiniteStateMachine

This creates an automaton, which is a finite state machine, whose transitions have input labels.

An automaton has additional features like creating a deterministic and a minimized automaton.

See class FiniteStateMachine for more information.

EXAMPLES:

We can create an automaton recognizing even numbers (given in binary and read from left to right) in the following way:

```python
sage: A = Automaton([('P', 'Q', 0), ('P', 'P', 1),
                  ('Q', 'P', 1), ('Q', 'Q', 0)],
                  initial_states=['P'], final_states=['Q'])
```

```python
sage: A
Automaton with 2 states

sage: A([0])
True

sage: A([1, 1, 0])
True

sage: A([1, 0, 1])
False
```

Note that the full output of the commands can be obtained by calling `process()` and looks like this:

```python
sage: A.process([1, 0, 1])
(False, 'P')
```

cartesian_product(other, only_accessible_components=True)

Return a new automaton which accepts an input if it is accepted by both given automata.

INPUT:

• other – an automaton

• only_accessible_components – If True (default), then the result is piped through accessible_components(). If no new_input_alphabet is given, it is determined by determine_alphabets().

OUTPUT:

A new automaton which computes the intersection (see below) of the languages of self and other.
The set of states of the new automaton is the Cartesian product of the set of states of both given automata. There is a transition \((A, B, (C, D), a)\) in the new automaton if there are transitions \((A, C, a)\) and \((B, D, a)\) in the old automata.

The methods `intersection()` and `cartesian_product()` are the same (for automata).

**EXAMPLES:**

```python
sage: aut1 = Automaton([(('1', '1'), ('2', '1'), 1),
                      (None, '2', '2'),
                      (None, '2', None)],
                     initial_states=['1'],
                     final_states=['2'],
                     determine_alphabets=True)

sage: aut2 = Automaton([(('A', 'A'), '1'),
                      (None, 'B', 0),
                      (None, 'B', 0),
                      (None, 'A', '1')],
                     initial_states=['A'],
                     final_states=['B'],
                     determine_alphabets=True)

sage: res = aut1.intersection(aut2)
sage: (aut1([1, 1]), aut2([1, 1]), res([1, 1]))
(True, False, False)
sage: (aut1([1, 0]), aut2([1, 0]), res([1, 0]))
(True, True, True)
sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'A') to ('2', 'B'): 0|-,
 Transition from ('2', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'B') to ('2', 'B'): 0|-,
 Transition from ('2', 'B') to ('2', 'A'): 1|-]
```

For automata with epsilon-transitions, intersection is not well defined. But for any finite state machine, epsilon-transitions can be removed by `remove_epsilon_transitions()`.

```python
sage: a1 = Automaton([((0, 0, 0),
                    (0, 1, None),
                    (1, 1, 1),
                    (1, 2, 1)],
                   initial_states=[0],
                   final_states=[1],
                   determine_alphabets=True)

sage: a2 = Automaton([((0, 0, 0), (0, 1, 1), (1, 1, 1)],
                   initial_states=[0],
                   final_states=[1],
                   determine_alphabets=True)

sage: a1.intersection(a2)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input) was found.
sage: a1.remove_epsilon_transitions()  # not tested (since not implemented yet)
sage: a1.intersection(a2)  # not tested
```
Return the complement of this automaton.

**OUTPUT:**

An Automaton.

If this automaton recognizes language $\mathcal{L}$ over an input alphabet $\mathcal{A}$, then the complement recognizes $\mathcal{A} \setminus \mathcal{L}$.

**EXAMPLES:**

```python
sage: A = automata.Word([0, 1])
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1]) if A(w)]
[[0, 1]]
sage: Ac = A.complement()
sage: Ac.transitions()
[Transition from 0 to 1: 0|--,
 Transition from 0 to 3: 1|--,
 Transition from 2 to 3: 0|--,
 Transition from 1 to 2: 1|--,
 Transition from 1 to 3: 0|--,
 Transition from 3 to 3: 0|--,
 Transition from 3 to 3: 1|--]
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1]) if Ac(w)]
[[], [0], [1], [0, 0], [1, 0], [1, 1]]
```

The automaton must be deterministic:

```python
sage: A = automata.Word([0]) * automata.Word([1])
sage: A.complement()
Traceback (most recent call last):
  ...
ValueError: The finite state machine must be deterministic.
sage: Ac = A.determinisation().complement()
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1]) if Ac(w)]
[[], [0], [1], [0, 0], [1, 0], [1, 1]]
```

determinisation()

Return a deterministic automaton which accepts the same input words as the original one.

**OUTPUT:**

A new automaton, which is deterministic.

The labels of the states of the new automaton are frozensets of states of self. The color of a new state is the frozenset of colors of the constituent states of self. Therefore, the colors of the constituent states have to be hashable. However, if all constituent states have color None, then the resulting color is None, too.

The input alphabet must be specified.

**EXAMPLES:**

```python
sage: aut = Automaton([('A', 'A', 0), ('A', 'B', 1), ('B', 'B', 1)],
                  initial_states=['A'], final_states=['B'])
```
sage: aut.determinisation().transitions()
[Transition from frozenset({'A'}) to frozenset(): 0|-,
 Transition from frozenset({'A'}) to frozenset({'B'}): 1|-,
 Transition from frozenset({'B'}) to frozenset(): 0|-,
 Transition from frozenset({'B'}) to frozenset(): 1|-,
 Transition from frozenset() to frozenset(): 0|-,
 Transition from frozenset() to frozenset(): 1|--]  

sage: A = Automaton([('A', 'A', 1), ('A', 'A', 0), ('A', 'B', 1),
                  ('B', 'C', 0), ('C', 'C', 1), ('C', 'C', 0)],
                  initial_states=['A'], final_states=['C'])

sage: A.determinisation().states()
[frozenset({'A'}),
 frozenset({'A', 'B'}),
 frozenset({'A', 'C'}),
 frozenset({'A', 'B', 'C'})]

sage: A = Automaton([(0, 1, 1), (0, 2, [1, 1]), (0, 3, [1, 1, 1]),
                  (1, 0, -1), (2, 0, -2), (3, 0, -3)],
                  initial_states=[0], final_states=[0, 1, 2, 3])

sage: B = A.determinisation().relabeled().coaccessible_components()
sage: sorted(B.transitions())
[Transition from 0 to 1: 1|-,
 Transition from 1 to 0: -1|-,
 Transition from 1 to 3: 1|-,
 Transition from 3 to 0: -2|-,
 Transition from 3 to 4: -3|-
]

Note that colors of states have to be hashable:

sage: A = Automaton([(0, 0, 0)], initial_states=[0])
sage: A.state(0).color = []
sage: A.determinisation()  
Traceback (most recent call last):
...  
TypeError: unhashable type: 'list'
sage: A.state(0).color = ()
sage: A.determinisation()  
Automaton with 1 state

If the colors of all constituent states are None, the resulting color is None, too (github issue #19199):

sage: A = Automaton([(0, 0, 0)], initial_states=[0])
sage: A.state(0).color = None
sage: A.determinisation()  
Automaton with 1 state

intersection(other, only_accessible_components=True)
Return a new automaton which accepts an input if it is accepted by both given automata.

INPUT:
• other – an automaton
• only_accessible_components – If True (default), then the result is piped through accessible_components(). If no new_input_alphabet is given, it is determined by determine_alphabets().

OUTPUT:
A new automaton which computes the intersection (see below) of the languages of self and other.

The set of states of the new automaton is the Cartesian product of the set of states of both given automata. There is a transition \((A, B), (C, D), a\) in the new automaton if there are transitions \((A, C), (B, D), a\) in the old automata.

The methods intersection() and cartesian_product() are the same (for automata).

EXAMPLES:

```python
sage: aut1 = Automaton([('1', '2', 1),
      ....:     ('2', '2', 1),
      ....:     ('2', '2', 0)],
      ....:     initial_states=['1'],
      ....:     final_states=['2'],
      ....:     determine_alphabets=True)

sage: aut2 = Automaton([('A', 'A', 1),
      ....:     ('A', 'B', 0),
      ....:     ('B', 'B', 0),
      ....:     ('B', 'A', 1)],
      ....:     initial_states=['A'],
      ....:     final_states=['B'],
      ....:     determine_alphabets=True)

sage: res = aut1.intersection(aut2)

sage: (aut1([1, 1]), aut2([1, 1]), res([1, 1]))
(True, False, False)

sage: (aut1([1, 0]), aut2([1, 0]), res([1, 0]))
(True, True, True)

sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'A') to ('2', 'B'): 0|-,
 Transition from ('2', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'B') to ('2', 'B'): 0|-,
 Transition from ('2', 'B') to ('2', 'A'): 1|-]
```

For automata with epsilon-transitions, intersection is not well defined. But for any finite state machine, epsilon-transitions can be removed by remove_epsilon_transitions().

```python
sage: a1 = Automaton([(0, 0, 0),
      ....:     (0, 1, None),
      ....:     (1, 1, 1),
      ....:     (1, 2, 1)],
      ....:     initial_states=[0],
      ....:     final_states=[1],
      ....:     determine_alphabets=True)

sage: a2 = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 1)],
      ....:     initial_states=[0],
      ....:     final_states=[1],
      ....:     determine_alphabets=True)
```

(continues on next page)
Combinatorics, Release 10.1

sage: a1.intersection(a2)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input) was found.
sage: a1.remove_epsilon_transitions()  # not tested (since not implemented yet)
sage: a1.intersection(a2)  # not tested

is_equivalent(other)
Test whether two automata are equivalent, i.e., accept the same language.

INPUT:
• other – an Automaton.

EXAMPLES:

```
sage: A = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 1)],
                  initial_states=[0],
                  final_states=[0])
sage: B = Automaton([('a', 'a', 0), ('a', 'b', 1), ('b', 'a', 1)],
                  initial_states=['a'],
                  final_states=['a'])
sage: A.is_equivalent(B)
True
sage: B.add_transition('b', 'a', 0)
Transition from 'b' to 'a': 0|-
sage: A.is_equivalent(B)
False
```

language(max_length=None, **kwargs)
Return all words accepted by this automaton.

INPUT:
• max_length – an integer or None (default). Only inputs of length at most max_length will be considered. If None, then this iterates over all possible words without length restrictions.
• kwargs – will be passed on to the process iterator. See process() for a description.

OUTPUT:
An iterator.

EXAMPLES:

```
sage: NAF = Automaton(
    ...: {'A': [('A', 0), ('B', 1), ('B', -1)],
    ...: 'B': [('A', 0)]},
    ...: initial_states=['A'], final_states=['A', 'B'])
sage: list(NAF.language(3))
[[],
 [0], [-1], [1],
 [-1, 0], [0, 0], [1, 0], [0, -1], [0, 1],
 [-1, 0, 0], [0, -1, 0], [0, 0, 0], [0, 1, 0], [1, 0, 0],
 [-1, 0, -1], [-1, 0, 1], [0, 0, -1],
 [0, 0, 1], [1, 0, -1], [1, 0, 1]]
```
minimization(algorithm=None)

Return the minimization of the input automaton as a new automaton.

**INPUT:**

- `algorithm` – Either Moore’s algorithm (by `algorithm='Moore'` or as default for deterministic automata) or Brzozowski’s algorithm (when `algorithm='Brzozowski'` or when the automaton is not deterministic) is used.

**OUTPUT:**

A new automaton.

The resulting automaton is deterministic and has a minimal number of states.

**EXAMPLES:**

```python
sage: A = Automaton([('A', 'A', 1), ('A', 'A', 0), ('A', 'B', 1),
.....: ('B', 'C', 0), ('C', 'C', 1), ('C', 'C', 0),
.....: initial_states=['A'], final_states=['C'])
sage: B = A.minimization(algorithm='Brzozowski')
sage: B_trans = B.transitions(B.states()[1])
sage: B_trans
# random
[Transition from frozenset({frozenset({'B', 'C'}),
    frozenset({'A', 'C'}),
    frozenset({'A', 'B', 'C'})})
    to frozenset({frozenset({'C'}),
    frozenset({'B', 'C'}),
    frozenset({'A', 'C'}),
    frozenset({'A', 'B', 'C'})}): 0|-
    Transition from frozenset({frozenset({'B', 'C'}),
    frozenset({'A', 'C'}),
    frozenset({'A', 'B', 'C'})})
    to frozenset({frozenset({'B', 'C'}),
    frozenset({'A', 'C'}),
    frozenset({'A', 'B', 'C'})}): 1|-]
sage: len(B.states())
3
sage: C = A.minimization(algorithm='Brzozowski')

NotImplementedError: Minimization via Moore's Algorithm is only implemented for deterministic finite state machines

process(*args, **kwargs)

Return whether the automaton accepts the input and the state where the computation stops.

INPUT:

• input_tape – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter use_multitape_input and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.

• initial_state or initial_states – the initial state(s) in which the machine starts. Either specify a single one with initial_state or a list of them with initial_states. If both are given, initial_state will be appended to initial_states. If neither is specified, the initial states of the finite state machine are taken.

• list_of_outputs – (default: None) a boolean or None. If True, then the outputs are given in list form (even if we have no or only one single output). If False, then the result is never a list (an exception is raised if the result cannot be returned). If list_of_outputs=None the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).

• only_accepted – (default: False) a boolean. If set, then the first argument in the output is guaranteed to be True (if the output is a list, then the first argument of each element will be True).

• full_output – (default: True) a boolean. If set, then the full output is given, otherwise only whether the sequence is accepted or not (the first entry below only).

• always_include_output – if set (not by default), always return a triple containing the (non-existing) output. This is in order to obtain output compatible with that of FiniteStateMachine.process(). If this parameter is set, full_output has no effect.

• format_output – a function that translates the written output (which is in form of a list) to something more readable. By default (None) identity is used here.

• check_epsilon_transitions – (default: True) a boolean. If False, then epsilon transitions are not taken into consideration during process.

• write_final_word_out – (default: True) a boolean specifying whether the final output words should be written or not.

• use_multitape_input – (default: False) a boolean. If True, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.

• process_all_prefixes_of_input – (default: False) a boolean. If True, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

• process_iterator_class – (default: None) a class inherited from FSMProcessIterator. If None, then FSMProcessIterator is taken. An instance of this class is created and is used during the processing.

OUTPUT:
The full output is a pair (or a list of pairs, cf. parameter list_of_outputs), where

- the first entry is True if the input string is accepted and
- the second gives the state reached after processing the input tape (This is a state with label None if the input could not be processed, i.e., if at one point no transition to go on could be found.).

If full_output is False, then only the first entry is returned.

If always_include_output is set, an additional third entry [] is included.

Note that in the case the automaton is not deterministic, all possible paths are taken into account. You can use determinisation() to get a deterministic automaton machine.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see __call__() for a version of process() with shortened output.

Internally this function creates and works with an instance of FSMProcessIterator. This iterator can also be obtained with iter_process().

If working with multi-tape finite state machines, all input words of transitions are words of k-tuples of letters. Moreover, the input tape has to consist of k tracks, i.e., be a list or tuple of k iterators, one for each track.

**Warning:** Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

**EXAMPLES:**

In the following examples, we construct an automaton which accepts non-adjacent forms (see also the example on non-adjacent forms in the documentation of the module Finite state machines, automata, transducers) and then test it by feeding it with several binary digit expansions.

```python
sage: NAF = Automaton(
    ...: {'_': [('_', 0), ('1', 1)], '1': [('_', 0)]},
    ...: initial_states=[('_'), final_states=[('_'), '1'])

sage: [NAF.process(w) for w in [[], [0, 1], [1, 1], [0, 1, 0, 1], [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]
[(True, '_'), (True, '1'), (False, None), (True, '1'), (False, None)]
```

If we just want a condensed output, we use:

```python
sage: [NAF.process(w, full_output=False) for w in [[], [0, 1], [1, 1], [0, 1, 0, 1], [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]
[True, True, False, True, False, False]
```
It is equivalent to:

```python
sage: [NAF(w) for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1], ....: [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]
[True, True, False, True, False, False]
```

The following example illustrates the difference between non-existing paths and reaching a non-final state:

```python
sage: NAF.process([2])
(False, None)
sage: NAF.add_transition(('a', 's', 2))
Transition from 'a' to 's': 2|-...

sage: NAF.process([2])
(False, 's')
```

A simple example of a (non-deterministic) multi-tape automaton is the following: It checks whether the two input tapes have the same number of ones:

```python
sage: M = Automaton([(='=', '=', (1, 1)), ....: ('=', '=', (None, 0)), ....: ('=', '<', (None, 1)), ....: ('<', '<', (None, 0)), ....: ('=', '>', (1, None)), ....: ('>', '>', (1, None)), ....: ('>', '>', (0, None))], ....: initial_states=['='], ....: final_states=['='])
sage: M.process(([1, 0, 1], [1, 0]), use_multitape_input=True)
(False, '>')
sage: M.process(([0, 1, 0], [0, 1, 1]), use_multitape_input=True)
(False, '<')
sage: M.process(([1, 1, 0, 1], [0, 0, 1, 0, 1, 1]), ....: use_multitape_input=True)
(True, '=')
```

Alternatively, we can use the following (non-deterministic) multi-tape automaton for the same check:

```python
sage: N = Automaton([(='=', '=', (0, 0)), ....: ('=', '<', (None, 1)), ....: ('<', '<', (None, 0)), ....: ('=', '>', (1, None)), ....: ('>', '>', (None, 0)), ....: ('>', '>', (0, None))], ....: initial_states=['='], ....: final_states=['='])
sage: N.process(([1, 0, 1], [1, 0]), use_multitape_input=True)
(False, '>')
sage: N.process(([0, 1, 0], [0, 1, 1]), use_multitape_input=True)
(False, '<')
sage: N.process(([1, 1, 0, 1], [0, 0, 1, 0, 1, 1]), ....: use_multitape_input=True)
```

(continues on next page)

**shannon_parry_markov_chain()**

Compute a time homogeneous Markov chain such that all words of a given length recognized by the original automaton occur as the output with the same weight; the transition probabilities correspond to the Parry measure.

**OUTPUT:**

A Markov chain. Its input labels are the transition probabilities, the output labels the labels of the original automaton. In order to obtain equal weight for all words of the same length, an “exit weight” is needed. It is stored in the attribute `color` of the states of the Markov chain. The weights of the words of the same length sum up to one up to an exponentially small error.

The stationary distribution of this Markov chain is saved as the initial probabilities of the states.

The transition probabilities correspond to the Parry measure (see [S1948] and [P1964]).

The automaton is assumed to be deterministic, irreducible and aperiodic. All states must be final.

**EXAMPLES:**

```sage
NAF = Automaton([[0, 0, 0), (0, 1, 1), (0, 1, -1),
.....: (1, 0, 0)], initial_states=[0],
.....: final_states=[0], 1])

P_NAF = NAF.shannon_parry_markov_chain()  # optional - sage.symbolic

for s in P_NAF.iter_states():  # optional - sage.symbolic
    print(s.color)
3/4
3/2

for s in P_NAF.states():  # optional - sage.symbolic
    print("{} {}\n.format(s, s.initial_probability))
0 2/3
1 1/3
```

The automaton is assumed to be deterministic, irreducible and aperiodic:
Combinatorics, Release 10.1

```python
sage: A = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 1), (1, 1, 0)],
                   initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
  ... Not ImplementedError: Automaton must be strongly connected.
sage: A = Automaton([(0, 0, 0), (0, 1, 0)],
                   initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
  ... Not ImplementedError: Automaton must be deterministic.
sage: A = Automaton([(0, 1, 0), (1, 0, 0)],
                   initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
  ... Not ImplementedError: Automaton must be aperiodic.
```

All states must be final:

```python
sage: A = Automaton([(0, 1, 0), (0, 0, 1), (1, 0, 0)],
                   initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
  ... Not ImplementedError: All states must be final.
```

ALGORITHM:
See [HKP2015a], Lemma 4.1.

REFERENCES:

**with_output**(word_out_function=None)

Construct a transducer out of this automaton.

INPUT:
- word_out_function – (default: None) a function. It transforms a transition to the output word for this transition.

  If this is None, then the output word will be equal to the input word of each transition.

OUTPUT:
A transducer.

EXAMPLES:

```python
sage: A = Automaton([(0, 0, 'A'), (0, 1, 'B'), (1, 0, 0)],
                   initial_states=[0])
sage: T = A.with_output(); T
Transducer with 3 states
sage: T.transitions()
[Transition from 0 to 0: 'A' | 'A',
 Transition from 0 to 1: 'B' | 'B',
 Transition from 1 to 2: 'C' | 'C']
```
This result is in contrast to:

```python
sage: Transducer(A).transitions()
[Transition from 0 to 0: 'A'|-,
 Transition from 0 to 1: 'B'|-,
 Transition from 1 to 2: 'C'|-]
```

where no output labels are created.

Here is another example:

```python
sage: T2 = A.with_output(lambda t: [c.lower() for c in t.word_in])
sage: T2.transitions()
[Transition from 0 to 0: 'A'|'a',
 Transition from 0 to 1: 'B'|'b',
 Transition from 1 to 2: 'C'|'c']
```

We can obtain the same result by composing two transducers. As inner transducer of the composition, we use `with_output()` without the optional argument `word_out_function` (which makes the output of each transition equal to its input); as outer transducer we use a map-transducer (for converting to lower case). This gives

```python
sage: L = transducers.map(lambda x: x.lower(), ['A', 'B', 'C'])
sage: L.composition(A.with_output()).relabeled().transitions()
[Transition from 0 to 0: 'A'|'a',
 Transition from 0 to 1: 'B'|'b',
 Transition from 1 to 2: 'C'|'c']
```

See also:

* `input_projection()`, `output_projection()`, `Transducer`, `transducers.map()`.

### sage.combinat.finite_state_machine.FSMLetterSymbol(letter)

Return a string associated to the input letter.

**INPUT:**

- `letter` – the input letter or None (representing the empty word).

**OUTPUT:**

If `letter` is None the symbol for the empty word `FSMEmptyWordSymbol` is returned, otherwise the string associated to the letter.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMLetterSymbol
sage: FSMLetterSymbol(0)
'0'
sage: FSMLetterSymbol(None)
'_'
```
class sage.combinat.finite_state_machine.FSMProcessIterator(
    fsm, input_tape=None,
    initial_state=None, initial_states=[],
    use_multitape_input=False,
    check_epsilon_transitions=True,
    write_final_word_out=True,
    format_output=None,
    process_all_prefixes_of_input=False,
    **kwargs)

Bases: SageObject, Iterator

This class takes an input, feeds it into a finite state machine (automaton or transducer, in particular), tests whether this was successful and calculates the written output.

INPUT:

- `fsm` – the finite state machine on which the input should be processed.
- `input_tape` – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- `initial_state` or `initial_states` – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- `format_output` – a function that translates the written output (which is in form of a list) to something more readable. By default (None) identity is used here.
- `check_epsilon_transitions` – (default: True) a boolean. If False, then epsilon transitions are not taken into consideration during process.
- `write_final_word_out` – (default: True) a boolean specifying whether the final output words should be written or not.
- `use_multitape_input` – (default: False) a boolean. If True, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- `process_all_prefixes_of_input` – (default: False) a boolean. If True, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

OUTPUT:

An iterator.

In its simplest form, it behaves like an iterator which, in each step, goes from one state to another. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the process iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read. When the process stops, a StopIteration exception is thrown.
Warning: Processing an input tape of length $n$ usually takes at least $n + 1$ iterations, since there will be $n + 1$ states visited (in the case the taken transitions have input words consisting of single letters).

An instance of this class is generated when `FiniteStateMachine.process()` or `FiniteStateMachine.iter_process()` of a finite state machine, an automaton, or a transducer is invoked.

When working with multi-tape finite state machines, all input words of transitions are words of $k$-tuples of letters. Moreover, the input tape has to consist of $k$ tracks, i.e., be a list or tuple of $k$ iterators, one for each track.

Warning: Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

The following transducer reads binary words and outputs a word, where blocks of ones are replaced by just a single one. Further only words that end with a zero are accepted.

```
sage: T = Transducer({
    'A': [('A', 0, 0), ('B', 1, None)],
    'B': [('B', 1, None), ('A', 0, [1, 0])],
    initial_states=['A'], final_states=['A'])
sage: input = [1, 1, 0, 0, 1, 0, 1, 1, 1, 0]
sage: T.process(input)
(True, 'A', [1, 0, 0, 1, 0, 1, 0])
```

The function `FiniteStateMachine.process()` (internally) uses a `FSMProcessIterator`. We can do that manually, too, and get full access to the iteration process:

```
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: it = FSMProcessIterator(T, input_tape=input)
sage: for current in it:
    print(current)
process (1 branch)
  + at state 'B'
  +-- tape at 1, [[]]
process (1 branch)
  + at state 'B'
  +-- tape at 2, [[]]
process (1 branch)
  + at state 'A'
  +-- tape at 3, [[1, 0]]
process (1 branch)
  + at state 'A'
  +-- tape at 4, [[1, 0, 0]]
process (1 branch)
  + at state 'B'
  +-- tape at 5, [[1, 0, 0]]
process (1 branch)
  + at state 'A'
  +-- tape at 6, [[1, 0, 0, 1, 0]]
process (1 branch)
  + at state 'B'
  +-- tape at 7, [[1, 0, 0, 1, 0]]
process (1 branch)
(continues on next page)
```
+ at state 'B'
++-- tape at 8, [[1, 0, 0, 1, 0]]
process (1 branch)
+ at state 'B'
++-- tape at 9, [[1, 0, 0, 1, 0]]
process (1 branch)
+ at state 'A'
++-- tape at 10, [[1, 0, 0, 0, 1, 0]]
process (0 branches)
sage: it.result()
[Branch(accept=True, state='A', output=[1, 0, 0, 1, 0, 1, 0])]
sage: T = Transducer([(0, 0, 0, 'a'), (0, 1, 0, 'b'),
                   ...: (1, 2, 1, 'c'), (2, 0, 0, 'd'),
                   ...: (2, 1, None, 'd'),
                   ...: initial_states=[0], final_states=[2])
sage: sorted(T.process([0, 0, 1], format_output=lambda o: ''.join(o)))
[(False, 1, 'abcd'), (True, 2, 'abc')]
sage: it = FSMProcessIterator(T, input_tape=[0, 0, 1],
               ...: format_output=lambda o: ''.join(o))
sage: for current in it:
               ...: print(current)
process (2 branches)
+ at state 0
++-- tape at 1, [['a']]
+ at state 1
++-- tape at 1, [['b']]
process (2 branches)
+ at state 0
++-- tape at 2, [['a', 'a']]
+ at state 1
++-- tape at 2, [['a', 'b']]
process (2 branches)
+ at state 1
++-- tape at 3, [['a', 'b', 'c', 'd']] 
+ at state 2
++-- tape at 3, [['a', 'b', 'c']] 
process (0 branches)
sage: sorted(it.result())
[Branch(accept=False, state=1, output='abcd'),
Branch(accept=True, state=2, output='abc')]

FiniteStateMachine.process(), Automaton.process(), Transducer.process(),
FiniteStateMachine.iter_process(), FiniteStateMachine.__call__(), next().

class Current
Bases: dict

This class stores the branches which have to be processed during iteration and provides a nicer formatting of them.

This class is derived from dict. It is returned by the next-function during iteration.
EXAMPLES:

In the following example you can see the dict directly and then the nicer output provided by this class:

```python
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
                          initial_states=['A'], final_states=['A'])

sage: it = FSMProcessIterator(inverter, input_tape=[0, 1])

sage: for current in it:
    print(dict(current))
    print(current)

{((1, 0),): {'A': Branch(tape_cache=tape at 1, outputs=[[1]])}}
process (1 branch)
+ at state 'A'
++ tape at 1, [[1]]
{((2, 0),): {'A': Branch(tape_cache=tape at 2, outputs=[[1, 0]])}}
process (1 branch)
+ at state 'A'
++ tape at 2, [[1, 0]]
{}
process (0 branches)
```

```python
class FinishedBranch(accept, state, output)

Bases: tuple

A named tuple representing the attributes of a branch, once it is fully processed.

accept
    Alias for field number 0

output
    Alias for field number 2

state
    Alias for field number 1

next()

Makes one step in processing the input tape.

INPUT:
Nothing.

OUTPUT:
It returns the current status of the iterator (see below). A StopIteration exception is thrown when there is/was nothing to do (i.e. all branches ended with previous call of next()).

The current status is a dictionary (encapsulated into an instance of Current). The keys are positions on the tape. The value corresponding to such a position is again a dictionary, where each entry represents a branch of the process. This dictionary maps the current state of a branch to a pair consisting of a tape cache and a list of output words, which were written during reaching this current state.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
                          initial_states=['A'], final_states=['A'])
```
```
sage: it = FSMProcessIterator(inverter, input_tape=[0, 1])
sage: next(it)
process (1 branch)
+ at state 'A'
--- tape at 1, [[1]]
sage: next(it)
process (1 branch)
+ at state 'A'
--- tape at 2, [[1, 0]]
sage: next(it)
process (0 branches)
sage: next(it)
Traceback (most recent call last):
  ... StopIteration

See also:
FiniteStateMachine.process(), Automaton.process(), Transducer.process(),
FiniteStateMachine.iter_process(), FiniteStateMachine.__call__(),
FSMProcessIterator.

**preview_word**(track_number=None, length=1, return_word=False)

Read a word from the input tape.

**INPUT:**

- **track_number** – an integer or None. If None, then a tuple of words (one from each track) is returned.
- **length** – (default: 1) the length of the word(s).
- **return_word** – (default: False) a boolean. If set, then a word is returned, otherwise a single letter (in which case length has to be 1).

**OUTPUT:**

A single letter or a word.

An exception StopIteration is thrown if the tape (at least one track) has reached its end.

Typically, this method is called from a hook-function of a state.

**EXAMPLES:**

```
sage: inverter = Transducer({'A': [('A', 0, 'one'),
.....: ('A', 1, 'zero')],
.....: initial_states=['A'], final_states=['A'])
sage: def state_hook(process, state, output):
.....:     print("We are now in state %s." % (state.label(),))
.....:     try:
.....:         w = process.preview_word()
.....:     except RuntimeError:
.....:         raise StopIteration
.....:     print("Next on the tape is a %s." % (w,))
sage: inverter.state('A').hook = state_hook
sage: it = inverter.iter_process(
.....:     input_tape=[0, 1, 1],
```
We are now in state A.
Next on the tape is a 0.
We are now in state A.
Next on the tape is a 1.
We are now in state A.
Next on the tape is a 1.
We are now in state A.
sage: it.result()
[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]

result(format_output=None)
Return the already finished branches during process.

INPUT:
• format_output – a function converting the output from list form to something more readable (default: output the list directly).

OUTPUT:
A list of triples (accepted, state, output).
See also the parameter format_output of FSMProcessIterator.

EXAMPLES:

sage: inverter = Transducer({'A': [('A', 0, 'one'), ('A', 1, 'zero')], ...
..: initial_states=['A'], final_states=['A'])

sage: it = inverter.iter_process(input_tape=[0, 1, 1])
sage: for _ in it:
..: pass
sage: it.result()
[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]

Using both the parameter format_output of FSMProcessIterator and the parameter format_output of result() leads to concatenation of the two functions:

sage: it = inverter.iter_process(input_tape=[0, 1, 1], ...
..: format_output=lambda L: ','.join(L))

sage: for _ in it:
..: pass
sage: it.result()
[(True, 'A', 'one, zero, zero')]

class sage.combinat.finite_state_machine.FSMState(label, word_out=None, is_initial=False, is_final=False, final_word_out=None, initial_probability=None, hook=None, color=None, allow_label=None=False)

Bases: SageObject
Class for a state of a finite state machine.

INPUT:

- **label** – the label of the state.
- **word_out** – (default: `None`) a word that is written when the state is reached.
- **is_initial** – (default: `False`)
- **is_final** – (default: `False`)
- **final_word_out** – (default: `None`) a word that is written when the state is reached as the last state of some input; only for final states.
- **initial_probability** – (default: `None`) The probability of starting in this state if it is a state of a Markov chain.
- **hook** – (default: `None`) A function which is called when the state is reached during processing input. It takes two input parameters: the first is the current state (to allow using the same hook for several states), the second is the current process iterator object (to have full access to everything; e.g. the next letter from the input tape can be read in). It can output the next transition, i.e. the transition to take next. If it returns `None` the process iterator chooses. Moreover, this function can raise a `StopIteration` exception to stop processing of a finite state machine the input immediately. See also the example below.
- **color** – (default: `None`) In order to distinguish states, they can be given an arbitrary “color” (an arbitrary object). This is used in `FiniteStateMachine.equivalence_classes()`: states of different colors are never considered to be equivalent. Note that `Automaton.determinisation()` requires that `color` is hashable.
- **allow_label_None** – (default: `False`) If `True` allows also `None` as label. Note that a state with label `None` is used in `FSMProcessIterator`.

OUTPUT:

A state of a finite state machine.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('state 1', word_out=0, is_initial=True)
```
```ruby
A
'state 1'
A.label()
'state 1'
B = FSMState('state 2')
A == B
False
```

We can also define a final output word of a final state which is used if the input of a transducer leads to this state. Such final output words are used in subsequential transducers.

```python
sage: C = FSMState('state 3', is_final=True, final_word_out='end')
```
```ruby
C.final_word_out
['end']
```

The final output word can be a single letter, `None` or a list of letters:

```python
sage: A = FSMState('A')
sage: A.is_final = True
```

Only final states can have a final output word which is not None:

```python
sage: B = FSMState('B')
sage: B.final_word_out is None
True
sage: B.final_word_out = 2
Traceback (most recent call last):
  ... ValueError: Only final states can have a final output word, but state B is not final.
```

Setting the `final_word_out` of a final state to None is the same as setting it to [] and is also the default for a final state:

```python
sage: C = FSMState('C', is_final=True)
sage: C.final_word_out
[]
sage: C.final_word_out = None
sage: C.final_word_out
[]
sage: C.final_word_out = []
sage: C.final_word_out
[]
```

It is not allowed to use None as a label:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: FSMState(None)
Traceback (most recent call last):
  ... ValueError: Label None reserved for a special state, choose another label.
```

This can be overridden by:

```python
sage: FSMState(None, allow_label_None=True)
None
```

Note that `Automaton.determinisation()` requires that color is hashable:

```python
sage: A = Automaton([[0, 0, 0]], initial_states=[0])
sage: A.state(0).color = []
sage: A.determinisation()
Traceback (most recent call last):
  ... TypeError: unhashable type: 'list'
```
We can use a hook function of a state to stop processing. This is done by raising a `StopIteration` exception. The following code demonstrates this:

```python
sage: T = Transducer([(0, 1, 9, 'a'), (1, 2, 9, 'b'),
   ....: (2, 3, 9, 'c'), (3, 4, 9, 'd')],
   ....: initial_states=[0],
   ....: final_states=[4],
   ....: input_alphabet=[9])
sage: def stop(process, state, output):
   ....:     raise StopIteration()

sage: T.state(3).hook = stop
sage: T.process([9, 9, 9, 9])
(False, 3, ['a', 'b', 'c'])
```

`copy()`

Return a (shallow) copy of the state.

**INPUT:**
Nothing.

**OUTPUT:**
A new state.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
```

```python
sage: A.is_initial = True
sage: A.is_final = True
sage: A.final_word_out = [1]
```

```python
sage: A.color = 'green'
```

```python
sage: A.initial_probability = 1/2
```

```python
sage: B = copy(A)
```

```python
sage: B.fully_equal(A)
True
sage: A.label() is B.label()
True
```

```python
sage: A.is_initial is B.is_initial
True
```

```python
sage: A.is_final is B.is_final
True
```

```python
sage: A.final_word_out is B.final_word_out
True
```

```python
sage: A.color is B.color
True
```

```python
sage: A.initial_probability is B.initial_probability
True
```

`deepcopy`(memo=None)
Return a deep copy of the state.

INPUT:

- memo – (default: None) a dictionary storing already processed elements.

OUTPUT:

A new state.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState((1, 3), color=[1, 2],
....:     is_final=True, final_word_out=3,
....:     initial_probability=1/3)
sage: B = deepcopy(A)
sage: B
(1, 3)
sage: B.label() == A.label()
True
sage: B.label is A.label
False
sage: B.color == A.color
True
sage: B.color is A.color
False
sage: B.is_final == A.is_final
True
sage: B.is_final is A.is_final
True
sage: B.final_word_out == A.final_word_out
True
sage: B.final_word_out is A.final_word_out
False
sage: B.initial_probability == A.initial_probability
True
```

**property final_word_out**

The final output word of a final state which is written if the state is reached as the last state of the input of the finite state machine. For a non-final state, the value is None.

final_word_out can be a single letter, a list or None, but for a final-state, it is always saved as a list.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True, final_word_out=2)
sage: A.final_word_out
[2]
sage: A.final_word_out = 3
sage: A.final_word_out
[3]
sage: A.final_word_out = [3, 4]
sage: A.final_word_out
[3, 4]
```

(continues on next page)
A non-final state cannot have a final output word:

```
sage: B.final_word_out = [3, 4]
Traceback (most recent call last):
  ... ValueError: Only final states can have a final output word, but state B is not final.
```

**fully_equal**(other, compare_color=True)
Check whether two states are fully equal, i.e., including all attributes except hook.

INPUT:
- self – a state.
- other – a state.
- compare_color – If True (default) colors are compared as well, otherwise not.

OUTPUT:
True or False.

Note that usual comparison by == does only compare the labels.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: B = FSMState('A', is_initial=True)
sage: A.fully_equal(B) False
sage: A == B True
sage: A.is_initial = True; A.color = 'green'
sage: A.fully_equal(B) False
sage: A.fully_equal(B, compare_color=False) True
```

**initial_probability** = None

**property is_final**
Describes whether the state is final or not.

True if the state is final and False otherwise.

EXAMPLES:
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True, final_word_out=3)

sage: A.is_final
True

sage: A.is_final = False
Traceback (most recent call last):
  ... ValueError: State A cannot be non-final, because it has a final output word. Only final states can have a final output word.

sage: A.final_word_out = None
sage: A.is_final = False
sage: A.is_final
False

is_initial = False

label()
Return the label of the state.

INPUT:
Nothing.

OUTPUT:
The label of the state.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('state')

sage: A.label()
'state'

relabeled(label, memo=None)
Return a deep copy of the state with a new label.

INPUT:

• label – the label of new state.

• memo – (default: None) a dictionary storing already processed elements.

OUTPUT:
A new state.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')

sage: A.relabeled('B')
'B'

class sage.combinat.finite_state_machine.FSMTransition(from_state, to_state, word_in=None, word_out=None, hook=None)

Bases: SageObject
Class for a transition of a finite state machine.

**INPUT:**
- `from_state` – state from which transition starts.
- `to_state` – state in which transition ends.
- `word_in` – the input word of the transitions (when the finite state machine is used as automaton)
- `word_out` – the output word of the transitions (when the finite state machine is used as transducer)

**OUTPUT:**
A transition of a finite state machine.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: A = FSMState('A')

sage: B = FSMState('B')

sage: S = FSMTransition(A, B, 0, 1)

sage: T = FSMTransition('A', 'B', 0, 1)

sage: T == S
True

sage: U = FSMTransition('A', 'B', 0)

sage: U == T
False
```

**copy()**
Return a (shallow) copy of the transition.

**OUTPUT:**
A new transition.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMTransition

sage: t = FSMTransition('A', 'B', 0)

sage: copy(t)
Transition from 'A' to 'B': 0|-
```

**deepcopy**(memo=None)
Return a deep copy of the transition.

**INPUT:**
- `memo` – (default: `None`) a dictionary storing already processed elements.

**OUTPUT:**
A new transition.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMTransition

sage: t = FSMTransition('A', 'B', 0)

sage: deepcopy(t)
Transition from 'A' to 'B': 0|-
```
from_state = None
State from which the transition starts. Read-only.

to_state = None
State in which the transition ends. Read-only.

word_in = None
Input word of the transition. Read-only.

word_out = None
Output word of the transition. Read-only.

sage.combinat.finite_state_machine.FSMWordSymbol(word)
Return a string of word. It may returns the symbol of the empty word FSMEmptyWordSymbol.

INPUT:
• word – the input word.

OUTPUT:
A string of word.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import FSMWordSymbol
sage: FSMWordSymbol([0, 1, 1])
'0,1,1'

class sage.combinat.finite_state_machine.FiniteStateMachine(data=None, initial_states=None, final_states=None, input_alphabet=None, output_alphabet=None, determine_alphabets=None, with_final_word_out=None, store_states_dict=True, on_duplicate_transition=None)

Bases: SageObject

Class for a finite state machine.

A finite state machine is a finite set of states connected by transitions.

INPUT:
• data – can be any of the following:
  1. a dictionary of dictionaries (of transitions),
  2. a dictionary of lists (of states or transitions),
  3. a list (of transitions),
  4. a function (transition function),
  5. an other instance of a finite state machine.
• initial_states and final_states – the initial and final states of this machine
• input_alphabet and output_alphabet – the input and output alphabets of this machine
• **determine_alphabets** — If True, then the function `determine_alphabets()` is called after `data` was read and processed, if False, then not. If it is None, then it is decided during the construction of the finite state machine whether `determine_alphabets()` should be called.

• **with_final_word_out** — If given (not None), then the function `with_final_word_out()` (more precisely, its inplace pendant `construct_final_word_out()`) is called with input `letters=with_final_word_out` at the end of the creation process.

• **store_states_dict** — If True, then additionally the states are stored in an internal dictionary for speed up.

• **on_duplicate_transition** — A function which is called when a transition is inserted into `self` which already existed (same `from_state`, same `to_state`, same `word_in`, same `word_out`).

This function is assumed to take two arguments, the first being the already existing transition, the second being the new transition (as an `FSMTransition`). The function must return the (possibly modified) original transition.

By default, we have `on_duplicate_transition=None`, which is interpreted as `on_duplicate_transition=duplicate_transition_ignore`, where `duplicate_transition_ignore` is a predefined function ignoring the occurrence. Other such predefined functions are `duplicate_transition_raise_error` and `duplicate_transition_add_input`.

**OUTPUT:**

A finite state machine.

The object creation of `Automaton` and `Transducer` is the same as the one described here (i.e. just replace the word `FiniteStateMachine` by `Automaton` or `Transducer`).

Each transition of an automaton has an input label. Automata can, for example, be determinised (see `Automaton.determinisation()`) and minimized (see `Automaton.minimization()`). Each transition of a transducer has an input and an output label. Transducers can, for example, be simplified (see `Transducer.simplification()`).

**EXAMPLES:**

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
```

See documentation for more examples.

We illustrate the different input formats:

1. The input-data can be a dictionary of dictionaries, where

   • the keys of the outer dictionary are state-labels (from-states of transitions),
   • the keys of the inner dictionaries are state-labels (to-states of transitions),
   • the values of the inner dictionaries specify the transition more precisely.

The easiest is to use a tuple consisting of an input and an output word:

```
sage: FiniteStateMachine({'a':{(b:0, 1), 'c':(1, 1)}})
Finite state machine with 3 states
```

Instead of the tuple anything iterable (e.g. a list) can be used as well.

If you want to use the arguments of `FSMTransition` directly, you can use a dictionary:

```
sage: FiniteStateMachine({'a':[(b:'word_in':0, 'word_out':1),
                               'c':(word_in:1, 'word_out':1})})
Finite state machine with 3 states
```

```
960 Chapter 5. Comprehensive Module List
```
In the case you already have instances of `FSMTransition`, it is possible to use them directly:

```
sage: FiniteStateMachine({'a':{'b':FSMTransition('a', 'b', 0, 1),
                                 'c':FSMTransition('a', 'c', 1, 1)}})
Finite state machine with 3 states
```

2. The input-data can be a dictionary of lists, where the keys are states or label of states.
   The list-elements can be states:

```
sage: a = FSMState('a')
sage: b = FSMState('b')
sage: c = FSMState('c')
sage: FiniteStateMachine({a:[b, c]})
Finite state machine with 3 states
```

Or the list-elements can simply be labels of states:

```
sage: FiniteStateMachine({'a':['b', 'c']})
Finite state machine with 3 states
```

The list-elements can also be transitions:

```
sage: FiniteStateMachine({'a':[FSMTransition('a', 'b', 0, 1),
                                 FSMLTransition('a', 'c', 1, 1)]})
Finite state machine with 3 states
```

Or they can be tuples of a label, an input word and an output word specifying a transition:

```
sage: FiniteStateMachine({'a':[('b', 0, 1), ('c', 1, 1)]})
Finite state machine with 3 states
```

3. The input-data can be a list, where its elements specify transitions:

```
sage: FiniteStateMachine([FSMTransition('a', 'b', 0, 1),
                                 FSMTransition('a', 'c', 1, 1)])
Finite state machine with 3 states
```

It is possible to skip `FSMTransition` in the example above:

```
sage: FiniteStateMachine([(a', 'b', 0, 1), ('a', 'c', 1, 1)])
Finite state machine with 3 states
```

The parameters of the transition are given in tuples. Anyhow, anything iterable (e.g. a list) is possible.
You can also name the parameters of the transition. For this purpose you take a dictionary:

```
sage: FiniteStateMachine([(from_state:'a', to_state:'b',
                                 word_in:0, word_out:1),
                                 (from_state:'a', to_state:'c',
                                 word_in:1, word_out:1)])
Finite state machine with 3 states
```

Other arguments, which `FSMTransition` accepts, can be added, too.

4. The input-data can also be function acting as transition function:
   This function has two input arguments:
   ```
   ```
Combinatorics, Release 10.1

1. a label of a state (from which the transition starts),
2. a letter of the (input-)alphabet (as input-label of the transition).

It returns a tuple with the following entries:
1. a label of a state (to which state the transition goes),
2. a letter of or a word over the (output-)alphabet (as output-label of the transition).

It may also output a list of such tuples if several transitions from the from-state and the input letter exist
(this means that the finite state machine is non-deterministic).

If the transition does not exist, the function should raise a LookupError or return an empty list.

When constructing a finite state machine in this way, some initial states and an input alphabet have to be
specified.

```python
sage: def f(state_from, read):
    if int(state_from) + read <= 2:
        state_to = 2*int(state_from)+read
        write = 0
    else:
        state_to = 2*int(state_from) + read - 5
        write = 1
    return (str(state_to), write)
sage: F = FiniteStateMachine(f, input_alphabet=[0, 1],
    initial_states=['0'],
    final_states=['0'])
sage: F([1, 0, 1])
(True, '0', [0, 0, 1])
```

5. The input-data can be an other instance of a finite state machine:

```python
sage: F = FiniteStateMachine()
sage: G = Transducer(F)
sage: G == F
True
```

The other parameters cannot be specified in that case. If you want to change these,
use the attributes `FSMState.is_initial`, `FSMState.is_final`, `input_alphabet`,
`output_alphabet`, `on_duplicate_transition` and methods `determine_alphabets()`,
`construct_final_word_out()` on the new machine, respectively.

The following examples demonstrate the use of `on_duplicate_transition`:

```python
sage: F = FiniteStateMachine([['a', 'a', 1/2], ['a', 'a', 1/2]])
sage: F.transitions()
[Transition from 'a' to 'a': 1/2|-]
```

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_error
sage: F1 = FiniteStateMachine([['a', 'a', 1/2], ['a', 'a', 1/2]],
    on_duplicate_transition=duplicate_transition_raise_error)
Traceback (most recent call last):
... ValueError: Attempting to re-insert transition Transition from 'a' to 'a': 1/2 |-`
```

962 Chapter 5. Comprehensive Module List
Use \texttt{duplicate\_transition\_add\_input} to emulate a Markov chain, the input labels are considered as transition probabilities:

\begin{verbatim}
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: F = FiniteStateMachine([['a', 'a', 1/2], ['a', 'a', 1/2]],
......: on_duplicate_transition=duplicate_transition_add_input)
sage: F.transitions()
[Transition from 'a' to 'a': 1|-
\end{verbatim}

Use \texttt{with\_final\_word\_out} to construct final output:

\begin{verbatim}
sage: T = Transducer([(0, 1, 0, 0), (1, 0, 0, 0)],
......: initial_states=[0],
......: final_states=[0],
......: with_final_word_out=1)
sage: for s in T.iter_final_states():
......: print("{0} {1}".format(s, s.final_word_out))
0 []
1 [0]
\end{verbatim}

\texttt{__call__}(*\texttt{args}, **\texttt{kwargs})

Call either method \texttt{composition()} or \texttt{process()} (with \texttt{full\_output=False}). If the input is not finite (\texttt{is\_finite} of input is False), then \texttt{iter\_process()} (with \texttt{iterator\_type='simple'} ) is called. Moreover, the flag \texttt{automatic\_output\_type} is set (unless \texttt{format\_output} is specified). See the documentation of these functions for possible parameters.

EXAMPLES:

The following code performs a \texttt{composition()}:

\begin{verbatim}
sage: F = Transducer([('A', 'B', 1, 0), ('B', 'B', 1, 1),
......: ('B', 'B', 0, 0)],
......: initial_states=['A'], final_states=['B'])
sage: G = Transducer([('1', 1, 0, 0), (1, 2, 1, 0),
......: (2, 2, 0, 1), (2, 1, 1, 1)],
......: initial_states=[1], final_states=[1])
sage: H = G(F)
sage: H.states()
[('A', 1), ('B', 1), ('B', 2)]
\end{verbatim}

An automaton or transducer can also act on an input (an list or other iterable of letters):

\begin{verbatim}
sage: binary_inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
......: initial_states=['A'], final_states=['A'])
sage: binary_inverter([0, 1, 0, 1, 1])
[1, 0, 1, 1, 0]
\end{verbatim}

We can also let them act on \texttt{words}:

\begin{verbatim}
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
sage: binary_inverter(W([0, 1, 1, 0, 1, 1]))
word: 100100
\end{verbatim}

Infinite words work as well:
When only one successful path is found in a non-deterministic transducer, the result of that path is returned.

```
sage: T = Transducer([(0, 1, 0, 1), (0, 2, 0, 2)],
        initial_states=[0], final_states=[1])
sage: T.process([0])
[(False, 2, [2]), (True, 1, [1])]
sage: T([0])
[1]
```

See also:

composition(), process(), iter_process(), Automaton.process(), Transducer.process().

**accessible_components()**

Return a new finite state machine with the accessible states of self and all transitions between those states.

**INPUT:**

Nothing.

**OUTPUT:**

A finite state machine with the accessible states of self and all transitions between those states.

A state is accessible if there is a directed path from an initial state to the state. If self has no initial states then a copy of the finite state machine self is returned.

**EXAMPLES:**

```
sage: F = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 0), (1, 0, 1)],
                initial_states=[0])
sage: F.accessible_components()
Automaton with 2 states
```

```
sage: F = Automaton([(0, 0, 1), (0, 0, 1), (1, 1, 0), (1, 0, 1)],
                initial_states=[0])
sage: F.accessible_components()
Automaton with 1 state
```

See also:

coaccessible_components()

**add_from_transition_function**(function, initial_states=None, explore_existing_states=True)

Constructs a finite state machine from a transition function.

**INPUT:**

- function may return a tuple (new_state, output_word) or a list of such tuples.
- initial_states – If no initial states are given, the already existing initial states of self are taken.
- If explore_existing_states is True (default), then already existing states in self (e.g. already given final states) will also be processed if they are reachable from the initial states.
OUTPUT:
Nothing.

EXAMPLES:

```python
sage: F = FiniteStateMachine(initial_states=['A'],
...:     input_alphabet=[0, 1])
sage: def f(state, input):
...:     return [('A', input), ('B', 1-input)]
sage: F.add_from_transition_function(f)
sage: F.transitions()
[Transition from 'A' to 'A': 0|0,
  Transition from 'A' to 'B': 0|1,
  Transition from 'A' to 'A': 1|1,
  Transition from 'A' to 'B': 1|0,
  Transition from 'B' to 'A': 0|0,
  Transition from 'B' to 'B': 0|1,
  Transition from 'B' to 'A': 1|1,
  Transition from 'B' to 'B': 1|0]
```

Initial states can also be given as a parameter:

```python
sage: F = FiniteStateMachine(input_alphabet=[0,1])
sage: def f(state, input):
...:     return [('A', input), ('B', 1-input)]
sage: F.add_from_transition_function(f,initial_states=['A'])
sage: F.initial_states()
['A']
```

Already existing states in the finite state machine (the final states in the example below) are also explored:

```python
sage: F = FiniteStateMachine(initial_states=[0],
...:     final_states=[1],
...:     input_alphabet=[0])
sage: def transition_function(state, letter):
...:     return 1 - state, []
sage: F.add_from_transition_function(transition_function)
sage: F.transitions()
[Transition from 0 to 1: 0|-,
  Transition from 1 to 0: 0|-
]
```

If `explore_existing_states=False`, however, this behavior is turned off, i.e., already existing states are not explored:

```python
sage: F = FiniteStateMachine(initial_states=[0],
...:     final_states=[1],
...:     input_alphabet=[0])
sage: def transition_function(state, letter):
...:     return 1 - state, []
sage: F.add_from_transition_function(transition_function,
...:     explore_existing_states=False)
sage: F.transitions()
[Transition from 0 to 1: 0|-]
```
add_state(state)

Adds a state to the finite state machine and returns the new state. If the state already exists, that existing state is returned.

INPUT:

• state is either an instance of FSMState or, otherwise, a label of a state.

OUTPUT:

The new or existing state.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import FSMState
sage: F = FiniteStateMachine()
(sage: A = FSMState('A', is_initial=True)
(sage: F.add_state(A)
' A'

add_states(states)

Adds several states. See add_state for more information.

INPUT:

• states – a list of states or iterator over states.

OUTPUT:

Nothing.

EXAMPLES:

sage: F = FiniteStateMachine()
(sage: F.add_states(['
A', 'B'])

add_transition(*args, **kwargs)

Adds a transition to the finite state machine and returns the new transition.

If the transition already exists, the return value of self.on_duplicate_transition is returned. See the documentation of FiniteStateMachine.

INPUT:

The following forms are all accepted:

sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: A = FSMState('A')
(sage: B = FSMState('B')
(sage: FSM = FiniteStateMachine()
(sage: FSM.add_transition(FSMTransition(A, B, 0, 1))
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
(sage: FSM.add_transition(A, B, 0, 1)
Transition from 'A' to 'B': 0|1

(continues on next page)
If the states `A` and `B` are not instances of `FSMState`, then it is assumed that they are labels of states.

**OUTPUT:**

The new transition.

### add_transitions_from_function(function, labels_as_input=True)

Adds one or more transitions if `function(state, state)` says that there are some.

**INPUT:**

- `function` – a transition function. Given two states `from_state` and `to_state` (or their labels if `label_as_input` is true), this function shall return a tuple `(word_in, word_out)` to add a transition from `from_state` to `to_state` with input and output labels `word_in` and `word_out`, respectively. If no such addition is to be added, the transition function shall return `None`. The transition function may also return a list of such tuples in order to add multiple transitions between the pair of states.
- `label_as_input` – (default: `True`)

**OUTPUT:**

Nothing.

**EXAMPLES:**

```python
sage: F = FiniteStateMachine()
sage: F.add_states(['A', 'B', 'C'])
sage: def f(state1, state2):
    ....:    if state1 == 'C':
```
**adjacency_matrix**(input=None, entry=None)

Return the adjacency matrix of the underlying graph.

**INPUT:**

- **input** – Only transitions with input label input are respected.
- **entry** – The function entry takes a transition and the return value is written in the matrix as the entry (transition.from_state, transition.to_state). The default value (None) of entry takes the variable x to the power of the sum of the output word of the transition.

**OUTPUT:**

A matrix.

If any label of a state is not an integer, the finite state machine is relabeled at the beginning. If there are more than one transitions between two states, then the different return values of entry are added up.

**EXAMPLES:**

```
sage: B = FiniteStateMachine({0:{0:(0, 0), 'a':(1, 0)},
...: 2:{0:(1, 1), 4:(0, 0)},
...: 3:{'a':(0, 1), 2:(1, 1)},
...: 4:{4:(1, 1), 3:(0, 1)}},
...: initial_states=[0])
sage: B.adjacency_matrix()  # optional - sage.
[1 1 0 0 0]
[0 0 1 1 0]
[x 0 0 0 1]
[0 x x 0 0]
[0 0 0 x x]
```
This is equivalent to:

```sage
def matrix(B):
    # optional - sage.
    return B

def adjacency_matrix(entry=lambda transition: 1):
    mat = [[1 if i==j else 0 for j in range(len(B))] for i in range(len(B))]
    for i in range(len(B)):
        for j in range(len(B)):
            if entry(B[i][j]):
                mat[i][j] = 1
    return mat

def var('t'):
    # optional - sage.
    return t

def adjacency_matrix(1, entry=lambda transition: exp(I*transition.word_out[0]*t)):
    mat = [[0 if i==j else 0 for j in range(len(B))] for i in range(len(B))]
    for i in range(len(B)):
        for j in range(len(B)):
            if entry(B[i][j]):
                mat[i][j] = 1
    return mat
```

It is also possible to use other entries in the adjacency matrix:

```sage
def var('t'):
    # optional - sage.
    return t

def adjacency_matrix(1, entry=lambda transition: exp(I*transition.word_out[0]*t)):
    mat = [[0 if i==j else 0 for j in range(len(B))] for i in range(len(B))]
    for i in range(len(B)):
        for j in range(len(B)):
            if entry(B[i][j]):
                mat[i][j] = 1
    return mat
```

asymptotic_moments(variable=None)

Return the main terms of expectation and variance of the sum of output labels and its covariance with the sum of input labels.

**INPUT:**

- variable – a symbol denoting the length of the input, by default *n*.

**OUTPUT:**

A dictionary consisting of

- **expectation** – \(en + \text{Order}(1)\),
- **variance** – \(vn + \text{Order}(1)\),
- **covariance** – \(cn + \text{Order}(1)\)
Assume that all input and output labels are numbers and that self is complete and has only one final component. Assume further that this final component is aperiodic. Furthermore, assume that there is exactly one initial state and that all states are final.

Denote by $X_n$ the sum of output labels written by the finite state machine when reading a random input word of length $n$ over the input alphabet (assuming equidistribution).

Then the expectation of $X_n$ is $en + O(1)$, the variance of $X_n$ is $vn + O(1)$ and the covariance of $X_n$ and the sum of input labels is $cn + O(1)$, cf. [HKW2015], Theorem 3.9.

In the case of non-integer input or output labels, performance degrades significantly. For rational input and output labels, consider rescaling to integers. This limitation comes from the fact that determinants over polynomial rings can be computed much more efficiently than over the symbolic ring. In fact, we compute (parts) of a trivariate generating function where the input and output labels are exponents of some indeterminates, see [HKW2015], Theorem 3.9 for details. If those exponents are integers, we can use a polynomial ring.

**EXAMPLES:**

1. A trivial example: write the negative of the input:

   ```python
   sage: T = Transducer([(0, 0, 0, 0), (0, 0, 1, -1)],
   ....:     initial_states=[0],
   ....:     final_states=[0])
   sage: T([0, 1, 1])
   [0, -1, -1]
   sage: moments = T.asymptotic_moments()  # optional - sage.symbolic
   sage: moments['expectation']  # optional - sage.symbolic
   -1/2*n + Order(1)
   sage: moments['variance']  # optional - sage.symbolic
   1/4*n + Order(1)
   sage: moments['covariance']  # optional - sage.symbolic
   -1/4*n + Order(1)
   ```

2. For the case of the Hamming weight of the non-adjacent-form (NAF) of integers, cf. the Wikipedia article Non-adjacent_form and the example on recognizing NAFs, the following agrees with the results in [HP2007].

   We first use the transducer to convert the standard binary expansion to the NAF given in [HP2007]. We use the parameter with_final_word_out such that we do not have to add sufficiently many trailing zeros:

   ```python
   sage: NAF = Transducer([(0, 0, 0, 0),
   ....:                    (0, '.1', 1, None),
   ....:                    ('.1', 0, 0, [1, 0]),
   ....:                    ('.1', 1, 1, [-1, 0]),
   ....:                    (1, 1, 1, 0),
   ....:                    (1, '.1', 0, None)],
   ....:                    initial_states=[0],
   ....:                    final_states=[0],
   ....:                    with_final_word_out=[0])
   ```
As an example, we compute the NAF of 27 by this transducer.

```python
sage: binary_27 = 27.bits()
sage: binary_27
[1, 1, 0, 1, 1]
sage: NAF_27 = NAF(binary_27)
sage: NAF_27
[-1, 0, -1, 0, 0, 1, 0]
sage: ZZ(NAF_27, base=2)
27
```

Next, we are only interested in the Hamming weight:

```python
sage: def weight(state, input):
....:     if input is None:
....:         result = 0
....:     else:
....:         result = ZZ(input != 0)
....:     return (0, result)
sage: weight_transducer = Transducer(weight,
....:     input_alphabet=[-1, 0, 1],
....:     initial_states=[0],
....:     final_states=[0])
sage: NAFweight = weight_transducer.composition(NAF)
sage: NAFweight.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to ('.1', 0): 1|-,
 Transition from ('.1', 0) to (0, 0): 0|1,0,
 Transition from ('.1', 0) to (1, 0): 1|1,0,
 Transition from (1, 0) to ('.1', 0): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]
sage: NAFweight(binary_27)
[1, 0, 1, 0, 0, 1, 0]
```

Now, we actually compute the asymptotic moments:

```python
sage: moments = NAFweight.asymptotic_moments()  # optional -
→ sage.symbolic
sage: moments['expectation']  # optional -
→ sage.symbolic
1/3*n + Order(1)
sage: moments['variance']  # optional -
→ sage.symbolic
2/27*n + Order(1)
sage: moments['covariance']  # optional -
→ sage.symbolic
Order(1)
```

3. This is Example 3.16 in [HKW2015], where a transducer with variable output labels is given. There, the aim was to choose the output labels of this very simple transducer such that the input and output sum are asymptotically independent, i.e., the constant \( c \) vanishes.
Therefore, the asymptotic covariance vanishes if and only if $a_2 = a_1$.

4. This is Example 4.3 in [HKW2015], dealing with the transducer converting the binary expansion of an integer into Gray code (cf. the Wikipedia article Gray code and the example on Gray code):

```
sage: moments = transducers.GrayCode().asymptotic_moments()  # optional - sage.symbolic
sage: moments['expectation']  # optional - sage.symbolic
1/2*n + Order(1)
sage: moments['variance']  # optional - sage.symbolic
1/4*n + Order(1)
sage: moments['covariance']  # optional - sage.symbolic
Order(1)
```

5. This is the first part of Example 4.4 in [HKW2015], counting the number of 10 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```
sage: block10 = transducers.CountSubblockOccurrences([1, 0], [0, 1])
sage: sorted(block10.transitions())
[Transition from (): 0|0,
 Transition from (): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]
sage: moments = block10.asymptotic_moments()  # optional - sage.symbolic
sage: moments['expectation']  # optional - sage.symbolic
1/4*n + Order(1)
sage: moments['variance']  # optional - sage.symbolic
1/16*n + Order(1)
sage: moments['covariance']  # optional - sage.symbolic
Order(1)
```
6. This is the second part of Example 4.4 in [HKW2015], counting the number of 11 blocks in the standard binary expansion. The least significant digit is at the left-most position:

\begin{verbatim}
\sage: block11 = transducers.CountSubblockOccurrences(
   ....:     [1, 1],
   ....:     input_alphabet=[0, 1])
\sage: sorted(block11.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|0,
 Transition from (1,) to (1,): 1|1]
\sage: var('N')
\sage: moments = block11.asymptotic_moments(N)
\sage: moments['expectation']
1/4*N + Order(1)
\sage: moments['variance']
5/16*N + Order(1)
\sage: correlation = (moments['covariance'].coefficient(N) / # optional -
   ....:     (1/2 * sqrt(moments['variance'].coefficient(N))))
\sage: correlation
2/5*sqrt(5)
\end{verbatim}

7. This is Example 4.5 in [HKW2015], counting the number of 01 blocks minus the number of 10 blocks in the standard binary expansion. The least significant digit is at the left-most position:

\begin{verbatim}
\sage: block01 = transducers.CountSubblockOccurrences(
   ....:     [0, 1],
   ....:     input_alphabet=[0, 1])
\sage: product_01x10 = block01.cartesian_product(block10)
\sage: block_difference = transducers.sub([0, 1])(product_01x10)
\sage: T = block_difference.simplification().relabelled()
\sage: T.transitions()
[Transition from 0 to 2: 0|-1,
 Transition from 0 to 0: 1|0,
 Transition from 1 to 2: 0|0,
 Transition from 1 to 0: 1|0,
 Transition from 2 to 2: 0|0,
 Transition from 2 to 0: 1|1]
\sage: moments = T.asymptotic_moments() # optional -
\sage: moments['expectation']
1/4*N + Order(1)
\sage: moments['variance']
5/16*N + Order(1)
\sage: correlation = (moments['covariance'].coefficient(N) / # optional -
   ....:     (1/2 * sqrt(moments['variance'].coefficient(N))))
\sage: correlation
2/5*sqrt(5)
\end{verbatim}
8. The finite state machine must have a unique final component:

```python
sage: T = Transducer(((0, -1, -1, -1), (0, 1, 1, 1),
                   (-1, -1, -1, -1), (-1, 1, 1, 1),
                   (1, 1, -1, 1), (1, 1, 1, 1)),
                   initial_states=[0],
                   final_states=[0, 1, -1])
```

This particular example, the first letter of the input decides whether we reach the loop at $-1$ or the loop at $1$. In the first case, we have $X_n = -n$, while we have $X_n = n$ in the second case. Therefore, the expectation $E(X_n)$ of $X_n$ is $E(X_n) = 0$. We get $(X_n - E(X_n))^2 = n^2$ in all cases, which results in a variance of $n^2$.

So this example shows that the variance may be non-linear if there is more than one final component.

**Algorithm:**
See [HKW2015], Theorem 3.9.

**References:**

`coaccessible_components()`
Return the sub-machine induced by the coaccessible states of this finite state machine.

**Output:**
A finite state machine of the same type as this finite state machine.

**Examples:**

```python
sage: A = automata.ContainsWord([1, 1],
                   input_alphabet=[0, 1]).complement().minimization().relabeled()
```

(continues on next page)
sage: C = A.coaccessible_components()
sage: C.transitions()
[Transition from 1 to 2: 0|--,
 Transition from 2 to 2: 0|--,
 Transition from 2 to 1: 1|--]

See also:
accessible_components(), induced_sub_finite_state_machine()

completion(sink=None)
Return a completion of this finite state machine.

INPUT:
- sink – either an instance of FSMState or a label for the sink (default: None). If None, the least available non-zero integer is used.

OUTPUT:
A FiniteStateMachine of the same type as this finite state machine.

The resulting finite state machine is a complete version of this finite state machine. A finite state machine is considered to be complete if each transition has an input label of length one and for each pair \((q, a)\) where \(q\) is a state and \(a\) is an element of the input alphabet, there is exactly one transition from \(q\) with input label \(a\).

If this finite state machine is already complete, a deep copy is returned. Otherwise, a new non-final state (usually called a sink) is created and transitions to this sink are introduced as appropriate.

EXAMPLES:

```python
sage: F = FiniteStateMachine([(0, 0, 0, 0),
....: (0, 1, 1, 1),
....: (1, 1, 0, 0)])
sage: F.is_complete()
False
sage: G1 = F.completion()
sage: G1.is_complete()
True
sage: G1.transitions()
[Transition from 0 to 0: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 0: 1|0,
 Transition from 1 to 2: 1|--,
 Transition from 2 to 2: 0|--,
 Transition from 2 to 2: 1|--]
sage: G2 = F.completion('Sink')
sage: G2.is_complete()
True
sage: G2.transitions()
[Transition from 0 to 0: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 0: 1|0,
 Transition from 1 to 'Sink': 1|--,
```
An input alphabet must be given:

```python
sage: F = FiniteStateMachine([(0, 0, 0, 0),
....: (0, 1, 1, 1),
....: (1, 1, 0, 0)],
....: determine_alphabets=False)
```

```python
Traceback (most recent call last):
... ValueError: No input alphabet is given. Try calling determine_alphabets().
```

Non-deterministic machines are not allowed.

```python
sage: F = FiniteStateMachine([(0, 0, 0, 0), (0, 1, 0, 0)])
```

```python
Traceback (most recent call last):
... ValueError: The finite state machine must be deterministic.
```

See also:

- `is_complete()`, `split_transitions()`, `determine_alphabets()`, `is_deterministic()`
- `composition(other, algorithm=None, only_accessible_components=True)`

Return a new transducer which is the composition of self and other.

**INPUT:**

- `other` – a transducer
- `algorithm` – can be one of the following
  
  - `direct` – The composition is calculated directly.

  There can be arbitrarily many initial and final states, but the input and output labels must have length 1.
– **explorative** – An explorative algorithm is used.

The input alphabet of `self` has to be specified.

**Warning:** The output of `other` is fed into `self`.

If algorithm is `None`, then the algorithm is chosen automatically (at the moment always `direct`, except when there are output words of `other` or input words of `self` of length greater than 1).

**OUTPUT:**

A new transducer.

The labels of the new finite state machine are pairs of states of the original finite state machines. The color of a new state is the tuple of colors of the constituent states.

**EXAMPLES:**

```
sage: F = Transducer([('A', 'B', 1, 0), ('B', 'A', 0, 1)],
                   initial_states=['A', 'B'], final_states=['B'],
                   determine_alphabets=True)
sage: G = Transducer([(1, 1, 0, 0), (1, 2, 0, 1), (2, 1, 1, 0), (2, 2, 0, 1), (2, 2, 1, 1)],
                   initial_states=[1], final_states=[2],
                   determine_alphabets=True)
sage: Hd = F.composition(G, algorithm='direct')
sage: Bd = F.composition(G, algorithm='explorative')
sage: Hd.initial_states()
[(1, 'B'), (1, 'A')]
sage: Bd.initial_states()
[(1, 'A'), (1, 'B')]
sage: Bd.transitions()
[[Transition from (1, 'B') to (1, 'A'): 1|1, Transition from (1, 'A') to (2, 'B'): 0|0, Transition from (2, 'B') to (2, 'A'): 0|1, Transition from (2, 'A') to (2, 'B'): 1|0]]
sage: Bd == Bd
True
```

The following example has output of length > 1, so the explorative algorithm has to be used (and is selected automatically).

```
sage: F = Transducer([('A', 'B', 1, [1, 0]), ('B', 'B', 1, 1),
                   (0, 1, 0, 0)],
                   initial_states=['A'], final_states=['B'])
sage: G = Transducer([(1, 1, 0, 0), (1, 2, 1, 0), (2, 1, 0, 0),
                   (2, 2, 1, 0)],
                   initial_states=[1], final_states=[2],
                   determine_alphabets=True)
sage: F.composition(G, algorithm='explorative')
```

(continues on next page)
\[
\begin{align*}
\text{sage: } & \text{H} = G.\text{composition}(F, \text{algorithm='explorative'}) \\
\text{sage: } & \text{H}.\text{transitions()} \\
& \begin{array}{l}
\text{Transition from (}'A', 1\text{) to (}'B', 2\text{): } 1\text{|0,1,} \\
\text{Transition from (}'B', 2\text{) to (}'B', 2\text{): } 0\text{|1,} \\
\text{Transition from (}'B', 1\text{) to (}'B', 1\text{): } 0\text{|0,} \\
\text{Transition from (}'B', 1\text{) to (}'B', 2\text{): } 1\text{|0}
\end{array}
\end{align*}
\]
\[
\text{sage: } H = G.\text{composition}(F) \\
\text{sage: } H == H \\
\text{True}
\]

Final output words are also considered:

\[
\begin{align*}
\text{sage: } & F = \text{Transducer}(\begin{array}{c}
\text{((}'A', 'B', 1, 0), ('B', 'A', 0, 1)\text{)}, \\
\text{((}'A', 'B', 1, 0), ('B', 'A', 1, 0)\text{)}}
\end{array}), \\
\text{sage: } F.\text{state('A').final_word_out = 0} \\
\text{sage: } F.\text{state('B').final_word_out = 1} \\
\text{sage: } G = \text{Transducer}(\begin{array}{c}
\text{((1, 1, 1, 0), (1, 2, 0, 1),} \\
\text{(2, 2, 1, 1), (2, 2, 0, 0)\text{)},}
\end{array}), \\
\text{sage: } G.\text{state(2).final_word_out = 0} \\
\text{sage: } H = F.\text{composition}(G, \text{algorithm='direct'}) \\
\text{sage: } H.\text{final_states()} \\
\text{[(2, 'B')]}
\end{align*}
\]

Note that (2, 'A') is not final, as the final output 0 of state 2 of G cannot be processed in state 'A' of F.

\[
\begin{align*}
\text{sage: } & [s.\text{final_word_out for s in H.final_states()}] \\
& [[1, 0]] \\
\text{sage: } [s.\text{final_word_out for s in H.final_states()}] \\
& [[1, 0]] \\
\text{sage: } H == H \\
\text{True}
\end{align*}
\]

Here is a non-deterministic example with intermediate output length > 1.

\[
\begin{align*}
\text{sage: } & F = \text{Transducer}(\begin{array}{c}
\text{((1, 1, 1, ['a', 'a']), (1, 2, 1, 'b')}, \\
\text{((2, 1, 2, 'a'), (2, 2, 2, 'b')\text{)},}
\end{array}), \\
\text{sage: } G = \text{Transducer}(\begin{array}{c}
\text{((}'A', 'A', 'a', 'i')}, \\
\text{((}'A', 'B', 'a', 'l')}, \\
\text{((}'B', 'B', 'b', 'e')},
\end{array}), \\
\text{sage: } G(F).\text{transitions()} \\
& \begin{array}{l}
\text{Transition from (1, 'A') to (1, 'A'): } 1|'i','i', \\
\text{Transition from (1, 'A') to (1, 'B'): } 1|'i','l', \\
\text{Transition from (1, 'B') to (2, 'B'): } 1|'e',
\end{array}
\end{align*}
\]
Transition from (2, 'A') to (1, 'A'): 2|'i',
Transition from (2, 'A') to (1, 'B'): 2|'l',
Transition from (2, 'B') to (2, 'B'): 2|'e']

Be aware that after composition, different transitions may share the same output label (same python object):

```
sage: F = Transducer([ ( 'A', 'B', 0, 0), ( 'B', 'A', 0, 0) ],
....................:  initial_states=['A'],
....................:  final_states=['A'])
sage: F.transitions()[0].word_out is F.transitions()[1].word_out
False
sage: G = Transducer([('C', 'C', 0, 1)],
....................:  initial_states=['C'],
....................:  final_states=['C'])
sage: H = G.composition(F)
sage: H.transitions()[0].word_out is H.transitions()[1].word_out
True
```

**concatenation**(other)

Concatenate this finite state machine with another finite state machine.

**INPUT:**

- *other* – a *FiniteStateMachine*.

**OUTPUT:**

A *FiniteStateMachine* of the same type as this finite state machine.

Assume that both finite state machines are automata. If \( \mathcal{L}_1 \) is the language accepted by this automaton and \( \mathcal{L}_2 \) is the language accepted by the other automaton, then the language accepted by the concatenated automaton is \( \{ w_1w_2 \mid w_1 \in \mathcal{L}_1, w_2 \in \mathcal{L}_2 \} \) where \( w_1w_2 \) denotes the concatenation of the words \( w_1 \) and \( w_2 \).

Assume that both finite state machines are transducers and that this transducer maps words \( w_1 \in \mathcal{L}_1 \) to words \( f_1(w_1) \) and that the other transducer maps words \( w_2 \in \mathcal{L}_2 \) to words \( f_2(w_2) \). Then the concatenated transducer maps words \( w_1w_2 \) with \( w_1 \in \mathcal{L}_1 \) and \( w_2 \in \mathcal{L}_2 \) to \( f_1(w_1)f_2(w_2) \). Here, \( w_1w_2 \) and \( f_1(w_1)f_2(w_2) \) again denote concatenation of words.

The input alphabet is the union of the input alphabets (if possible) and `None` otherwise. In the latter case, try calling `determine_alphabets()`.

Instead of `A.concatenation(B)`, the notation `A * B` can be used.

**EXAMPLES:**

Concatenation of two automata:

```
sage: A = automata.Word([0])
sage: B = automata.Word([1])
sage: C = A.concatenation(B)
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
 Transition from (0, 1) to (1, 0): -|-,
 Transition from (1, 0) to (1, 1): 1|-]
sage: [w
....................:  for w in ([0, 0], [0, 1], [1, 0], [1, 1])]
```
....: if C(w)
[[0, 1]]
sage: from sage.combinat.finite_state_machine import (
....: is_Automaton, is_Transducer)
sage: is_Automaton(C)
True

Concatenation of two transducers:

sage: A = Transducer([(0, 1, 0, 1), (0, 1, 1, 2)],
....: initial_states=[0],
....: final_states=[1])
sage: B = Transducer([(0, 1, 0, 1), (0, 1, 1, 0)],
....: initial_states=[0],
....: final_states=[1])
sage: C = A.concatenation(B)
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|1,
 Transition from (0, 0) to (0, 1): 1|2,
 Transition from (0, 1) to (1, 0): -|-,
 Transition from (1, 0) to (1, 1): 0|1,
 Transition from (1, 0) to (1, 1): 1|0]
sage: [(w, C(w)) for w in ([0, 0], [0, 1], [1, 0], [1, 1])]
([(0, 0), (1, 1)],
 (0, 1), (1, 0),
 (1, 0), (2, 1),
 (1, 1), (2, 0))]
sage: is_Transducer(C)
True

Alternative notation as multiplication:

sage: C == A * B
True

Final output words are taken into account:

sage: A = Transducer([(0, 1, 0, 1)],
....: initial_states=[0],
....: final_states=[1])
sage: A.state(1).final_word_out = 2
sage: B = Transducer([(0, 1, 0, 3)],
....: initial_states=[0],
....: final_states=[1])
sage: B.state(1).final_word_out = 4
sage: C = A * B
sage: C([0, 0])
[1, 2, 3, 4]

Handling of the input alphabet:

sage: A = Automaton(([0, 0]))
sage: B = Automaton(([0, 0, 1], input_alphabet=[1, 2])
(continues on next page)
```python
sage: C = Automaton([(0, 0, 2)], determine_alphabets=False)
sage: D = Automaton([(0, 0, [[0, 0]])], input_alphabet=[[0, 0]])
sage: A.input_alphabet
[0]
sage: B.input_alphabet
[1, 2]
sage: C.input_alphabet is None
True
sage: D.input_alphabet
[[0, 0]]
sage: (A * B).input_alphabet
[0, 1, 2]
sage: (A * C).input_alphabet is None
True
sage: (A * D).input_alphabet is None
True
```

See also:

disjoint_union(), determine_alphabets().

**construct_final_word_out**(letters, allow_non_final=True)

This is an inplace version of with_final_word_out(). See with_final_word_out() for documentation and examples.

**copy()**

Return a (shallow) copy of the finite state machine.

OUTPUT:

A new finite state machine.

**deepcopy**(memo=None)

Return a deep copy of the finite state machine.

INPUT:

* memo – (default: None) a dictionary storing already processed elements.

OUTPUT:

A new finite state machine.

EXAMPLES:

```python
sage: F = FiniteStateMachine([(‘A’, ‘A’, 0, 1), (‘A’, ‘A’, 1, 0)])
sage: deepcopy(F)
Finite state machine with 1 state
```

**default_format_letter = <sage.misc.latex.Latex object>**

**default_format_transition_label**(word)

Default formatting of words in transition labels for LaTeX output.

INPUT:

word – list of letters

OUTPUT:
String representation of word suitable to be typeset in mathematical mode.

- For a non-empty word: Concatenation of the letters, piped through self.format_letter and separated by blanks.
- For an empty word: sage.combinat.finite_state_machine.EmptyWordLaTeX.

There is also a variant format_transition_label_reversed() writing the words in reversed order.

**EXAMPLES:**

1. Example of a non-empty word:

   ```python
   sage: T = Transducer()
   sage: print(T.default_format_transition_label(["a", 'alpha', 'a_1', '0', 0, (0, 1)]))
   a alpha a_1 0 0 \left(0, 1\right)
   ```

2. In the example above, 'a' and 'alpha' should perhaps be symbols:

   ```python
   sage: var("a alpha a_1")
   #optional - sage.symbolic
   (a, alpha, a_1)
   sage: print(T.default_format_transition_label([a, alpha, a_1]))
   #optional - sage.symbolic
   a \alpha a_{1}
   ```

3. Example of an empty word:

   ```python
   sage: print(T.default_format_transition_label([]))
   \varepsilon
   ```

   We can change this by setting sage.combinat.finite_state_machine.EmptyWordLaTeX:

   ```python
   sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
   sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
   ```

4. This method is the default value for FiniteStateMachine.format_transition_label. That can be changed to be any other function:

   ```python
   sage: A = Automaton([(0, 1, 0)])
   sage: def custom_format_transition_label(word):
   ....:     return "t"
   sage: A.latex_options(format_transition_label=custom_format_transition_label)
   sage: print(latex(A))
   \begin{tikzpicture}\[auto, initial text=, >=latex\]
   \node[state] (v0) at (3.000000, 0.000000) {$0$};
   \node[state] (v1) at (-3.000000, 0.000000) {$1$};
   \path[->] (v0) edge node[rotate=360.00, anchor=south] {$t$} (v1);
   \end{tikzpicture}
   ```
**delete_state(s)**
Deletes a state and all transitions coming or going to this state.

**INPUT:**
- s – a label of a state or an `FSMState`.

**OUTPUT:**
Nothing.

**EXAMPLES:**
```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t1 = FSMTransition('A', 'B', 0)
sage: t2 = FSMTransition('B', 'B', 1)
sage: F = FiniteStateMachine([t1, t2])
sage: F.delete_state('A')
sage: F.transitions()
[Transition from 'B' to 'B': 1|-]
```

**delete_transition(t)**
Deletes a transition by removing it from the list of transitions of the state, where the transition starts.

**INPUT:**
- t – a transition.

**OUTPUT:**
Nothing.

**EXAMPLES:**
```
sage: F = FiniteStateMachine([('A', 'B', 0), ('B', 'A', 1)])
sage: F.delete_transition(('A', 'B', 0))
sage: F.transitions()
[Transition from 'B' to 'A': 1|-]
```

**determine_alphabets(reset=True)**
Determine the input and output alphabet according to the transitions in this finite state machine.

**INPUT:**
- reset – If `reset` is `True`, then the existing input and output alphabets are erased, otherwise new letters are appended to the existing alphabets.

**OUTPUT:**
Nothing.

After this operation the input alphabet and the output alphabet of this finite state machine are a list of letters.

**Todo:** At the moment, the letters of the alphabets need to be hashable.

**EXAMPLES:**
```
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
.....:            (2, 2, 1, 1), (2, 2, 0, 0)],
```
sage: T.state(1).final_word_out = [1, 4]
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
sage: T.determine_alphabets()
sage: (T.input_alphabet, T.output_alphabet)
([0, 1, 2], [0, 1, 4])

See also:
determine_input_alphabet(), determine_output_alphabet().

determine_input_alphabet(reset=True)

Determine the input alphabet according to the transitions of this finite state machine.

INPUT:

• reset — a boolean (default: True). If True, then the existing input alphabet is erased, otherwise new letters are appended to the existing alphabet.

OUTPUT:

Nothing.

After this operation the input alphabet of this finite state machine is a list of letters.

Todo: At the moment, the letters of the alphabet need to be hashable.

EXAMPLES:

sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
....:                   (2, 2, 1, 1), (2, 2, 0, 0)],
....:                   final_states=[1],
....:                   determine_alphabets=False)
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
sage: T.determine_input_alphabet()
sage: (T.input_alphabet, T.output_alphabet)
([0, 1, 2], None)

See also:
determine_output_alphabet(), determine_alphabets().

determine_output_alphabet(reset=True)

Determine the output alphabet according to the transitions of this finite state machine.

INPUT:

• reset — a boolean (default: True). If True, then the existing output alphabet is erased, otherwise new letters are appended to the existing alphabet.

OUTPUT:

Nothing.

After this operation the output alphabet of this finite state machine is a list of letters.
Todo: At the moment, the letters of the alphabet need to be hashable.

EXAMPLES:

```sage
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
....:                   (2, 2, 1, 1), (2, 2, 0, 0)],
....:                   final_states=[1],
....:                   determine_alphabets=False)
sage: T.state(1).final_word_out = [1, 4]
sage: (T.input_alphabet, T.output_alphabet)
(None, None)
sage: T.determine_output_alphabet()
sage: (T.input_alphabet, T.output_alphabet)
(None, [0, 1, 4])
```

See also:

`determine_input_alphabet()`, `determine_alphabets()`.

digraph(`edge_labels='words_in_out'`)

Return the graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

- `edge_label`: (default: `'words_in_out'`) can be
  - `'words_in_out'` (labels will be strings `'i|o'`)
  - a function with which takes as input a transition and outputs (returns) the label

OUTPUT:
A directed graph.

EXAMPLES:

```sage
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: T = Transducer()
sage: T.graph()
Looped multi-digraph on 0 vertices
sage: T.add_state(A)
'A'
sage: T.graph()
Looped multi-digraph on 1 vertex
sage: T.add_transition(('A', 'A', 0, 1))
Transition from 'A' to 'A': 0|1
sage: T.graph()
Looped multi-digraph on 1 vertex
```

See also:

`DiGraph`

disjoint_union(`other`)

Return the disjoint union of this and another finite state machine.

INPUT:
• other – a FiniteStateMachine.

OUTPUT:

A finite state machine of the same type as this finite state machine.

In general, the disjoint union of two finite state machines is non-deterministic. In the case of a automata, the language accepted by the disjoint union is the union of the languages accepted by the constituent automata. In the case of transducer, for each successful path in one of the constituent transducers, there will be one successful path with the same input and output labels in the disjoint union.

The labels of the states of the disjoint union are pairs (i, s): for each state s of this finite state machine, there is a state (0, s) in the disjoint union; for each state s of the other finite state machine, there is a state (1, s) in the disjoint union.

The input alphabet is the union of the input alphabets (if possible) and None otherwise. In the latter case, try calling determine_alphabets().

The disjoint union can also be written as A + B or A | B.

EXAMPLES:

```
sage: A = Automaton([(0, 1, 0), (1, 0, 1)],
.....:    initial_states=[0],
.....:    final_states=[0])
sage: A([0, 1, 0, 1])
True
sage: B = Automaton([(0, 1, 0), (1, 2, 0), (2, 0, 1)],
.....:    initial_states=[0],
.....:    final_states=[0])
sage: B([0, 0, 1])
True
sage: C = A.disjoint_union(B)
sage: C
Automaton with 5 states
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
    Transition from (0, 1) to (0, 0): 1|-,
    Transition from (1, 0) to (1, 1): 0|-,
    Transition from (1, 1) to (1, 2): 0|-,
    Transition from (1, 2) to (1, 0): 1|-]
sage: C([0, 0, 1])
True
sage: C([0, 1, 0, 1])
True
sage: C([1])
False
sage: C.initial_states()
[(0, 0), (1, 0)]
```

Instead of .disjoint_union, alternative notations are available:

```
sage: C1 = A + B
sage: C1 == C
True
sage: C2 = A | B
```

(continues on next page)
In general, the disjoint union is not deterministic:

```python
sage: C.is_deterministic()
False
sage: D = C.determinisation().minimisation()
```

Disjoint union of transducers:

```python
sage: T1 = Transducer([(0, 0, 0, 1)],
                   initial_states=[0],
                   final_states=[0])
sage: T2 = Transducer([(0, 0, 0, 2)],
                   initial_states=[0],
                   final_states=[0])
sage: T1([0])
[1]
sage: T2([0])
[2]
sage: T = T1.disjoint_union(T2)
sage: T([0])
Traceback (most recent call last):
... ValueError: Found more than one accepting path.
```

Handling of the input alphabet (see github issue #18989):

```python
sage: A = Automaton([(0, 0, 0)])
sage: B = Automaton([(0, 0, 1)], input_alphabet=[1, 2])
sage: C = Automaton([(0, 0, 2)], determine_alphabets=False)
sage: D = Automaton([(0, 0, [[0, 0]])], input_alphabet=[[0, 0]])
sage: A.input_alphabet
[0]
sage: B.input_alphabet
[1, 2]
sage: C.input_alphabet is None
True
sage: D.input_alphabet
[[0, 0]]
sage: (A + B).input_alphabet
[0, 1, 2]
```
sage: (A + C).input_alphabet is None
True
sage: (A + D).input_alphabet is None
True

See also:
Automaton.intersection(), Transducer.intersection(), determine_alphabets().

empty_copy(memo=None, new_class=None)

Return an empty deep copy of the finite state machine, i.e., input_alphabet, output_alphabet,
on_duplicate_transition are preserved, but states and transitions are not.

INPUT:

• memo – a dictionary storing already processed elements.
• new_class – a class for the copy. By default (None), the class of self is used.

OUTPUT:
A new finite state machine.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_error
sage: F = FiniteStateMachine([('A', 'A', 0, 2), ('A', 'A', 1, 3)],
....: input_alphabet=[0, 1],
....: output_alphabet=[2, 3],
....: on_duplicate_transition=duplicate_transition_raise_error)

sage: FE = F.empty_copy(); FE
Empty finite state machine

sage: FE.input_alphabet
[0, 1]
sage: FE.output_alphabet
[2, 3]
sage: FE.on_duplicate_transition == duplicate_transition_raise_error
True

epsilon_successors(state)

Return the dictionary with states reachable from state without reading anything from an input tape as
keys. The values are lists of outputs.

INPUT:

• state – the state whose epsilon successors should be determined.

OUTPUT:
A dictionary mapping states to a list of output words.

The states in the output are the epsilon successors of state. Each word of the list of output words is a
word written when taking a path from state to the corresponding state.

EXAMPLES:
sage: T = Transducer([(0, 1, None, 'a'), (1, 2, None, 'b')])
sage: T.epsilon_successors(0)
{1: [['a']], 2: [['a', 'b']]}
sage: T.epsilon_successors(1)
{2: [['b']]}
sage: T.epsilon_successors(2)
{}

If there is a cycle with only epsilon transitions, then this cycle is only processed once and there is no infinite loop:

sage: S = Transducer([(0, 1, None, 'a'), (1, 0, None, 'b')])
sage: S.epsilon_successors(0)
{0: [['a', 'b']], 1: ['a']}
sage: S.epsilon_successors(1)
{0: ['b'], 1: ['b', 'a']}

equivalence_classes()

Return a list of equivalence classes of states.

OUTPUT:

A list of equivalence classes of states.

Two states \(a\) and \(b\) are equivalent if and only if there is a bijection \(\varphi\) between paths starting at \(a\) and paths starting at \(b\) with the following properties: Let \(p_a\) be a path from \(a\) to \(a'\) and \(p_b\) a path from \(b\) to \(b'\) such that \(\varphi(p_a) = p_b\), then

- \(p_a\.word\_in = p_b\.word\_in\),
- \(p_a\.word\_out = p_b\.word\_out\),
- \(a'\) and \(b'\) have the same output label, and
- \(a'\) and \(b'\) are both final or both non-final and have the same final output word.

The function `equivalence_classes()` returns a list of the equivalence classes to this equivalence relation.

This is one step of Moore’s minimization algorithm.

See also:

`minimization()`

EXAMPLES:

sage: fsm = FiniteStateMachine([('A', 'B', 0, 1), ('A', 'B', 1, 0),
...                           ('B', 'C', 0, 1), ('B', 'C', 1, 1),
...                           ('C', 'D', 0, 1), ('C', 'D', 1, 0),
...                           ('D', 'A', 0, 1), ('D', 'A', 1, 1)])
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
sage: fsm.state('A').is_final = True
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
(continues on next page)
final_components()

Return the final components of a finite state machine as finite state machines.

OUTPUT:

A list of finite state machines, each representing a final component of self.

A final component of a transducer $T$ is a strongly connected component $C$ such that there are no transitions of $T$ leaving $C$.

The final components are the only parts of a transducer which influence the main terms of the asymptotic behaviour of the sum of output labels of a transducer, see [HKP2015] and [HKW2015].

EXAMPLES:

```python
sage: T = Transducer([["A", "B", 0, 0], ["B", "C", 0, 1],
                  ....: ["C", "B", 0, 1], ["A", "D", 1, 0],
                  ....: ["D", "D", 0, 0], ["A", "E", 0, 0]],
                  ....: ["A", "E", 2, 0], ["E", "E", 0, 0]])
sage: FC = T.final_components()
sage: sorted(FC[0].transitions())
[Transition from 'B' to 'C': 0|1,
 Transition from 'C' to 'B': 0|1]
```

Another example (cycle of length 2):

```python
sage: T = Automaton([[0, 1, 0], [1, 0, 0]])
sage: len(T.final_components()) == 1
True
sage: T.final_components()[0].transitions()
[Transition from 0 to 1: 0|--,
 Transition from 1 to 0: 0|--]
```

final_states()

Return a list of all final states.

OUTPUT:

A list of all final states.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState("A", is_final=True)
sage: B = FSMState("B", is_initial=True)
sage: C = FSMState("C", is_final=True)
sage: F = FiniteStateMachine([(A, B), (A, C)])
```
format_letter = <sage.misc.latex.Latex object>

format_letter_negative(letter)

Format negative numbers as overlined numbers, everything else by standard LaTeX formatting.

INPUT:
letter – anything.

OUTPUT:
Overlined absolute value if letter is a negative integer, latex(letter) otherwise.

EXAMPLES:

sage: A = Automaton([[0, 0, -1]])

sage: list(map(A.format_letter_negative, [-1, 0, 1, 'a', None]))
['\overline{1}', 0, 1, \text{\texttt{a}}, \mathrm{None}]

sage: A.latex_options(format_letter=A.format_letter_negative)

sage: print(latex(A))
\begin{tikzpicture}
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\path[->] (v0) edge[loop above] node {$\overline{1}$} ();
\end{tikzpicture}

format_transition_label(word)

Default formatting of words in transition labels for LaTeX output.

INPUT:
word – list of letters

OUTPUT:
String representation of word suitable to be typeset in mathematical mode.

• For a non-empty word: Concatenation of the letters, piped through self.format_letter and separated by blanks.

• For an empty word: sage.combinat.finite_state_machine.EmptyWordLaTeX.

There is also a variant format_transition_label_reversed() writing the words in reversed order.

EXAMPLES:

1. Example of a non-empty word:

2. In the example above, 'a' and 'alpha' should perhaps be symbols:
3. Example of an empty word:

```python
sage: print(T.default_format_transition_label([]))
\varepsilon
```

We can change this by setting `sage.combinat.finite_state_machine.EmptyWordLaTeX`:

```python
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
sage: T.default_format_transition_label([])
''
```

Finally, we restore the default value:

```python
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

4. This method is the default value for `FiniteStateMachine.format_transition_label`. That can be changed to be any other function:

```python
sage: A = Automaton([(0, 1, 0)])
sage: def custom_format_transition_label(word):
    return "t"
sage: A.latex_options(format_transition_label=custom_format_transition_label)
sage: print(latex(A))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\node[state] (v1) at (-3.000000, 0.000000) {$1$};
\path[->] (v0) edge node[rotate=360.00, anchor=south] {\texttt{t}} (v1);
\end{tikzpicture}
```

`format_transition_label_reversed(word)`

Format words in transition labels in reversed order.

**INPUT:**

- `word` – list of letters.

**OUTPUT:**

String representation of `word` suitable to be typeset in mathematical mode, letters are written in reversed order.

This is the reversed version of `default_format_transition_label()`.

In digit expansions, digits are frequently processed from the least significant to the most significant position, but it is customary to write the least significant digit at the right-most position. Therefore, the labels have to be reversed.

**EXAMPLES:**
sage: T = Transducer([(0, 0, 0, [1, 2, 3])])
sage: T.format_transition_label_reversed([1, 2, 3])
'3 2 1'
sage: T.latex_options(format_transition_label=T.format_transition_label_reversed)
sage: print(latex(T))
\begin{tikzpicture}[auto, initial text=, >=latex]
  \node[state] (v0) at (3.000000, 0.000000) {$0$};
  \path[->] (v0) edge[loop above] node {$0\mid 3 2 1$} ();
\end{tikzpicture}

\textbf{graph}(\texttt{edge\_labels='words\_in\_out'})

Return the graph of the finite state machine with labeled vertices and labeled edges.

\textbf{INPUT}:

\begin{itemize}
  \item \texttt{edge\_label}: (default: 'words\_in\_out') can be
    \begin{itemize}
      \item 'words\_in\_out' (labels will be strings 'i|o')
      \item a function with which takes as input a transition and outputs (returns) the label
    \end{itemize}
\end{itemize}

\textbf{OUTPUT}:

A directed graph.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: from sage.combinat.finite_state_machine import FSMState
tsage: A = FSMState('A')
tsage: T = Transducer()
tsage: T.graph()
Looped multi-digraph on 0 vertices
sage: T.add_state(A)
'A'
tsage: T.graph()
Looped multi-digraph on 1 vertex
sage: T.add_transition(('A', 'A', 0, 1))
Transition from 'A' to 'A': 0|1
sage: T.graph()
Looped multi-digraph on 1 vertex
\end{verbatim}

See also:

DiGraph

\textbf{has\_final\_state}(\texttt{state})

Return whether \texttt{state} is one of the final states of the finite state machine.

\textbf{INPUT}:

\begin{itemize}
  \item \texttt{state} can be a \texttt{FSMState} or a label.
\end{itemize}

\textbf{OUTPUT}:

True or False.

\textbf{EXAMPLES}:
Combinatorics, Release 10.1

```
sage: FiniteStateMachine(final_states=['A']).has_final_state('A')
True
```

**has_final_state()**

Return whether the finite state machine has a final state.

OUTPUT:

True or False.

EXAMPLES:

```
sage: FiniteStateMachine().has_final_states()
False
```

```
has_initial_state(state)
```

Return whether `state` is one of the initial states of the finite state machine.

INPUT:

• `state` can be a `FSMState` or a label.

OUTPUT:

True or False.

EXAMPLES:

```
sage: F = FiniteStateMachine([(A, 'A'), initial_states=['A'])
sage: F.has_initial_state('A')
True
```

```
has_initial_states()
```

Return whether the finite state machine has an initial state.

OUTPUT:

True or False.

EXAMPLES:

```
sage: FiniteStateMachine().has_initial_states()
False
```

```
has_state(state)
```

Return whether `state` is one of the states of the finite state machine.

INPUT:

• `state` can be a `FSMState` or a label of a state.

OUTPUT:

True or False.

EXAMPLES:

```
sage: FiniteStateMachine().has_state('A')
False
```
**has_transition**(*transition*)

Return whether *transition* is one of the transitions of the finite state machine.

**INPUT:**

• *transition* has to be a *FSMTransition*.

**OUTPUT:**

True or False.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMTransition
tsage: t = FSMTransition('A', 'A', 0, 1)
sage: FiniteStateMachine().has_transition(t)
False
sage: FiniteStateMachine().has_transition(('A', 'A', 0, 1))
Traceback (most recent call last):
... TypeError: Transition is not an instance of FSMTransition.
```

**induced_sub_finite_state_machine**(*states*)

Return a sub-finite-state-machine of the finite state machine induced by the given states.

**INPUT:**

• *states* – a list (or an iterator) of states (either labels or instances of *FSMState*) of the sub-finite-state-machine.

**OUTPUT:**

A new finite state machine. It consists (of deep copies) of the given states and (deep copies) of all transitions of *self* between these states.

**EXAMPLES:**

```python
sage: FSM = FiniteStateMachine([(0, 1, 0), (0, 2, 0), ....:(1, 2, 0), (2, 0, 0)])
sage: sub_FSM = FSM.induced_sub_finite_state_machine([0, 1])
sage: sub_FSM.states()
[0, 1]
sage: sub_FSM.transitions()
[Transition from 0 to 1: 0|-
```

**initial_states**()

Return a list of all initial states.

**OUTPUT:**

A list of all initial states.

**EXAMPLES:**

```python
```
input_alphabet = None
A list of letters representing the input alphabet of the finite state machine.
It can be set by the parameter input_alphabet when initializing a finite state machine, see FiniteStateMachine.

It can also be set by the method determine_alphabets().

See also:
FiniteStateMachine, determine_alphabets(), output_alphabet.

input_projection()
Return an automaton where the output of each transition of self is deleted.

OUTPUT:
An automaton.

EXAMPLES:

sage: F = FiniteStateMachine([('A', 'B', 0, 1), ('A', 'A', 1, 1), ....: ('B', 'B', 1, 0)])
sage: G = F.input_projection()
sage: G.transitions()
[Transition from 'A' to 'B': 0|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 1|-]

intersection(other)

is_Markov_chain(is_zero=None)
Checks whether self is a Markov chain where the transition probabilities are modeled as input labels.

INPUT:
• is_zero – by default (is_zero=None), checking for zero is simply done by is_zero(). This parameter can be used to provide a more sophisticated check for zero, e.g. in the case of symbolic probabilities, see the examples below.

OUTPUT:
True or False.

on_duplicate_transition must be duplicate_transition_add_input(), the sum of the input weights of the transitions leaving a state must add up to 1 and the sum of initial probabilities must add up to 1 (or all be None).

EXAMPLES:

sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input

(continues on next page)
Combinatorics, Release 10.1

sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
                   ....: [1, 0, 1/2, 0], [1, 1, 1/2, 1]],
                   ....: on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
True

**on_duplicate_transition** must be **duplicate_transition_add_input()**:

sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
                   ....: [1, 0, 1/2, 0], [1, 1, 1/2, 1]])
sage: F.is_Markov_chain()
False

Sum of input labels of the transitions leaving states must be 1:

sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
                   ....: [1, 0, 1/2, 0]],
                   ....: on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
False

The initial probabilities of all states must be None or they must sum up to 1. The initial probabilities of all states have to be set in the latter case:

sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
                   ....: [1, 0, 1, 0]],
                   ....: on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
True
sage: F.state(0).initial_probability = 1/4
sage: F.is_Markov_chain()
False
sage: F.state(1).initial_probability = 7
sage: F.is_Markov_chain()
False
sage: F.state(1).initial_probability = 3/4
sage: F.is_Markov_chain()
True

If the probabilities are variables in the symbolic ring, **assume()** will do the trick:

sage: var('p q')
˓→# optional - sage.symbolic
(p, q)
sage: F = Transducer([[0, 0, p, 1], [0, 0, q, 0]],
                   ....: on_duplicate_transition=duplicate_transition_add_input)
sage: assume(p + q == 1)
˓→# optional - sage.symbolic
sage: (p + q - 1).is_zero()
˓→# optional - sage.symbolic
True
sage: F.is_Markov_chain()

(continues on next page)
If the probabilities are variables in some polynomial ring, the parameter `is_zero` can be used:

```python
sage: R.<p, q> = PolynomialRing(QQ)
sage: def is_zero_polynomial(polynomial):
    ...:     return polynomial in (p + q - 1)*R
sage: F = Transducer([(0, 0, p, 1), (0, 0, q, 0)],
    ...:       on_duplicate_transition=duplicate_transition_add_input)
sage: F.state(0).initial_probability = p + q
sage: F.is_Markov_chain()
False
sage: F.is_Markov_chain(is_zero_polynomial)
True
```

### `is_complete()`

Return whether the finite state machine is complete.

**OUTPUT:**

True or False

A finite state machine is considered to be complete if each transition has an input label of length one and for each pair \((q, a)\) where \(q\) is a state and \(a\) is an element of the input alphabet, there is exactly one transition from \(q\) with input label \(a\).

**EXAMPLES:**

```python
sage: fsm = FiniteStateMachine([[0, 0, 0, 0],
    ...:     (0, 1, 1, 1),
    ...:     (1, 1, 0, 0)],
    ...:     determine_alphabets=False)
sage: fsm.is_complete()
Traceback (most recent call last):
...:
ValueError: No input alphabet is given. Try calling determine_alphabets().
sage: fsm.input_alphabet = [0, 1]
sage: fsm.is_complete()
False
sage: fsm.add_transition((1, 1, 1, 1))
Transition from 1 to 1: 1|1
sage: fsm.is_complete()
True
sage: fsm.add_transition((0, 0, 1, 0))
Transition from 0 to 0: 1|0
sage: fsm.is_complete()
False
```

### `is_connected()`
**is_deterministic()**

Return whether the finite finite state machine is deterministic.

**OUTPUT:**

True or False

A finite state machine is considered to be deterministic if each transition has input label of length one and for each pair \((q, a)\) where \(q\) is a state and \(a\) is an element of the input alphabet, there is at most one transition from \(q\) with input label \(a\). Furthermore, the finite state may not have more than one initial state.

**EXAMPLES:**

```python
sage: fsm = FiniteStateMachine()
sage: fsm.add_transition(('A', 'B', 0, []))
Transition from 'A' to 'B': 0|-sage: fsm.is_deterministic()
True
sage: fsm.add_transition(('A', 'C', 0, []))
Transition from 'A' to 'C': 0|-sage: fsm.is_deterministic()
False
sage: fsm.add_transition(('A', 'B', [0,1], []))
Transition from 'A' to 'B': 0,1|-sage: fsm.is_deterministic()
False
```

Check that [github issue #18556](https://github.com) is fixed:

```python
sage: Automaton().is_deterministic()
True
sage: Automaton(initial_states=[0]).is_deterministic()
True
sage: Automaton(initial_states=[0, 1]).is_deterministic()
False
```

**is_monochromatic()**

Check whether the colors of all states are equal.

**OUTPUT:**

True or False

**EXAMPLES:**

```python
sage: G = transducers.GrayCode()
sage: [s.color for s in G.iter_states()]
[None, None, None]
sage: G.is_monochromatic()
True
sage: G.state(1).color = 'blue'
sage: G.is_monochromatic()
False
```

**iter_final_states()**

Return an iterator of the final states.

**OUTPUT:**

5.1. Comprehensive Module List 999
An iterator over all initial states.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True)
sage: B = FSMState('B', is_initial=True)
sage: C = FSMState('C', is_final=True)
sage: F = FiniteStateMachine([(A, B), (A, C)])
sage: [s.label() for s in F.iter_final_states()]
['A', 'C']
```

**iter_initial_states()**

Return an iterator of the initial states.

**OUTPUT:**

An iterator over all initial states.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_initial=True)
sage: B = FSMState('B')
sage: F = FiniteStateMachine([(A, B, 1, 0)])
```

```python
sage: [s.label() for s in F.iter_initial_states()]
['A']
```

**iter_process**(input_tape=None, initial_state=None, process_iterator_class=None, iterator_type=None, automatic_output_type=False, **kwargs)

This function returns an iterator for processing the input. See `process()` (which runs this iterator until the end) for more information.

**INPUT:**

- `iterator_type` – If `None` (default), then an instance of `FSMProcessIterator` is returned. If this is 'simple' only an iterator over one output is returned (an exception is raised if this is not the case, i.e., if the process has branched).

See `process()` for a description of the other parameters.

**OUTPUT:**

An iterator.

**EXAMPLES:**

We can use `iter_process()` to deal with infinite words:

```python
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:     initial_states=['A'], final_states=['A'])
sage: words.FibonacciWord() word: 0100101001001010010100100101001001010010...
```

```python
sage: it = inverter.iter_process(
....:     words.FibonacciWord(), iterator_type='simple')
sage: Words([0, 1])(it) word: 1011010110110110110110110110110110110110...
```

This can also be done by:
or even simpler by:

```sage
sage: inverter(words.FibonacciWord())
word: 1011010110110101101011011010110110101101...
```

To see what is going on, we use `iter_process()` without arguments:

```sage
from itertools import islice
sage: it = inverter.iter_process(words.FibonacciWord())
sage: for current in islice(it, 4):
    print(current)
```

The following show the difference between using the 'simple'-option and not using it. With this option, we have

```sage
sage: it = inverter.iter_process(input_tape=[0, 1, 1],
    iterator_type='simple')
sage: for i, o in enumerate(it):
    print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 0
step 2: output 0
```

So `iter_process()` is a generator expression which gives a new output letter in each step (and not more). In many cases this is sufficient.

Doing the same without the 'simple'-option does not give the output directly; it has to be extracted first. On the other hand, additional information is presented:

```sage
sage: it = inverter.iter_process(input_tape=[0, 1, 1])
sage: for current in it:
    print(current)
```

(continues on next page)
One can see the growing of the output (the list of lists at the end of each entry).

Even if the transducer has transitions with empty or multiletter output, the simple iterator returns one new output letter in each step:

```python
sage: T = Transducer([[(0, 0, 0, [])],
            (0, 0, 1, [1]),
            (0, 0, 2, [2, 2])],
            initial_states=[0])
sage: it = T.iter_process(input_tape=[0, 1, 2, 0, 1, 2],
            iterator_type='simple')
```

```python
sage: for i, o in enumerate(it):
    print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 2
step 2: output 2
step 3: output 1
step 4: output 2
step 5: output 2
```

See also:

**iter_states()**

Return an iterator of the states.

**OUTPUT:**

An iterator of the states of the finite state machine.

**EXAMPLES:**

```python
sage: FSM = Automaton([(1, 2, 1), (2, 2, 0)])
sage: [s.label() for s in FSM.iter_states()]
['1', '2']
```

**iter_transitions(from_state=None)**

Return an iterator of all transitions.

**INPUT:**

- `from_state` – (default: None) If from_state is given, then a list of transitions starting there is given.

**OUTPUT:**

An iterator of all transitions.

**EXAMPLES:**
Compute the Kleene closure of this finite state machine.

**OUTPUT:**

A *FiniteStateMachine* of the same type as this finite state machine.

Assume that this finite state machine is an automaton recognizing the language \( L \). Then the Kleene star recognizes the language \( L^* = \{ w_1 \ldots w_n \mid n \geq 0, w_j \in L \text{ for all } j \} \).

Assume that this finite state machine is a transducer realizing a function \( f \) on some alphabet \( L \). Then the Kleene star realizes a function \( g \) on \( L^* \) with \( g(w_1 \ldots w_n) = f(w_1) \ldots f(w_n) \).

**EXAMPLES:**

Kleene star of an automaton:

```python
sage: A = automata.Word([0, 1])
sage: B = A.kleene_star()
sage: B.transitions()
[Transition from 0 to 1: 0|-
, Transition from 2 to 0: -|--,
Transition from 1 to 2: 1|--]
sage: from sage.combinat.finite_state_machine import (is_Automaton, is_Transducer)
sage: is_Automaton(B)
True
sage: [w for w in ([], [0, 1], [0, 1, 0], [0, 1, 0, 1], [0, 1, 1, 1])
.....: if B(w)]
[[],
 [0, 1],
 [0, 1, 0],
 [0, 1, 0, 1]]
```

Kleene star of a transducer:

```python
sage: T = Transducer([(0, 1, 0, 1), (0, 1, 1, 0)],
.....: initial_states=[0],
.....: final_states=[1])
sage: S = T.kleene_star()
sage: S.transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|--,
 Transition from 1 to 0: -|-
]
sage: is_Transducer(S)
True
```

(continues on next page)
\[
\text{sage: for } w \text{ in } ([], [0], [1], [0, 0], [0, 1]): \\
\text{....: print("{} {}".format(w, S.process(w)))}
\]
\[
[\text{[True, 0, []]} \\
[\text{[True, 0, [1]], (True, 1, [1])] } \\
[\text{[True, 0, [0]], (True, 1, [0])] } \\
[\text{[True, 0, [1, 1]], (True, 1, [1, 1])] } \\
[\text{[True, 0, [1, 0]], (True, 1, [1, 0])] }
\]

Final output words are taken into account:

\[
\text{sage: T = Transducer([([0, 1, 0, 1]), } \\
\text{....: initial_states=[0], } \\
\text{....: final_states=[1]])}
\]
\[
\text{sage: T.state(1).final_word_out = 2}
\]
\[
\text{sage: S = T.kleene_star()}
\]
\[
\text{sage: sorted(S.process([0, 0]))}
\]
\[
[\text{[(True, 0, [1, 2, 1, 2]), (True, 1, [1, 2, 1, 2]) ]}
\]

Final output words may lead to undesirable situations if initial states and final states coincide:

\[
\text{sage: T = Transducer(initial_states=[0], final_states=[0])}
\]
\[
\text{sage: T.state(0).final_word_out = 1}
\]
\[
\text{sage: S = T.kleene_star()}
\]
\[
\text{sage: S([])}
\]
\[
\text{Traceback (most recent call last):}
\]
\[
\text{...}
\]
\[
\text{RuntimeError: State 0 is in an epsilon cycle (no input), but output is written.}
\]

\text{language(max_length=None, **kwargs)}

Return all words that can be written by this transducer.

\text{INPUT:}

\begin{itemize}
\item \text{max_length} – an integer or \text{None} (default). Only output words which come from inputs of length at most \text{max_length} will be considered. If \text{None}, then this iterates over all possible words without length restrictions.
\item \text{kwargs} – will be passed on to the \text{process iterator}. See \text{process()} for a description.
\end{itemize}

\text{OUTPUT:}

An iterator.

\text{EXAMPLES:}

\[
\text{sage: NAF = Transducer((['I', 0, 0, None], ('I', 1, 1, None)),} \\
\text{....: (0, 0, 0, 0), (0, 1, 1, 0),} \\
\text{....: (1, 0, 0, 1), (1, 2, 1, -1),} \\
\text{....: (2, 1, 0, 0), (2, 2, 1, 0),} \\
\text{....: initial_states=['I'], final_states=[0],} \\
\text{....: input_alphabet=['I', 1])}
\]
\[
\text{sage: sorted(NAF.language(4),}
\]

Combinatorics, Release 10.1

Automaton.language(), process().

latex_options(coordinates=None, format_state_label=None, format_letter=None,
 format_transition_label=None, loop_where=None, initial_where=None,
 accepting_style=None, accepting_distance=None, accepting_where=None,
 accepting_show_empty=None)

Set options for LaTeX output via latex() and therefore view().

INPUT:

• coordinates – a dictionary or a function mapping labels of states to pairs interpreted as coordinates. If no coordinates are given, states are placed equidistantly on a circle of radius 3. See also set_coordinates().

• format_state_label – a function mapping labels of states to a string suitable for typesetting in LaTeX’s mathematics mode. If not given, latex() is used.

• format_letter – a function mapping letters of the input and output alphabets to a string suitable for typesetting in LaTeX’s mathematics mode. If not given, default_format_transition_label() uses latex().

• format_transition_label – a function mapping words over the input and output alphabets to a string suitable for typesetting in LaTeX’s mathematics mode. If not given, default_format_transition_label() is used.

• loop_where – a dictionary or a function mapping labels of initial states to one of 'above', 'left', 'below', 'right'. If not given, 'above' is used.

• initial_where – a dictionary or a function mapping labels of initial states to one of 'above', 'left', 'below', 'right'. If not given, TikZ’ default (currently 'left') is used.

• accepting_style – one of 'accepting by double' and 'accepting by arrow'. If not given, 'accepting by double' is used unless there are non-empty final output words.
Combinatorics, Release 10.1

- **accepting_distance** – a string giving a LaTeX length used for the length of the arrow leading from a final state. If not given, TikZ' default (currently '3ex') is used unless there are non-empty final output words, in which case '7ex' is used.

- **accepting_where** – a dictionary or a function mapping labels of final states to one of 'above', 'left', 'below', 'right'. If not given, TikZ' default (currently 'right') is used. If the final state has a final output word, it is also possible to give an angle in degrees.

- **accepting_show_empty** – if True the arrow of an empty final output word is labeled as well. Note that this implicitly implies accepting_style='accepting by arrow'. If not given, the default False is used.

OUTPUT:

Nothing.

As TikZ (cf. the Wikipedia article PGF/TikZ) is used to typeset the graphics, the syntax is oriented on TikZ' syntax.

This is a convenience function collecting all options for LaTeX output. All of its functionality can also be achieved by directly setting the attributes

- **coordinates**, **format_label**, **loop_where**, **initial_where**, and **accepting_where** of FSMState (here, **format_label** is a callable without arguments, everything else is a specific value);

- **format_label** of FSMTransition (**format_label** is a callable without arguments);

This function, however, also (somewhat) checks its input and serves to collect documentation on all these options.

The function can be called several times, only those arguments which are not None are taken into account. By the same means, it can be combined with directly setting some attributes as outlined above.

**EXAMPLES:**

See also the section on LaTeX output in the introductory examples of this module.

```sage
T = Transducer(initial_states=[4],
   final_states=[0, 3])
sage: for j in srange(4):
   ....:   T.add_transition(4, j, 0, [0, j])
   ....:   T.add_transition(j, 4, 0, [0, -j])
   ....:   T.add_transition(j, j, 0, 0)
Transition from 4 to 0: 0|0,0
Transition from 0 to 4: 0|0,0

\end{tikzpicture}
(continues on next page)
markov_chain_simplification()

Consider self as Markov chain with probabilities as input labels and simplify it.

INPUT:
Nothing.

OUTPUT:
Simplified version of self.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: T = Transducer([[1, 2, 1/4, 0], [1, -2, 1/4, 0], [1, -2, 1/2, 0],
.....: [2, 2, 1/4, 1], [2, -2, 1/4, 1], [-2, -2, 1/4, 1],
.....: [-2, 2, 1/4, 1], [2, 3, 1/2, 2], [-2, 3, 1/2, 2]],
.....: initial_states=[1],
.....: final_states=[3],
.....: on_duplicate_transition=duplicate_transition_add_input)
```

```python
sage: T1 = T.markov_chain_simplification()
sage: sorted(T1.transitions())
[Transition from ((1,),) to ((2, -2),): 1|0,
 Transition from ((2, -2),) to ((2, -2),): 1/2|1,
 Transition from ((2, -2),) to ((3,),): 1/2|2]
```

merged_transitions()

Merges transitions which have the same from_state, to_state and word_out while adding their word_in.

INPUT:
Nothing.

OUTPUT:
A finite state machine with merged transitions. If no mergers occur, return self.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: T = Transducer([[1, 2, 1/4, 1], [1, -2, 1/4, 1], [1, -2, 1/2, 1],
.....: [2, 2, 1/4, 1], [2, -2, 1/4, 1], [-2, -2, 1/4, 1],
.....: [-2, 2, 1/4, 1], [2, 3, 1/2, 1], [-2, 3, 1/2, 1]],
.....: on_duplicate_transition=duplicate_transition_add_input)
```

```python
sage: T1 = T.merged_transitions()
sage: T1 is T
False
sage: sorted(T1.transitions())
[Transition from -2 to -2: 1/4|1,
 Transition from -2 to 2: 1/4|1,
 Transition from -2 to 3: 1/2|1,
```

(continues on next page)
Transition from 1 to 2: 1/4|1,
Transition from 1 to -2: 3/4|1,
Transition from 2 to -2: 1/4|1,
Transition from 2 to 2: 1/4|1,
Transition from 2 to 3: 1/2|1

Applying the function again does not change the result:

```python
sage: T2 = T1.merged_transitions()
sage: T2 is T1
True
```

**Moments Waiting Time**

If this finite state machine acts as a Markov chain, return the expectation and variance of the number of steps until first writing True.

**INPUT:**

- `test` – (default: `bool`) a callable deciding whether an output label is to be considered True. By default, the standard conversion to boolean is used.
- `is_zero` – (default: `None`) a callable deciding whether an expression for a probability is zero. By default, checking for zero is simply done by `is_zero()`. This parameter can be used to provide a more sophisticated check for zero, e.g. in the case of symbolic probabilities, see the examples below. This parameter is passed on to `is_Markov_chain()`. This parameter only affects the input of the Markov chain.
- `expectation_only` – (default: `False`) if set, the variance is not computed (in order to save time). By default, the variance is computed.

**OUTPUT:**

A dictionary (if `expectation_only=False`) consisting of

- `expectation`,
- `variance`.

Otherwise, just the expectation is returned (no dictionary for `expectation_only=True`).

Expectation and variance of the number of steps until first writing True (as determined by the parameter `test`).

**Algorithm:**

Relies on a (classical and easy) probabilistic argument, cf. [FGT1992], Eqns. (6) and (7).

For the variance, see [FHP2015], Section 2.

**Examples:**

1. The simplest example is to wait for the first 1 in a 0-1-string where both digits appear with probability 1/2. In fact, the waiting time equals $k$ if and only if the string starts with $0^{k-1}1$. This event occurs with probability $2^{-k}$. Therefore, the expected waiting time and the variance are $\sum_{k\geq 1} k2^{-k} = 2$ and $\sum_{k\geq 1}(k-2)2^{-k} = 2$:

```python
sage: var('k')
# ~
optional - sage.symbolic
k
```
We now compute the same expectation and variance by using a Markov chain:

```python
sage: from sage.combinat.finite_state_machine import (....: duplicate_transition_add_input)

sage: T = Transducer(....: [(0, 0, 1/2, 0), (0, 0, 1/2, 1)],....: on_duplicate_transition=\....:    duplicate_transition_add_input,....: initial_states=[0],....: final_states=[0])

sage: T.moments_waiting_time()
{'expectation': 2, 'variance': 2}

sage: T.moments_waiting_time(expectation_only=True)
2
```

In the following, we replace the output 0 by -1 and demonstrate the use of the parameter `test`:

```python
sage: T.delete_transition((0, 0, 1/2, 0))

sage: T.add_transition((0, 0, 1/2, -1))

Transition from 0 to 0: 1/2|-1

sage: T.moments_waiting_time(test=lambda x: x<0)
{'expectation': 2, 'variance': 2}
```

2. Make sure that the transducer is actually a Markov chain. Although this is checked by the code, unexpected behaviour may still occur if the transducer looks like a Markov chain. In the following example, we 'forget' to assign probabilities, but due to a coincidence, all 'probabilities' add up to one. Nevertheless, 0 is never written, so the expectation is 1.

```python
sage: T = Transducer([(0, 0, 0, 0), (0, 0, 1, 1)],....: on_duplicate_transition=\....:    duplicate_transition_add_input,....: initial_states=[0],....: final_states=[0])

sage: T.moments_waiting_time()
{'expectation': 1, 'variance': 0}
```

3. If `True` is never written, the moments are `+Infinity`:

```python
sage: T = Transducer([(0, 0, 1, 0)],....: on_duplicate_transition=\....:    duplicate_transition_add_input,....: initial_states=[0],....: final_states=[0])

sage: T.moments_waiting_time()
{'expectation': +Infinity, 'variance': +Infinity}
```

4. Let $h$ and $r$ be positive integers. We consider random strings of letters $1, \ldots, r$ where the letter $j$ occurs
with probability $p_j$. Let $B$ be the random variable giving the first position of a block of $h$ consecutive identical letters. Then

$$
\mathbb{E}(B) = \frac{1}{\sum_{i=1}^{r} \frac{1}{p_i^{-1} + \cdots + p_i^{-h}}},
$$

$$
\mathbb{V}(B) = \sum_{i=1}^{r} \frac{p_i + p_i^h}{1 - p_i^h} \cdot \frac{2h p_i^h(1 - p_i)}{(1 - p_i^h)^2} \cdot \left( \sum_{i=1}^{r} \frac{1}{p_i^{-1} + \cdots + p_i^{-h}} \right)^2
$$

cf. [S1986], p. 62, or [FHP2015], Theorem 1. We now verify this with a transducer approach.

```python
sage: def test(h, r):
    R = PolynomialRing(QQ, names=['p_%d' % j for j in range(r)])
    p = R.gens()

    def is_zero(polynomial):
        return polynomial in (sum(1/sum(p[j]**(-i)) for i in range(1, h+1)) for j in range(r))

    theory_expectation = 1/(sum(1/sum(p[j]**(-i)) for i in range(1, h+1)) for j in range(r))

    theory_variance = sum((p[i] + p[i]**h)/(1 - p[i]**h) - 2*h*p[i]**h * (1 - p[i])/(1 - p[i]**h)**2 for i in range(r)) * theory_expectation^2

    alphabet = list(range(r))
    counters = [transducers.CountSubblockOccurrences([j]*h, alphabet) for j in alphabet]
    all_counter = counters[0].cartesian_product(counters[1:])
    adder = transducers.add(input_alphabet=[0, 1], number_of_operands=r)
    probabilities = Transducer([(0, 0, p[j], j) for j in alphabet], initial_states=[0], final_states=[0], on_duplicate_transition=duplicate_translation_add_input)
    chain = adder(all_counter(probabilities))
    result = chain.moments_waiting_time(is_zero=is_zero)
    return is_zero((result['expectation'] - theory_expectation).numerator()) and is_zero((result['variance'] - theory_variance).numerator())

sage: test(2, 2)
True
```

(continues on next page)
5. Consider the alphabet \{0, \ldots, r-1\}, some 1 \leq j \leq r and some \( h \geq 1 \). For some probabilities \( p_0, \ldots, p_{r-1} \), we consider infinite words where the letters occur independently with the given probabilities. The random variable \( B_j \) is the first position \( n \) such that there exist \( j \) of the \( r \) letters having an \( h \)-run. The expectation of \( B_j \) is given in [FHP2015], Theorem 2. Here, we verify this result by using transducers:

```python
sage: def test(h, r, j):
    ...:    R = PolynomialRing(QQ,
    ...:                        names=['p_%d' % i for i in range(r)])
    ...:    p = R.gens()
    ...:    def is_zero(polynomial):
    ...:        return polynomial in (sum(p) - 1) * R
    ...:    alphabet = list(range(r))
    ...:    counters = [
    ...:        transducers.Wait([0, 1])(
    ...:            transducers.CountSubblockOccurrences(
    ...:                [i]*h,
    ...:                alphabet))
    ...:        for i in alphabet]
    ...:    all_counter = counters[0].cartesian_product(
    ...:        counters[1:])
    ...:    adder = transducers.add(input_alphabet=[0, 1],
    ...:                            number_of_operands=r)
    ...:    threshold = transducers.map(
    ...:        f=lambda x: x >= j,
    ...:        input_alphabet=srange(r+1))
    ...:    probabilities = Transducer(
    ...:        [(0, 0, p[i], i) for i in alphabet],
    ...:        initial_states=[0],
    ...:        final_states=[0],
    ...:        on_duplicate_transition=duplicate_transition_add_input)
    ...:    chain = threshold(adder(all_counter(
    ...:        probabilities)))
    ...:    result = chain.moments_waiting_time(
    ...:        is_zero=is_zero,
    ...:        expectation_only=True)
    ...:    R_v = PolynomialRing(QQ,
    ...:                        names=['p_%d' % i for i in range(r)])
    ...:    v = R_v.gens()
    ...:    S = 1/(1 - sum(v[i]/(1+v[i])
    ...:                        for i in range(r)))
    ...:    alpha = [(p[i] - p[i]^h)/(1 - p[i])
    ...:             for i in range(r)]
    ...:    gamma = [p[i]/(1 - p[i]) for i in range(r)]
    ...:    alphabet_set = set(alphabet)
```

(continues on next page)
.....:  expectation = 0
.....:  for q in range(j):
.....:    for M in Subsets(alphabet_set, q):
.....:      summand = S
.....:      for i in M:
.....:        summand = summand.subs({v[i]: gamma[i]}) -
.....:            summand.subs({v[i]: alpha[i]})
.....:      for i in alphabet_set - set(M):
.....:        summand = summand.subs({v[i]: alpha[i]})
.....:      expectation += summand
.....:  return is_zero((result - expectation).numerator())

sage: test(2, 3, 2)
True

REFERENCES:

number_of_words(variable=None, base_ring=None)

Return the number of successful input words of given length.

INPUT:

* variable – a symbol denoting the length of the words, by default $n$.

* base_ring – Ring (default: QQbar) in which to compute the eigenvalues.

OUTPUT:

A symbolic expression.

EXAMPLES:

sage: NAFpm = Automaton([(0, 0, 0), (0, 1, 1),
.....:                     (0, 1, -1), (1, 0, 0)],
.....:                     initial_states=[0],
.....:                     final_states=[0, 1])
sage: N = NAFpm.number_of_words(); N
# optional ~
˓→sage.symbolic
4/3*2^n - 1/3*(-1)^n
sage: all(len(list(NAFpm.language(s)))
˓→sage.symbolic
.....: - len(list(NAFpm.language(s-1))) == N.subs(n=s)
.....:  for s in srange(1, 6))
True

An example with non-rational eigenvalues. By default, eigenvalues are elements of the field of
algebraic numbers.

sage: NAFp = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 0)],
.....:                    initial_states=[0],
.....:                    final_states=[0, 1])
sage: N = NAFp.number_of_words(); N
# optional ~
˓→sage.symbolic
1.1708203932499369*1.618033988749895^n
(continues on next page)
We specify a suitable base_ring to obtain a radical expression. To do so, we first compute the characteristic polynomial and then construct a number field generated by its roots.

```python
sage: N = NAFp.adjacency_matrix(entry=lambda t: 1)
sage: N.characteristic_polynomial() # optional -
˓→sage.symbolic
x^2 - x - 1
sage: R.<phi> = NumberField(x^2-x-1, embedding=1.6) # optional -
˓→sage.symbolic
sage: N = NAFp.number_of_words(base_ring=R); N # optional -
˓→sage.symbolic
1/2*(1/2*sqrt(5) + 1/2)^n*(3*sqrt(1/5) + 1)
- 1/2*(-1/2*sqrt(5) + 1/2)^n*(3*sqrt(1/5) - 1)
sage: all(len(list(NAFp.language(s))) # optional -
˓→len(list(NAFp.language(s-1))) == N.subs(n=s)
˓→for s in srange(1, 6))
True
```

In this special case, we might also use the constant golden_ratio:

```python
sage: R.<phi> = NumberField(x^2-x-1, embedding=golden_ratio) # optional -
˓→sage.symbolic
sage: N = NAFp.number_of_words(base_ring=R); N # optional -
˓→sage.symbolic
1/5*(3*golden_ratio + 1)*golden_ratio^n
- 1/5*(3*golden_ratio - 4)*(-golden_ratio + 1)^n
sage: all(len(list(NAFp.language(s))) # optional -
˓→len(list(NAFp.language(s-1))) == N.subs(n=s)
˓→for s in srange(1, 6))
True
```

The adjacency matrix of the following example is a Jordan matrix of size 3 to the eigenvalue 4:

```python
sage: J3 = Automaton([(0, 1, -1), (1, 2, -1)],
˓→initial_states=[0],
˓→final_states=[0, 1, 2])
sage: for i in range(3):
˓→for j in range(4):
˓→new_transition = J3.add_transition(i, i, j)
sage: J3.adjacency_matrix(entry=lambda t: 1)
[4 1 0]
[0 4 1]
[0 0 4]
sage: N = J3.number_of_words(); N # optional -
(continues on next page)
```
Here is an automaton without cycles, so with eigenvalue 0.

```
sage: A = Automaton([(j, j+1, 0) for j in range(3)],
.....:           initial_states=[0],
.....:           final_states=list(range(3)))
sage: A.number_of_words()  # optional - sage.symbolic
1/2*0^(n - 2)*(n - 1)*n + 0^(n - 1)*n + 0^n
```

on_duplicate_transition(old_transition, new_transition)

Which function to call when a duplicate transition is inserted.

It can be set by the parameter on_duplicate_transition when initializing a finite state machine, see `FiniteStateMachine`.

See also:

`FiniteStateMachine, is_Markov_chain(), markov_chain_simplification()`.

output_alphabet = None

A list of letters representing the output alphabet of the finite state machine.

It can be set by the parameter output_alphabet when initializing a finite state machine, see `FiniteStateMachine`.

It can also be set by the method determine_alphabets().

See also:

`FiniteStateMachine, determine_alphabets(), input_alphabet`.

output_projection()

Return a automaton where the input of each transition of self is deleted and the new input is the original output.

OUTPUT:

An automaton.

EXAMPLES:

```
sage: F = FiniteStateMachine([(‘A’, ’B’, 0, 1), (’A’, ’A’, 1, 1),
.....:                  (’B’, ’B’, 1, 0)])
sage: G = F.output_projection()
sage: G.transitions()
[Transition from ’A’ to ’B’: 1|-
, Transition from ’A’ to ’A’: 1|-
, Transition from ’B’ to ’B’: 0|-
]
```

Final output words are also considered correctly:
sage: H = Transducer([(('A', 'B', 0, 1), ('A', 'A', 1, 1)),
            ('B', 'B', 1, 0), ('A', ('final', 0), 0, 0)],
            final_states=['A', 'B'])

sage: H.state('B').final_word_out = 2

sage: J = H.output_projection()

sage: J.states()
['A', 'B', ('final', 0), ('final', 1)]

sage: J.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'A' to ('final', 0): 0|-,
 Transition from 'B' to 'B': 0|-,
 Transition from 'B' to ('final', 1): 2|-]

sage: J.final_states()
['A', ('final', 1)]

plot()
Plots a graph of the finite state machine with labeled vertices and labeled edges.

INPUT:
Nothing.

OUTPUT:
A plot of the graph of the finite state machine.

predecessors(state, valid_input=None)
Lists all predecessors of a state.

INPUT:
- state – the state from which the predecessors should be listed.
- valid_input – If valid_input is a list, then we only consider transitions whose input labels are contained in valid_input. state has to be a FSMState (not a label of a state). If input labels of length larger than 1 are used, then valid_input has to be a list of lists.

OUTPUT:
A list of states.

EXAMPLES:

sage: A = Transducer([('I', 'A', 'a', 'b'), ('I', 'B', 'b', 'c'),
            ('I', 'C', 'c', 'a'), ('A', 'F', 'b', 'a'),
            ('B', 'F', ['c', 'b'], 'b'), ('C', 'F', 'a', 'c')],
            initial_states=['I'], final_states=['F'])

sage: A.predecessors(A.state('A'))
['A', 'I']

sage: A.predecessors(A.state('F'), valid_input=['b', 'a'])
['F', 'C', 'A', 'I']

sage: A.predecessors(A.state('F'), valid_input=[[c, b], 'a'])
['F', 'C', 'B']

prepone_output()
For all paths, shift the output of the path from one transition to the earliest possible preceding transition of the path.
INPUT:
Nothing.

OUTPUT:
Nothing.

Apply the following to each state $s$ (except initial states) of the finite state machine as often as possible:

If the letter $a$ is a prefix of the output label of all transitions from $s$ (including the final output of $s$), then remove it from all these labels and append it to all output labels of all transitions leading to $s$.

We assume that the states have no output labels, but final outputs are allowed.

EXAMPLES:

```
sage: A = Transducer([('A', 'B', 1, 1),
....:                 ('B', 'B', 0, 0),
....:                 ('B', 'C', 1, 0)],
....:                 initial_states=['A'],
....:                 final_states=['C'])
sage: A.prepone_output()
sage: A.transitions()
[Transition from 'A' to 'B': 1|1,0,
 Transition from 'B' to 'B': 0|0,
 Transition from 'B' to 'C': 1|--]
```

```
sage: B = Transducer([('A', 'B', 0, 1),
....:                 ('B', 'C', 1, [1, 1]),
....:                 ('B', 'C', 0, 1)],
....:                 initial_states=['A'],
....:                 final_states=['C'])
sage: B.prepone_output()
sage: B.transitions()
[Transition from 'A' to 'B': 0|1,1,
 Transition from 'B' to 'C': 1|1,
 Transition from 'B' to 'C': 0|--]
```

If initial states are not labeled as such, unexpected results may be obtained:

```
sage: C = Transducer([(0,1,0,0)])
sage: C.prepone_output()
verbose 0 (...: finite_state_machine.py, prepone_output)
All transitions leaving state 0 have an output label with prefix 0. However, there is no inbound transition and it is not an initial state. This routine (possibly called by simplification) therefore erased this prefix from all outbound transitions.
sage: C.transitions()
[Transition from 0 to 1: 0|--]
```

Also the final output of final states can be changed:

```
sage: T = Transducer([('A', 'B', 0, 1),
....:                 ('B', 'C', 1, [1, 1]),
....:                 ('B', 'C', 0, 1)],
(continues on next page)```
Output labels do not have to be hashable:

```
sage: C = Transducer([(0, 1, 0, []),
....: (1, 0, 0, [vector([0, 0]), 0]),
....: (1, 1, 1, [vector([0, 0]), 1]),
....: (0, 0, 1, 0)],
....: determine_alphabets=False,
....: initial_states=[0])
sage: C.prepone_output()
sage: sorted(C.transitions())
[Transition from 0 to 1: 0|(0, 0),
 Transition from 0 to 0: 1|0,
 Transition from 1 to 0: 0|0,
 Transition from 1 to 1: 1|1,(0, 0)]
```

**process(***args, **kwargs)**

Return whether the finite state machine accepts the input, the state where the computation stops and which output is generated.

**INPUT:**

- **input_tape** – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter use_multitape_input and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.

- **initial_state** or **initial_states** – the initial state(s) in which the machine starts. Either specify a single one with initial_state or a list of them with initial_states. If both are given,
initial_state will be appended to initial_states. If neither is specified, the initial states of the finite state machine are taken.

- **list_of_outputs** – (default: None) a boolean or None. If True, then the outputs are given in list form (even if we have no or only one single output). If False, then the result is never a list (an exception is raised if the result cannot be returned). If list_of_outputs=None, the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).

- **only_accepted** – (default: False) a boolean. If set, then the first argument in the output is guaranteed to be True (if the output is a list, then the first argument of each element will be True).

- **always_include_output** – if set (not by default), always include the output. This is inconsequential for a FiniteStateMachine, but can be used in derived classes where the output is suppressed by default, cf. Automaton.process().

- **format_output** – a function that translates the written output (which is in form of a list) to something more readable. By default (None) identity is used here.

- **check_epsilon_transitions** – (default: True) a boolean. If False, then epsilon transitions are not taken into consideration during process.

- **write_final_word_out** – (default: True) a boolean specifying whether the final output words should be written or not.

- **use_multitape_input** – (default: False) a boolean. If True, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.

- **process_all_prefixes_of_input** – (default: False) a boolean. If True, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

- **process_iterator_class** – (default: None) a class inherited from FSMProcessIterator. If None, then FSMProcessIterator is taken. An instance of this class is created and is used during the processing.

- **automatic_output_type** – (default: False) a boolean. If set and the input has a parent, then the output will have the same parent. If the input does not have a parent, then the output will be of the same type as the input.

**OUTPUT:**

A triple (or a list of triples, cf. parameter list_of_outputs), where

- the first entry is True if the input string is accepted,

- the second gives the reached state after processing the input tape (This is a state with label None if the input could not be processed, i.e., if at one point no transition to go on could be found.), and

- the third gives a list of the output labels written during processing (in the case the finite state machine runs as transducer).

Note that in the case the finite state machine is not deterministic, all possible paths are taken into account.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.
The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see `__call__()` for a version of `process()` with shortened output.

Internally this function creates and works with an instance of `FSMProcessIterator`. This iterator can also be obtained with `iter_process()`.

If working with multi-tape finite state machines, all input words of transitions are words of \( k \)-tuples of letters. Moreover, the input tape has to consist of \( k \) tracks, i.e., be a list or tuple of \( k \) iterators, one for each track.

**Warning:** Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

**EXAMPLES:**

```python
sage: binary_inverter = FiniteStateMachine({'A': [('A', 0, 1), ('A', 1, 0)]},
......: initial_states=['A'], final_states=[
......: 'A'])
sage: binary_inverter.process([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

Alternatively, we can invoke this function by:

```python
sage: binary_inverter([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

Below we construct a finite state machine which tests if an input is a non-adjacent form, i.e., no two neighboring letters are both nonzero (see also the example on non-adjacent forms in the documentation of the module `Finite state machines, automata, transducers`):

```python
sage: NAF = FiniteStateMachine(
......: {'_': [('_', 0, 1), (1, 1)], 1: [('_', 0)]},
......: initial_states=['_'], final_states=['_', 1])
sage: [NAF.process(w)[0] for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
......: [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
[True, True, False, True, False, False]
```

Working only with the first component (i.e., returning whether accepted or not) usually corresponds to using the more specialized class `Automaton`.

Non-deterministic finite state machines can be handled as well.

```python
sage: T = Transducer([(0, 1, 0, 0), (0, 2, 0, 0),
......: (0, 1, 1, 'c'), (1, 0, [], 'd'),
......: (1, 1, 1, 'e')],
```

Here is another non-deterministic finite state machine. Note that we use `format_output` (see `FSMProcessIterator`) to convert the written outputs (all characters) to strings.

```python
sage: T = Transducer([(0, 1, [0, 0], 'a'), (0, 2, [0, 0, 1], 'b'),
......: (0, 1, 1, 'c'), (1, 0, [], 'd'),
......: (1, 1, 1, 'e')],
```

(continues on next page)
A simple example of a multi-tape finite state machine is the following: It writes the length of the first tape many letters $a$ and then the length of the second tape many letters $b$:

Sage:
```python
M = FiniteStateMachine([(0, 0, (1, None), 'a'),
(0, 1, [], []),
(1, 1, (None, 1), 'b')],
initial_states=[0],
final_states=[1])
```

Sage:
```python
M.process(([1, 1], [1]), use_multitape_input=True)
```

(Traceback)

See also:

Automaton.process(), Transducer.process(), iter_process(), __call__(), FSMProcessIterator.

product_FiniteStateMachine(other, function, new_input_alphabet=None, only_accessible_components=True, final_function=None, new_class=None)

Return a new finite state machine whose states are $d$-tuples of states of the original finite state machines.

**INPUT:**

- other – a finite state machine (for $d = 2$) or a list (or iterable) of $d - 1$ finite state machines.

- function has to accept $d$ transitions from $A_j$ to $B_j$ for $j \in \{1, \ldots, d\}$ and returns a pair (word_in, word_out) which is the label of the transition $A = (A_1, \ldots, A_d)$ to $B = (B_1, \ldots, B_d)$. If there is no transition from $A$ to $B$, then function should raise a LookupError.

- new_input_alphabet (optional) – the new input alphabet as a list.

- only_accessible_components – If True (default), then the result is piped through accessible_components(). If no new_input_alphabet is given, it is determined by determine_alphabets().
• **final_function** – A function mapping \(d\) final states of the original finite state machines to the final output of the corresponding state in the new finite state machine. By default, the final output is the empty word if both final outputs of the constituent states are empty; otherwise, a `ValueError` is raised.

• **new_class** – Class of the new finite state machine. By default (None), the class of `self` is used.

**OUTPUT:**

A finite state machine whose states are \(d\)-tuples of states of the original finite state machines. A state is initial or final if all constituent states are initial or final, respectively.

The labels of the transitions are defined by `function`.

The final output of a final state is determined by calling `final_function` on the constituent states.

The color of a new state is the tuple of colors of the constituent states of `self` and `other`. However, if all constituent states have color `None`, then the state has color `None`, too.

**EXAMPLES:**

```python
sage: F = Automaton([('A', 'B', 1), ('A', 'A', 0), ('B', 'A', 2)],
                 initial_states=['A'], final_states=['B'],
                 determine_alphabets=True)
sage: G = Automaton([(1, 1, 1)], initial_states=[1], final_states=[1])
sage: def addition(transition1, transition2):
    ....:     return (transition1.word_in[0] + transition2.word_in[0],
    ....:                 None)

sage: H = F.product_FiniteStateMachine(G, addition, [0, 1, 2, 3], only_
                                          accessible_components=False)
sage: H.transitions()
[Transition from ('A', 1) to ('B', 1): 2|-,
  Transition from ('A', 1) to ('A', 1): 1|-,
  Transition from ('B', 1) to ('A', 1): 3|-]
sage: [s.color for s in H.iter_states()]
[None, None]
sage: H1 = F.product_FiniteStateMachine(G, addition, [0, 1, 2, 3], only_
                                          accessible_components=False)
sage: H1.states()[0].label()[0] is F.states()[0]
True
sage: H1.states()[0].label()[1] is G.states()[0]
True

sage: F = Automaton([(0,1,1/4), (0,0,3/4), (1,1,3/4), (1,0,1/4)],
                 initial_states=[0] )
sage: G = Automaton([(0,0,1), (1,1,3/4), (1,0,1/4)],
                 initial_states=[0] )
sage: H = F.product_FiniteStateMachine(
    G, lambda t1,t2: (t1.word_in[0]*t2.word_in[0], None))
sage: H.states()
[(0, 0), (1, 0)]
```

(continues on next page)
Also final output words are considered according to the function `final_function`:

```
sage: F = Transducer([(0, 1, 0, 1), (1, 1, 1, 1), (1, 1, 0, 1)], final_states=[1])
sage: G = Transducer([(0, 0, 0, 1), (0, 0, 1, 0)], final_states=[0])
sage: def minus(t1, t2):
    return (t1.word_in[0] - t2.word_in[0], t1.word_out[0] - t2.word_out[0])
sage: H = F.product_FiniteStateMachine(G, minus)
```

Traceback (most recent call last):
...
ValueError: A final function must be given.

```
sage: def plus(s1, s2):
    return s1.final_word_out[0] + s2.final_word_out[0]
sage: H = F.product_FiniteStateMachine(G, minus, final_function=plus)
```

```
sage: H.final_states()
[(1, 0)]
sage: H.final_states()[0].final_word_out[2]
```

Products of more than two finite state machines are also possible:

```
sage: def plus(s1, s2, s3):
    if s1.word_in == s2.word_in == s3.word_in:
        return (s1.word_in, sum(s.word_out[0] for s in (s1, s2, s3)))
    else:
        raise LookupError
```

```
sage: T0 = transducers.CountSubblockOccurrences([0, 0], [0, 1, 2])
sage: T1 = transducers.CountSubblockOccurrences([1, 1], [0, 1, 2])
sage: T2 = transducers.CountSubblockOccurrences([2, 2], [0, 1, 2])
sage: T = T0.product_FiniteStateMachine([T1, T2], plus)
```

```
sage: T.transitions()
[Transition from ((), (), ()) to ((0,), (), ()): 0|0,
 Transition from ((), (), ()) to ((1,), (), ()): 1|0,
 Transition from ((), (), ()) to (((), () (2,)): 2|0,
 Transition from ((), (0,), () to ((0,), (0,0): 0|1,
 Transition from ((), (0,), () to (((), (1,)): 1|0,
 Transition from ((), (0,), () to ((), (2,)): 2|0,
 Transition from ((), (1,), () to ((0,), (0): 0|0,
 Transition from ((), (1,), () to ((1,), (0,)): 1|1,
 Transition from ((), (1,), () to ((0, (2,)): 2|0,
 Transition from ((), (2,)) to ((0,), (0): 0|0,
 (continues on next page)
Transition from ((), (), (2,)) to ((), (1,), ()): 1|0
Transition from ((), (), (2,)) to ((), (), (2,)): 2|1

sage: T([0, 0, 1, 1, 2, 2, 0, 1, 2, 2])
[0, 1, 0, 1, 0, 1, 0, 0, 0, 1]

other can also be an iterable:

sage: T == T0.product_FiniteStateMachine(iter([T1, T2]), plus)
True

projection(what='input')

Return an Automaton which transition labels are the projection of the transition labels of the input.

INPUT:

• what – (default: input) either input or output.

OUTPUT:

An automaton.

EXAMPLES:

sage: F = FiniteStateMachine([(A, B, 0, 1),
(A, A, 1, 1),
....:
(B, B, 1, 0)])
sage: G = F.projection(what='output')
sage: G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]

quotient(classes)

Construct the quotient with respect to the equivalence classes.

INPUT:

• classes is a list of equivalence classes of states.

OUTPUT:

A finite state machine.

The labels of the new states are tuples of states of the self, corresponding to classes.

Assume that c is a class, and a and b are states in c. Then there is a bijection \( \varphi \) between the transitions from \( a \) and the transitions from \( b \) with the following properties: if \( \varphi(a) = b \), then

• \( t_a.\text{word}_\text{in} = t_b.\text{word}_\text{in} \),
• \( t_a.\text{word}_\text{out} = t_b.\text{word}_\text{out} \), and
• \( t_a \) and \( t_b \) lead to some equivalent states \( a' \) and \( b' \).

Non-initial states may be merged with initial states, the resulting state is an initial state.

All states in a class must have the same is_final, final_word_out and word_out values.

EXAMPLES:
 sage: fsm = FiniteStateMachine([("A", "B", 0, 1), ("A", "B", 1, 0),
....:                      ("B", "C", 0, 0), ("B", "C", 1, 1),
....:                      ("C", "D", 0, 1), ("C", "D", 1, 0),
....:                      ("D", "A", 0, 0), ("D", "A", 1, 1)])
 sage: fsmq = fsm.quotient([[fsm.state("A"), fsm.state("C")],
....:                      [fsm.state("B"), fsm.state("D")]])
 sage: fsmq.transitions()
 [Transition from ('A', 'C') to ('B', 'D'): 0|1,
 Transition from ('A', 'C') to ('B', 'D'): 1|0,
 Transition from ('B', 'D') to ('A', 'C'): 0|0,
 Transition from ('B', 'D') to ('A', 'C'): 1|1]
 sage: fsmq.relabeled().transitions()
 [Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|0,
 Transition from 1 to 0: 1|1]
 sage: fsmq1 = fsm.quotient(fsm.equivalence_classes())
 sage: fsmq1 == fsmq
 True
 sage: fsmq1.quotient([[fsm.state("A"), fsm.state("B"), fsm.state("C"), fsm.state("D"))])
 Traceback (most recent call last):
 ....
 AssertionError: Transitions of state 'A' and 'B' are incompatible.

relabeled(memo=None, labels=None)

Return a deep copy of the finite state machine, but the states are relabeled.

INPUT:

• memo – (default: None) a dictionary storing already processed elements.

• labels – (default: None) a dictionary or callable mapping old labels to new labels. If None, then the new labels are integers starting with 0.

OUTPUT:

A new finite state machine.

EXAMPLES:

 sage: FSM1 = FiniteStateMachine([('A', 'B'), ('B', 'C'), ('C', 'A')])
 sage: FSM1.states()
 ['A', 'B', 'C']
 sage: FSM2 = FSM1.relabeled()
 sage: FSM2.states()
 [0, 1, 2]
 sage: FSM3 = FSM1.relabeled(labels={"A": "a", "B": "b", "C": "c"})
 sage: FSM3.states()
 ['a', 'b', 'c']
 sage: FSM4 = FSM2.relabeled(labels=lambda x: 2*x)
sage: FSM4.states()
[0, 2, 4]

remove_epsilon_transitions()

set_coordinates(coordinates, default=True)

Set coordinates of the states for the LaTeX representation by a dictionary or a function mapping labels to coordinates.

INPUT:
• coordinates – a dictionary or a function mapping labels of states to pairs interpreted as coordinates.
• default – If True, then states not given by coordinates get a default position on a circle of radius 3.

OUTPUT:
Nothing.

EXAMPLES:

sage: F = Automaton([[0, 1, 1], [1, 2, 2], [2, 0, 0]])
sage: F.set_coordinates({0: (0, 0), 1: (2, 0), 2: (1, 1)})
sage: F.state(0).coordinates
(0, 0)

We can also use a function to determine the coordinates:

sage: F = Automaton([[0, 1, 1], [1, 2, 2], [2, 0, 0]])
sage: F.set_coordinates(lambda l: (l, 3/(l+1)))
sage: F.state(2).coordinates
(2, 1)

split_transitions()

Return a new transducer, where all transitions in self with input labels consisting of more than one letter are replaced by a path of the corresponding length.

OUTPUT:
A new transducer.

EXAMPLES:

sage: A = Transducer([('A', 'B', [1, 2, 3], 0)],
.....: initial_states=['A'], final_states=['B'])
sage: A.split_transitions().states()
[['A', (0)], ('B', (0)), ('A', (1)), ('A', (1, 2))]

state(state)

Return the state of the finite state machine.

INPUT:
• state – If state is not an instance of FSMState, then it is assumed that it is the label of a state.

OUTPUT:
The state of the finite state machine corresponding to state.

If no state is found, then a LookupError is thrown.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: FSM = FiniteStateMachine([(A, 'B'), (C, A)])
sage: FSM.state('A') == A
True
sage: FSM.state('xyz')
Traceback (most recent call last):
...
LookupError: No state with label xyz found.
```

`states()`

Return the states of the finite state machine.

OUTPUT:

The states of the finite state machine as list.

EXAMPLES:

```python
sage: FSM = Automaton([(1, 2, 1), (2, 2, 0)])
sage: FSM.states()
['1', '2']
```

`transition(transition)`

Return the transition of the finite state machine.

INPUT:

- transition – If transition is not an instance of FSMTransition, then it is assumed that it is a tuple (from_state, to_state, word_in, word_out).

OUTPUT:

The transition of the finite state machine corresponding to transition.

If no transition is found, then a LookupError is thrown.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: F = FiniteStateMachine([t])
```

`transitions(from_state=None)`

Return a list of all transitions.

INPUT:

- from_state – (default: None) If from_state is given, then a list of transitions starting there is given.
OUTPUT:
A list of all transitions.

EXAMPLES:

```
sage: FSM = Automaton([(1, '2', 1), (2, '2', 0)])
sage: FSM.transitions()
[Transition from 1 to 2: 1|-,
 Transition from 2 to 2: 0|-]
```

**transposition(reverse_output_labels=True)**

Return a new finite state machine, where all transitions of the input finite state machine are reversed.

**INPUT:**

- **reverse_output_labels** – a boolean (default: True): whether to reverse output labels.

**OUTPUT:**

A new finite state machine.

**EXAMPLES:**

```
sage: aut = Automaton([(A, 'A', 0), (A, 'A', 1), (A, 'B', 0)],
....: initial_states=[A], final_states=[B])
sage: aut.transposition().transitions('B')
[Transition from B to A: 0|-]
```

```
sage: aut = Automaton([(1, '2', 1), (2, '2', 0)],
....: initial_states=[1], final_states=[1, 2])
sage: aut.transposition().initial_states()
['1', '2']
```

```
sage: A = Automaton([(0, 1, [1, 0])],
....: initial_states=[0],
....: final_states=[1])
sage: A([1, 0])
True
sage: A.transposition()([0, 1])
True
```

```
sage: T = Transducer([(0, 1, [1, 0], [1, 0])],
....: initial_states=[0],
....: final_states=[1])
sage: T([1, 0])
[1, 0]
sage: T.transposition()([0, 1])
[0, 1]
sage: T.transposition(reverse_output_labels=False)([0, 1])
[1, 0]
```

**with_final_word_out(letters, allow_non_final=True)**

Constructs a new finite state machine with final output words for all states by implicitly reading trailing letters until a final state is reached.

**INPUT:**
• **letters** – either an element of the input alphabet or a list of such elements. This is repeated cyclically when needed.

• **allow_non_final** – a boolean (default: True) which indicates whether we allow that some states may be non-final in the resulting finite state machine. I.e., if False then each state has to have a path to a final state with input label matching **letters**.

**OUTPUT:**

A finite state machine.

The inplace version of this function is `construct_final_word_out()`.

Suppose for the moment a single element **letter** as input for **letters**. This is equivalent to **letters** = [**letter**]. We will discuss the general case below.

Let **word_in** be a word over the input alphabet and assume that the original finite state machine transforms **word_in** to **word_out** reaching a possibly non-final state **s**. Let further **k** be the minimum number of **letters** **letter** such that there is a path from **s** to some final state **f** whose input label consists of **k** copies of **letter** and whose output label is **path_word_out**. Then the state **s** of the resulting finite state machine is a final state with final output **path_word_out** + **f.final_word_out**. Therefore, the new finite state machine transforms **word_in** to **word_out** + **path_word_out** + **f.final_word_out**.

This is e.g. useful for finite state machines operating on digit expansions: there, it is sometimes required to read a sufficient number of trailing zeros (at the most significant positions) in order to reach a final state and to flush all carries. In this case, this method constructs an essentially equivalent finite state machine in the sense that it not longer requires adding sufficiently many trailing zeros. However, it is the responsibility of the user to make sure that if adding trailing zeros to the input anyway, the output is equivalent.

If **letters** consists of more than one letter, then it is assumed that (not necessarily complete) cycles of **letters** are appended as trailing input.

**See also:**

*example on Gray code*

**EXAMPLES:**

1. A simple transducer transforming 00 blocks to 01 blocks:

   ```python
   sage: T = Transducer([(0, 1, 0, 0), (1, 0, 0, 1)],
                           initial_states=[0],
                           final_states=[0])
   sage: T.process([0, 0, 0])
   (False, 1, [0, 1, 0])
   sage: T.process([0, 0, 0, 0])
   (True, 0, [0, 1, 0, 1])
   sage: F = T.with_final_word_out(0)
   sage: for f in F.iter_final_states():
       print("{}").format(f, f.final_word_out))
   0 []
   1 [1]
   sage: F.process([0, 0, 0])
   (True, 1, [0, 1, 0, 1])
   sage: F.process([0, 0, 0, 0])
   (True, 0, [0, 1, 0, 1])
   ```

2. A more realistic example: Addition of 1 in binary. We construct a transition function transforming the input to its binary expansion:
sage: def binary_transition(carry, input):
    ....:     value = carry + input
    ....:     if value.mod(2) == 0:
    ....:         return (value/2, 0)
    ....:     else:
    ....:         return ((value-1)/2, 1)

Now, we only have to start with a carry of 1 to get the required transducer:

sage: T = Transducer(binary_transition,
    ....:     input_alphabet=[0, 1],
    ....:     initial_states=[1],
    ....:     final_states=[0])

We test this for the binary expansion of 7:

sage: T.process([1, 1, 1])
(False, 1, [0, 0, 0])

The final carry 1 has not be flushed yet, we have to add a trailing zero:

sage: T.process([1, 1, 1, 0])
(True, 0, [0, 0, 0, 1])

We check that with this trailing zero, the transducer performs as advertised:

sage: all(ZZ(T(k.bits()+[0]), base=2) == k + 1
    ....:     for k in srange(16))
True

However, most of the time, we produce superfluous trailing zeros:

sage: T(11.bits()+[0])
[0, 0, 1, 1, 0]

We now use this method:

sage: F = T.with_final_word_out(0)
sage: for f in F.iter_final_states():
    ....:     print("{} {}\n1 [1]
0 []

The same tests as above, but we do not have to pad with trailing zeros anymore:

sage: F.process([1, 1, 1])
(True, 1, [0, 0, 0, 1])
sage: all(ZZ(F(k.bits()), base=2) == k + 1
    ....:     for k in srange(16))
True

No more trailing zero in the output:
3. Here is an example, where we allow trailing repeated 10:

```python
sage: T = Transducer([(0, 1, 0, 'a'),
                   (1, 2, 1, 'b'),
                   (2, 0, 0, 'c')],
                   initial_states=[0],
                   final_states=[0])
sage: F = T.with_final_word_out([0, 1])
sage: for f in T.iter_final_states():
    print(str(f) + ' ' + f.final_word_out)
0
1 bc
```

Trying this with trailing repeated 01 does not produce a `final_word_out` for state 1, but for state 2:

```python
sage: F = T.with_final_word_out([0, 1])
sage: for f in T.iter_final_states():
    print(str(f) + ' ' + f.final_word_out)
0
1 c
```

4. Here another example with a more-letter trailing input:

```python
sage: T = Transducer([(0, 1, 0, 'a'),
                   (1, 2, 0, 'b'), (1, 2, 1, 'b'),
                   (2, 3, 0, 'c'), (2, 0, 1, 'e'),
                   (3, 1, 0, 'd'), (3, 1, 1, 'd')],
                   initial_states=[0],
                   final_states=[0],
                   with_final_word_out=[0, 0, 1, 1])
sage: for f in T.iter_final_states():
    print(str(f) + ' ' + f.final_word_out)
0
1 bcdbcdbe
2 cdbce
3 dbce
```

```python
class sage.combinat.finite_state_machine.Transducer(data=None, initial_states=None,
final_states=None, input_alphabet=None, output_alphabet=None,
determine_alphabets=None, with_final_word_out=None,
store_states_dict=True, on_duplicate_transition=None)

Bases: FiniteStateMachine

This creates a transducer, which is a finite state machine, whose transitions have input and output labels.
An transducer has additional features like creating a simplified transducer.
```
See class *FiniteStateMachine* for more information.

**EXAMPLES:**

We can create a transducer performing the addition of 1 (for numbers given in binary and read from right to left) in the following way:

```python
sage: T = Transducer([(['C', 'C', 1, 0), ('C', 'N', 0, 1),
.....: ('N', 'N', 0, 0), ('N', 'N', 1, 1)],
.....: initial_states=['C'], final_states=['N'])

sage: T
Transducer with 2 states
sage: T([0])
[1]
[0, 0, 1]

sage: ZZ(T(15.digits(base=2)+[0]), base=2)
16
```

Note that we have padded the binary input sequence by a 0 so that the transducer can reach its final state.

**cartesian_product** *(other, only_accessible_components=True)*

Return a new transducer which can simultaneously process an input with the machines *self* and *other* where the output labels are *d*-tuples of the original output labels.

**INPUT:**

- *other* - a finite state machine (if *d* = 2) or a list (or other iterable) of *d* − 1 finite state machines

- *only_accessible_components* – If True (default), then the result is piped through *accessible_components*. If no new_input_alphabet is given, it is determined by *determine_alphabets*.

**OUTPUT:**

A transducer which can simultaneously process an input with *self* and the machine(s) in *other*.

The set of states of the new transducer is the Cartesian product of the set of states of *self* and *other*.

Let \( \langle A_j, B_j, a_j, b_j \rangle \) for \( j \in \{1, \ldots, d\} \) be transitions in the machines *self* and in *other*. Then there is a transition \( \langle (A_1, \ldots, A_d), (B_1, \ldots, B_d), a, (b_1, \ldots, b_d) \rangle \) in the new transducer if \( a_1 = \cdots = a_d =: a \).

**EXAMPLES:**

```python
sage: transducer1 = Transducer([(['A', 'A', 0, 0), ('A', 'A', 1, 1)],
.....: initial_states=['A'], final_states=['A'],
.....: determine_alphabets=True)

sage: transducer2 = Transducer([(['0', 1, 0, ['b', 'c']]),
.....: ('0', 0, 1, 'b'),
.....: ('1', 1, 0, 'a'),
.....: initial_states=[0], final_states=[1],
.....: determine_alphabets=True)

sage: result = transducer1.cartesian_product(transducer2)

sage: result
Transducer with 2 states
sage: result.transitions()
```

(continues on next page)
[Transition from ('A', 0) to ('A', 1): 0|{(0, 'b'), (None, 'c')},
Transition from ('A', 0) to ('A', 0): 1|(1, 'b'),
Transition from ('A', 1) to ('A', 1): 0|{(0, 'a')}]

sage: result([1, 0, 0])
[(1, 'b'), (0, 'b'), (None, 'c'), (0, 'a')]

sage: (transducer1([1, 0, 0]), transducer2([1, 0, 0]))
([1, 0, 0], ['b', 'b', 'c', 'a'])

Also final output words are correctly processed:

sage: transducer1.state('A').final_word_out = 2
sage: result = transducer1.cartesian_product(transducer2)

sage: result.final_states()[0].final_word_out
[(2, None)]

The following transducer counts the number of 11 blocks minus the number of 10 blocks over the alphabet [0, 1].

sage: count_11 = transducers.CountSubblockOccurrences(
    .....: [1, 1],
    .....: input_alphabet=[0, 1])
sage: count_10 = transducers.CountSubblockOccurrences(
    .....: [1, 0],
    .....: input_alphabet=[0, 1])
sage: count_11x10 = count_11.cartesian_product(count_10)
sage: difference = transducers.sub([0, 1])(count_11x10)
sage: T = difference.simplification().relabeled()
sage: T.initial_states()
[1]
sage: sorted(T.transitions())
[Transition from 0 to 1: 0|-1,
Transition from 0 to 0: 1|1,
Transition from 1 to 1: 0|0,
Transition from 1 to 0: 1|0]
sage: input = [0, 1, 1, 0, 1, 0, 0, 0, 1, 1, 1, 0]
sage: output = [0, 0, 1, -1, 0, -1, 0, 0, 0, 1, 1, -1]
sage: T(input) == output
True

If other is an automaton, then cartesian_product() returns self where the input is restricted to the input accepted by other.

For example, if the transducer transforms the standard binary expansion into the non-adjacent form and the automaton recognizes the binary expansion without adjacent ones, then the Cartesian product of these two is a transducer which does not change the input (except for changing a to (a, None) and ignoring a leading 0).

sage: NAF = Transducer([[(0, 1, 0, None),
    .....: (0, 2, 1, None),
    .....: (1, 1, 0, 0),
    .....: (1, 2, 1, 0),
    .....: (2, 1, 0, 1),
    .....: (2, 3, 1, -1)],

(continues on next page)
This is obvious because if the standard binary expansion does not have adjacent ones, then it is the same as the non-adjacent form.

Be aware that `cartesian_product()` is not commutative.

The Cartesian product of more than two finite state machines can also be computed:
intersection(other, only_accessibile_components=True)

Return a new transducer which accepts an input if it is accepted by both given finite state machines producing the same output.

INPUT:

- other – a transducer
- only_accessibile_components – If True (default), then the result is piped through accessible_components(). If no new_input_alphabet is given, it is determined by determine_alphabets().

OUTPUT:

A new transducer which computes the intersection (see below) of the languages of self and other.

The set of states of the transducer is the Cartesian product of the set of states of both given transducer. There is a transition ((A, B), (C, D), a, b) in the new transducer if there are transitions (A, C, a, b) and (B, D, a, b) in the old transducers.

EXAMPLES:

```
sage: transducer1 = Transducer([(1, 2, 1, 0),
                               (2, 2, 1, 0),
                               (2, 2, 0, 1)],
                               initial_states=[1],
                               final_states=[2])
sage: transducer2 = Transducer([(A, A, None, b),
                                (A, B, a, c'),
                                (B, B, a, c')],
                                initial_states=[A],
                                final_states=[B])
sage: res = transducer1.intersection(transducer2)
sage: res.transitions()
[Transition from (1', 'A') to (2', 'A'): 1|0,
 Transition from (2', 'A') to (2', 'A'): 1|0]
```

In general, transducers are not closed under intersection. But for transducer which do not have epsilon-transitions, the intersection is well defined (cf. [BaWo2012]). However, in the next example the intersection of the two transducers is not well defined. The intersection of the languages consists of \( (a^n, b^n c^n) \). This set is not recognizable by a finite transducer.

```
sage: t1 = Transducer([(0, 0, 'a', 'b'),
                   (0, 1, None, 'c')],
                   initial_states=[0],
                   final_states=[0, 1])
sage: t2 = Transducer([(A, A, None, b),
                     (A, B, 'a', c'),
                     (B, B, 'a', c')],
                     initial_states=[A],
                     final_states=[A, B])
sage: t2.intersection(t1)
Traceback (most recent call last):
...
```
ValueError: An epsilon-transition (with empty input or output) was found.

REFERENCES:

process(*args, **kwargs)

Return whether the transducer accepts the input, the state where the computation stops and which output is generated.

INPUT:

- input_tape – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter use_multitape_input and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.

- initial_state or initial_states – the initial state(s) in which the machine starts. Either specify a single one with initial_state or a list of them with initial_states. If both are given, initial_state will be appended to initial_states. If neither is specified, the initial states of the finite state machine are taken.

- list_of_outputs – (default: None) a boolean or None. If True, then the outputs are given in list form (even if we have no or only one single output). If False, then the result is never a list (an exception is raised if the result cannot be returned). If list_of_outputs=None the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).

- only_accepted – (default: False) a boolean. If set, then the first argument in the output is guaranteed to be True (if the output is a list, then the first argument of each element will be True).

- full_output – (default: True) a boolean. If set, then the full output is given, otherwise only the generated output (the third entry below only). If the input is not accepted, a ValueError is raised.

- always_include_output – if set (not by default), always include the output. This is inconsequential for a Transducer, but can be used in other classes derived from FiniteStateMachine where the output is suppressed by default, cf. Automaton.process().

- format_output – a function that translates the written output (which is in form of a list) to something more readable. By default (None) identity is used here.

- check_epsilon_transitions – (default: True) a boolean. If False, then epsilon transitions are not taken into consideration during process.

- write_final_word_out – (default: True) a boolean specifying whether the final output words should be written or not.

- use_multitape_input – (default: False) a boolean. If True, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.

- process_all_prefixes_of_input – (default: False) a boolean. If True, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

- process_iterator_class – (default: None) a class inherited from FSMProcessIterator. If None, then FSMProcessIterator is taken. An instance of this class is created and is used during the processing.

- automatic_output_type – (default: False) a boolean If set and the input has a parent, then the output will have the same parent. If the input does not have a parent, then the output will be of the same type as the input.
The full output is a triple (or a list of triples, cf. parameter list_of_outputs), where

- the first entry is True if the input string is accepted,
- the second gives the reached state after processing the input tape (This is a state with label None if the input could not be processed, i.e., if at one point no transition to go on could be found.), and
- the third gives a list of the output labels written during processing.

If full_output is False, then only the third entry is returned.

Note that in the case the transducer is not deterministic, all possible paths are taken into account.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see __call__() for a version of process() with shortened output.

Internally this function creates and works with an instance of FSMProcessIterator. This iterator can also be obtained with iter_process().

If working with multi-tape finite state machines, all input words of transitions are words of \( k \)-tuples of letters. Moreover, the input tape has to consist of \( k \) tracks, i.e., be a list or tuple of \( k \) iterators, one for each track.

**Warning:** Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

**EXAMPLES:**

```python
sage: binary_inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
       initial_states=['A'], final_states=['A'])
sage: binary_inverter.process([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

If we are only interested in the output, we can also use:

```python
sage: binary_inverter([0, 1, 0, 0, 1, 1])
[1, 0, 1, 1, 0, 0]
```

This can also be used with words as input:

```python
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
sage: w = W([0, 1, 0, 0, 1, 1]); w
word: 010011
```

(continues on next page)
In this case it is automatically determined that the output is a word. The call above is equivalent to:

```
sage: binary_inverter.process(w,
    ....:   full_output=False,
    ....:   list_of_outputs=False,
    ....:   automatic_output_type=True)
word: 101100
```

The following transducer transforms $0^n1$ to $1^n2$:

```
sage: T = Transducer([(0, 0, 0, 1), (0, 1, 1, 2)])
sage: T.state(0).is_initial = True
sage: T.state(1).is_final = True
```

We can see the different possibilities of the output by:

```
sage: [T.process(w) for w in [[1], [0, 1], [0, 0, 1], [0, 1, 1],
    ....:   [0], [0, 0], [2, 0], [0, 1, 2]]
[True, 1, [2]], (True, 1, [1, 2]),
  (True, 1, [1, 1, 2]), (False, None, None),
  (False, 0, [1]), (False, 0, [1, 1]),
  (False, None, None), (False, None, None)]
```

If we just want a condensed output, we use:

```
sage: [T.process(w, full_output=False)
    ....:   for w in [[1], [0, 1], [0, 0, 1]]
[[2], [1, 2], [1, 1, 2]]
sage: T.process([0], full_output=False)
Traceback (most recent call last):
  ... ValueError: Invalid input sequence.
sage: T.process([0, 1, 2], full_output=False)
Traceback (most recent call last):
  ... ValueError: Invalid input sequence.
```

It is equivalent to:

```
sage: [T(w) for w in [[1], [0, 1], [0, 0, 1]]
[[2], [1, 2], [1, 1, 2]]
sage: T([0])
Traceback (most recent call last):
  ... ValueError: Invalid input sequence.
sage: T([0, 1, 2])
Traceback (most recent call last):
  ... ValueError: Invalid input sequence.
```

A cycle with empty input and empty output is correctly processed:
sage: T = Transducer([(0, 1, None, None), (1, 0, None, None)],
                  initial_states=[0], final_states=[1])
sage: T.process([])
[(False, 0, []), (True, 1, [])]
sage: _ = T.add_transition(-1, 0, 0, 'r')
sage: T.state(-1).is_initial = True
sage: T.state(0).is_initial = False
sage: T.process([0])
[(False, 0, ['r']), (True, 1, ['r'])]

If there is a cycle with empty input but non-empty output, the possible outputs would be an infinite set:

sage: T = Transducer([(0, 1, None, 'z'), (1, 0, None, None)],
                  initial_states=[0], final_states=[1])
sage: T.process([])
Traceback (most recent call last):
  ... RuntimeWarning: State 0 is in an epsilon cycle (no input),
  but output is written.

But if this cycle with empty input and non-empty output is not reached, the correct output is produced:

sage: _ = T.add_transition(-1, 0, 0, 'r')
sage: T.state(-1).is_initial = True
sage: T.state(0).is_initial = False
sage: T.process([0])
(False, -1, [])
sage: T.process([0])
Traceback (most recent call last):
  ... RuntimeWarning: State 0 is in an epsilon cycle (no input),
  but output is written.

If we set check_epsilon_transitions=False, then no transitions with empty input are considered
anymore. Thus cycles with empty input are no problem anymore:

sage: T.process([0], check_epsilon_transitions=False)
(False, 0, ['r'])

A simple example of a multi-tape transducer is the following: It writes the length of the first tape many
letters a and then the length of the second tape many letters b:

sage: M = Transducer([(0, 0, (1, None), 'a'),
                   ....: (0, 1, [], []),
                   ....: (1, 1, (None, 1), 'b')],
                   initial_states=[0],
                   final_states=[1])
sage: M.process(((1, 1), [1]), use_multitape_input=True)
(True, 1, ['a', 'a', 'b'])

See also:

FiniteStateMachine.process(), Automaton.process(), iter_process(), __call__(), FSMProcessIterator.
simplification()

Return a simplified transducer.

OUTPUT:

A new transducer.

This function simplifies a transducer by Moore’s algorithm, first moving common output labels of transitions leaving a state to output labels of transitions entering the state (cf. prepone_output()).

The resulting transducer implements the same function as the original transducer.

EXAMPLES:

```
sage: fsm = Transducer([("A", "B", 0, 1), ("A", "B", 1, 0),
                      ....: ("B", "C", 0, 1), ("C", "D", 1, 0),
                      ....: ("D", "A", 0, 0)]
                )
sage: fsms = fsm.simplification()

sage: fsms
Transducer with 2 states

sage: fsms.transitions()
[Transition from ('B', 'D') to ('A', 'C'): 0|0,
 Transition from ('B', 'D') to ('A', 'C'): 1|1,
 Transition from ('A', 'C') to ('B', 'D'): 0|1,
 Transition from ('A', 'C') to ('B', 'D'): 1|0]
sage: fsms.relabeled().transitions()
[Transition from 0 to 1: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 0: 1|0]

sage: fsm = Transducer([("A", "A", 0, 0),
                      ....: ("A", "B", 1, 1),
                      ....: ("A", "C", 1, -1),
                      ....: ("B", "A", 2, 0),
                      ....: ("C", "A", 2, 0)]
                )
sage: fsm_simplified = fsm.simplification()

sage: fsm_simplified
Transducer with 2 states

sage: fsm_simplified.transitions()
[Transition from ('A',) to ('A',): 0|0,
 Transition from ('A',) to ('B', 'C'): 1|1,0,
 Transition from ('A',) to ('B', 'C'): 1|-1,0,
 Transition from ('B', 'C') to ('A',): 2|-

sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: T = Transducer([("A", 'A', 1/2, 0),
                  ....: ('A', 'B', 1/4, 1),
                  ....: ('A', 'C', 1/4, 1),
                  ....: ('B', 'A', 1, 0),
                  ....: ('C', 'A', 1, 0)],
                  ....: initial_states=[0],
                  ....: final_states=['A', 'B', 'C'],

(continues on next page)
Illustrating the use of colors in order to avoid identification of states:

```python
sage: T = Transducer( [[0,0,0,0], [0,1,1,1],
....:                   [1,0,0,0], [1,1,1,1]],
....:                   initial_states=[0],
....:                   final_states=[0,1])
sage: sorted(T.simplification().transitions())
[Transition from (0, 1) to (0, 1): 0|0,
 Transition from (0, 1) to (0, 1): 1|1]
sage: T.state(0).color = 0
sage: T.state(0).color = 1
sage: sorted(T.simplification().transitions())
[Transition from (0,) to (0,): 0|0,
 Transition from (0,) to (1,): 1|1,
 Transition from (1,) to (0,): 0|0,
 Transition from (1,) to (1,): 1|1]
```

sage.combinat.finite_state_machine.duplicate_transition_add_input

Alternative function for handling duplicate transitions in finite state machines. This implementation adds the input label of the new transition to the input label of the old transition. This is intended for the case where a Markov chain is modelled by a finite state machine using the input labels as transition probabilities.

See the documentation of the on_duplicate_transition parameter of FiniteStateMachine.

**INPUT:**

- old_transition – A transition in a finite state machine.
- new_transition – A transition, identical to old_transition, which is to be inserted into the finite state machine.

**OUTPUT:**

A transition whose input weight is the sum of the input weights of old_transition and new_transition.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_add_input(FSMTransition('a', 'a', 1/2),
....:                                  FSMTransition('a', 'a', 1/2))
Transition from 'a' to 'a': 1|-
```

Input labels must be lists of length 1:

```python
sage: duplicate_transition_add_input(FSMTransition('a', 'a', [1, 1]),
....:                                  FSMTransition('a', 'a', [1, 1]))
```

Traceback (most recent call last):
sage.combinat.finite_state_machine.duplicate_transition_ignore(old_transition, new_transition)

Default function for handling duplicate transitions in finite state machines. This implementation ignores the occurrence.

See the documentation of the on_duplicate_transition parameter of FiniteStateMachine.

INPUT:

- old_transition – A transition in a finite state machine.
- new_transition – A transition, identical to old_transition, which is to be inserted into the finite state machine.

OUTPUT:

The same transition, unchanged.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_ignore
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_ignore(FSMTransition(0, 0, 1), FSMTransition(0, 0, 1))
Transition from 0 to 0: 1|-
```

sage.combinat.finite_state_machine.duplicate_transition_raise_error(old_transition, new_transition)

Alternative function for handling duplicate transitions in finite state machines. This implementation raises a ValueError.

See the documentation of the on_duplicate_transition parameter of FiniteStateMachine.

INPUT:

- old_transition – A transition in a finite state machine.
- new_transition – A transition, identical to old_transition, which is to be inserted into the finite state machine.

OUTPUT:

Nothing. A ValueError is raised.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_error
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_raise_error(FSMTransition(0, 0, 1), FSMTransition(0, 0, 1))
Traceback (most recent call last):
  ... ValueError: Attempting to re-insert transition Transition from 0 to 0: 1|-
```
sage.combinat.finite_state_machine.equal(iterator)
Checks whether all elements of iterator are equal.

INPUT:
• iterator – an iterator of the elements to check

OUTPUT:
True or False.
This implements https://stackoverflow.com/a/3844832/1052778.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import equal
sage: equal([0, 0, 0])
True
sage: equal([0, 1, 0])
False
sage: equal([])
True
sage: equal(iter([None, None]))
True
```

We can test other properties of the elements than the elements themselves. In the following example, we check whether all tuples have the same lengths:

```python
sage: equal(len(x) for x in [(1, 2), (2, 3), (3, 1)])
True
sage: equal(len(x) for x in [(1, 2), (1, 2, 3), (3, 1)])
False
```

sage.combinat.finite_state_machine.full_group_by(l, key=<function <lambda> at 0x7fdecdedcaf0>)
Group iterable l by values of key.

INPUT:
• iterable l
• key function key

OUTPUT:
A list of pairs (k, elements) such that key(e)=k for all e in elements.
This is similar to itertools.groupby() except that lists are returned instead of iterables and no prior sorting is required.

We do not require
• that the keys are sortable (in contrast to the approach via sorted() and itertools.groupby()) and
• that the keys are hashable (in contrast to the implementation proposed in https://stackoverflow.com/a/15250161).

However, it is required
• that distinct keys have distinct str-representations.

The implementation is inspired by https://stackoverflow.com/a/15250161, but non-hashable keys are allowed.

EXAMPLES:
```python
sage: from sage.combinat.finite_state_machine import full_group_by
sage: t = [2/x, 1/x, 2/x]  # optional - sage.symbolic
sage: r = full_group_by([0, 1, 2], key=lambda i: t[i])  # optional - sage.symbolic
sage: sorted(r, key=lambda p: p[1])  # optional - sage.symbolic
[(2/x, [0, 2]), (1/x, [1])]
```

Note that the behavior is different from `itertools.groupby()` because neither $1/x < 2/x$ nor $2/x < 1/x$ does hold.

Here, the result \( r \) has been sorted in order to guarantee a consistent order for the doctest suite.

`sage.combinat.finite_state_machine.is_Automaton(FSM)`
Tests whether or not \( FSM \) inherits from `Automaton`.

`sage.combinat.finite_state_machine.is_FSMProcessIterator(PI)`
Tests whether or not \( PI \) inherits from `FSMProcessIterator`.

`sage.combinat.finite_state_machine.is_FSMState(S)`
Tests whether or not \( S \) inherits from `FSMState`.

`sage.combinat.finite_state_machine.is_FSMTransition(T)`
Tests whether or not \( T \) inherits from `FSMTransition`.

`sage.combinat.finite_state_machine.is_FiniteStateMachine(FSM)`
Tests whether or not \( FSM \) inherits from `FiniteStateMachine`.

`sage.combinat.finite_state_machine.is_Transducer(FSM)`
Tests whether or not \( FSM \) inherits from `Transducer`.

`sage.combinat.finite_state_machine.setup_latex_preamble()`
This function adds the package `tikz` with support for automata to the preamble of Latex so that the finite state machines can be drawn nicely.

See the section on `LaTeX output` in the introductory examples of this module.

`sage.combinat.finite_state_machine.startswith(list_, prefix)`
Determine whether list starts with the given prefix.

**INPUT:**
- `list_` – list
- `prefix` – list representing the prefix

**OUTPUT:**
True or False.
Similar to \texttt{str.startswith()}. 

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.finite_state_machine import startswith
sage: startswith([1, 2, 3], [1, 2])
True
sage: startswith([1], [1, 2])
False
sage: startswith([1, 3, 2], [1, 2])
False
\end{verbatim}

\texttt{sage.combinat.finite_state_machine.tupleofwords_to_wordoftuples(tupleofwords)}

Transposes a tuple of words over the alphabet to a word of tuples.

\textbf{INPUT:}

- \texttt{tupleofwords} – a tuple of a list of letters.

\textbf{OUTPUT:}

A list of tuples.

Missing letters in the words are padded with the letter \texttt{None} (from the empty word).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.finite_state_machine import (sage: tupleofwords_to_wordoftuples) sage: tupleofwords_to_wordoftuples( ([1, 2], [3, 4, 5, 6], [7]))
[(1, 3, 7), (2, 4, None), (None, 5, None), (None, 6, None)]
\end{verbatim}

\texttt{sage.combinat.finite_state_machine.wordoftuples_to_tupleofwords(wordoftuples)}

Transposes a word of tuples to a tuple of words over the alphabet.

\textbf{INPUT:}

- \texttt{wordoftuples} – a list of tuples of letters.

\textbf{OUTPUT:}

A tuple of lists.

Letters \texttt{None} (empty word) are removed from each word in the output.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.finite_state_machine import (sage: wordoftuples_to_tupleofwords) sage: wordoftuples_to_tupleofwords( ([1, 2), (1, None), (1, None), (1, 2), (None, 2)])
([1, 1, 1, 1], [2, 2, 2])
\end{verbatim}
5.1.108 Common Automata and Transducers (Finite State Machines Generators)

Automata and Transducers in Sage can be built through the `automata` and `transducers` objects, respectively. It contains generators for common finite state machines. For example,

```sage
sage: I = transducers.Identity([0, 1, 2])
```

generates an identity transducer on the alphabet \{0, 1, 2\}.

To construct automata and transducers manually, you can use the classes `Automaton` and `Transducer`, respectively. See `Finite state machines, automata, transducers` for more details and a lot of examples.

Automata

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>AnyLetter()</code></td>
<td>Return an automaton recognizing any letter.</td>

Functions and methods

class sage.combinat.finite_state_machine_generators.AutomatonGenerators

Bases: object

A collection of constructors for several common automata.

A list of all automata in this database is available via tab completion. Type “automata.” and then hit tab to see which automata are available.

The automata currently in this class include:

• AnyLetter()
• AnyWord()
• EmptyWord()
• Word()
• ContainsWord()

AnyLetter(input_alphabet)

Return an automaton recognizing any letter of the given input alphabet.

INPUT:
• input_alphabet – a list, the input alphabet

OUTPUT:
An Automaton.

EXAMPLES:

```
sage: A = automata.AnyLetter([0, 1])
sage: A([])
False
sage: A([0])
True
sage: A([1])
True
sage: A([0, 0])
False
```

See also:

AnyWord()

AnyWord(input_alphabet)

Return an automaton recognizing any word of the given input alphabet.

INPUT:
• input_alphabet – a list, the input alphabet

OUTPUT:
An Automaton.
EXAMPLES:

```python
sage: A = automata.AnyWord([0, 1])
sage: A([0])
True
sage: A([1])
True
sage: A([0, 1])
True
sage: A([0, 2])
False
```

This is equivalent to taking the `kleene_star()` of `AnyLetter()` and minimizing the result. This method immediately gives a minimized version:

```python
sage: B = automata.AnyLetter([0, 1]).kleene_star().minimization().reabeled()
sage: B == A
True
```

See also:

`AnyLetter()`, `Word()`.

**ContainsWord**(word, input_alphabet)

Return an automaton recognizing the words containing the given word as a factor.

**INPUT:**

- word – a list (or other iterable) of letters, the word we are looking for.
- input_alphabet – a list or other iterable, the input alphabet.

**OUTPUT:**

An `Automaton`.

**EXAMPLES:**

```python
sage: A = automata.ContainsWord([0, 1, 0, 1, 1], input_alphabet=[0, 1])
sage: A([1, 0, 1, 0, 1, 0, 1, 1, 0, 0])
True
sage: A([1, 0, 1, 0, 1, 0, 1])
False
```

This is equivalent to taking the concatenation of `AnyWord()`, `Word()` and `AnyWord()` and minimizing the result. This method immediately gives a minimized version:

```python
sage: B = (automata.AnyWord([0, 1]) *
.....:   automata.Word([0, 1, 0, 1, 1], [0, 1]) *
.....:   automata.AnyWord([0, 1])).minimization()
sage: B.is_equivalent(A)
True
```

See also:

`CountSubblockOccurrences()`, `AnyWord()`, `Word()`.
**EmptyWord***(input_alphabet=None)*

Return an automaton recognizing the empty word.

**INPUT:**
- *input_alphabet* – (default: None) an iterable or None.

**OUTPUT:**
An Automaton.

**EXAMPLES:**

```
sage: A = automata.EmptyWord()
sage: A([])
True
sage: A([0])
False
```

See also:
*AnyLetter(), AnyWord().*

**Word**(word, *input_alphabet=None*)

Return an automaton recognizing the given word.

**INPUT:**
- *word* – an iterable.
- *input_alphabet* – a list or None. If None, then the letters occurring in the word are used.

**OUTPUT:**
An Automaton.

**EXAMPLES:**

```
sage: A = automata.Word([0])
sage: A.transitions()
[Transition from 0 to 1: 0|-]
sage: [A(w) for w in ([], [0], [1])]
[False, True, False]
sage: A = automata.Word([0, 1, 0])
sage: A.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 1 to 2: 1|-,
 Transition from 2 to 3: 0|-]
sage: [A(w) for w in ([], [0], [0, 1], [0, 1, 1], [0, 1, 0])]
[False, False, False, False, True]
```

If the input alphabet is not given, it is derived from the given word.

```
sage: A.input_alphabet
[0, 1]
sage: A = automata.Word([0, 1, 0], input_alphabet=[0, 1, 2])
sage: A.input_alphabet
[0, 1, 2]
```
See also:

\texttt{AnyWord()}, \texttt{ContainsWord()}.

class \texttt{sage.combinat.finite_state_machine_generators.TransducerGenerators}

Bases: \texttt{object}

A collection of constructors for several common transducers.

A list of all transducers in this database is available via tab completion. Type "transducers." and then hit tab to see which transducers are available.

The transducers currently in this class include:

\begin{itemize}
  \item \texttt{Identity()}
  \item \texttt{abs()}
  \item \texttt{operator()}
  \item \texttt{all()}
  \item \texttt{any()}
  \item \texttt{add()}
  \item \texttt{sub()}
  \item \texttt{CountSubblockOccurrences()}
  \item \texttt{Wait()}
  \item \texttt{GrayCode()}
  \item \texttt{Recursion()}
\end{itemize}

\textbf{CountSubblockOccurrences}(\texttt{block, input_alphabet})

Returns a transducer counting the number of (possibly overlapping) occurrences of a block in the input.

\textbf{INPUT}:

- \texttt{block} – a list (or other iterable) of letters.
- \texttt{input_alphabet} – a list or other iterable.

\textbf{OUTPUT}:

A transducer counting (in unary) the number of occurrences of the given block in the input. Overlapping occurrences are counted several times.

Denoting the block by $b_0 \ldots b_{k-1}$, the input word by $i_0 \ldots i_L$ and the output word by $o_0 \ldots o_L$, we have $o_j = 1$ if and only if $i_{j-k+1} \ldots i_j = b_0 \ldots b_{k-1}$. Otherwise, $o_j = 0$.

\textbf{EXAMPLES}:

1. Counting the number of $\emptyset$ blocks over the alphabet $[\emptyset, 1]$:

\begin{verbatim}
sage: T = transducers.CountSubblockOccurrences(
         ....: [1, 0],
         ....: [\emptyset, 1])
sage: sorted(T.transitions())
[Transition from () to (): \emptyset|\emptyset,
 Transition from () to (1,): 1|\emptyset,
 Transition from (1,) to (): \emptyset|1,
 Transition from (1,) to (1,): 1|\emptyset]
\end{verbatim}

(continues on next page)
sage: T.input_alphabet
[0, 1]
sage: T.output_alphabet
[0, 1]
sage: T.initial_states()
[()]
sage: T.final_states()
[(), (1,)]

Check some sequence:

sage: T([0, 1, 0, 1, 1, 0])
[0, 0, 1, 0, 0, 1]

2. Counting the number of 11 blocks over the alphabet [0, 1]:

sage: T = transducers.CountSubblockOccurrences(
    ....:     [1, 1],
    ....:     [0, 1])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
  Transition from () to (1,): 1|0,
  Transition from (1,) to (): 0|0,
  Transition from (1,) to (1,): 1|1]

Check some sequence:

sage: T([0, 1, 0, 1, 1, 0])
[0, 0, 0, 0, 1, 0]

3. Counting the number of 1010 blocks over the alphabet [0, 1, 2]:

sage: T = transducers.CountSubblockOccurrences(
    ....:     [1, 0, 1, 0],
    ....:     [0, 1, 2])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
  Transition from () to (1,): 1|0,
  Transition from () to (): 2|0,
  Transition from (1,) to (1, 0): 0|0,
  Transition from (1,) to (1,): 1|0,
  Transition from (1,) to (): 2|0,
  Transition from (1, 0) to (): 0|0,
  Transition from (1, 0) to (1, 0, 1): 1|0,
  Transition from (1, 0) to (): 2|0,
  Transition from (1, 0, 1) to (): 0|1,
  Transition from (1, 0, 1) to (1,): 1|0,
  Transition from (1, 0, 1) to (): 2|0]
sage: input = [0, 1, 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, 2]
sage: output = [0, 0, 0, 0, 1, 0, 1, 0, 0, 0, 0, 1, 0]
sage: T(input) == output
True
See also:

*ContainsWord()*

**GrayCode()**

Returns a transducer converting the standard binary expansion to Gray code.

**INPUT:**

Nothing.

**OUTPUT:**

A transducer.

Cf. the Wikipedia article Gray_code for a description of the Gray code.

**EXAMPLES:**

```python
sage: G = transducers.GrayCode()
sage: G
Transducer with 3 states
sage: for v in srange(10):
    ....:     print("{} {}".format(v, G(v.digits(base=2))))
0 []
1 [1]
2 [1, 1]
3 [0, 1]
4 [0, 1, 1]
5 [1, 1, 1]
6 [1, 0, 1]
7 [0, 0, 1]
8 [0, 0, 1, 1]
9 [1, 0, 1, 1]
```

In the example *Gray Code* in the documentation of the *Finite state machines, automata, transducers* module, the Gray code transducer is derived from the algorithm converting the binary expansion to the Gray code. The result is the same as the one given here.

**Identity(input_alphabet)**

Returns the identity transducer realizing the identity map.

**INPUT:**

- input_alphabet – a list or other iterable.

**OUTPUT:**

A transducer mapping each word over input_alphabet to itself.

**EXAMPLES:**

```python
sage: T = transducers.Identity([0, 1])
sage: sorted(T.transitions())
[Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
```
Recursion\(\text{(recursions, base, function=\text{None}, var=\text{None}, input\_alphabet=\text{None}, word\_function=\text{None}, is\_zero=\text{None}, output\_rings=[\text{Integer Ring, Rational Field}]})\)

Return a transducer realizing the given recursion when reading the digit expansion with base \text{base}.

**INPUT:**

- \text{recursions} – list or iterable of equations. Each equation has either the form
  \[ f(ba^k \cdot n + r) == f(ba^k \cdot n + s) + t \]
  for some integers \(0 \leq k < K\), \(r\) and some \(t\)—valid for all \(n\) such that the arguments on both sides are non-negative—
  or the form
  \[ f(r) == t \]
  for some integer \(r\) and some \(t\).

  Alternatively, an equation may be replaced by a \text{transducers.RecursionRule} with the attributes \(K, r, k, s, t\) as above or a tuple \((r, t)\). Note that \(t\) must be a list in this case.

- \text{base} – base of the digit expansion.

- \text{function} – symbolic function \(f\) occurring in the recursions.

- \text{var} – symbolic variable.

- \text{input\_alphabet} – (default: \text{None}) a list of digits to be used as the input alphabet. If \text{None} and the base is an integer, \text{input\_alphabet} is chosen to be \text{srange(base.abs())}.

- \text{word\_function} – (default: \text{None}) a symbolic function. If not \text{None}, \text{word\_function(arg1, .. ., argn)} in a symbolic recurrence relation is interpreted as a transition with output \([\text{arg1, .. ., argn}]\). This could not be entered in a symbolic recurrence relation because lists do not coerce into the \text{SymbolicRing}.

- \text{is\_zero} – (default: \text{None}) a callable. The recursion relations are only well-posed if there is no cycle with non-zero output and input consisting of zeros. This parameter is used to determine whether the output of such a cycle is non-zero. By default, the output must evaluate to \text{False} as a boolean.

- \text{output\_rings} – (default: \([\text{ZZ, QQ}]\)) a list of rings. The output labels are converted into the first ring of the list in which they are contained. If they are not contained in any ring, they remain in whatever ring they are after parsing the recursions, typically the symbolic ring.

**OUTPUT:**

A transducer \(T\).

The transducer is constructed such that \(T(\text{expansion}) == f(n)\) if \text{expansion} is the digit expansion of \(n\) to the base \text{base} with the given input alphabet as set of digits. Here, the + on the right hand side of the recurrence relation is interpreted as the concatenation of words.

The formal equations and initial conditions in the recursion have to be selected such that \(f\) is uniquely defined.

**EXAMPLES:**

- The following example computes the Hamming weight of the ternary expansion of integers.
Combinatorics, Release 10.1

sage: function('f') #optional - sage.symbolic
f
sage: var('n') #optional - sage.symbolic
n
sage: T = transducers.Recursion([ #optional - sage.symbolic
    f(3*n + 1) == f(n) + 1,
    f(3*n + 2) == f(n) + 1,
    f(3*n) == f(n),
    f(0) == 0],
    3, f, n)
sage: T.transitions() #optional - sage.symbolic
[(Transition from (0, 0) to (0, 0): 0|-,
  Transition from (0, 0) to (0, 0): 1|1,
  Transition from (0, 0) to (0, 0): 2|1)

To illustrate what this transducer does, we consider the example of $n = 601$:

sage: ternary_expansion = 601.digits(base=3) #optional - sage.symbolic
sage: ternary_expansion #optional - sage.symbolic
[1, 2, 0, 1, 1, 2]
sage: weight_sequence = T(ternary_expansion) #optional - sage.symbolic
sage: weight_sequence #optional - sage.symbolic
[1, 1, 1, 1, 1]
sage: sum(weight_sequence) #optional - sage.symbolic
5

Note that the digit zero does not show up in the output because the equation $f(3*n) = f(n)$ means that no output is added to $f(n)$.

- The following example computes the Hamming weight of the non-adjacent form, cf. the Wikipedia article Non-adjacent_form.

sage: function('f') #optional - sage.symbolic
f
sage: var('n') #optional - sage.symbolic
n
sage: T = transducers.Recursion([ #optional - sage.symbolic
    f(4*n + 1) == f(n) + 1,
    f(4*n - 1) == f(n) + 1,
    f(2*n) == f(n),
    f(0) == 0],
    2, f, n)
sage: T.transitions()  
#optional - sage.symbolic
[Transition from (0, 0) to (0, 0): 0|-,
  Transition from (0, 0) to (1, 1): 1|-,
  Transition from (1, 1) to (0, 0): 0|1,
  Transition from (1, 1) to (1, 0): 1|1,
  Transition from (1, 0) to (1, 1): 0|-,
  Transition from (1, 0) to (1, 0): 1|-
]
sage: [(s.label(), s.final_word_out)  
#optional - sage.symbolic
....: for s in T.iter_final_states()]
[((0, 0), []),
 ((1, 1), [1]),
 ((1, 0), [1])]

As we are interested in the weight only, we also output 1 for numbers congruent to 3 mod 4. The actual expansion is computed in the next example.

Consider the example of $29 = (100\bar{1}01)_2$ (as usual, the digit $-1$ is denoted by $\bar{1}$ and digits are written from the most significant digit at the left to the least significant digit at the right; for the transducer, we have to give the digits in the reverse order):

sage: NAF = [1, 0, -1, 0, 0, 1]
sage: ZZ(NAF, base=2)  
29
sage: binary_expansion = 29.digits(base=2)
sage: binary_expansion  
[1, 0, 1, 1, 1]
sage: T(binary_expansion)  
#optional - sage.symbolic
[1, 1, 1]
sage: sum(T(binary_expansion))  
#optional - sage.symbolic
3

Indeed, the given non-adjacent form has three non-zero digits.

- The following example computes the non-adjacent form from the binary expansion, cf. the Wikipedia article Non-adjacent_form. In contrast to the previous example, we actually compute the expansion, not only the weight.

  We have to write the output 0 when converting an even number. This cannot be encoded directly by an equation in the symbolic ring, because $f(2*n) == f(n) + 0$ would be equivalent to $f(2*n) == f(n)$ and an empty output would be written. Therefore, we wrap the output in the symbolic function $w$ and use the parameter word_function to announce this.

  Similarly, we use $w(-1, 0)$ to write an output word of length 2 in one iteration. Finally, we write $f(0) == w()$ to write an empty word upon completion.

Moreover, there is a cycle with output $[0]$ which—from the point of view of this method—is a contradicting recursion. We override this by the parameter is_zero.

sage: var('n')  
#optional - sage.symbolic
n
sage: function('f w')  #... optional - sage.symbolic
(f, w)
sage: T = transducers.Recursion([  #...
  f(2*n) == f(n) + w(0),
  f(4*n + 1) == f(n) + w(1, 0),
  f(4*n - 1) == f(n) + w(-1, 0),
  f(0) == w(),
  2, f, n,
  word_function=w,
  is_zero=lambda x: sum(x).is_zero())
sage: T.transitions()  #...
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,0,
 Transition from (1, 1) to (1, 0): 1|-1,0,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]

We again consider the example of \( n = 29 \):

sage: T(29.digits(base=2))  #...
[1, 0, -1, 0, 0, 1, 0]

The same transducer can also be entered bypassing the symbolic equations:

sage: R = transducers.RecursionRule
sage: TR = transducers.Recursion(
  R(K=1, r=0, k=0, s=0, t=[0]),
  R(K=2, r=1, k=0, s=0, t=[1, 0]),
  R(K=2, r=-1, k=0, s=0, t=[-1, 0]),
  (0, []),
  2,
  is_zero=lambda x: sum(x).is_zero())

sage: TR == T  #...
True

• Here is an artificial example where some of the \( s \) are negative:

sage: function('f')  #...
(f, w)
sage: var('n')

(continues on next page)
Abelian complexity of the paperfolding sequence (cf. [HKP2015], Example 2.8):

```python
sage: T = transducers.Recursion([  
... optional - sage.symbolic
  ....: f(4*n) == f(2*n),  
  ....: f(4*n+2) == f(2*n+1)+1,  
  ....: f(16*n+1) == f(8*n+1),  
  ....: f(16*n+5) == f(4*n+1)+2,  
  ....: f(16*n+11) == f(4*n+3)+2,  
  ....: f(16*n+15) == f(2*n+2)+1,  
  ....: f(1) == 2, f(0) == 0]  
....: + [f(16*n+jj) == f(2*n+1)+2 for jj in [3,7,9,13]],  
....: 2, f, n)
```

```python
sage: T.transitions()  
```

(continues on next page)
Transition from (3, 2) to (3, 3): 0|-
Transition from (3, 2) to (7, 3): 1|-,
Transition from (1, 3) to (1, 3): 0|-,
Transition from (1, 3) to (1, 1): 1|2,
Transition from (5, 3) to (1, 2): 0|2,
Transition from (5, 3) to (1, 1): 1|2,
Transition from (3, 3) to (1, 1): 0|2,
Transition from (3, 3) to (3, 2): 1|2,
Transition from (7, 3) to (1, 1): 0|2,
Transition from (7, 3) to (2, 1): 1|1,
Transition from (2, 1) to (1, 1): 0|1,
Transition from (2, 1) to (2, 1): 1|-

sage: for s in T.iter_states():
    ....:     print("{} {}".format(s, s.final_word_out))
(0, 0) []
(0, 1) []
(1, 1) [2]
(1, 2) [2]
(3, 2) [2, 2]
(1, 3) [2]
(5, 3) [2, 2]
(3, 3) [2, 2]
(7, 3) [2, 2]
(2, 1) [1, 2]

sage: list(sum(T(n.bits())) for n in srange(1, 21))
#...
[2, 3, 4, 3, 4, 5, 4, 3, 4, 5, 6, 5, 4, 5, 4, 3, 4, 5, 6, 5]

We now demonstrate the use of the output_rings parameter. If no output_rings are specified, the output labels are converted into ZZ:

sage: function('f')
#...
f
sage: var('n')
#...
n
sage: T = transducers.Recursion([...
#...
....:     f(2^n + 1) == f(n) + 1,
....:     f(2^n) == f(n),
....:     f(0) == 2],
....:     2, f, n)
sage: for t in T.transitions():
    ....:     print([x.parent() for x in t.word_out])
[]
[Integer Ring]
sage: [x.parent() for x in T.states()[0].final_word_out]
#...
[Integer Ring]

5.1. Comprehensive Module List
In contrast, if `output_rings` is set to the empty list, the results are not converted:

```python
sage: T = transducers.Recursion([  
    # optional - sage.symbolic
    ....: f(2^n + 1) == f(n) + 1,
    ....: f(2^n) == f(n),
    ....: f(0) == 2],
    ....: 2, f, n, output_rings=[])  
sage: for t in T.transitions():  
    # optional - sage.symbolic
    ....: print([x.parent() for x in t.word_out])
[]

sage: [x.parent() for x in T.states()[0].final_word_out]  
# optional - sage.symbolic
[Symbolic Ring]
```

Finally, we use a somewhat questionable conversion:

```python
sage: T = transducers.Recursion([  
    # optional - sage.rings.finite_rings sage.symbolic
    ....: f(2^n + 1) == f(n) + 1,
    ....: f(2^n) == f(n),
    ....: f(0) == 0],
    ....: 2, f, n, output_rings=[GF(5)])  
sage: for t in T.transitions():  
    # optional - sage.rings.finite_rings sage.symbolic
    ....: print([x.parent() for x in t.word_out])
[]

sage: [x.parent() for x in T.states()[0].final_word_out]  
# optional - sage.symbolic
[Symbolic Ring]
```

**Todo:** Extend the method to

- non-integral bases,
- higher dimensions.

**ALGORITHM:**

See [HKP2015], Section 6. However, there are also recursion transitions for states of level $\kappa$ if the recursion rules allow such a transition. Furthermore, the intermediate step of a non-deterministic transducer is left out by implicitly using recursion transitions. The well-posedness is checked in a truncated version of the recursion digraph.

```python
class RecursionRule(K, r, k, s, t)  
Bases: tuple
    
K  
    Alias for field number 0

k  
    Alias for field number 2

r  
    Alias for field number 1
```

1060 Chapter 5. Comprehensive Module List
\textbf{Wait}(\textit{input\_alphabet}, \textit{threshold}=1)

Writes False until reading the threshold-th occurrence of a true input letter; then writes True.

\textbf{INPUT}:

- \textit{input\_alphabet} – a list or other iterable.
- \textit{threshold} – a positive integer specifying how many occurrences of True inputs are waited for.

\textbf{OUTPUT}:

A transducer writing False until the threshold-th true (Python’s standard conversion to boolean is used to convert the actual input to boolean) input is read. Subsequently, the transducer writes True.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: T = transducers.Wait([0, 1])
sage: T([0, 0, 1, 0, 1, 0])
[False, False, True, True, True, True]
sage: T2 = transducers.Wait([0, 1], threshold=2)
sage: T2([0, 0, 1, 0, 1, 0])
[False, False, False, False, True, True]
\end{verbatim}

\textbf{abs}(\textit{input\_alphabet})

Returns a transducer which realizes the letter-wise absolute value of an input word over the given input alphabet.

\textbf{INPUT}:

- \textit{input\_alphabet} – a list or other iterable.

\textbf{OUTPUT}:

A transducer mapping \(i_0 \ldots i_k\) to \(|i_0| \ldots |i_k|\).

\textbf{EXAMPLES}:

The following transducer realizes letter-wise absolute value:

\begin{verbatim}
sage: T = transducers.abs([-1, 0, 1])
sage: T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([-1, -1, 0, 1])
[1, 1, 0, 1]
\end{verbatim}

\textbf{add}(\textit{input\_alphabet}, \textit{number\_of\_operands}=2)

Returns a transducer which realizes addition on pairs over the given input alphabet.

\textbf{INPUT}: 

- \textit{input\_alphabet}
- \textit{number\_of\_operands} – a positive integer specifying how many operands are used.
• `input_alphabet` – a list or other iterable.
• `number_of_operands` – (default: 2) it specifies the number of input arguments the operator takes.

OUTPUT:
A transducer mapping an input word \((i_0, \ldots, i_{od}) \ldots (i_{k1}, \ldots, i_{kd})\) to the word \((i_0 + \cdots + i_{od}) \ldots (i_{k1} + \cdots + i_{kd})\).

The input alphabet of the generated transducer is the Cartesian product of `number_of_operands` copies of `input_alphabet`.

EXAMPLES:
The following transducer realizes letter-wise addition:

```python
sage: T = transducers.add([0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 2]
```

More than two operands can also be handled:

```python
sage: T3 = transducers.add([0, 1], number_of_operands=3)
sage: T3.input_alphabet
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1),
 (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1)]
sage: T3([(0, 0, 0), (0, 1, 0), (0, 1, 1), (1, 1, 1)])
[0, 1, 2, 3]
```

`all(input_alphabet, number_of_operands=2)`

Returns a transducer which realizes logical and over the given input alphabet.

INPUT:
• `input_alphabet` – a list or other iterable.
• `number_of_operands` – (default: 2) specifies the number of input arguments for the and operation.

OUTPUT:
A transducer mapping an input word \((i_0, \ldots, i_{od}) \ldots (i_{k1}, \ldots, i_{kd})\) to the word \((i_0 \land \cdots \land i_{od}) \ldots (i_{k1} \land \cdots \land i_{kd})\).

The input alphabet of the generated transducer is the Cartesian product of `number_of_operands` copies of `input_alphabet`.

EXAMPLES:
The following transducer realizes letter-wise logical and:
```python
sage: T = transducers.all([False, True])
sage: T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|False,
 Transition from 0 to 0: (True, False)|False,
 Transition from 0 to 0: (True, True)|True]
sage: T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([[False, False], [False, True], [True, False], [True, True]])
[False, True, True, True]
```

More than two operands and other input alphabets (with conversion to boolean) are also possible:

```python
sage: T3 = transducers.all([0, 1], number_of_operands=3)
sage: T3([[0, 0, 0], [1, 0, 0], [1, 1, 1]])
[False, False, True]
```

**any**(*input_alphabet, number_of_operands=2*)

Returns a transducer which realizes logical or over the given input alphabet.

**INPUT:**

- *input_alphabet* – a list or other iterable.
- *number_of_operands* – (default: 2) specifies the number of input arguments for the or operation.

**OUTPUT:**

A transducer mapping an input word \((i_0, \ldots, i_{d_0}) \ldots (i_k, \ldots, i_{kd})\) to the word \((i_0 \lor \ldots \lor i_{d_0}) \ldots (i_k \lor \ldots \lor i_{kd})\).

The input alphabet of the generated transducer is the Cartesian product of *number_of_operands* copies of *input_alphabet*.

**EXAMPLES:**

The following transducer realizes letter-wise logical or:

```python
sage: T = transducers.any([False, True])
sage: T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|False,
 Transition from 0 to 0: (True, False)|False,
 Transition from 0 to 0: (True, True)|True]
sage: T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([[False, False], [False, True], [True, False], [True, True]])
[False, True, True, True]
```

More than two operands and other input alphabets (with conversion to boolean) are also possible:
sage: T3 = transducers.any([0, 1], number_of_operands=3)
sage: T3([(0, 0, 0), (1, 0, 0), (1, 1, 1)])
[False, True, True]

map(f, input_alphabet)
Return a transducer which realizes a function on the alphabet.

INPUT:

- f – function to realize.
- input_alphabet – a list or other iterable.

OUTPUT:
A transducer mapping an input letter $x$ to $f(x)$.

EXAMPLES:
The following binary transducer realizes component-wise absolute value (this transducer is also available as $abs()$):

```
sage: T = transducers.map(abs, [-1, 0, 1])
sage: T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.input_alphabet
[-1, 0, 1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([-1, 1, 0, 1])
[1, 1, 0, 1]
```

See also:
`Automaton.with_output()`.

operator(operator, input_alphabet, number_of_operands=2)
Returns a transducer which realizes an operation on tuples over the given input alphabet.

INPUT:

- operator – operator to realize. It is a function which takes number_of_operands input arguments (each out of input_alphabet).
- input_alphabet – a list or other iterable.
- number_of_operands – (default: 2) it specifies the number of input arguments the operator takes.

OUTPUT:
A transducer mapping an input letter $(i_1, \ldots, i_n)$ to operator$(i_1, \ldots, i_n)$. Here, $n$ equals number_of_operands.

The input alphabet of the generated transducer is the Cartesian product of number_of_operands copies of input_alphabet.

EXAMPLES:
The following binary transducer realizes component-wise addition (this transducer is also available as `add()`):

```sage
sage: import operator
sage: T = transducers.operator(operator.add, [0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T(((0, 0), (0, 1), (1, 0), (1, 1)))
[0, 1, 1, 2]
```

Note that for a unary operator the input letters of the new transducer are tuples of length 1:

```sage
sage: T = transducers.operator(abs,
...:                           [-1, 0, 1],
...:                           number_of_operands=1)
sage: T([-1, 1, 0])
Traceback (most recent call last):
... ValueError: Invalid input sequence.
sage: T(((1,), (1,), (0,)))
[1, 1, 0]
```

Compare this with the transducer generated by `map()`:

```sage
sage: T = transducers.map(abs,
...:                        [-1, 0, 1])
sage: T([-1, 1, 0])
[1, 1, 0]
```

In fact, this transducer is also available as `abs()`:

```sage
sage: T = transducers.abs([-1, 0, 1])
sage: T([-1, 1, 0])
[1, 1, 0]
```

**sub**(*input_alphabet*)

Returns a transducer which realizes subtraction on pairs over the given input alphabet.

**INPUT:**

- *input_alphabet* – a list or other iterable.

**OUTPUT:**

A transducer mapping an input word \((i_0, i'_0) \ldots (i_k, i'_k)\) to the word \((i_0 - i'_0) \ldots (i_k - i'_k)\).

The input alphabet of the generated transducer is the Cartesian product of two copies of *input_alphabet*. 

**EXAMPLES:**
The following transducer realizes letter-wise subtraction:

```
sage: T = transducers.sub([0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|-1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|0]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, -1, 1, 0]
```

`weight(input_alphabet, zero=0)`

Returns a transducer which realizes the Hamming weight of the input over the given input alphabet.

**INPUT:**

- `input_alphabet` – a list or other iterable.
- `zero` – the zero symbol in the alphabet used

**OUTPUT:**

A transducer mapping \(i_0 \ldots i_k\) to \((i_0 \neq 0) \ldots (i_k \neq 0)\).

The Hamming weight is defined as the number of non-zero digits in the input sequence over the alphabet `input_alphabet` (see Wikipedia article Hamming weight). The output sequence of the transducer is a unary encoding of the Hamming weight. Thus the sum of the output sequence is the Hamming weight of the input.

**EXAMPLES:**

```
sage: W = transducers.weight([-1, 0, 2])
sage: W.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 2|1]
sage: unary_weight = W([-1, 0, 0, 2, -1])
sage: unary_weight
[1, 0, 0, 1, 1]
sage: weight = add(unary_weight)
sage: weight
3
```

Also the joint Hamming weight can be computed:

```
sage: v1 = vector([-1, 0])
sage: v0 = vector([0, 0])
sage: W = transducers.weight([v1, v0])
sage: unary_weight = W([v1, v0, v1, v0])
sage: add(unary_weight)
2
```
For the input alphabet \([-1, 0, 1]\) the weight transducer is the same as the absolute value transducer \(\text{abs}()\):

```python
sage: W = transducers.weight([-1, 0, 1])
sage: A = transducers.abs([-1, 0, 1])
sage: W == A
True
```

For other input alphabets, we can specify the zero symbol:

```python
sage: W = transducers.weight(['a', 'b'], zero='a')
sage: add(W(['a', 'b', 'b']))
2
```

5.1.109 Free Quasisymmetric functions

AUTHORS:

- Frédéric Chapoton, Darij Grinberg (2017)

```python
class sage.combinat.fqsym.FQSymBases(base):
    Bases: Category_realization_of_parent

    The category of graded bases of \(FQSym\) indexed by permutations.

class ElementMethods
    Bases: object

    omega_involution()

    Return the image of the element \(self\) of \(FQSym\) under the omega involution.

    The \(\omega\) involution is defined as the linear map \(FQSym \rightarrow FQSym\) that sends each basis element \(F_u\) of the F-basis of \(FQSym\) to the basis element \(F_{w_0u}\), where \(w_0\) is the longest word (i.e., \(w_0(i) = n+1-i\)) in the symmetric group \(S_n\) that contains \(u\). The \(\omega\) involution is a graded algebra automorphism and a coalgebra anti-automorphism of \(FQSym\). Every permutation \(u \in S_n\) satisfies

    \[
    \omega(F_u) = F_{w_0u}, \quad \omega(G_u) = G_{w_0u},
    \]

    where standard notations for classical bases of \(FQSym\) are being used (that is, \(F\) for the F-basis, and \(G\) for the G-basis). In other words, writing permutations in one-line notation, we have

    \[
    \omega(F(u_1, u_2, \ldots, u_n)) = F(u_n, u_{n-1}, \ldots, u_1), \quad \omega(G(u_1, u_2, \ldots, u_n)) = G(n+1-u_1, n+1-u_2, \ldots, n+1-u_n).
    \]

    If we also consider the \(\omega\) involution (\(omega_involution()\)) of the quasisymmetric functions (by slight abuse of notation), and if we let \(\pi\) be the canonical projection \(FQSym \rightarrow QSym\), then \(\pi \circ \omega = \omega \circ \pi\).

    Additionally, consider the \(\psi\) involution (\(psi_involution()\)) of the noncommutative symmetric functions, and if we let \(\iota\) be the canonical inclusion \(NSym \rightarrow FQSym\), then \(\omega \circ \iota = \iota \circ \psi\).

Todo: Duality?

See also:

\(psi_involution(), star_involution()\)

EXAMPLES:
The omega involution is an algebra homomorphism:

```
sage: (F[1,2] * F[1]).omega_involution()
sage: F[1,2].omega_involution() * F[1].omega_involution()
```

The omega involution intertwines the antipode and the inverse of the antipode:

```
sage: all( F(I).antipode().omega_involution().antipode()
....:     == F(I).omega_involution()
....:     for I in Permutations(4) )
True

Testing the $\pi \circ \omega = \omega \circ \pi$ relation noticed above:

```
sage: all( M[I].omega_involution().to_qsym()
....:     == M[I].to_qsym().omega_involution()
....:     for I in Permutations(4) )
True
```

Testing the $\omega \circ \iota = \iota \circ \psi$ relation:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].psi_involution().to_fqsym() == S[I].to_fqsym().omega_
....:     -involution()
....:     for I in Compositions(4) )
True
```

Todo: Check further commutative squares.

**psi_involution()**

Return the image of the element self of $FQSym$ under the psi involution.

The $\psi$ involution is defined as the linear map $FQSym \rightarrow FQSym$ that sends each basis element $F_u$ of the F-basis of $FQSym$ to the basis element $F_{w_0 \cdot u}$, where $w_0$ is the longest word (i.e., $w_0(i) = n+1-i$) in the symmetric group $S_n$ that contains $u$. The $\psi$ involution is a graded coalgebra automorphism and an algebra anti-automorphism of $FQSym$. Every permutation $u \in S_n$ satisfies

$$\psi(F_u) = F_{w_0 \cdot u}, \quad \psi(G_u) = G_{w_0 \cdot u}.$$
where standard notations for classical bases of $FQSym$ are being used (that is, $F$ for the $F$-basis, and $G$ for the $G$-basis). In other words, writing permutations in one-line notation, we have

$$
\psi(F(u_1, u_2, \ldots, u_n)) = F(n+1-u_1, n+1-u_2, \ldots, n+1-u_n), \quad \psi(G(u_1, u_2, \ldots, u_n)) = G(u_n, u_{n-1}, \ldots, u_1).
$$

If we also consider the $\psi$ involution (\texttt{psi_involution()}) of the quasisymmetric functions (by slight abuse of notation), and if we let $\pi$ be the canonical projection $FQSym \to QSym$, then $\pi \circ \psi = \psi \circ \pi$.

Additionally, consider the $\omega$ involution (\texttt{omega_involution()}) of the noncommutative symmetric functions, and if we let $\iota$ be the canonical inclusion $NSym \to FQSym$, then $\psi \circ \iota = \iota \circ \omega$.

Todo: Duality?

See also: \texttt{omega_involution()}, \texttt{star_involution()}

**EXAMPLES:**

```sage
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2, 3, 1]].psi_involution()
F[2, 1, 3]

sage: (3^6F[[1]] - 4^5F[[1]] + 5^4F[[1, 2]]).psi_involution()
-4^5F[[1]] + 3^6F[[1]] + 5^4F[[2, 1]]

sage: G = FQSym.G()
sage: G[[2, 3, 1]].psi_involution()
G[1, 3, 2]

sage: M = FQSym.M()
sage: M[[2, 3, 1]].psi_involution()
-M[1, 2, 3] - M[1, 3, 2] - M[2, 3, 1]
```

The $\psi$ involution intertwines the antipode and the inverse of the antipode:

```sage
sage: all( F(I).antipode().psi_involution().antipode() == F(I).psi_involution() for I in Permutations(4) )
True
```

Testing the $\pi \circ \psi = \psi \circ \pi$ relation above:

```sage
sage: all( M[I].psi_involution().to_qsym() == M[I].to_qsym().psi_involution() for I in Permutations(4) )
True
```

Testing the $\psi \circ \iota = \iota \circ \omega$ relation:

```sage
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].omega_involution().to_fqsym() == S[I].to_fqsym().psi_involution() for I in Compositions(4) )
True
```
Todo: Check further commutative squares.

```
star_involution()
```

Return the image of the element `self` of `FQSym` under the star involution.

The star involution is defined as the linear map `FQSym → FQSym` that sends each basis element \( F_u \) of the \( \mathbb{F} \)-basis of `FQSym` to the basis element \( F_{w_0 u w_0} \), where \( w_0 \) is the longest word (i.e., \( w_0(i) = n + 1 - i \)) in the symmetric group \( S_n \) that contains \( u \). The star involution is a graded Hopf algebra anti-automorphism of `FQSym`. It is denoted by \( f \mapsto f^* \). Every permutation \( u \in S_n \) satisfies

\[
(F_u)^* = F_{w_0 u w_0}, \quad (G_u)^* = G_{w_0 u w_0}, \quad (M_u)^* = M_{w_0 u w_0},
\]

where standard notations for classical bases of `FQSym` are being used (that is, \( F \) for the \( \mathbb{F} \)-basis, \( G \) for the `G`-basis, and \( M \) for the Monomial basis). In other words, writing permutations in one-line notation, we have

\[
(F(u_1, u_2, ..., u_n))^* = F(n+1-u_n, n+1-u_{n-1}, ..., n+1-u_1), \quad (G(u_1, u_2, ..., u_n))^* = G(n+1-u_n, n+1-u_{n-1}, ..., n+1-u_1),
\]

and

\[
(M(u_1, u_2, ..., u_n))^* = M(n+1-u_n, n+1-u_{n-1}, ..., n+1-u_1).
\]

Let us denote the star involution by \( (\cdot)^* \) as well.

If we also denote by \( (\cdot)^* \) the star involution of of the quasisymmetric functions (`star_involution()`)
and if we let \( \pi : FQSym \to QSym \) be the canonical projection then \( \pi \circ (\cdot)^* = (\cdot)^* \circ \pi \). Similar for the noncommutative symmetric functions (`star_involution()`) with \( \pi : NSym \to FQSym \) being the canonical inclusion and the word quasisymmetric functions (`star_involution()`) with \( \pi : FQSym \to WQSym \) the canonical inclusion.

Todo: Duality?

See also: `omega_involution()`, `psi_involution()`

EXEMPLARY:

```python
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].star_involution()
F[3, 1, 2]
sage: (3*F[[1]] - 4*F[[1]] + 5*F[[1,2]]).star_involution()
-4*F[] + 3*F[1] + 5*F[1, 2]
sage: G = FQSym.G()
sage: G[[2,3,1]].star_involution()
G[3, 1, 2]
sage: M = FQSym.M()
sage: M[[2,3,1]].star_involution()
M[3, 1, 2]
```

The star involution commutes with the antipode:
\texttt{sage: all( F(I).antipode().star_involution() \n....: == F(I).star_involution().antipode() \n....: for I in Permutations(4) )
True}

Testing the $\pi \circ (*) = (*) \circ \pi$ relation:

\texttt{sage: all( M[I].star_involution().to_qsym() \n....: == M[I].to_qsym().star_involution() \n....: for I in Permutations(4) )
True}

Similar for $NSym$:

\texttt{sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
\texttt{sage: all( S[I].star_involution().to_fqsym() == S[I].to_fqsym().star_\\\nonvolution() \n....: for I in Compositions(4) )
True}

Similar for $WQSym$:

\texttt{sage: WQSym = algebras.WQSym(ZZ)
\texttt{sage: all( F(I).to_wqsym().star_involution() \n....: == F(I).star_involution().to_wqsym() \n....: for I in Permutations(4) )
True}

\textbf{Todo:} Check further commutative squares.

\texttt{\texttt{to_qsym}()}

Return the image of \texttt{self} under the canonical projection $FQSym \to QSym$.

The canonical projection $FQSym \to QSym$ is a surjective homomorphism of Hopf algebras. It sends a basis element $F_w$ of $FQSym$ to the basis element $F_{\Comp w}$ of the fundamental basis of $QSym$, where $\Comp w$ stands for the descent composition \texttt{(sage.combinat.permutation.Permutation.descents_composition())} of the permutation $w$.

\textbf{See also:} 
\texttt{QuasiSymmetricFunctions} for a definition of $QSym$.

\textbf{EXAMPLES:}

\texttt{sage: G = algebras.FQSym(QQ).G()
sage: x = G[1, 3, 2]
sage: x.to_qsym()}
\texttt{F[2, 1]}
\texttt{sage: G[2, 3, 1].to_qsym()}
\texttt{F[1, 2]}
\texttt{sage: F = algebras.FQSym(QQ).F()}
\texttt{sage: F[2, 3, 1].to_qsym()}
\texttt{F[2, 1]}

(continues on next page)
sage: (F[2, 3, 1] + F[1, 3, 2] + F[1, 2, 3]).to_qsym()
sage: F2 = algebras.FQSym(GF(2)).F()
sage: F2[2, 3, 1].to_qsym()
F[2, 1]
sage: (F2[2, 3, 1] + F2[1, 3, 2] + F2[1, 2, 3]).to_qsym()
F[3]

\textbf{to\_symmetric\_group\_algebra}(n=\texttt{None})

Return the element of a symmetric group algebra corresponding to the element \texttt{self} of $\mathcal{F}\mathcal{Q}\mathcal{Sym}$.

**INPUT:**
- \texttt{n} – integer (default: the maximal degree of \texttt{self}); the rank of the target symmetric group algebra

**EXAMPLES:**

\begin{verbatim}
sage: A = algebras.FQSym(QQ).G()
sage: x = A([1,3,2,4]) + 5/2 * A([2,3,4,1])
sage: x.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[4, 1, 2, 3]
\end{verbatim}

\textbf{to\_wqsym}()

Return the image of \texttt{self} under the canonical inclusion map $\mathcal{F}\mathcal{Q}\mathcal{Sym} \rightarrow \mathcal{W}\mathcal{Q}\mathcal{Sym}$.

The canonical inclusion map $\mathcal{F}\mathcal{Q}\mathcal{Sym} \rightarrow \mathcal{W}\mathcal{Q}\mathcal{Sym}$ is an injective homomorphism of Hopf algebras. It sends a basis element $G_\omega$ of $\mathcal{F}\mathcal{Q}\mathcal{Sym}$ to the sum of basis elements $M_u$ of $\mathcal{W}\mathcal{Q}\mathcal{Sym}$, where $u$ ranges over all packed words whose standardization is $\omega$.

**See also:**
\texttt{WordQuasiSymmetricFunctions} for a definition of $\mathcal{W}\mathcal{Q}\mathcal{Sym}$.

**EXAMPLES:**

\begin{verbatim}
sage: G = algebras.FQSym(QQ).G()
sage: x = G[1, 3, 2]
sage: x.to_wqsym()
M[{1}, {3}, {2}] + M[{1, 3}, {2}]
sage: G[1, 2].to_wqsym()
M[{1}, {2}] + M[{1, 2}]
sage: F = algebras.FQSym(QQ).F()
sage: F[3, 1, 2].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
sage: G[2, 3, 1].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
\end{verbatim}

\textbf{class} ParentMethods

<table>
<thead>
<tr>
<th>Bases:</th>
<th>object</th>
</tr>
</thead>
</table>

\textbf{basis}(\texttt{degree=\texttt{None}})

The basis elements (optionally: of the specified degree).

**OUTPUT:** Family

**EXAMPLES:**
```python
sage: FQSym = algebras.FQSym(QQ)
sage: G = FQSym.G()
sage: G.basis()
Lazy family (Term map from Standard permutations to Free Quasi-symmetric functions over Rational Field in the G basis(i))_{i in Standard permutations}
sage: G.basis().keys()
Standard permutations
sage: G.basis(degree=3).keys()
Standard permutations of 3
sage: G.basis(degree=3).list()
[G[1, 2, 3], G[1, 3, 2], G[2, 1, 3], G[2, 3, 1], G[3, 1, 2], G[3, 2, 1]]
```

**from_symmetric_group_algebra(x)**

Return the element of $FQSym$ corresponding to the element $x$ of a symmetric group algebra.

EXAMPLES:

```python
sage: A = algebras.FQSym(QQ).F()
sage: SGA4 = SymmetricGroupAlgebra(QQ, 4)
sage: x = SGA4([1,3,2,4]) + 5/2 * SGA4([1,2,4,3])
sage: A.from_symmetric_group_algebra(x)
5/2*F[1, 2, 4, 3] + F[1, 3, 2, 4]
sage: A.from_symmetric_group_algebra(SGA4.zero())
0
```

**is_commutative()**

Return whether this $FQSym$ is commutative.

EXAMPLES:

```python
sage: F = algebras.FQSym(ZZ).F()
sage: F.is_commutative()
False
```

**is_field(proof=True)**

Return whether this $FQSym$ is a field.

EXAMPLES:

```python
sage: F = algebras.FQSym(QQ).F()
sage: F.is_field()
False
```

**one_basis()**

Return the index of the unit.

EXAMPLES:

```python
sage: A = algebras.FQSym(QQ).F()
sage: A.one_basis()
[]
```

**prec()**

Return the $<$ product.
On the F-basis of $\text{FQSym}$, this product is determined by $F_x \prec F_y = \sum F_z$, where the sum ranges over all $z$ in the shifted shuffle of $x$ and $y$ with the additional condition that the first letter of the result comes from $x$.

The usual symbol for this operation is $\prec$.

See also:

`product()`, `succ()`

**EXAMPLES:**

```python
sage: A = algebras.FQSym(QQ).F()
sage: x = A([2,1])
sage: A.prec(x, x)
sage: y = A([2,1,3])
sage: A.prec(x, y)
+ F[2, 4, 3, 5, 1]
sage: A.prec(y, x)
```

`prec_by_coercion(x, y)`

Return $x \prec y$, computed using coercion to the F-basis.

See `prec()` for the definition of the objects involved.

**EXAMPLES:**

```python
sage: G = algebras.FQSym(ZZ).G()
sage: a = G([1])
sage: b = G([2, 3, 1])
sage: G.prec(a, b) + G.succ(a, b) == a * b  # indirect doctest
True
```

`some_elements()`

Return some elements of the free quasi-symmetric functions.

**EXAMPLES:**

```python
sage: A = algebras.FQSym(QQ)
sage: F = A.F()
sage: F.some_elements()
[F[], F[1], F[1, 2] + F[2, 1], F[] + F[1, 2] + F[2, 1]]
sage: G = A.G()
sage: G.some_elements()
[G[], G[1], G[1, 2] + G[2, 1], G[] + G[1, 2] + G[2, 1]]
sage: M = A.M()
sage: M.some_elements()
[M[], M[1], M[1, 2] + 2*M[2, 1], M[] + M[1, 2] + 2*M[2, 1]]
```

`succ()`

Return the $\succ$ product.

On the F-basis of $\text{FQSym}$, this product is determined by $F_x \succ F_y = \sum F_z$, where the sum ranges over all $z$ in the shifted shuffle of $x$ and $y$ with the additional condition that the first letter of the result comes from $x$.

The usual symbol for this operation is $\succ$. 

See also:

`product()`, `prec()`
The usual symbol for this operation is $\succ$.

**See also:**

`product()`, `prec()`

**EXAMPLES:**

```
sage: A = algebras.FQSym(QQ).F()
sage: x = A([1])
sage: A.succ(x, x)
F[2, 1]
sage: y = A([3,1,2])
sage: A.succ(x, y)
F[4, 1, 2, 3] + F[4, 2, 1, 3] + F[4, 2, 3, 1]
sage: A.succ(y, x)
F[4, 3, 1, 2]
```

```
sage: G = algebras.FQSym(ZZ).G()
sage: G.succ(G([1]), G([2, 3, 1]))
# indirect doctest
```

**succ_by_coercion**($x$, $y$)

Return $x \succ y$, computed using coercion to the F-basis.

**EXAMPLES:**

```
sage: G = algebras.FQSym(ZZ).G()
sage: G.succ(G([1]), G([2, 3, 1]))
# indirect doctest
```

**super_categories**()

The super categories of `self`.

**EXAMPLES:**

```
sage: from sage.combinat.fqsym import FQSymBases
sage: FQSym = algebras.FQSym(ZZ)
sage: bases = FQSymBases(FQSym)
sage: bases.super_categories()
[Category of realizations of Free Quasi-symmetric functions over Integer Ring,
 Join of Category of realizations of hopf algebras over Integer Ring
 and Category of graded algebras over Integer Ring
 and Category of graded coalgebras over Integer Ring,
 Category of graded connected hopf algebras with basis over Integer Ring]
```

**class** `sage.combinat.fqsym.FQSymBasis_abstract`(alg)

Bases: `CombinatorialFreeModule`, `BindableClass`

Abstract base class for bases of FQSym.

This must define two attributes:

- `_prefix` – the basis prefix
- `_basis_name` – the name of the basis and must match one of the names that the basis can be constructed from FQSym
an_element()

Return an element of self.

EXAMPLES:

```sage
sage: A = algebras.FQSym(QQ)
sage: F = A.F()
sage: F.an_element()
sage: G = A.G()
sage: G.an_element()
sage: M = A.M()
sage: M.an_element()
M[1] + 2*M[1, 2] + 4*M[2, 1]
```

class sage.combinat.fqsym.FreeQuasisymmetricFunctions(R)

Bases: UniqueRepresentation, Parent

The free quasi-symmetric functions.

The Hopf algebra \( \mathcal{F} \mathcal{S} \mathcal{Y} \mathcal{M} \) of free quasi-symmetric functions over a commutative ring \( R \) is the free \( R \)-module with basis indexed by all permutations (i.e., the indexing set is the disjoint union of all symmetric groups). Its product is determined by the shifted shuffles of two permutations, whereas its coproduct is given by splitting a permutation (regarded as a word) into two (at every possible point) and standardizing the two pieces. This Hopf algebra was introduced in [MR]. See [GriRei18] (Chapter 8) for a treatment using modern notations.

In more detail: For each \( n \geq 0 \), consider the symmetric group \( S_n \). Let \( S \) be the disjoint union of the \( S_n \) over all \( n \geq 0 \). Then, \( \mathcal{F} \mathcal{S} \mathcal{Y} \mathcal{M} \) is the free \( R \)-module with basis \( (\mathcal{F} w) \) \( w \in S \). This \( R \)-module is graded, with the \( n \)-th graded component being spanned by all \( \mathcal{F} w \) for \( w \in S_n \). A multiplication is defined on \( \mathcal{F} \mathcal{S} \mathcal{Y} \mathcal{M} \) as follows: For any two permutations \( u \in S_k \) and \( v \in S_l \), we set

\[
F_u F_v = \sum F_w,
\]

where the sum is over all shuffles of \( u \) with \( v[k] \). Here, the permutations \( u \) and \( v \) are regarded as words (by writing them in one-line notation), and \( v[k] \) means the word obtained from \( v \) by increasing each letter by \( k \) (for example, \((1, 4, 2, 3))[5] = (6, 9, 7, 8)\)); and the shuffles \( w \) are translated back into permutations. This defines an associative multiplication on \( \mathcal{F} \mathcal{S} \mathcal{Y} \mathcal{M} \); its unity is \( \mathcal{F} e \), where \( e \) is the identity permutation in \( S_0 \).

In Section 1.3 of [AguSot05], Aguiar and Sottile construct a different basis of \( \mathcal{F} \mathcal{S} \mathcal{Y} \mathcal{M} \). Their basis, called the monomial basis and denoted by \((\mathcal{M} u)\), is also indexed by permutations. It is connected to the above \( F \)-basis by the relation

\[
F_u = \sum \mathcal{M}_v,
\]

where the sum ranges over all permutations \( v \) such that each inversion of \( u \) is an inversion of \( v \). (An inversion of a permutation \( w \) means a pair \((i, j)\) of positions satisfying \( i < j \) and \( w(i) > w(j) \).) The above relation yields a unitriangular change-of-basis matrix, and thus can be used to compute the \( \mathcal{M} u \) by Mobius inversion.

Another classical basis of \( \mathcal{F} \mathcal{S} \mathcal{Y} \mathcal{M} \) is \((G_w)_{w \in S}\), where \( G_w = F_{w^{-1}} \). This is just a relabeling of the basis \((F_w)_{w \in S}\), but is a more natural choice from some viewpoints.

The algebra \( \mathcal{F} \mathcal{S} \mathcal{Y} \mathcal{M} \) is often identified with (“realized as”) a subring of the ring of all bounded-degree non-commutative power series in countably many indeterminates (i.e., elements in \( R\langle \langle x_1, x_2, x_3, \ldots \rangle \rangle \) of bounded degree). Namely, consider words over the alphabet \( \{1, 2, 3, \ldots \}\); every noncommutative power series is an infinite \( R \)-linear combination of these words. Consider the \( R \)-linear map that sends each \( G_u \) to the sum of all words whose standardization (also known as “standard permutation”; see \texttt{standard_permutation()} \) is \( u \). This map is an injective \( R \)-algebra homomorphism, and thus embeds \( \mathcal{F} \mathcal{S} \mathcal{Y} \mathcal{M} \) into the latter ring.
As an associative algebra, $FQSym$ has the richer structure of a dendriform algebra. This means that the associative product $*$ is decomposed as a sum of two binary operations

$$xy = x \succ y + x \prec y$$

that satisfy the axioms:

$$(x \succ y) \prec z = x \succ (y \prec z),$$

$$(x \prec y) \prec z = x \prec (yz),$$

$$(xy) \succ z = x \succ (y \succ z).$$

These two binary operations are defined similarly to the (associative) product above: We set

$$F_u \prec F_v = \sum F_w,$$

where the sum is now over all shuffles of $u$ with $v[k]$ whose first letter is taken from $u$ (rather than from $v[k]$). Similarly,

$$F_u \succ F_v = \sum F_w,$$

where the sum is over all remaining shuffles of $u$ with $v[k]$.

**Todo:** Decide what $1 \prec 1$ and $1 \succ 1$ are.

**Note:** The usual binary operator $*$ is used for the associative product.

**EXAMPLES:**

```python
sage: F = algebras.FQSym(ZZ).F()
sage: x,y,z = F([1]), F([1,2]), F([1,3,2])
sage: (x * y) * z
F[1, 2, 3, 4, 6, 5] + ...
```

The product of $FQSym$ is associative:

```python
sage: x * (y * z) == (x * y) * z
True
```

The associative product decomposes into two parts:

```python
sage: x * y == F.prec(x, y) + F.succ(x, y)
True
```

The axioms of a dendriform algebra hold:

```python
sage: F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
sage: F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
sage: F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```
**FQSym** is also known as the Malvenuto-Reutenauer algebra:

```python
sage: algebras.MalvenutoReutenauer(ZZ)
Free Quasi-symmetric functions over Integer Ring
```

**REFERENCES:**
- [MR]
- [LR1998]
- [GriRei18]

**class F(alg)**

Bases: `FQSymBasis_abstract`

The F-basis of **FQSym**.

This is the basis $(F_w)$, with $w$ ranging over all permutations. See the documentation of `FreeQuasisymmetricFunctions` for details.

**EXAMPLES:**

```python
sage: FQSym = algebras.FQSym(QQ)
sage: FQSym.F()
Free Quasi-symmetric functions over Rational Field in the F basis
```

**class Element**

Bases: `IndexedFreeModuleElement`

**to_symmetric_group_algebra**(*n=None*)

Return the element of a symmetric group algebra corresponding to the element `self` of **FQSym**.

**INPUT:**
- `n` – integer (default: the maximal degree of `self`); the rank of the target symmetric group algebra

**EXAMPLES:**

```python
sage: A = algebras.FQSym(QQ).F()
sage: x = A([1,3,2,4]) + 5/2 * A([1,2,4,3])
sage: x.to_symmetric_group_algebra()
5/2*[1, 2, 4, 3] + [1, 3, 2, 4]
sage: x.to_symmetric_group_algebra(n=7)
5/2*[1, 2, 4, 3, 5, 6, 7] + [1, 3, 2, 4, 5, 6, 7]
sage: a = A.zero().to_symmetric_group_algebra(); a
0
sage: parent(a)
Symmetric group algebra of order 0 over Rational Field
```

**coproduct_on_basis**(x)

Return the coproduct of $F_\sigma$ for $\sigma$ a permutation (here, $\sigma$ is x).

**EXAMPLES:**
sage: A = algebras.FQSym(QQ).F()
sage: x = A(1)

sage: ascii_art(A.coproduct(A.one()))  # indirect doctest
1 # 1

sage: ascii_art(A.coproduct(x))  # indirect doctest
1 # F + F # 1
    [1]  [1]

sage: A = algebras.FQSym(QQ).F()
sage: x, y, z = A(1), A([2,1]), A([3,2,1])
sage: A.coproduct(z)

degree_on_basis(\(t\))

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the \(n\) for which the permutation belongs to \(S_n\)).

EXAMPLES:

sage: A = algebras.FQSym(QQ).F()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2

prec_product_on_basis(\(x, y\))

Return the \(\prec\) product of two permutations.

This is the shifted shuffle of \(x\) and \(y\) with the additional condition that the first letter of the result comes from \(x\).

The usual symbol for this operation is \(\prec\).

See also:

product_on_basis(), succ_product_on_basis()

EXAMPLES:

sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([2,1])
sage: A.prec_product_on_basis(x, x)
sage: y = Permutation([])
sage: A.prec_product_on_basis(x, y) == A(x)
True
sage: A.prec_product_on_basis(y, x) == 0
True

product_on_basis(\(x, y\))

Return the \(\ast\) associative product of two permutations.

This is the shifted shuffle of \(x\) and \(y\).
See also:

\texttt{succ\_product\_on\_basis()}, \texttt{prec\_product\_on\_basis()}

EXAMPLES:

\begin{verbatim}
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1])
sage: A.product_on_basis(x, x)
F[1, 2] + F[2, 1]
sage: A.succ_product_on_basis(x, x)
F[3, 1, 2, 4] + F[3, 1, 4, 2] + F[3, 4, 1, 2]
sage: y = Permutation([])
sage: A.succ_product_on_basis(x, y) == 0
True
sage: A.succ_product_on_basis(y, x) == A(x)
True
\end{verbatim}

\texttt{succ\_product\_on\_basis}(x, y)

Return the \(\succ\) product of two permutations.

This is the shifted shuffle of \(x\) and \(y\) with the additional condition that the first letter of the result comes from \(y\).

The usual symbol for this operation is \(\succ\).

See also:

\textbullet\ \texttt{product\_on\_basis()}, \texttt{prec\_product\_on\_basis()}

EXAMPLES:

\begin{verbatim}
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1,2])
sage: A.succ_product_on_basis(x, x)
F[3, 1, 2, 4] + F[3, 1, 4, 2] + F[3, 4, 1, 2]
sage: y = Permutation([])
sage: A.succ_product_on_basis(x, y) == 0
True
sage: A.succ_product_on_basis(y, x) == A(x)
True
\end{verbatim}

class \texttt{G(alg)}

Bases: \texttt{FQSymBasis\_abstract}

The G-basis of \texttt{FQSym}.

This is the basis \((G_w)\), with \(w\) ranging over all permutations. See the documentation of \texttt{FreeQuasisymmetricFunctions} for details.

EXAMPLES:

\begin{verbatim}
sage: FQSym = algebras.FQSym(QQ)
sage: G = FQSym.G(); G
Free Quasi-symmetric functions over Rational Field in the G basis
sage: G([3, 1, 2]).coproduct()
sage: G([3, 1, 2]) * G([2, 1])
\end{verbatim}
degree_on_basis($t$)
Return the degree of a permutation in the algebra of free quasi-symmetric functions.
This is the size of the permutation (i.e., the $n$ for which the permutation belongs to $S_n$).

EXAMPLES:
```
sage: A = algebras.FQSym(QQ).G()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2
```

class M($\text{alg}$)
Bases: FQSymBasis_abstract
The M-basis of $\mathcal{FQSym}$.
This is the Monomial basis ($\mathcal{M}_w$), with $w$ ranging over all permutations. See the documentation of FQSym for details.

EXAMPLES:
```
sage: FQSym = algebras.FQSym(QQ)
sage: M = FQSym.M(); M
Free Quasi-symmetric functions over Rational Field in the Monomial basis
sage: M[[3, 1, 2]].coproduct()
sage: M[[3, 2, 1]].coproduct()
sage: M[[1, 2]] * M[[1]]
```

class Element
Bases: IndexedFreeModuleElement

star_involution()
Return the image of the element self of $\mathcal{FQSym}$ under the star involution.
See FQSymBases.ElementMethods.star_involution() for a definition of the involution and for examples.
See also:
omega_involution().psi_involution()

EXAMPLES:
```
sage: FQSym = algebras.FQSym(ZZ)
sage: M = FQSym.M()
sage: M[[2,3,1]].star_involution()
M[3, 1, 2]
sage: M[].star_involution()
M[]
```
**coproduct_on_basis(\(x\))**

Return the coproduct of \(M_\sigma\) for \(\sigma\) a permutation (here, \(\sigma\) is \(x\)).

This uses Theorem 3.1 in [AguSot05].

**EXAMPLES:**

```python
sage: M = algebras.FQSym(QQ).M()
sage: x = M([1])
sage: ascii_art(M.coproduct(M.one()))  # indirect doctest
1 # 1
sage: ascii_art(M.coproduct(x))  # indirect doctest
1 # M + M # 1
   [1]   [1]
sage: M.coproduct(M([2, 1, 3]))
M[] # M[2, 1, 3] + M[2, 1, 3] # M[]
sage: M.coproduct(M([2, 3, 1]))
sage: M.coproduct(M([3, 2, 1]))
   + M[3, 2, 1] # M[]
sage: M.coproduct(M([3, 4, 2, 1]))
   + M[3, 4, 2, 1] # M[]
sage: M.coproduct(M([3, 4, 1, 2]))
```

**degree_on_basis()**

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the \(n\) for which the permutation belongs to \(S_n\)).

**EXAMPLES:**

```python
sage: A = algebras.FQSym(QQ).M()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2
```

**a_realization()**

Return a particular realization of \(self\) (the F-basis).

**EXAMPLES:**

```python
sage: FQSym = algebras.FQSym(QQ)
sage: FQSym.a_realization()
Free Quasi-symmetric functions over Rational Field in the F basis
```
5.1.110 Free modules

class sage.combinat.free_module.CartesianProductWithFlattening(flatten)
    Bases: object

    A class for Cartesian product constructor, with partial flattening

class sage.combinat.free_module.CombinatorialFreeModule(R, basis_keys=None, element_class=None, category=None, prefix=None, names=None, **kwds)
    Bases: UniqueRepresentation, Module, IndexedGenerators

    Class for free modules with a named basis

    INPUT:
    
    • R - base ring
    • basis_keys - list, tuple, family, set, etc. defining the indexing set for the basis of this module
    • element_class - the class of which elements of this module should be instances (optional, default None, in which case the elements are instances of IndexedFreeModuleElement)
    • category - the category in which this module lies (optional, default None, in which case use the "category of modules with basis" over the base ring R); this should be a subcategory of ModulesWithBasis

    For the options controlling the printing of elements, see IndexedGenerators.

    Note: These print options may also be accessed and modified using the print_options() method, after the module has been defined.

    EXAMPLES:

    We construct a free module whose basis is indexed by the letters a, b, c:

    sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
    sage: F
    Free module generated by {'a', 'b', 'c'} over Rational Field

    Its basis is a family, indexed by a, b, c:

    sage: e = F.basis()
    sage: e
    Finite family {'a': B['a'], 'b': B['b'], 'c': B['c']}

    sage: [x for x in e]
    [B['a'], B['b'], B['c']]
    sage: [k for k in e.keys()]
    ['a', 'b', 'c']

    Let us construct some elements, and compute with them:

    sage: e['a']
    B['a']
    sage: 2*e['a']
    2*B['a']
    (continues on next page)
Some uses of `sage.categories.commutative_additive_semigroups.CommutativeAdditiveSemigroups.ParentMethods.summation()` and `sum()`:

```python
sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.summation(F.monomial(1), F.monomial(3))
sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.sum(F.monomial(i) for i in [1,2,3])
```

Note that free modules with a given basis and parameters are unique:

```python
sage: F1 = CombinatorialFreeModule(QQ, (1,2,3,4))
sage: F1 is F
True
```

The identity of the constructed free module depends on the order of the basis and on the other parameters, like the prefix. Note that `CombinatorialFreeModule` is a `UniqueRepresentation`. Hence, two combinatorial free modules evaluate equal if and only if they are identical:

```python
sage: F1 = CombinatorialFreeModule(QQ, (1,2,3,4))
sage: F1 is F
True
sage: F1 = CombinatorialFreeModule(QQ, [4,3,2,1])
sage: F1 == F
False
sage: F2 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F')
sage: F2 == F
False
```

Because of this, if you create a free module with certain parameters and then modify its prefix or other print options, this affects all modules which were defined using the same parameters.

```python
sage: F2.print_options(prefix='x')
sage: F2.prefix()
'x'
sage: F3 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F')
sage: F3 is F2  # F3 was defined just like F2
True
sage: F3.prefix()
'x'
sage: F4 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F', bracket=True)
sage: F4 == F2  # F4 was NOT defined just like F2
False
sage: F4.prefix()
'F'
sage: F2.print_options(prefix='F')  #reset for following doctests
```

The constructed module is in the category of modules with basis over the base ring:
CombinatorialFreeModule(QQ, Partitions()).category()  # →
Category of vector spaces with basis over Rational Field

If furthermore the index set is finite (i.e. in the category Sets().Finite()), then the module is declared as being finite dimensional:

CombinatorialFreeModule(QQ, [1,2,3,4]).category()
Category of finite dimensional vector spaces with basis over Rational Field

CombinatorialFreeModule(QQ, Partitions(3), # →
˓→optional - sage.combinat
˓→category=Algebras(QQ).WithBasis()).category()
Category of finite dimensional algebras with basis over Rational Field

See sage.categories.examples.algebras_with_basis and sage.categories.examples.hopf_algebras_with_basis for illustrations of the use of the category keyword, and see sage.combinat.root_system.weight_space.WeightSpace for an example of the use of element_class.

Customizing print and LaTeX representations of elements:

F = CombinatorialFreeModule(QQ, ['a','b'], prefix='x')
original_print_options = F.print_options()
sorted(original_print_options.items())
[('bracket', None), ('iterate_key', False),
('latex_bracket', False), ('latex_names', None),
('latex_prefix', None), ('latex_scalar_mult', None),
('names', None), ('prefix', 'x'), ('scalar_mult', '*'),
('sorting_key', <function ...<lambda> at ...>),
('sorting_reverse', False), ('string_quotes', True),
('tensor_symbol', None)]

e = F.basis()
e['a'] - 3 * e['b']
x['a'] - 3*x['b']

F.print_options(prefix='x', scalar_mult=' ', bracket='{}')
e['a'] - 3 * e['b']
x{'a'} - 3 x{'b'}

F.print_options(latex_prefix='y')
F.print_options(sorting_reverse=True)
e['a'] - 3 * e['b']
-3 x{'b'} + x{'a'}

F.print_options(**original_print_options)  # reset print options

F = CombinatorialFreeModule(QQ, [(1,2), (3,4)])
e = F.basis()
Combinatorics, Release 10.1

(continued from previous page)

\begin{verbatim}
sage: e[(1,2)] - 3 * e[(3,4)]
B[(1, 2)] - 3*B[(3, 4)]

sage: F.print_options(bracket=['_','_'])
sage: e[(1,2)] - 3 * e[(3,4)]
B_{(1, 2)} - 3*B_{(3, 4)}

sage: F.print_options(prefix='', bracket=False)
sage: e[(1,2)] - 3 * e[(3,4)]
(1, 2) - 3*(3, 4)
\end{verbatim}

CartesianProduct
alias of CombinatorialFreeModule_CartesianProduct

Element
alias of IndexedFreeModuleElement

Tensor
alias of CombinatorialFreeModule_Tensor

c\text{hange\_ring}(R)
Return the base change of self to \(R\).

EXAMPLES:

\begin{verbatim}
sage: F = CombinatorialFreeModule(ZZ, ['a','b','c']); F
Free module generated by \{a', b', c'\} over Integer Ring
sage: F_QQ = F.change_ring(QQ); F_QQ
Free module generated by \{a', b', c'\} over Rational Field
sage: F_QQ.change_ring(ZZ) == F
True
\end{verbatim}

c\text{onstruction}()
The construction functor and base ring for self.

EXAMPLES:

\begin{verbatim}
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'],
                          category=AlgebrasWithBasis(QQ))
sage: F.construction()
(VectorFunctor, Rational Field)
\end{verbatim}

c\text{dimension}()
Return the dimension of the free module (which is given by the number of elements in the basis).

EXAMPLES:

\begin{verbatim}
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.dimension()
3
sage: F.basis().cardinality()
3
sage: F.basis().keys().cardinality()
3
\end{verbatim}
Rank is available as a synonym:

```
sage: F.rank()
3
```

```
sage: s = SymmetricFunctions(QQ).schur()  # optional - sage.combinat
sage: s.dimension()  # optional - sage.combinat
+Infinity
```

**element_class()**

The (default) class for the elements of this parent

Overrides `Parent.element_class()` to force the construction of Python class. This is currently needed to inherit really all the features from categories, and in particular the initialization of `_mul_` in `Magmas.PARENT_METHODS__init_extra__()`.

**EXAMPLES:**

```
sage: A = Algebras(QQ).WithBasis().example(); A  # optional - sage.combinat
An example of an algebra with basis:
the free algebra on the generators ('a', 'b', 'c') over Rational Field

sage: A.element_class.mro()  # optional - sage.combinat
[<class 'sage.categories.examples.algebras_with_basis.FreeAlgebra_with_category.element_class'>,
 <class 'sage.modules.with_basis.indexed_element.IndexedFreeModuleElement'>,
 ...]

sage: a,b,c = A.algebra_generators()  # optional - sage.combinat
sage: a * b  # optional - sage.combinat
B[word: ab]
```

**from_vector(vector, order=None, coerce=True)**

Build an element of `self` from a (sparse) vector.

**See also:**

`get_order()`, `CombinatorialFreeModule.Element._vector_()`

**EXAMPLES:**

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)  # optional - sage.combinat
sage: b = QS3.from_vector(vector((2, 0, 0, 0, 0, 4))); b  # optional - sage.combinat
2*[1, 2, 3] + 4*[3, 2, 1]

sage: a = 2*QS3([1,2,3]) + 4*QS3([3,2,1])  # optional - sage.combinat
sage: a == b  # optional - sage.combinat
True
```
get_order()

Return the order of the elements in the basis.

EXAMPLES:

```
sage: QS2 = SymmetricGroupAlgebra(QQ,2)  # optional - sage.combinat
sage: QS2.get_order()  # note: order changed on 2009-03-13  # optional - sage.combinat
[[2, 1], [1, 2]]
```

get_order_key()

Return a comparison key on the basis indices that is compatible with the current term order.

EXAMPLES:

```
sage: A = FiniteDimensionalAlgebrasWithBasis(QQ).example()
sage: A.set_order(['x', 'y', 'a', 'b'])
sage: Akey = A.get_order_key()
sage: sorted(A.basis().keys(), key=Akey)
['x', 'y', 'a', 'b']
sage: A.set_order(list(reversed(A.basis().keys())))
sage: Akey = A.get_order_key()
sage: sorted(A.basis().keys(), key=Akey)
['b', 'a', 'y', 'x']
```

is_exact()

Return True if elements of self have exact representations, which is true of self if and only if it is true of self.basis().keys() and self.base_ring().

EXAMPLES:

```
sage: GroupAlgebra(GL(3, GF(7))).is_exact()  # optional - sage.groups sage.rings.finite_rings
True
sage: GroupAlgebra(GL(3, GF(7)), RR).is_exact()  # optional - sage.groups sage.rings.finite_rings
False
sage: GroupAlgebra(GL(3, pAdicRing(7))).is_exact()  # not implemented correctly
(not my fault)!  # optional - sage.groups sage.rings.padics
False
```

linear_combination(iter_of_elements_coeff, factor_on_left=True)

Return the linear combination \( \lambda_1 v_1 + \cdots + \lambda_k v_k \) (resp. the linear combination \( v_1 \lambda_1 + \cdots + v_k \lambda_k \)) where iter_of_elements_coeff iterates through the sequence \((v_1, \lambda_1), \ldots, (v_k, \lambda_k)\).

INPUT:

- **iter_of_elements_coeff** – iterator of pairs (element, coeff) with element in self and coeff in self.base_ring()
- **factor_on_left** – (optional) if True, the coefficients are multiplied from the left if False, the coefficients are multiplied from the right

EXAMPLES:
```python
sage: F = CombinatorialFreeModule(QQ, [1,2])
sage: f = F.an_element(); f
sage: F.linear_combination( (f,i) for i in range(5) )
```

### monomial()

Return the basis element indexed by $i$.

**INPUT:**

- $i$ – an element of the index set

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.monomial('a')
B['a']
```

$F.monomial$ is in fact (almost) a map:

```python
sage: F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'} over Rational Field
```

### rank()

Return the dimension of the free module (which is given by the number of elements in the basis).

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.rank()
3
```

**Rank is available as a synonym:**

```python
sage: F.rank()
3
```

```python
sage: s = SymmetricFunctions(QQ).schur()
  # optional - sage.combinat
sage: s.dimension()
  # optional - sage.combinat
+Infinity
```

### set_order(order)

Set the order of the elements of the basis.

If $set_order()$ has not been called, then the ordering is the one used in the generation of the elements of self’s associated enumerated set.
**Warning:** Many cached methods depend on this order, in particular for constructing subspaces and quotients. Changing the order after some computations have been cached does not invalidate the cache, and is likely to introduce inconsistencies.

**EXAMPLES:**

```python
sage: QS2 = SymmetricGroupAlgebra(QQ,2)  # optional - sage.combinat
sage: b = list(QS2.basis().keys())  # optional - sage.combinat
sage: b.reverse()  # optional - sage.combinat
sage: QS2.set_order(b)  # optional - sage.combinat
sage: QS2.get_order()  # optional - sage.combinat
[[2, 1], [1, 2]]
```

### sum(iter_of_elements)

Return the sum of all elements in `iter_of_elements`.

Overrides method inherited from commutative additive monoid as it is much faster on dicts directly.

**INPUT:**

- `iter_of_elements` – iterator of elements of `self`

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(QQ,[1,2])
sage: f = F.an_element(); f
sage: F.sum( f for _ in range(5) )
```

### sum_of_terms(terms, distinct=False)

Construct a sum of terms of `self`.

**INPUT:**

- `terms` – a list (or iterable) of pairs (index, coeff)
- `distinct` – (default: False) whether the indices are guaranteed to be distinct

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.sum_of_terms(((('a',2), ('c',3))))
2*B['a'] + 3*B['c']
```

If `distinct` is True, then the construction is optimized:

```python
sage: F.sum_of_terms(((('a',2), ('c',3)), distinct = True))
2*B['a'] + 3*B['c']
```
**Warning:** Use `distinct=True` only if you are sure that the indices are indeed distinct:

```sage
F.sum_of_terms([('a',2), ('a',3)], distinct = True)
3*B['a']
```

Extreme case:

```sage
F.sum_of_terms([])
0
```

### term(index, coeff=None)

Construct a term in `self`.

**INPUT:**

- `index` – the index of a basis element
- `coeff` – an element of the coefficient ring (default: one)

**EXAMPLES:**

```sage
F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.term('a', 3)
3*B['a']
sage: F.term('a')
B['a']
```

Design: should this do coercion on the coefficient ring?

### zero()

**EXAMPLES:**

```sage
F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.zero()
0
```

---

**class** `sage.combinat.free_module.CombinatorialFreeModule_CartesianProduct` *(modules, **options)*

**Bases:** `CombinatorialFreeModule`

An implementation of Cartesian products of modules with basis

**EXAMPLES:**

We construct two free modules, assign them short names, and construct their Cartesian product:

```sage
F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
H = CombinatorialFreeModule(ZZ, [4,7]); H.rename("H")
sage: S = cartesian_product([F, G])
sage: S
F (+) G
sage: S.basis()
Lazy family (Term map
from Disjoint union of Family ({4, 5}, {4, 6})
to F (+) G(i))_{i in Disjoint union of Family ({4, 5}, {4, 6})}
```
Note that the indices of the basis elements of $F$ and $G$ intersect non trivially. This is handled by forcing the union to be disjoint:

```python
sage: list(S.basis())
[B[(0, 4)], B[(0, 5)], B[(1, 4)], B[(1, 6)]]
```

We now compute the Cartesian product of elements of free modules:

```python
sage: f = F.monomial(4) + 2*F.monomial(5)
sage: g = 2*G.monomial(4) + G.monomial(6)
sage: h = H.monomial(4) + H.monomial(7)
sage: cartesian_product([f, g])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)]
sage: cartesian_product([f, g, h])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)] + B[(2, 4)] + B[(2, 7)]
sage: cartesian_product([f, g, h]).parent()
F (+) G (+) H
```

TODO: choose an appropriate semantic for Cartesian products of Cartesian products (associativity?):

```python
sage: S = cartesian_product([cartesian_product([F, G]), H])
```

```python
class Element
Bases: IndexedFreeModuleElement
cartesian_embedding(i)

Return the natural embedding morphism of the $i$-th Cartesian factor (summand) of $self$ into $self$.

INPUT:

• $i$ – an integer

EXAMPLES:

```python
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
sage: S = cartesian_product([F, G])
sage: phi = S.cartesian_embedding(0)
sage: phi(F.monomial(4) + 2 * F.monomial(5))
B[(0, 4)] + 2*B[(0, 5)]
sage: phi(F.monomial(4) + 2 * F.monomial(6)).parent() == S
True
```
```

cartesian_factors()

Return the factors of the Cartesian product.

EXAMPLES:

```python
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
sage: S = cartesian_product([F, G])
sage: S.cartesian_factors()
(F, G)
```
cartesian_projection(i)

Return the natural projection onto the i-th Cartesian factor (summand) of self.

INPUT:

• i – an integer

EXAMPLES:

```sage
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
sage: S = cartesian_product([F, G])
sage: x = S.monomial((0,4)) + 2 * S.monomial((0,5)) + 3 * S.monomial((1,6))
sage: S.cartesian_projection(0)(x)
sage: S.cartesian_projection(1)(x)
3*B[6]
sage: S.cartesian_projection(0)(x).parent() == F
True
sage: S.cartesian_projection(1)(x).parent() == G
True
```

summand_embedding(i)

Return the natural embedding morphism of the i-th Cartesian factor (summand) of self into self.

INPUT:

• i – an integer

EXAMPLES:

```sage
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
sage: S = cartesian_product([F, G])
sage: phi = S.cartesian_embedding(0)
sage: phi(F.monomial(4) + 2 * F.monomial(5))
B[(0, 4)] + 2*B[(0, 5)]
sage: phi(F.monomial(4) + 2 * F.monomial(6)).parent() == S
True
```

summand_projection(i)

Return the natural projection onto the i-th Cartesian factor (summand) of self.

INPUT:

• i – an integer

EXAMPLES:

```sage
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
sage: S = cartesian_product([F, G])
sage: x = S.monomial((0,4)) + 2 * S.monomial((0,5)) + 3 * S.monomial((1,6))
sage: S.cartesian_projection(0)(x)
sage: S.cartesian_projection(1)(x)
3*B[6]
sage: S.cartesian_projection(0)(x).parent() == F
(continues on next page)
```
Combinatorics, Release 10.1

class sage.combinat.free_module.CombinatorialFreeModule_Tensor(modules, **options)
Bases: CombinatorialFreeModule

Tensor Product of Free Modules

EXAMPLES:
We construct two free modules, assign them short names, and construct their tensor product:

\[
\begin{align*}
\text{sage: } & F = \text{CombinatorialFreeModule}(\mathbb{Z}, [1,2]); F.rename("F") \\
\text{sage: } & G = \text{CombinatorialFreeModule}(\mathbb{Z}, [3,4]); G.rename("G") \\
\text{sage: } & T = \text{tensor}([F, G]); T \\
& F \# G \\
\text{sage: } & T.category() \\
& \text{Category of tensor products of finite dimensional modules with basis over Integer Ring} \\
\text{sage: } & T.construction() \quad \# \text{todo: not implemented} \\
& \text{[tensor, ]} \\
\end{align*}
\]

T is a free module, with same base ring as F and G:

\[
\begin{align*}
\text{sage: } & T.base_ring() \\
& \text{Integer Ring} \\
\text{sage: } & T.basis().keys().list() \\
& [(1, 3), (1, 4), (2, 3), (2, 4)] \\
\end{align*}
\]

FIXME: Should elements of a CartesianProduct be tuples (making them hashable)?

Here are the basis elements themselves:

\[
\begin{align*}
\text{sage: } & T.basis().cardinality() \\
& 4 \\
\text{sage: } & \text{list}(T.basis()) \\
\end{align*}
\]

The tensor product is associative and flattens sub tensor products:

\[
\begin{align*}
\text{sage: } & H = \text{CombinatorialFreeModule}(\mathbb{Z}, [5,6]); H.rename("H") \\
\text{sage: } & \text{tensor}([F, \text{tensor}([G, H])]) \\
& F \# G \# H \\
\text{sage: } & \text{tensor}([\text{tensor}([F, G]), H]) \\
& F \# G \# H \\
\end{align*}
\]
We now compute the tensor product of elements of free modules:

```
sage: f = F.monomial(1) + 2 * F.monomial(2)
sage: g = 2*G.monomial(3) + G.monomial(4)
sage: h = H.monomial(5) + H.monomial(6)
sage: tensor([f, g])
```

Again, the tensor product is associative on elements:

```
sage: tensor([f, tensor([g, h])]) == tensor([f, g, h])
True
sage: tensor([tensor([f, g]), h]) == tensor([f, g, h])
True
```

Note further that the tensor product spaces need not preexist:

```
sage: t = tensor([f, g, h])
sage: t.parent()
F # G # H
```

`tensor_constructor(modules)`

**INPUT:**

- `modules` – a tuple $(F_1, \ldots, F_n)$ of free modules whose tensor product is self

Returns the canonical multilinear morphism from $F_1 \times \cdots \times F_n$ to $F_1 \otimes \cdots \otimes F_n$

**EXAMPLES:**

```
sage: F = CombinatorialFreeModule(ZZ, [1,2]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [3,4]); G.rename("G")
sage: H = CombinatorialFreeModule(ZZ, [5,6]); H.rename("H")

sage: f = F.monomial(1) + 2*F.monomial(2)
sage: g = 2*G.monomial(3) + G.monomial(4)
sage: h = H.monomial(5) + H.monomial(6)
sage: FG = tensor([F, G])
sage: phi_fg = FG.tensor_constructor((F, G))
sage: phi_fg(f, g)

sage: FGH = tensor([F, G, H])
sage: phi_fgh = FGH.tensor_constructor((F, G, H))
sage: phi_fgh(f, g, h)

sage: phi_fg_h = FGH.tensor_constructor((F, G, H))
sage: phi_fg_h(phi_fg(f, g), h)
```

(continues on next page)

tensor_factors()  
Return the tensor factors of this tensor product.

EXAMPLES:

```python
sage: F = CombinatorialFreeModule(ZZ, [1,2])
sage: F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [3,4])
sage: G.rename("G")
sage: T = tensor([F, G]); T
F # G
sage: T.tensor_factors()
(F, G)
```

### 5.1.111 Free Dendriform Algebras

AUTHORS:

Frédéric Chapoton (2017)

class sage.combinat.free_dendriform_algebra.DendriformFunctor(vars)

Bases: ConstructionFunctor

A constructor for dendriform algebras.

EXAMPLES:

```python
sage: P = algebras.FreeDendriform(ZZ, 'x,y')
sage: x, y = P.gens()
sage: F = P.construction()[0]; F
Dendriform[x,y]

sage: A = GF(5)['a,b']
sage: a, b = A.gens()
sage: F(A)
Free Dendriform algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5

sage: f = A.hom([a+b,a-b],A)
sage: F(f)
Generic endomorphism of Free Dendriform algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5

sage: F(f)(a * F(A)(x))
(a+b)*B[x[[],[]]]
```

merge(other)

Merge self with another construction functor, or return None.

EXAMPLES:
sage: F = sage.combinat.free_dendriform_algebra.DendriformFunctor(['x', 'y'])
sage: G = sage.combinat.free_dendriform_algebra.DendriformFunctor(['t'])
sage: F.merge(G)
Dendriform[x,y,t]
sage: F.merge(F)
Dendriform[x,y]

Now some actual use cases:

sage: R = algebras.FreeDendriform(ZZ, ['x','y','z'])
sage: x,y,z = R.gens()
sage: 1/2 * x
1/2*B[x[., .]]
sage: parent(1/2 * x)
Free Dendriform algebra on 3 generators ['x', 'y', 'z'] over Rational Field

sage: S = algebras.FreeDendriform(QQ, ['z','t'])
sage: z,t = S.gens()
sage: x + t
B[t[., .]] + B[x[., .]]
sage: parent(x + t)
Free Dendriform algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field

rank = 9

class sage.combinat.free_dendriform_algebra.FreeDendriformAlgebra(R, names=None)

Bases: CombinatorialFreeModule

The free dendriform algebra.

Dendriform algebras are associative algebras, where the associative product $*$ is decomposed as a sum of two binary operations

\[ x * y = x \succ y + x \prec y \]

that satisfy the axioms:

\[ (x \succ y) \prec z = x \succ (y \prec z), \]
\[ (x \prec y) \prec z = x \prec (y * z). \]
\[ (x * y) \succ z = x \succ (y \succ z). \]

The free Dendriform algebra on a given set $E$ has an explicit description using (planar) binary trees, just as the free associative algebra can be described using words. The underlying vector space has a basis indexed by finite binary trees endowed with a map from their vertices to $E$. In this basis, the associative product of two (decorated) binary trees $S * T$ is the sum over all possible ways of identifying (glueing) the rightmost path in $S$ and the leftmost path in $T$.

The decomposition of the associative product as the sum of two binary operations $\succ$ and $\prec$ is made by separating the terms according to the origin of the root vertex. For $x \succ y$, one keeps the terms where the root vertex comes from $y$, whereas for $x \prec y$ one keeps the terms where the root vertex comes from $x$.

The free dendriform algebra can also be considered as the free algebra over the Dendriform operad.

Note: The usual binary operator $*$ is used for the associative product.
EXAMPLES:

```python
sage: F = algebras.FreeDendriform(ZZ, 'xyz')
sage: x,y,z = F.gens()
sage: (x * y) * z
B[x[., y[., z[., .]], .]], B[x[., z[y[., .], .]], .], B[y[x[., .], z[., .]], .], B[z[x[., y[., .]], .], .], B[z[y[x[., .]], .], .]
```

The free dendriform algebra is associative:

```python
sage: x * (y * z) == (x * y) * z
True
```

The associative product decomposes in two parts:

```python
sage: x * y == F.prec(x, y) + F.succ(x, y)
True
```

The axioms hold:

```python
sage: F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
sage: F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
sage: F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

When there is only one generator, unlabelled trees are used instead:

```python
sage: F1 = algebras.FreeDendriform(QQ)
sage: w = F1.gen(0); w
B[., .]
sage: w * w * w
B[., [., [., .]]], B[., [[., .], .]], B[[., .], [., .]], B[[., .], [., .]], B[[., .], [., .]], B[[., .], [., .]]
```

The set $E$ can be infinite:

```python
sage: F = algebras.FreeDendriform(QQ, ZZ)
sage: w = F.gen(1); w
B[1[., .]]
sage: x = F.gen(2); x
B[-1[., .]]
sage: w*x
B[-1[1[., .], .]], B[1[., -1[., .]]]
```

REFERENCES:

- [LR1998]

`algebra_generators()`

Return the generators of this algebra.

These are the binary trees with just one vertex.

EXAMPLES:
sage: A = algebras.FreeDendriform(ZZ, 'fgh'); A
Free Dendriform algebra on 3 generators ['f', 'g', 'h']
over Integer Ring
sage: list(A.algebra_generators())
[BB[., .], BB[., .], BB[., .]]

sage: A = algebras.FreeDendriform(QQ, ['x1', 'x2'])
sage: list(A.algebra_generators())
[BB[x1[., .], BB[x2[., .], .]]

an_element()

Return an element of self.

EXAMPLES:

sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.an_element()
BB[x[., .]] + 2*BB[x[., x[., .]]] + 2*BB[BB[x[., .], .]]

change_ring(R)

Return the free dendriform algebra in the same variables over \( R \).

INPUT:

- \( R \) – a ring

EXAMPLES:

sage: A = algebras.FreeDendriform(ZZ, 'fgh')
sage: A.change_ring(QQ)
Free Dendriform algebra on 3 generators ['f', 'g', 'h'] over
Rational Field

construction()

Return a pair \((F, R)\), where \( F \) is a \texttt{DendriformFunctor} and \( R \) is a ring, such that \( F(R) \) returns self.

EXAMPLES:

sage: P = algebras.FreeDendriform(ZZ, 'x,y')
sage: x, y = P.gens()
sage: F, R = P.construction()
sage: F
Dendriform[x,y]
sage: R
Integer Ring
sage: F(ZZ) is P
True
sage: F(QQ)
Free Dendriform algebra on 2 generators ['x', 'y'] over Rational Field

coproduct_on_basis(x)

Return the coproduct of a binary tree.

EXAMPLES:
```python
sage: A = algebras.FreeDendriform(QQ)
sage: x = A.gen(0)
sage: ascii_art(A.coproduct(A.one()))  # indirect doctest
1 # 1
sage: ascii_art(A.coproduct(x))  # indirect doctest
1 # B + B # 1
    o  o
sage: A = algebras.FreeDendriform(QQ, 'xyz')
sage: x, y, z = A.gens()
sage: w = A.under(z, A.over(x, y))
sage: A.coproduct(z)
B[.] # B[z[., .]] + B[z[., .]] # B[.]
sage: A.coproduct(w)
B[.] # B[x[z[., .], y[., .]]] + B[x[., .]] # B[z[., y[., .]]] + B[x[., .]] # B[y[z[., .], .]] + B[x[., .]] # B[z[., .]] + B[x[z[., .], .]] # B[y[., .]] + B[x[z[., .], .], y[., .]]] # B[.]
```

**degree_on_basis(i)**

Return the degree of a binary tree in the free Dendriform algebra.

This is the number of vertices.

**EXAMPLES:**

```python
sage: A = algebras.FreeDendriform(QQ, '@')
sage: RT = A.basis().keys()
sage: u = RT([], '@')
sage: A.degree_on_basis(u.over(u))
2
```

**gen(i)**

Return the i-th generator of the algebra.

**INPUT:**

- i – an integer

**EXAMPLES:**

```python
sage: F = algebras.FreeDendriform(ZZ, 'xyz')
sage: F.gen(0)
B[x[., .]]
sage: F.gen(4)
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```

**gens()**

Return the generators of self (as an algebra).

**EXAMPLES:**

```python
```
sage: A = algebras.FreeDendriform(ZZ, 'fgh')
sage: A.gens()
(B[f[., .]], B[g[., .]], B[h[., .]])

one_basis()
Return the index of the unit.

EXAMPLES:

sage: A = algebras.FreeDendriform(QQ, '@')
sage: A.one_basis()

sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.one_basis()

over()
Return the over product.
The over product $x/y$ is the binary tree obtained by grafting the root of $y$ at the rightmost leaf of $x$.
The usual symbol for this operation is $/$. 

See also: product(), succ(), prec(), under()

EXAMPLES:

sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.over(x, x)
B[[., [., .]]]

prec()
Return the $≺$ dendriform product. 

This is the sum over all possible ways to identify the rightmost path in $x$ and the leftmost path in $y$, with the additional condition that the root vertex of the result comes from $x$.
The usual symbol for this operation is $≺$.

See also: product(), succ(), over(), under()

EXAMPLES:

sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.prec(x, x)
B[[., [., .]]]

prec_product_on_basis(x, y)
Return the $≺$ dendriform product of two trees.
This is the sum over all possible ways of identifying the rightmost path in $x$ and the leftmost path in $y$, with the additional condition that the root vertex of the result comes from $x$.

The usual symbol for this operation is $\prec$.

See also:

- `product_on_basis()`, `succ_product_on_basis()`

EXAMPLES:

```sage
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.prec_product_on_basis(x, x)
B[[., [., .]]]
```

**product_on_basis**($x, y$)

Return the $*$ associative dendriform product of two trees.

This is the sum over all possible ways of identifying the rightmost path in $x$ and the leftmost path in $y$. Every term corresponds to a shuffle of the vertices on the rightmost path in $x$ and the vertices on the leftmost path in $y$.

See also:

- `succ_product_on_basis()`, `prec_product_on_basis()`

EXAMPLES:

```sage
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.product_on_basis(x, x)
B[[., [., .]]] + B[[[., .], .]]
```

**some_elements**()

Return some elements of the free dendriform algebra.

EXAMPLES:

```sage
sage: A = algebras.FreeDendriform(QQ)
sage: A.some_elements()
[B[., ], B[[., .]], B[[., [., .]]] + B[[[., .], .]], B[.] + B[[., [., .]]] + B[[[., .], .]]]
```

With several generators:

```sage
sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.some_elements()
[B[., ], B[x[., .]], B[x[., x[., .]]] + B[x[x[., .], .]], B[.] + B[x[., x[., .]]] + B[x[x[., .], .]]]
```
**succ()**

Return the $\succ$ dendriform product.

This is the sum over all possible ways of identifying the rightmost path in $x$ and the leftmost path in $y$, with the additional condition that the root vertex of the result comes from $y$.

The usual symbol for this operation is $\succ$.

**See also:**

- **product()**, **prec()**, **over()**, **under()**

**EXAMPLES:**

```python
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.succ(x, x)
B[[][., .], .]
```

**succ_product_on_basis(x, y)**

Return the $\succ$ dendriform product of two trees.

This is the sum over all possible ways to identify the rightmost path in $x$ and the leftmost path in $y$, with the additional condition that the root vertex of the result comes from $y$.

The usual symbol for this operation is $\succ$.

**See also:**

- **product_on_basis()**, **prec_product_on_basis()**

**EXAMPLES:**

```python
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.succ_product_on_basis(x, x)
B[[][., .], .]
```

**under()**

Return the under product.

The over product $x \setminus y$ is the binary tree obtained by grafting the root of $x$ at the leftmost leaf of $y$.

The usual symbol for this operation is $\setminus$.

**See also:**

- **product()**, **succ()**, **prec()**, **over()**

**EXAMPLES:**

```python
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.under(x, x)
B[[][., .], .]
```
variable_names()
Return the names of the variables.

EXAMPLES:

```sage
sage: R = algebras.FreeDendriform(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}
```

### 5.1.112 Free Pre-Lie Algebras

**AUTHORS:**

• Florent Hivert, Frédéric Chapoton (2011)

**class** `sage.combinat.free_prelie_algebra.FreePreLieAlgebra(R, names=None)`

Bases: `CombinatorialFreeModule`

The free pre-Lie algebra.

Pre-Lie algebras are non-associative algebras, where the product * satisfies

\[(x * y) * z - x * (y * z) = (x * z) * y - x * (z * y).\]

We use here the convention where the associator

\[(x, y, z) := (x * y) * z - x * (y * z)\]

is symmetric in its two rightmost arguments. This is sometimes called a right pre-Lie algebra.

They have appeared in numerical analysis and deformation theory.

The free Pre-Lie algebra on a given set $E$ has an explicit description using rooted trees, just as the free associative algebra can be described using words. The underlying vector space has a basis indexed by finite rooted trees endowed with a map from their vertices to $E$. In this basis, the product of two (decorated) rooted trees $S * T$ is the sum over vertices of $S$ of the rooted tree obtained by adding one edge from the root of $T$ to the given vertex of $S$. The root of these trees is taken to be the root of $S$. The free pre-Lie algebra can also be considered as the free algebra over the PreLie operad.

**Warning:** The usual binary operator * can be used for the pre-Lie product. Beware that it must be parenthesized properly, as the pre-Lie product is not associative. By default, a multiple product will be taken with left parentheses.

**EXAMPLES:**

```sage
sage: F = algebras.FreePreLie(ZZ, 'xyz')
sage: x,y,z = F.gens()
sage: (x * y) * z
B[x[y[z[]]]] + B[x[y[], z[]]]
sage: (x * y) * z - x * (y * z) == (x * z) * y - x * (z * y)
True
```

The free pre-Lie algebra is non-associative:
sage: x * (y * z) == (x * y) * z
False

The default product is with left parentheses:

sage: x * y * z == (x * y) * z
True
sage: x * y * z * x == ((x * y) * z) * x
True

The NAP product as defined in [Liv2006] is also implemented on the same vector space:

sage: N = F.nap_product
sage: N(x*y,z*z)
B[x[y[], z[z[]]]]

When None is given as input, unlabelled trees are used instead:

sage: F1 = algebras.FreePreLie(QQ, None)
sage: w = F1.gen(0); w
B[]
sage: w * w * w * w
B[[[[]]][[[]]][[[[[]]]]]] + B[[[[]]][[[[]]]]][[[[[]]]]] + 3*B[[[[]]][[[[]]]]][[[[]]]] + B[[[[]]][[[[]]]]][[[[]]]] + B[[[[]]][[[[]]]]][[[[]]]]

However, it is equally possible to use labelled trees instead:

sage: F1 = algebras.FreePreLie(QQ, 'q')
sage: w = F1.gen(0); w
B[q[]]
sage: w * w * w * w
B[q[q[q[[]]]]][q[q[q[[]]]]][q[q[q[[]]]]] + B[q[q[q[[]]]]][q[q[q[[]]]]][q[q[q[[]]]]] + 3*B[q[q[q[[]]]]][q[q[q[[]]]]][q[q[q[[]]]]] + B[q[q[q[[]]]]][q[q[q[[]]]]][q[q[q[[]]]]]

The set $E$ can be infinite:

sage: F = algebras.FreePreLie(QQ, ZZ)
sage: w = F.gen(1); w
B[1[]]
sage: x = F.gen(2); x
B[-1[]]
sage: y = F.gen(3); y
B[2[]]
sage: w*x
B[1[-1[]]]
sage: (w*x)*y
B[1[-1[2[]]]] + B[1[-1[], 2[]]]
sage: w*(x*y)
B[1[-1[2[]]]]

Elements of a free pre-Lie algebra can be lifted to the universal enveloping algebra of the associated Lie algebra. The universal enveloping algebra is the Grossman-Larson Hopf algebra:

sage: F = algebras.FreePreLie(QQ,'abc')
sage: a,b,c = F.gens()
Combinatorics, Release 10.1

sage: (a*b+b*c).lift()
B[#[a[[]]]] + B[#[b[[]]]]

Note: Variables names can be None, a list of strings, a string or an integer. When None is given, unlabelled rooted trees are used. When a single string is given, each letter is taken as a variable. See sage.combinat.words.alphabet.build_alphabet().

Warning: Beware that the underlying combinatorial free module is based either on RootedTrees or on LabelledRootedTrees, with no restriction on the labellings. This means that all code calling the basis() method would not give meaningful results, since basis() returns many “chaff” elements that do not belong to the algebra.

REFERENCES:
• [ChLi]
• [Liv2006]

class Element
    Bases: IndexedFreeModuleElement

    lift()
    Lift element to the Grossman-Larson algebra.

    EXAMPLES:

    sage: F = algebras.FreePreLie(QQ, 'abc')
sage: elt = F.an_element().lift(); elt
B[#[a[a[a[[]]]]]] + B[#[a[a[], a[[]]]]]
sage: parent(elt)
Grossman-Larson Hopf algebra on 3 generators ['a', 'b', 'c'] over Rational Field

algebra_generators()
    Return the generators of this algebra.

    These are the rooted trees with just one vertex.

    EXAMPLES:

    sage: A = algebras.FreePreLie(ZZ, 'fgh'); A
Free PreLie algebra on 3 generators ['f', 'g', 'h'] over Integer Ring
sage: list(A.algebra_generators())
[B[f[]], B[g[]], B[h[]]]

    sage: A = algebras.FreePreLie(QQ, ['x1','x2'])
sage: list(A.algebra_generators())
[B[x1[]], B[x2[]]]

    an_element()
    Return an element of self.
EXAMPLES:

```python
sage: A = algebras.FreePreLie(QQ, 'xy')
sage: A.an_element()
B[x[x[x[x[]]]]] + B[x[], x[x[]]]
```

**bracket_on_basis**(x, y)

Return the Lie bracket of two trees.

This is the commutator 
\[ [x, y] = x * y - y * x \]
of the pre-Lie product.

See also:

**pre_Lie_product_on_basis()**

EXAMPLES:

```python
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: y = RT([x])
sage: A.bracket_on_basis(x, y)
-B[[[[[], [[[]]]]]] + B[[[], [[]]]] - B[[[]], [[]]]]
```

**change_ring**(*R*)

Return the free pre-Lie algebra in the same variables over *R*.

**INPUT:**

- *R* – a ring

**EXAMPLES:**

```python
sage: A = algebras.FreePreLie(ZZ, 'fgh')
sage: A.change_ring(QQ)
Free PreLie algebra on 3 generators ['f', 'g', 'h'] over Rational Field
```

**construction**()

Return a pair (*F*, *R*), where *F* is a **PreLieFunctor** and *R* is a ring, such that *F*(*R*) returns **self**.

**EXAMPLES:**

```python
sage: P = algebras.FreePreLie(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F, R = P.construction()
sage: F
PreLie[x,y]
sage: R
Integer Ring
sage: F(ZZ) is P
True
sage: F(QQ)
Free PreLie algebra on 2 generators ['x', 'y'] over Rational Field
```

**degree_on_basis**(t)

Return the degree of a rooted tree in the free Pre-Lie algebra.
This is the number of vertices.

EXAMPLES:

```sage
A = algebras.FreePreLie(QQ, None)
RT = A.basis().keys()
A.degree_on_basis(RT([RT([[]])]))
2
```

gen(i)

Return the i-th generator of the algebra.

INPUT:

• i – an integer

EXAMPLES:

```sage
F = algebras.FreePreLie(ZZ, 'xyz')
F.gen(0)
B[x[]]
F.gen(4)
Traceback (most recent call last):
... 
IndexError: argument i (= 4) must be between 0 and 2
```

gens()

Return the generators of self (as an algebra).

EXAMPLES:

```sage
A = algebras.FreePreLie(ZZ, 'fgh')
A.gens()
(B[f[]], B[g[]], B[h[]])
```

nap_product()

Return the NAP product.

See also:

nap_product_on_basis()

EXAMPLES:

```sage
A = algebras.FreePreLie(QQ, None)
RT = A.basis().keys()
x = A(RT([RT([[]])]))
A.nap_product(x, x)
B[[]] B[[]]
```

nap_product_on_basis(x, y)

Return the NAP product of two trees.

This is the grafting of the root of y over the root of x. The root of the resulting tree is the root of x.

See also:

nap_product()
EXAMPLES:

```python
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([[[]]])
sage: A.nap_product_on_basis(x, x)
B[[[], [[]]]]
```

**pre_Lie_product()**

Return the pre-Lie product.

See also:

**pre_Lie_product_on_basis()**

EXAMPLES:

```python
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = A(RT([[]]))
sage: A.pre_Lie_product(x, x)
B[[[[]]]] + B[[[], [[]]]]
```

**pre_Lie_product_on_basis(x, y)**

Return the pre-Lie product of two trees.

This is the sum over all graftings of the root of $y$ over a vertex of $x$. The root of the resulting trees is the root of $x$.

See also:

**pre_Lie_product()**

EXAMPLES:

```python
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([[]])
sage: A.product_on_basis(x, x)
B[[[[]]]] + B[[[], [[]]]]
```

**product_on_basis(x, y)**

Return the pre-Lie product of two trees.

This is the sum over all graftings of the root of $y$ over a vertex of $x$. The root of the resulting trees is the root of $x$.

See also:

**pre_Lie_product()**

EXAMPLES:
some_elements()
Return some elements of the free pre-Lie algebra.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, 'None')
sage: A.some_elements()
[B[], B[[[]]], B[[[[[]]]]] + B[], [[[]]], B[[[[[[[]]]]]]] + B[], [], []], B[[]]]
```

With several generators:

```
sage: A = algebras.FreePreLie(QQ, 'xy')
sage: A.some_elements()
[B[x[]], B[x[x[]]], B[x[x[x[x]]]] + B[x[x[], x[x[]]]], B[x[x[x[]]]] + B[x[x[], x[]]], B[x[x[y[]]]] + B[x[x[], y[]]]]
```

variable_names()
Return the names of the variables.

EXAMPLES:

```
sage: R = algebras.FreePreLie(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}
sage: R = algebras.FreePreLie(QQ, 'None')
sage: R.variable_names()
{'o'}
```

class sage.combinat.free_prelie_algebra.PreLieFunctor(vars)
Bases: ConstructionFunctor
A constructor for pre-Lie algebras.

EXAMPLES:

```
sage: P = algebras.FreePreLie(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F = P.construction()[0]; F
PreLie[x,y]
sage: A = GF(5)[['a,b']]
sage: a, b = A.gens()
sage: F(A)
Free Prelie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring in a, b over Finite Field of size 5
sage: f = A.hom([a+b,a-b],A)
sage: F(f)
Generic endomorphism of Free Prelie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring in a, b over Finite Field of size 5
```

(continues on next page)
merge\(\text{other}\)
Merge self with another construction functor, or return None.

EXAMPLES:
\[
\begin{align*}
sage: & F = \text{sage.combinat.free_prelie_algebra.PreLieFunctor(['x', 'y'])} \\
&sage: G = \text{sage.combinat.free_prelie_algebra.PreLieFunctor(['t'])} \\
&sage: F.merge(G) \\
&\text{PreLie}[x,y,t] \\
&sage: F.merge(F) \\
&\text{PreLie}[x,y]
\end{align*}
\]

Now some actual use cases:
\[
\begin{align*}
sage: & R = \text{algebras.FreeLie(ZZ, 'xyz')} \\
&sage: x,y,z = R.gens() \\
&sage: 1/2 * x \\
&1/2*B[x[]] \\
&sage: \text{parent}(1/2 * x) \\
&\text{Free PreLie algebra on 3 generators ['x', 'y', 'z'] over Rational Field} \\
&sage: S = \text{algebras.FreeLie(QQ, 'zt')} \\
&sage: z,t = S.gens() \\
&sage: x + t \\
&B[t[]] + B[x[]] \\
&sage: \text{parent}(x + t) \\
&\text{Free PreLie algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field}
\end{align*}
\]

rank = 9

### 5.1.113 Fully packed loops

AUTHORS:
- Vincent Knight, James Campbell, Kevin Dilks, Emily Gunawan (2015): Initial version
- Vincent Delecroix (2017): cleaning and enhanced plotting function

class \text{sage.combinat.fully_packed_loop.FullyPackedLoop}(parent, generator)

A class for fully packed loops.

A fully packed loop is a collection of non-intersecting lattice paths on a square grid such that every vertex is part of some path, and the paths are either closed internal loops or have endpoints corresponding to alternate points on the boundary [Pro2001]. They are known to be in bijection with alternating sign matrices.

See also:
AlternatingSignMatrix

To each fully packed loop, we assign a link pattern, which is the non-crossing matching attained by seeing which points on the boundary are connected by open paths in the fully packed loop.
We can create a fully packed loop using the corresponding alternating sign matrix and also extract the link pattern:

\[
\begin{align*}
\text{sage: } & A = \text{AlternatingSignMatrix}([[0, 0, 1], [0, 1, 0], [1, 0, 0]]) \\
\text{sage: } & fpl = \text{FullyPackedLoop}(A) \\
\text{sage: } & fpl.\text{link}\_\text{pattern}() \\
& [(1, 4), (2, 3), (5, 6)] \\
\text{sage: } & fpl \\
\text{+ -- + +} \\
\text{+ + -- +} \\
\text{-- + + + --} \\
\text{sage: } & B = \text{AlternatingSignMatrix}([[1, 0, 0], [0, 1, 0], [0, 0, 1]]) \\
\text{sage: } & fplb = \text{FullyPackedLoop}(B) \\
\text{sage: } & fplb.\text{link}\_\text{pattern}() \\
& [(1, 6), (2, 5), (3, 4)] \\
\text{sage: } & fplb \\
\text{+ + -- +} \\
\text{-- + + + --} \\
\text{sage: } & fpl.plot() \\
\text{Graphics object consisting of 3 graphics primitives} \\
\end{align*}
\]

The class also has a plot method:

\[
\text{sage: } fpl.plot() \\
\text{optional - sage.plot} \\
\text{which gives:}
\]

Note that we can also create a fully packed loop from a six vertex model configuration:
Here are some more examples using bigger ASMs:

```sage
A = AlternatingSignMatrix([[0,1,0,0],[0,0,1,0],[1,-1,0,1],[0,1,0,0]])
sage: S = SixVertexModel(4, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.link_pattern()
[(1, 2), (3, 6), (4, 5), (7, 8)]
sage: fpl
```

(continues on next page)
```python
sage: m = AlternatingSignMatrix([[0,0,1,0,0,0],
                               [1,0,-1,0,1,0],
                               [0,0,0,1,0,0],
                               [0,1,0,0,-1,1],
                               [0,0,0,0,1,0],
                               [0,0,1,0,0,0]])

sage: fpl = FullyPackedLoop(m)
sage: fpl

sage: m = AlternatingSignMatrix([[0,1,0,0,0,0,0],
                               [1,-1,0,0,1,0,0],
                               [0,0,0,1,0,0,0],
                               [0,1,0,0,-1,1,0],
                               [0,0,0,0,1,0,0],
                               [0,0,1,0,-1,0,1],
                               [0,0,0,0,1,0,0]])

sage: fpl = FullyPackedLoop(m)
sage: fpl
```

(continues on next page)
Gyration on an alternating sign matrix/fully packed loop \(fpl\) of the link pattern corresponding to \(fpl\):

```
sage: ASMs = AlternatingSignMatrices(3).list()
sage: ncp = FullyPackedLoop(ASMs[1]).link_pattern() # fpl's gyration orbit size is 2
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
    ....:     for i in range(5):
    ....:         a,b=a%6+1,b%6+1;
    ....:         rotated_ncp.append((a,b))
sage: PerfectMatching(ASMs[1].gyration().to_fully_packed_loop().link_pattern()) ==\n    ....:     PerfectMatching(rotated_ncp)
True
sage: fpl = FullyPackedLoop(ASMs[0])
sage: ncp = fpl.link_pattern() # fpl's gyration size is 3
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
    ....:     for i in range(5):
    ....:         a,b=a%6+1,b%6+1;
    ....:         rotated_ncp.append((a,b))
sage: PerfectMatching(ASMs[0].gyration().to_fully_packed_loop().link_pattern()) ==\n    ....:     PerfectMatching(rotated_ncp)
True
sage: mat = AlternatingSignMatrix([[0,0,1,0,0,0,0],[1,0,-1,0,1,0,0],
    ....:      [0,0,0,0,1,0,0],[0,1,-1,0,0,1,0],[0,0,1,0,0,0,0],[0,0,0,1,0,0,0],[0,0,0,0,\n    ....:      1,0,0],[0,0,0,0,0,0,1]])
sage: fpl = FullyPackedLoop(mat) # n=7
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
    ....:     for i in range(13):
    ....:         a,b=a%6+1,b%6+1;
    ....:         rotated_ncp.append((a,b))
```

(continues on next page)
....:     a,b=a%14+1,b%14+1;
....:     rotated_ncp.append((a,b))
sage:    PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) ==
....:    PerfectMatching(rotated_ncp)
True

sage:    mat = AlternatingSignMatrix([[0,0,0,1,0,0], [0,0,1,-1,1,0],
....:    [0,1,0,0,-1,1], [1,0,-1,1,0,0], [0,0,1,0,0,0], [0,0,0,0,1,0]])
sage:    fpl = FullyPackedLoop(mat)  # n =6
sage:    ncp = fpl.link_pattern()
sage:    rotated_ncp=[]
sage:    for (a,b) in ncp:  
....:        for i in range(11):
....:            a,b=a%12+1,b%12+1;
....:        rotated_ncp.append((a,b))
sage:    PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) ==
....:    PerfectMatching(rotated_ncp)
True

More examples:

We can initiate a fully packed loop using an alternating sign matrix:

sage:    A = AlternatingSignMatrix([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
sage:    fpl = FullyPackedLoop(A)
sage:    fpl

```
|   |   |
|   |   |
+ -- + + |
|   |   |
-- + + + --
|   |   |
+ + -- + |
|   |   |
|   |   |
```
sage:    FullyPackedLoops(3)(A) == fpl
True

We can also input a matrix:

sage: FullyPackedLoop([[0, 0, 1], [0, 1, 0], [1, 0, 0]])

```
|   |   |
|   |   |
+ -- + + |
|   |   |
-- + + + --
|   |   |
+ + -- + |
|   |   |
```
Otherwise we initiate a fully packed loop using a six vertex model:

```python
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl
```

```
+ -- + +
|   |
+ -- + +
|   |
-- + + + --
|   |
|   |
|   |
```

```
sage: FullyPackedLoops(3)(S) == FullyPackedLoop(S)
True
```

```
sage: fpl.six_vertex_model().to_alternating_sign_matrix()
[[0 0 1]
 [0 1 0]
 [1 0 0]]
```

We can also input the matrix associated to a six vertex model:

```python
sage: SixVertexModel(2)([[3,1],[5,3]])
```

```
^     ^
|     |
--> # <- # <--
|     |
V     V
```

```
sage: FullyPackedLoop([[3,1],[5,3]])
```

```
+ + --
|   |
+ + --
|   |
-- + +
|   |
```
Note that the matrix corresponding to a six vertex model without the ice boundary condition is not allowed:

```
sage: SixVertexModel(2)([[3,1],[5,5]])
```

```
^   ^
|   |
--> # <- # <--
|   ^
V  V
--> # -> # -->
|   |
V  V
```

```
sage: FullyPackedLoop([[3,1],[5,5]])
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

```
sage: FullyPackedLoops(2)([[3,1],[5,5]])
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

Note that if anything else is used to generate the fully packed loop an error will occur:

```
sage: fpl = FullyPackedLoop(5)
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

```
sage: fpl = FullyPackedLoop((1, 2, 3))
```

Traceback (most recent call last):
...
ValueError: the alternating sign matrices must be square

```
sage: SVM = SixVertexModel(3)[0]
sage: FullyPackedLoop(SVM)
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

REFERENCES:

- [Pro2001]
- [Str2015]

`gyration()`

Return the fully packed loop obtained by applying gyration to the alternating sign matrix in bijection with `self`.

Gyration was first defined in [Wie2000] as an action on fully-packed loops.
EXAMPLES:

```python
sage: A = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.gyration().to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = AlternatingSignMatrix([[0, 0, 1], [1, 0, 0], [0, 1, 0]])
sage: f = FullyPackedLoop(asm)
sage: f.gyration().to_alternating_sign_matrix()
[0 1 0]
[0 0 1]
[1 0 0]
```

`link_pattern()`

Return a link pattern corresponding to a fully packed loop.

Here we define a link pattern \(LP\) to be a partition of the list \([1, \ldots, 2k]\) into 2-element sets (such a partition is also known as a perfect matching) such that the following non-crossing condition holds: Let the numbers \(1, \ldots, 2k\) be written on the perimeter of a circle. For every 2-element set \((a, b)\) of the partition \(LP\), draw an arc linking the two numbers \(a\) and \(b\). We say that \(LP\) is non-crossing if every arc can be drawn so that no two arcs intersect.

Since every endpoint of a fully packed loop \(fp\) is connected to a different endpoint, there is a natural surjection from the fully packed loops on an \(n \times n\) grid onto the link patterns on the list \([1, \ldots, 2n]\). The pairs of connected endpoints of a fully packed loop \(fp\) correspond to the 2-element tuples of the corresponding link pattern.

See also:

*PerfectMatching*

**Note:** by convention, we choose the top left vertex to be even. See [Pro2001] and [Str2015].

EXAMPLES:

We can extract the underlying link pattern (a non-crossing partition) from a fully packed loop:

```python
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.link_pattern()
[(1, 2), (3, 6), (4, 5)]
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(B)
sage: fpl.link_pattern()
[(1, 6), (2, 5), (3, 4)]
```

Gyration on an alternating sign matrix/fully packed loop \(fp\) corresponds to a rotation (i.e. \(a\) becomes \(a-1 \mod 2n\)) of the link pattern corresponding to \(fp\):

```python
sage: ASMs = AlternatingSignMatrices(3).list()
sage: ncp = FullyPackedLoop(ASMs[1]).link_pattern()
sage: rotated_ncp=
```

(continues on next page)
sage: for (a,b) in ncp:
.....:     for i in range(5):
.....:         a,b=a%6+1,b%6+1;
.....:         rotated_ncp.append((a,b))

sage: PerfectMatching(ASMs[1].gyration().to_fully_packed_loop().link_pattern())
True

sage: fpl = FullyPackedLoop(ASMs[0])
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(5):
.....:         a,b=a%6+1,b%6+1;
.....:         rotated_ncp.append((a,b))

sage: PerfectMatching(ASMs[0].gyration().to_fully_packed_loop().link_pattern())
True

sage: mat = AlternatingSignMatrix([[0,0,1,0,0,0,0], [1,0,-1,0,1,0,0], [0,0,1,0,0,0,0], [0,1,-1,0,0,1,0], [0,0,1,0,0,0,0], [0,0,0,0,0,1]])
sage: fpl = FullyPackedLoop(mat) 
# n=7
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(13):
.....:         a,b=a%14+1,b%14+1;
.....:         rotated_ncp.append((a,b))

sage: PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern())
True

sage: mat = AlternatingSignMatrix([[0,0,0,1,0,0,0], [0,0,1,-1,1,0], [0,1,0,0,-1,1], [1,0,-1,0,0,0], [0,0,1,0,0,0], [0,0,0,0,0,1]])
sage: fpl = FullyPackedLoop(mat)
sage: ncp = fpl.link_pattern()
sage: rotated_ncp=[]
sage: for (a,b) in ncp:
.....:     for i in range(11):
.....:         a,b=a%12+1,b%12+1;
.....:         rotated_ncp.append((a,b))

sage: PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern())
True

plot(link=True, loop=True, loop_fill=False, **options)

Return a graphical object of the Fully Packed Loop.
Each option can be specified separately for links (the curves that join boundary points) and the loops. In
order to do so, you need to prefix its name with either 'link_' or 'loop_'. As an example, setting
"color='red'" will color both links and loops in red while setting "link_color='red'" will only apply the
color option for the links.

INPUT:

- link, loop - (boolean, default True) whether to plot the links or the loops
- color, link_color, loop_color - (optional, a string or a RGB triple)
- colors, link_colors, loop_colors - (optional, list) a list of colors
- color_map, link_color_map, loop_color_map - (string, optional) a name of a matplotlib color map for the link or the loop
- link_color_randomize - (boolean, default False) when link_colors or link_color_map is
  specified it randomizes its order. Setting this option to True makes it unlikely to have two neighboring
  links with the same color.
- loop_fill - (boolean, optional) whether to fill the interior of the loops

EXAMPLES:

To plot the fully packed loop associated to the following alternating sign matrix

\[
\begin{pmatrix}
0 & 1 & 1 \\
1 & -1 & 1 \\
0 & 1 & 0
\end{pmatrix}
\]

simply do:

```python
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.plot()  #<optional - sage.plot>
```

Graphics object consisting of 3 graphics primitives

The resulting graphics is as follows

```
[ ]
```

You can also have the three links in different colors with:

```python
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.plot(link_color_map='rainbow')  #<optional - sage.plot>
```

Graphics object consisting of 3 graphics primitives

You can plot the 42 fully packed loops of size \(4 \times 4\) using:
Here is an example of a $20 \times 20$ fully packed loop:

```
sage: s = "00000000000000+0000000000000000+00-0+00000000000+00-00+0000-+00000000+000-0+0-+0-+0000
.....: 0000+-00+00-+00000000-0000+000-+00000000-00-0+0--00000000-0+-00+-00000000-0+
.....: 000+-000+-00000000+--000+00-000+000+-000+-0+00000000-0+
```

(continues on next page)
sage: a = matrix(20, [('0':0, '+':1, '-': -1)[i] for i in s])
sage: fpl = FullyPackedLoop(a)
sage: fpl.plot(loop_fill=True, loop_color_map='rainbow')
optional - sage.plot
Graphics object consisting of 27 graphics primitives

**six_vertex_model()**

Return the underlying six vertex model configuration.

EXAMPLES:

sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(B)
sage: fpl
```
sage: fpl.six_vertex_model()
```

(continues on next page)
to_alternating_sign_matrix()

Return the alternating sign matrix corresponding to this class.

See also:

AlternatingSignMatrix

EXAMPLES:

```python
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.to_alternating_sign_matrix()
[ 0 1 0]
[ 1 -1 1]
[ 0 1 0]
sage: A = AlternatingSignMatrix([[0, 1, 0, 0], [0, 0, 1, 0], [1, -1, 0, 1], [0, 1, 0, 0]])
sage: S = SixVertexModel(4, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.to_alternating_sign_matrix()
[ 0 1 0 0]
[ 0 0 1 0]
[ 1 -1 0 1]
[ 0 1 0 0]
```

class sage.combinat.fully_packed_loop.FullyPackedLoops(n)

Bases: Parent, UniqueRepresentation

Class of all fully packed loops on an \( n \times n \) grid.

They are known to be in bijection with alternating sign matrices.

See also:

AlternatingSignMatrices

INPUT:

- \( n \) – the number of row (and column) or grid

EXAMPLES:

This will create an instance to manipulate the fully packed loops of size 3:
When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```
sage: M = FullyPackedLoops(1)
sage: len(M)
1
sage: M = FullyPackedLoops(4)
sage: len(M)
42
sage: all(len(SixVertexModel(n, boundary_conditions='ice'))
.....:     == FullyPackedLoops(n).cardinality() for n in range(1, 7))
True
```

### Element

**cardinality()**

Return the cardinality of **self**.

The number of fully packed loops on $n \times n$ grid

$$\prod_{k=0}^{n-1} \left( \frac{(3k + 1)!}{(n + k)!} \right) = \frac{1!4!7!10!\cdots(3n - 2)!}{n!(n + 1)!(n + 2)!(n + 3)!\cdots(2n - 1)!}.$$  

**EXAMPLES:**

```
sage: [AlternatingSignMatrices(n).cardinality() for n in range(10)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460]
```

**size()**

Return the size of the matrices in **self**.

### 5.1.114 Gelfand-Tsetlin Patterns

**AUTHORS:**

**REFERENCES:**

class `sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPattern`

Bases: `ClonableArray`

A Gelfand-Tsetlin (sometimes written as Gelfand-Zetlin or Gelfand-Cetlin) pattern. They were originally defined in [GC50].
A Gelfand-Tsetlin pattern is a triangular array:

\[
\begin{array}{cccccc}
  a_{1,1} & a_{1,2} & a_{1,3} & \cdots & a_{1,n} \\
  a_{2,2} & a_{2,3} & \cdots & a_{2,n} \\
  a_{3,3} & & \cdots & a_{3,n} \\
  & & & \ddots & \\
  a_{n,n} & & & & & \\
\end{array}
\]

such that \(a_{i,j} \geq a_{i+1,j+1} \geq a_{i,j+1}\).

Gelfand-Tsetlin patterns are in bijection with semistandard Young tableaux by the following algorithm. Let \(G\) be a Gelfand-Tsetlin pattern with \(\lambda^{(k)}\) being the \((n-k+1)\)-st row (note that this is a partition). The definition of \(G\) implies

\[
\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(n)},
\]

where \(\lambda^{(0)}\) is the empty partition, and each skew shape \(\lambda^{(k)}/\lambda^{(k-1)}\) is a horizontal strip. Thus define \(T(G)\) by inserting \(k\) into the squares of the skew shape \(\lambda^{(k)}/\lambda^{(k-1)}\), for \(k = 1, \ldots, n\).

To each entry in a Gelfand-Tsetlin pattern, one may attach a decoration of a circle or a box (or both or neither). These decorations appear in the study of Weyl group multiple Dirichlet series, and are implemented here following the exposition in [BBF].

**Note:** We use the “right-hand” rule for determining circled and boxed entries.

**Warning:** The entries in Sage are 0-based and are thought of as flushed to the left in a matrix. In other words, the coordinates of entries in the Gelfand-Tsetlin patterns are thought of as the matrix:

\[
\begin{bmatrix}
  g_{0,0} & g_{0,1} & g_{0,2} & \cdots & g_{0,n-2} & g_{n-1,n-1} \\
  g_{1,0} & g_{1,1} & g_{1,2} & \cdots & g_{1,n-2} \\
  g_{2,0} & g_{2,1} & g_{2,2} & \cdots & \vdots \\
  \vdots & \vdots & \vdots & \ddots & \vdots \\
  g_{n-2,0} & g_{n-2,1} \\
  g_{n-1,0}
\end{bmatrix}
\]

However, in the discussions, we will be using the **standard** numbering system.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3, 2, 1], [2, 1], [1]])
[[3, 2, 1], [2, 1], [1]]
sage: G.pp()
3  2  1
  2  1
  1
sage: G = GelfandTsetlinPattern([[7, 7, 4, 0], [7, 7, 3], [7, 5], [5]])
[[7, 7, 4, 0], [7, 7, 3], [7, 5], [5]]
sage: G.pp()
7  7  4  0
  7  7  3
  7  5
  5
sage: G.to_tableau().pp()
1  1  1  1  2  2
```

(continues on next page)
Tokuyama_coefficient(name='t')
Return the Tokuyama coefficient attached to self.

Following the exposition of [BBF], Tokuyama’s formula asserts
\[
\sum_G (t + 1)^{s(G)} z_1^{d_{n+1}} z_2^{d_n - d_{n+1}} \cdots z_{n+1}^{d_1 - d_2} = \prod_{i<j} (z_j + tz_i),
\]
where the sum is over all strict Gelfand-Tsetlin patterns with fixed top row \(\lambda + \rho\), with \(\lambda\) a partition with at most \(n + 1\) parts and \(\rho = (n, n-1, \ldots, 1, 0)\), and \(s_\lambda\) is a Schur function.

INPUT:
• name – (Default: 't') An alternative name for the variable \(t\).

EXAMPLES:

```
sage: P = GelfandTsetlinPattern([[3, 2, 1], [2, 2], [2]])
sage: P.Tokuyama_coefficient()
0
sage: G = GelfandTsetlinPattern([[3, 2, 1], [3, 1], [2]])
sage: G.Tokuyama_coefficient()
t^2 + t
sage: G = GelfandTsetlinPattern([[2, 1, 0], [1, 1], [1]])
sage: G.Tokuyama_coefficient()
0
sage: G = GelfandTsetlinPattern([[5, 3, 2, 1, 0], [4, 3, 2, 0], [4, 2, 1], [3, 2], [3]])
sage: G.Tokuyama_coefficient()
t^8 + 3*t^7 + 3*t^6 + t^5
```

bender_knuth_involution(i)
Return the image of self under the \(i\)-th Bender-Knuth involution.
If the triangle self has size \(n\) then this is defined for \(0 < i < n\).
The entries of self can take values in any ordered ring. Usually, this will be the integers but can also be the rationals or the real numbers.
This implements the construction of the Bender-Knuth involution using toggling due to Berenstein-Kirillov.
This agrees with the Bender-Knuth involution on semistandard tableaux.

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[5, 3, 2, 1, 0], [4, 3, 2, 0], [4, 2, 1], [3, 2], [3]])
sage: G.bender_knuth_involution(2)
[[5, 3, 2, 1, 0], [4, 3, 2, 0], [4, 2, 1], [4, 1], [3]]
sage: G = GelfandTsetlinPattern([[3, 2, 0], [2, 2, 0], [2]])
sage: G.bender_knuth_involution(2)
[[3, 2, 0], [2.80000000000000, 2], [2]]
```

boxed_entries()
Return the position of the boxed entries of self.
Using the *right-hand* rule, an entry \( a_{i,j} \) is boxed if \( a_{i,j} = a_{i-1,j-1} \); i.e., \( a_{i,j} \) has the same value as its neighbor to the northwest.

**EXAMPLES:**

```python
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.boxed_entries()
((1, 0),)
```

**check()**

Check that this is a valid Gelfand-Tsetlin pattern.

**EXAMPLES:**

```python
sage: G = GelfandTsetlinPatterns()
sage: G([[3,2,1],[2,1],[1]]).check()
```

**circled_entries()**

Return the circled entries of self.

Using the *right-hand* rule, an entry \( a_{i,j} \) is circled if \( a_{i,j} = a_{i-1,j} \); i.e., \( a_{i,j} \) has the same value as its neighbor to the northeast.

**EXAMPLES:**

```python
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.circled_entries()
((1, 1), (2, 0))
```

**is_strict()**

Return True if self is a strict Gelfand-Tsetlin pattern.

A Gelfand-Tsetlin pattern is said to be *strict* if every row is strictly decreasing.

**EXAMPLES:**

```python
sage: GelfandTsetlinPattern([[7,3,1],[6,2],[4]]).is_strict()
True
sage: GelfandTsetlinPattern([[3,2,1],[3,1],[1]]).is_strict()
True
sage: GelfandTsetlinPattern([[6,0,0],[3,0],[2]]).is_strict()
False
```

**number_of_boxes()**

Return the number of boxed entries. See *boxed_entries()*. 

**EXAMPLES:**

```python
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.number_of_boxes()
1
```

**number_of_circles()**

Return the number of boxed entries. See *circled_entries()*. 

**EXAMPLES:**
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.number_of_circles()
2

\textbf{number\_of\_special\_entries()}

Return the number of special entries. See \texttt{special\_entries()}. 

\textbf{EXAMPLES:}

sage: G = GelfandTsetlinPattern([[4,2,1],[4,1],[2]])
sage: G.number_of_special_entries()
1

\textbf{pp()}

Pretty print self.

\textbf{EXAMPLES:}

sage: G = GelfandTsetlinPatterns()
sage: G([[3,2,1],[2,1],[1]]).pp()

3  2  1
  2  1
   1

\textbf{row\_sums()}

Return the list of row sums.

For a Gelfand-Tsetlin pattern $G$, the \( i \)-th row sum $d_i$ is

$$d_i = d_i(G) = \sum_{j=1}^{n} a_{i,j}.$$ 

\textbf{EXAMPLES:}

sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.row_sums()
[11, 9, 7, 5, 3]
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[2]])
sage: G.row_sums()
[6, 4, 2]

\textbf{special\_entries()}

Return the special entries.

An entry $a_{i,j}$ is special if $a_{i-1,j-1} > a_{i,j} > a_{i-1,j}$, that is to say, the entry is neither boxed nor circled and is not in the first row. The name was coined by \cite{Tok88}.

\textbf{EXAMPLES:}

sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.special_entries()
\()
sage: G = GelfandTsetlinPattern([[4,2,1],[4,1],[2]])
sage: G.special_entries()
((2, 0),)
to_tableau()

Return self as a semistandard Young tableau.

The conversion from a Gelfand-Tsetlin pattern to a semistandard Young tableaux is as follows. Let \( G \) be a Gelfand-Tsetlin pattern with \( \lambda^{(k)} \) being the \((n-k+1)\)-st row (note that this is a partition). The definition of \( G \) implies

\[
\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(n)},
\]

where \( \lambda^{(0)} \) is the empty partition, and each skew shape \( \lambda^{(k)}/\lambda^{(k-1)} \) is a horizontal strip. Thus define \( T(G) \) by inserting \( k \) into the squares of the skew shape \( \lambda^{(k)}/\lambda^{(k-1)} \), for \( k = 1, \ldots, n \).

**EXAMPLES:**

```sage
G = GelfandTsetlinPatterns()
sage: elt = G([[3,2,1],[2,1],[1]])
sage: T = elt.to_tableau(); T
[[1, 2, 3], [2, 3], [3]]
sage: T.pp()
1 2 3
2 3
3
sage: G(T) == elt
True
```

weight()

Return the weight of self.

Define the weight of \( G \) to be the content of the tableau to which \( G \) corresponds under the bijection between Gelfand-Tsetlin patterns and semistandard tableaux. More precisely,

\[
\text{wt}(G) = (d_n, d_{n-1} - d_n, \ldots, d_1 - d_2),
\]

where the \( d_i \) are the row sums.

**EXAMPLES:**

```sage
G = GelfandTsetlinPattern([[2,1,0],[1,0],[1]])
sage: G.weight()
(1, 0, 2)
sage: G = GelfandTsetlinPattern([[4,2,1],[3,1],[2]])
sage: G.weight()
(2, 2, 3)
```

class sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPatterns(n, k, strict)

Bases: UniqueRepresentation, Parent

Gelfand-Tsetlin patterns.

**INPUT:**

- \( n \) – The width or depth of the array, also known as the rank
- \( k \) – (Default: None) If specified, this is the maximum value that can occur in the patterns
- \( \text{top\_row} \) – (Default: None) If specified, this is the fixed top row of all patterns
- \( \text{strict} \) – (Default: False) Set to True if all patterns are strict patterns
Element

alias of GelfandTsetlinPattern

random_element()

Return a uniformly random Gelfand-Tsetlin pattern.

EXAMPLES:

```
sage: g = GelfandTsetlinPatterns(4, 5)
sage: x = g.random_element()
sage: x in g
True
sage: len(x)
4
sage: all(y in range(5+1) for z in x for y in z)
True
sage: x.check()
```

```
sage: g = GelfandTsetlinPatterns(4, 5, strict=True)
sage: x = g.random_element()
sage: x in g
True
sage: len(x)
4
sage: all(y in range(5+1) for z in x for y in z)
True
sage: x.check()
sage: x.is_strict()
True
```

class sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPatternsTopRow(top_row, strict)

Bases: GelfandTsetlinPatterns

Gelfand-Tsetlin patterns with a fixed top row.

Tokuyama_formula(name='t')

Return the Tokuyama formula of self.

Following the exposition of [BBF], Tokuyama’s formula asserts

\[
\sum_{G} (t+1)^{s(G)} n^{d_{n+1}} z_1^d_{n+1} z_2^d_{n+2} \cdots z_{n+1}^d_{n} = s_\lambda(z_1, \ldots, z_{n+1}) \prod_{i < j} (z_j + t z_i),
\]

where the sum is over all strict Gelfand-Tsetlin patterns with fixed top row \( \lambda + \rho \), with \( \lambda \) a partition with at most \( n + 1 \) parts and \( \rho = (n, n-1, \ldots, 1, 0) \), and \( s_\lambda \) is a Schur function.

INPUT:

- name – (Default: 't') An alternative name for the variable \( t \).

EXAMPLES:

```
sage: GT = GelfandTsetlinPatterns(top_row=[2,1,0], strict=True)
sage: GT.Tokuyama_formula()
t+3*t^3*x1^2*x2 + t^3*x^2*x1*x2 + t^2*x^2*x1^2*x3 + t^2*x^2*x1*x2*x3 + t*x^2*x1^2*x3 + t*x^2*x1*x2*x3 + t^3*x^2*x3 + t^3*x^2*x1^2*x2 + x2*x3^2
```

```
sage: GT = GelfandTsetlinPatterns(top_row=[3,2,1], strict=True)
```
sage: GT.Tokuyama_formula()
\begin{align*}
t^3 x_1^3 x_2^2 x_3 + t^2 x_1^2 x_2^3 x_3 + t^2 x_1 x_2^3 x_3^2 + t^2 x_1^2 x_2^2 x_3^2 + \\
... x_1^2 x_2^3 x_3^2 + t x_1^2 x_2^3 x_3^2 + t^2 x_1^2 x_2^2 x_3 + x_1 x_2^2 x_3^3
\end{align*}

sage: GT = GelfandTsetlinPatterns(top_row=[1,1,1], strict=True)
sage: GT.Tokuyama_formula()
\emptyset

random_element()

Return a uniformly random Gelfand-Tsetlin pattern with specified top row.

EXAMPLES:

```
sage: g = GelfandTsetlinPatterns(top_row=[4, 3, 1, 1])
sage: x = g.random_element()
sage: x in g
True
sage: x[0] == [4, 3, 1, 1]
True
sage: x.check()
```

```
sage: g = GelfandTsetlinPatterns(top_row=[4, 3, 2, 1], strict=True)
sage: x = g.random_element()
sage: x in g
True
sage: x[0] == [4, 3, 2, 1]
True
sage: x.is_strict()
True
sage: x.check()
```

top_row()

Return the top row of self.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns(top_row=[4, 4, 3, 1])
sage: G.top_row()
(4, 4, 3, 1)
```

5.1.115 Paths in Directed Acyclic Graphs

sage.combinat.graph_path.GraphPaths(g, source=None, target=None)

Return the combinatorial class of paths in the directed acyclic graph g.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
```

If source and target are not given, then the returned class contains all paths (including trivial paths containing only one vertex).
```python
sage: p = GraphPaths(G); p
Paths in Multi-digraph on 5 vertices
sage: p.cardinality()
37
sage: path = p.random_element()
sage: all(G.has_edge(*path[i:i+2]) for i in range(len(path) -1))
True
```

If the source is specified, then the returned class contains all of the paths starting at the vertex source (including the trivial path).

```python
sage: p = GraphPaths(G, source=3); p
Paths in Multi-digraph on 5 vertices starting at 3
sage: p.list()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
```

If the target is specified, then the returned class contains all of the paths ending at the vertex target (including the trivial path).

```python
sage: p = GraphPaths(G, target=3); p
Paths in Multi-digraph on 5 vertices ending at 3
sage: p.cardinality()
5
sage: p.list()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
```

If both the target and source are specified, then the returned class contains all of the paths from source to target.

```python
sage: p = GraphPaths(G, source=1, target=3); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
sage: p.cardinality()
3
sage: p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]
```

Note that G must be a directed acyclic graph.

```python
sage: G = DiGraph({1:[2,2,3,5], 2:[3,4], 3:[4], 4:[5,5], 5:[6]}, multiedges=True)
sage: GraphPaths(G)
Traceback (most recent call last):
  ...
  TypeError: g must be a directed acyclic graph
```

```python
class sage.combinat.graph_path.GraphPaths_all(g)
    Bases: Parent, GraphPaths_common

    EXAMPLES:
    ```
    sage: G = DiGraph({1:[2,2,3,5], 2:[3,4], 3:[4], 4:[5,5], 5:[6]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.cardinality()
37

    list()
    Return a list of the paths of self.
```
```
EXAMPLES:

```python
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: len(GraphPaths(G).list())
37
```

```python
class sage.combinat.graph_path.GraphPaths_common
    Bases: object

    incoming_edges(v)
    Return a list of v's incoming edges.

    EXAMPLES:

    ```python
    sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.incoming_edges(2)
[(1, 2, None), (1, 2, None)]
    ```

    incoming_paths(v)
    Return a list of paths that end at v.

    EXAMPLES:

    ```python
    sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.incoming_paths(2)
[[2], [1, 2], [1, 2]]
    ```

    outgoing_edges(v)
    Return a list of v's outgoing edges.

    EXAMPLES:

    ```python
    sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.outgoing_edges(2)
[(2, 3, None), (2, 3, None), (2, 4, None)]
    ```

    outgoing_paths(v)
    Return a list of the paths that start at v.

    EXAMPLES:

    ```python
    sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.outgoing_paths(3)
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
sage: gp.outgoing_paths(2)
[[2], [2, 3], [2, 3, 4], [2, 3, 4, 5], [2, 3, 4, 5], [2, 4], ...
```

(continues on next page)
paths()

Return a list of all the paths of self.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: len(gp.paths())
37
```

paths_from_source_to_target(source, target)

Return a list of paths from source to target.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.paths_from_source_to_target(2,4)
[[2, 3, 4], [2, 4]]
```

class sage.combinat.graph_path.GraphPaths_s(g, source)

Bases: Parent, GraphPaths_common

list()

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G, 4)
sage: p.list()
[[4], [4, 5], [4, 5]]
```

class sage.combinat.graph_path.GraphPaths_st(g, source, target)

Bases: Parent, GraphPaths_common

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: GraphPaths(G,1,2).cardinality()
2
sage: GraphPaths(G,1,3).cardinality()
3
sage: GraphPaths(G,1,4).cardinality()
5
sage: GraphPaths(G,1,5).cardinality()
10
sage: GraphPaths(G,2,3).cardinality()
1
sage: GraphPaths(G,2,4).cardinality()
2
sage: GraphPaths(G,2,5).cardinality()
4
```

(continues on next page)
**Combinatorics, Release 10.1**

```python
sage: GraphPaths(G,3,4).cardinality()
sage: GraphPaths(G,3,5).cardinality()
sage: GraphPaths(G,4,5).cardinality()
```

```python
list()
EXAMPLES:

```python
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G,1,2)
sage: p.list()
```

```python
class sage.combinat.graph_path.GraphPaths_t(g, target)

Bases: Parent, GraphPaths_common

list()
EXAMPLES:

```python
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G, target=4)
sage: p.list()
```

### 5.1.116 Gray codes

#### Functions

```python
sage.combinat.gray_codes.combinations(n, t)
```

Iterator through the switches of the revolving door algorithm.

The revolving door algorithm is a way to generate all combinations of a set (i.e. the subset of given cardinality) in such way that two consecutive subsets differ by one element. At each step, the iterator output a pair \((i, j)\) where the item \(i\) has to be removed and \(j\) has to be added.

The ground set is always \(\{0, 1, ..., n - 1\}\). Note that \(n\) can be infinity in that algorithm.

See [Knu2011] Section 7.2.1.3, “Generating All Combinations”.

**INPUT:**

- \(n\) – (integer or Infinity) – size of the ground set
- \(t\) – (integer) – size of the subsets
EXAMPLES:

```python
sage: from sage.combinat.gray_codes import combinations
sage: b = [1, 1, 1, 0, 0]
sage: for i, j in combinations(5, 3):
    ....:     b[i] = 0; b[j] = 1
    ....:     print(b)
[1, 0, 1, 1, 0]
[0, 1, 1, 1, 0]
[1, 1, 0, 1, 0]
[1, 0, 0, 1, 1]
[0, 1, 0, 1, 1]
[0, 0, 1, 1, 1]
[1, 0, 1, 0, 1]
[0, 1, 1, 0, 1]
[1, 1, 0, 0, 1]
[1, 0, 0, 0, 1]

sage: s = set([0, 1])
sage: for i, j in combinations(4, 2):
    ....:     s.remove(i)
    ....:     s.add(j)
    ....:     print(sorted(s))
[1, 2]
[0, 2]
[2, 3]
[1, 3]
[0, 3]

Note that n can be infinity:

```python
sage: c = combinations(Infinity, 4)
sage: s = set([0, 1, 2, 3])
sage: for _ in range(10):
    ....:     i, j = next(c)
    ....:     s.remove(i); s.add(j)
    ....:     print(sorted(s))
[0, 1, 3, 4]
[1, 2, 3, 4]
[0, 2, 3, 4]
[0, 1, 2, 4]
[0, 1, 4, 5]
[1, 2, 4, 5]
[0, 2, 4, 5]
[2, 3, 4, 5]
[1, 3, 4, 5]
[0, 3, 4, 5]

sage: for _ in range(1000):
    ....:     i, j = next(c)
    ....:     s.remove(i); s.add(j)
sage: sorted(s)
[0, 4, 13, 14]
```

```
sage.combinat.gray_codes.product(m)
    Iterator over the switch for the iteration of the product $[m_0] \times [m_1] \ldots \times [m_k]$.
```

5.1. Comprehensive Module List
The iterator return at each step a pair \((p,i)\) which corresponds to the modification to perform to get the next element. More precisely, one has to apply the increment \(i\) at the position \(p\). By construction, the increment is either +1 or -1.

This is algorithm H in [Knu2011] Section 7.2.1.1, “Generating All \(n\)-Tuples”: loopless reflected mixed-radix Gray generation.

INPUT:

- \(m\) – a list or tuple of positive integers that correspond to the size of the sets in the product

EXAMPLES:

```python
sage: from sage.combinat.gray_codes import product
sage: l = [0,0,0]
sage: for p,i in product([3,3,3]):
    ....:  l[p] += i
    ....:  print(l)
[1, 0, 0]
[2, 0, 0]
[2, 1, 0]
[1, 1, 0]
[0, 1, 0]
[0, 2, 0]
[1, 2, 0]
[2, 2, 0]
[2, 2, 1]
[1, 2, 1]
[0, 2, 1]
[0, 1, 1]
[1, 1, 1]
[2, 1, 1]
[2, 0, 1]
[1, 0, 1]
[0, 0, 1]
[0, 0, 2]
[1, 0, 2]
[2, 0, 2]
[2, 1, 2]
[1, 1, 2]
[0, 1, 2]
[0, 2, 2]
[1, 2, 2]
[2, 2, 2]
sage: l = [0,0]
sage: for i,j in product([2,1]):
    ....:  1[i] += j
    ....:  print(1)
[1, 0]
```
5.1.117 Growth diagrams and dual graded graphs

AUTHORS:
- Martin Rubey (2016-09): Initial version
- Martin Rubey (2017-09): generalize, more rules, improve documentation
- Travis Scrimshaw (2017-09): switch to rule-based framework

Todo:
- provide examples for the P and Q-symbol in the skew case
- implement a method providing a visualization of the growth diagram with all labels, perhaps as LaTeX code
- when shape is given, check that it is compatible with filling or labels
- optimize rules, mainly for RuleRSK and RuleBurge
- implement backward rules for GrowthDiagram.rules.Domino
- implement backward rule from [LLMSSZ2013], [LS2007]
- make semistandard extension generic
- accommodate dual filtered graphs

A guided tour

Growth diagrams, invented by Sergey Fomin [Fom1994], [Fom1995], provide a vast generalization of the Robinson-Schensted-Knuth (RSK) correspondence between matrices with non-negative integer entries and pairs of semistandard Young tableaux of the same shape.

The main fact is that many correspondences similar to RSK can be defined by providing a pair of so-called local rules: a ‘forward’ rule, whose input are three vertices $y$, $t$ and $x$ of a certain directed graph (in the case of Robinson-Schensted: the directed graph corresponding to Young’s lattice) and an integer (in the case of Robinson-Schensted: 0 or 1), and whose output is a fourth vertex $z$. This rule should be invertible in the following sense: there is a so-called ‘backward’ rule that recovers the integer and $t$ given $y$, $z$ and $x$.

As an example, the growth rules for the classical RSK correspondence are provided by RuleRSK. To produce a growth diagram, pass the desired rule and a permutation to GrowthDiagram:

```sage
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: w = [2,3,6,1,4,5]; G = GrowthDiagram(RuleRSK, w); G
0 0 0 1 0 0
1 0 0 0 0 0
0 1 0 0 0 0
0 0 0 0 1 0
0 0 0 0 1 0
0 0 1 0 0 0
```

The forward rule just mentioned assigns 49 partitions to the corners of each of the 36 cells of this matrix (i.e., 49 the vertices of a $(6 + 1) \times (6 + 1)$ grid graph), with the exception of the corners on the left and top boundary, which are initialized with the empty partition. More precisely, for each cell, the forward_rule() computes the partition $z$ labelling the lower right corner, given the content $c$ of a cell and the other three partitions:
Warning: Note that a growth diagram is printed with matrix coordinates, the origin being in the top-left corner. Therefore, the growth is from the top left to the bottom right!

The partitions along the boundary opposite of the origin, reading from the bottom left to the top right, are obtained by using the method `out_labels()`:

```python
sage: G.out_labels()

[[],
 [1],
 [2],
 [3],
 [3, 1],
 [3, 2],
 [4, 2],
 [4, 1],
 [3, 1],
 [2, 1],
 [1, 1],
 [1],
 []]
```

However, in the case of a rectangular filling, it is more practical to split this sequence of labels in two. Interpreting the sequence of partitions along the right boundary as a standard Young tableau, we then obtain the so-called `P_symbol()`, the partitions along the bottom boundary yield the so-called `Q_symbol()`. These coincide with the output of the classical `RSK()` insertion algorithm:

```python
sage: ascii_art([G.P_symbol(), G.Q_symbol()])

[[1 3 4 5 1 2 3 6]
 [2 6 , 4 5 ]

sage: ascii_art(RSK(w))

[[1 3 4 5 1 2 3 6]
 [2 6 , 4 5 ]
```

The filling can be recovered knowing the partitions labelling the corners of the bottom and the right boundary alone, by repeatedly applying the `backward_rule()`. Therefore, to initialize a `GrowthDiagram`, we can provide these labels instead of the filling:

```python
sage: GrowthDiagram(RuleRSK, labels=G.out_labels())
```

```
0 0 0 1 0 0
1 0 0 0 0 0
0 1 0 0 0 0
0 0 0 0 1 0
0 0 0 0 0 1
0 0 1 0 0 0
```
In general, growth diagrams are defined for $0 - 1$-fillings of arbitrary skew shapes. In the case of the Robinson-Schensted-Knuth correspondence, even arbitrary non-negative integers are allowed. In other cases, entries may be either zero or an $r$-th root of unity - for example, RuleDomino insertion is defined for signed permutations, that is, $r = 2$. Traditionally, words and permutations are also used to specify a filling in special cases.

To accommodate all this, the filling may be passed in various ways. The most general possibility is to pass a dictionary of coordinates to (signed) entries, where zeros can be omitted. In this case, when the parameter shape is not explicitly specified, it is assumed to be the minimal rectangle containing the origin and all coordinates with non-zero entries.

For example, consider the following generalized permutation:

\[
\begin{array}{cccc}
1 & 2 & 2 & 2 \\
4 & 2 & 3 & 3 \\
\end{array}
\]

that we encode as the dictionary:

```
sage: P = {(1-1,4-1): 1, (2-1,2-1): 1, (2-1,3-1): 2, (4-1,2-1): 1, (4-1,3-1): 1}
```

Note that we are subtracting 1 from all entries because of zero-based indexing, we obtain:

```
sage: GrowthDiagram(RuleRSK, P)
0 0 0 0
0 1 0 1
0 2 0 1
1 0 0 0
```

Alternatively, we could create the same growth diagram using a matrix.

Let us also mention that one can pass the arguments specifying a growth diagram directly to the rule:

```
sage: RuleRSK(P)
0 0 0 0
0 1 0 1
0 2 0 1
1 0 0 0
```

In contrast to the classical insertion algorithms, growth diagrams immediately generalize to fillings whose shape is an arbitrary skew partition:

```
sage: GrowthDiagram(RuleRSK, [3,1,2], shape=SkewPartition([[3,3,2],[1,1]]))
. 1 0
. 0 1
1 0
```

As an important example, consider the Stanley-Sundaram correspondence between oscillating tableaux and (partial) perfect matchings. Perfect matchings of $\{1,\ldots, 2r\}$ are in bijection with $0 - 1$-fillings of a triangular shape with $2r - 1$ rows, such that for each $k$ there is either exactly one non-zero entry in row $k$ or exactly one non-zero entry in column $2r - k$. Explicitly, if $(i, j)$ is a pair in the perfect matching, the entry in column $i - 1$ and row $2r - j$ equals 1. For example:

```
sage: m = [[1,5],[3,4],[2,7],[6,8]]
sage: G = RuleRSK({(i-1, 8-j): 1 for i,j in m}, shape=[7,6,5,4,3,2,1]); G
0 0 0 0 0 1 0
0 1 0 0 0 0
```

(continues on next page)
The partitions labelling the bottom-right corners along the boundary opposite of the origin then form a so-called oscillating tableau - the remaining partitions along the bottom-right boundary are redundant:

\[
\begin{array}{llllll}
\text{sage: } & G.\text{out_labels()}[1::2] \\
& [[1], [1, 1], [2, 1], [1, 1], [1], [1, 1], [1]]
\end{array}
\]

Another great advantage of growth diagrams is that we immediately have access to a skew version of the correspondence, by providing different initialization for the labels on the side of the origin. We reproduce the original example of Bruce Sagan and Richard Stanley, see also Tom Roby's thesis [Rob1991]:

\[
\begin{array}{llllll}
\text{sage: } & w = \{(1-1, 4-1): 1, (2-1, 2-1): 1, (4-1, 3-1): 1\} \\
\text{sage: } & T = \text{SkewTableau}([\text{[None, None], [None, 5], [1]]}) \\
\text{sage: } & U = \text{SkewTableau}([\text{[None, None], [None, 3], [5]])} \\
\text{sage: } & \text{labels} = T.\text{to_chain()}[::1] + U.\text{to_chain()}[1:] \\
\text{sage: } & G = \text{GrowthDiagram}(\text{RuleRSK}, \text{filling}=w, \text{shape}=[5,5,5,5,5], \text{labels}=\text{labels}); G \\
& 0 0 0 0 0 \\
& 0 1 0 0 0 \\
& 0 0 0 1 0 \\
& 1 0 0 0 0 \\
& 0 0 0 0 0 \\
\text{sage: } & \text{ascii_art([G.P_symbol(), G.Q_symbol()])} \\
& \begin{array}{cccc}
. & . & 2 & 3 \\
. & . & . & . \\
. & 4 & . & 2 \\
1 & . & 3 \\
5 & , & 5 \\
\end{array}
\end{array}
\]

Similarly, there is a correspondence for skew oscillating tableau. Let us conclude by reproducing Example 4.2.6 from [Rob1991]. The oscillating tableau, as given, is:

\[
\begin{array}{llllll}
\text{sage: } & o = [[2, 1], [2, 2], [3, 2], [4, 2], [4, 1], [4, 1, 1], [3, 1, 1], [3, 1], [3, 2], [3, 1], [2, 1]]
\end{array}
\]

From this, we have to construct the list of labels of the corners along the bottom-right boundary. The labels with odd indices are given by the oscillating tableau, the other labels are obtained by taking the smaller of the two neighbouring partitions:

\[
\begin{array}{llllll}
\text{sage: } & l = [o[i//2] \text{ if is_even(i) else min(o[(i-1)//2], o[(i+1)//2])} \\
& \text{sage: } & \text{for i in range(2*len(o)-1)} \] \\
& \text{sage: } & \text{la = list(range(len(o)-2, 0, -1))} \\
& \text{sage: } & G = \text{RuleRSK}(\text{labels}=l[1:-1], \text{shape}=la); G \\
& 0 0 0 0 0 0 0 1 0 \\
& 0 1 0 0 0 0 0 0 \\
& 0 0 0 0 0 0 0 \\
& 0 0 0 0 0 0 \\
& 0 0 0 0 0 \\
& 0 0 0 0 \\
& 0 0 0 \\
& 0 0 \\
\end{array}
\]

(continues on next page)
The skew tableaux can now be read off the partitions labelling the left and the top boundary. These can be accessed using the method `in_labels()`:

```python
sage: ascii_art( SkewTableau( chain=G.in_labels()[len(o)-2:]), ....: SkewTableau( chain=G.in_labels()[len(o)-2::-1]) )
```

```
. 1 . 7
5 4
```

### Rules currently available

As mentioned at the beginning, the Robinson-Schensted-Knuth correspondence is just a special case of growth diagrams. In particular, we have implemented the following local rules:

- RSK (`RuleRSK`).
- A variation of RSK originally due to Burge (`RuleBurge`).
- A correspondence producing binary words originally due to Viennot (`RuleBinaryWord`).
- A correspondence producing domino tableaux (`RuleDomino`) originally due to Barbasch and Vogan.
- A correspondence for shifted shapes (`RuleShiftedShapes`), where the original insertion algorithm is due to Sagan and Worley, and Haiman.
- The Sylvester correspondence, producing binary trees (`RuleSylvester`).
- The Young-Fibonacci correspondence (`RuleYoungFibonacci`).
- LLMS insertion (`RuleLLMS`).

### Background

At the heart of Fomin’s framework is the notion of dual graded graphs. This is a pair of digraphs $P, Q$ (multiple edges being allowed) on the same set of vertices $V$, that satisfy the following conditions:

- the graphs are graded, that is, there is a function $\rho : V \to \mathbb{N}$, such that for any edge $(v, w)$ of $P$ and also of $Q$ we have $\rho(w) = \rho(v) + 1$,
- there is a vertex 0 with rank zero, and
- there is a positive integer $r$ such that $DU = UD + rI$ on the free $\mathbb{Z}$-module $\mathbb{Z}[V]$, where $D$ is the down operator of $Q$, assigning to each vertex the formal sum of its predecessors, $U$ is the up operator of $P$, assigning to each vertex the formal sum of its successors, and $I$ is the identity operator.

Note that the condition $DU = UD + rI$ is symmetric with respect to the interchange of the graphs $P$ and $Q$, because the up operator of a graph is the transpose of its down operator.

For example, taking for both $P$ and $Q$ to be Young’s lattice and $r = 1$, we obtain the dual graded graphs for classical Schensted insertion.

Given such a pair of graphs, there is a bijection between the $r$-colored permutations on $k$ letters and pairs $(p, q)$, where $p$ is a path in $P$ from zero to a vertex of rank $k$ and $q$ is a path in $Q$ from zero to the same vertex.
It turns out that - in principle - this bijection can always be described by so-called local forward and backward rules, see [Fom1995] for a detailed description. Knowing at least the forward rules, or the backward rules, you can implement your own growth diagram class.

### Implementing your own growth diagrams

The class `GrowthDiagram` is written so that it is easy to implement growth diagrams you come across in your research. Moreover, the class tolerates some deviations from Fomin’s definitions. For example, although the general Robinson-Schensted-Knuth correspondence between integer matrices and semistandard tableaux is, strictly speaking, not a growth on dual graded graphs, it is supported by our framework.

For illustration, let us implement a growth diagram class with the backward rule only. Suppose that the vertices of the graph are the non-negative integers, the rank is given by the integer itself, and the backward rule is $(y, z, x) \mapsto \min(x, y)$ if $y = z$ or $x = z$ and $(y, z, x) \mapsto (\min(x, y), 1)$ otherwise.

We first need to import the base class for a rule:

```python
sage: from sage.combinat.growth import Rule
```

Next, we implement the backward rule and the rank function and provide the bottom element `zero` of the graph. For more information, see `Rule`.

```python
sage: class RulePascal(Rule):
    ....:     zero = 0
    ....:     def rank(self, v):
    ....:         return v
    ....:     def backward_rule(self, y, z, x):
    ....:         return (min(x, y), 0 if y==z or x==z else 1)
```

We can now compute the filling corresponding to a sequence of labels as follows:

```python
sage: GrowthDiagram(RulePascal(), labels=[0,1,2,1,2,1,0])
1 0 0
0 0 1
0 1
```

Of course, since we have not provided the forward rule, we cannot compute the labels belonging to a filling:

```python
sage: GrowthDiagram(RulePascal(), [3,1,2])
Traceback (most recent call last):
...
AttributeError: 'RulePascal' object has no attribute 'forward_rule'
```

We now re-implement the rule where we provide the dual graded graphs:

```python
sage: class RulePascal(Rule):
    ....:     zero = 0
    ....:     def rank(self, v):
    ....:         return v
    ....:     def backward_rule(self, y, z, x):
    ....:         return (min(x, y), 0 if y==z or x==z else 1)
    ....:     def vertices(self, n):
    ....:         return [n]
    ....:     def is_P_edge(self, v, w):
    ....:         return w == v + 1
    ....:     def is_Q_edge(self, v, w):
    ....:         return w == v + 1
```

Are they really dual?
With our current definition, duality fails - in fact, there are no dual graded graphs on the integers without multiple edges. Consequently, also the backward rule cannot work as `backward_rule` requires additional information (the edge labels as arguments).

Let us thus continue with the example from Section 4.7 of [Fom1995] instead, which defines dual graded graphs with multiple edges on the integers. The color `self.zero_edge`, which defaults to 0 is reserved for degenerate edges, but may be abused for the unique edge if one of the graphs has no multiple edges. For greater clarity in this example we set it to None:

```python
sage: class RulePascal(Rule):
    ...:     zero = 0
    ...:     has_multiple_edges = True
    ...:     zero_edge = None
    ...:     def rank(self, v): return v
    ...:     def vertices(self, n): return [n]
    ...:     def is_P_edge(self, v, w): return [0] if w == v + 1 else []
    ...:     def is_Q_edge(self, v, w): return list(range(w)) if w == v+1 else []

We verify these are 1 dual at level 5:

```python
sage: RulePascal()._check_duality(5)
```

Finally, let us provide the backward rule. The arguments of the rule are vertices together with the edge labels now, specifying the path from the lower left to the upper right of the cell. The horizontal edges come from $Q$, whereas the vertical edges come from $P$.

Thus, the definition in Section 4.7 of [Fom1995] translates as follows:

```python
sage: class RulePascal(Rule):
    ...:     zero = 0
    ...:     has_multiple_edges = True
    ...:     zero_edge = None
    ...:     def rank(self, v): return v
    ...:     def vertices(self, n): return [n]
    ...:     def is_P_edge(self, v, w): return [0] if w == v + 1 else []
    ...:     def is_Q_edge(self, v, w): return list(range(w)) if w == v+1 else []
    ...:     def backward_rule(self, y, g, z, h, x):
    ...:         if g is None:
    ...:             return (0, x, None, 0)
    ...:         if h is None:
    ...:             return (None, y, g, 0)
    ...:         if g == 0:
    ...:             return (None, y, None, 1)
    ...:         else:
    ...:             return (0, x-1, g-1, 0)
```

The labels are now alternating between vertices and edge-colors:

```
5.1. Comprehensive Module List
```
class sage.combinat.growth.GrowthDiagram(rule, filling=None, shape=None, labels=None)

Bases: SageObject

A generalized Schensted growth diagram in the sense of Fomin.

Growth diagrams were introduced by Sergey Fomin [Fom1994], [Fom1995] and provide a vast generalization of the Robinson-Schensted-Knuth (RSK) correspondence between matrices with non-negative integer entries and pairs of semistandard Young tableaux of the same shape.

A growth diagram is based on the notion of dual graded graphs, a pair of digraphs $P, Q$ (multiple edges being allowed) on the same set of vertices $V$, that satisfy the following conditions:

- the graphs are graded, that is, there is a function $\rho : V \rightarrow \mathbb{N}$, such that for any edge $(v, w)$ of $P$ and also of $Q$ we have $\rho(w) = \rho(v) + 1$,
- there is a vertex $0$ with rank zero, and
- there is a positive integer $r$ such that $DU = UD + rI$ on the free $\mathbb{Z}$-module $\mathbb{Z}[V]$, where $D$ is the down operator of $Q$, assigning to each vertex the formal sum of its predecessors, $U$ is the up operator of $P$, assigning to each vertex the formal sum of its successors, and $I$ is the identity operator.

Growth diagrams are defined by providing a pair of local rules: a ‘forward’ rule, whose input are three vertices $y, t$ and $x$ of the dual graded graphs and an integer, and whose output is a fourth vertex $z$. This rule should be invertible in the following sense: there is a so-called ‘backward’ rule that recovers the integer and $t$ given $y$, $z$ and $x$.

All implemented growth diagram rules are available by GrowthDiagram.rules.<tab>. The current list is:

- RuleRSK – RSK
- RuleBurge – a variation of RSK originally due to Burge
- RuleBinaryWord – a correspondence producing binary words originally due to Viennot
- RuleDomino – a correspondence producing domino tableaux originally due to Barbasch and Vogan
- RuleShiftedShapes – a correspondence for shifted shapes, where the original insertion algorithm is due to Sagan and Worley, and Haiman.
- RuleSylvester – the Sylvester correspondence, producing binary trees
- RuleYoungFibonacci – the Young-Fibonacci correspondence
- RuleLLMS – LLMS insertion

INPUT:

- rule – Rule; the growth diagram rule
- filling – (optional) a dictionary whose keys are coordinates and values are integers, a list of lists of integers, or a word with integer values; if a word, then negative letters but without repetitions are allowed and interpreted as coloured permutations
- shape – (optional) a (possibly skew) partition
Combinatorics, Release 10.1

- **labels** – (optional) a list that specifies a path whose length in the half-perimeter of the shape; more details given below

If filling is not given, then the growth diagram is determined by applying the backward rule to labels decorating the boundary opposite of the origin of the shape. In this case, labels are interpreted as labelling the boundary opposite of the origin.

Otherwise, shape is inferred from filling or labels if possible and labels is set to rule.zero if not specified. Here, labels are labelling the boundary on the side of the origin.

For labels, if rule.has_multiple_edges is True, then the elements should be of the form $(v_1, e_1, \ldots, e_{n-1}, v_n)$, where $n$ is the half-perimeter of shape, and $(v_{i-1}, e_i, v_i)$ is an edge in the dual graded graph for all $i$. Otherwise, it is a list of $n$ vertices.

**Note:** Coordinates are of the form (col, row) where the origin is in the upper left, to be consistent with permutation matrices and skew tableaux (in English convention). This is different from Fomin’s convention, who uses a Cartesian coordinate system.

Conventions are chosen such that for permutations, the same growth diagram is constructed when passing the permutation matrix instead.

**EXAMPLES:**

We create a growth diagram using the forward RSK rule and a permutation:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: pi = Permutation([4, 1, 2, 3])
sage: G = GrowthDiagram(RuleRSK, pi); G
0 1 0 0
0 0 1 0
0 0 0 1
1 0 0 0
sage: G.out_labels()
[[], [1], [1, 1], [2, 1], [3, 1], [3], [2], [1], []]
```

Passing the permutation matrix instead gives the same result:

```
sage: G = GrowthDiagram(RuleRSK, pi.to_matrix())
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 3 1 3 4 ]
[ 4 , 2 ]
```

We give the same example but using a skew shape:

```
sage: shape = SkewPartition([[4,4,4,2],[1,1]])
sage: G = GrowthDiagram(RuleRSK, pi, shape=shape); G
. 1 0 0
. 0 1 0
0 0 0 1
1 0
sage: G.out_labels()
[[], [1], [1, 1], [1], [2], [3], [2], [1], []]
```

We construct a growth diagram using the backwards RSK rule by specifying the labels:
sage: GrowthDiagram(RuleRSK, labels=G.out_labels())
0 1 0 0
0 0 1 0
0 0 0 1
1 0

P_chain()  
Return the labels along the vertical boundary of a rectangular growth diagram.

EXAMPLES:

sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: G = GrowthDiagram(BinaryWord, [4, 1, 2, 3])
sage: G.P_chain()  
[word: , word: 1, word: 11, word: 111, word: 1011]

Check that github issue #25631 is fixed:

sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord(filling = {}).P_chain()  
[word: ]

P_symbol()  
Return the labels along the vertical boundary of a rectangular growth diagram as a generalized standard tableau.

EXAMPLES:

sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[[ 1 2 2 1 3 3 ],
 [ 2 , 2 ]]

Q_chain()  
Return the labels along the horizontal boundary of a rectangular growth diagram.

EXAMPLES:

sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: G = GrowthDiagram(BinaryWord, [[0,1,0,0], [0,0,1,0], [0,0,0,1], [1,0,0,
˓→0]])

sage: G.Q_chain()  
[word: , word: 1, word: 10, word: 101, word: 1011]

Check that github issue #25631 is fixed:

sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord(filling = {}).Q_chain()  
[word: ]

Q_symbol()  
Return the labels along the horizontal boundary of a rectangular growth diagram as a generalized standard tableau.

EXAMPLES:
conjugate()

Return the conjugate growth diagram of self.

This is the growth diagram with the filling reflected over the main diagonal.

The sequence of labels along the boundary on the side of the origin is the reversal of the corresponding sequence of the original growth diagram.

When the filling is a permutation, the conjugate filling corresponds to its inverse.

EXAMPLES:

```sage
RuleRSK = GrowthDiagram.rules.RSK()
G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
Gc = G.conjugate()
(Gc.P_symbol(), Gc.Q_symbol()) == (G.Q_symbol(), G.P_symbol())
True
```

filling()

Return the filling of the diagram as a dictionary.

EXAMPLES:

```sage
RuleRSK = GrowthDiagram.rules.RSK()
G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
G.filling()
{(0, 1): 1, (1, 0): 1, (2, 1): 2}
```

half_perimeter()

Return half the perimeter of the shape of the growth diagram.

in_labels()

Return the labels along the boundary on the side of the origin.

EXAMPLES:

```sage
RuleRSK = GrowthDiagram.rules.RSK()
G = GrowthDiagram(RuleRSK, labels=[[2,2],[3,2],[3,3],[3,2]]); G
[[2, 2], [2, 2], [2, 2], [3, 2]]
G.in_labels()
[[2, 2], [2, 2], [2, 2], [3, 2]]
```

is_rectangular()

Return True if the shape of the growth diagram is rectangular.

EXAMPLES:

```sage
RuleRSK = GrowthDiagram.rules.RSK()
G = GrowthDiagram(RuleRSK, [2,3,1]).is_rectangular()
True
```
sage: GrowthDiagram(RuleRSK, [[1,0,1],[0,1]]).is_rectangular()
False

out_labels()
Return the labels along the boundary opposite of the origin.

EXAMPLES:

sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: G.out_labels()
[[], [1], [1, 1], [3, 1], [1], []]

rotate()
Return the growth diagram with the filling rotated by 180 degrees.

The rotated growth diagram is initialized with labels=None, that is, all labels along the boundary on the side of the origin are set to rule.zero.

For RSK-growth diagrams and rectangular fillings, this corresponds to evacuation of the $P$- and the $Q$-symbol.

EXAMPLES:

sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: Gc = G.rotate()
sage: ascii_art([Gc.P_symbol(), Gc.Q_symbol()])
[ 1 1 1 1 1 2 ]
[ 2 , 3 ]
sage: ascii_art([Tableau(t).evacuation() for t in [G.P_symbol(), G.Q_symbol()]])
[ 1 1 1 1 1 2 ]
[ 2 , 3 ]

rules
alias of Rules

shape()
Return the shape of the growth diagram as a skew partition.

WARNING: In the literature the label on the corner opposite of the origin of a rectangular filling is often called the shape of the filling. This method returns the shape of the region instead.

EXAMPLES:

sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [1]).shape()
[1] / []

to_biword()
Return the filling as a biword, if the shape is rectangular.
EXAMPLES:

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: P = Tableau([[1,2,2],[2]])
sage: Q = Tableau([[1,3,3],[2]])
sage: bw = RSK_inverse(P, Q); bw
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-1]+P.to_chain()[:-1]); G
0 1 0
1 0 2
```

```python
sage: P = SemistandardTableau([[1, 1, 2], [2]])
sage: Q = SemistandardTableau([[1, 2, 2], [2]])
sage: G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-1]+P.to_chain()[:-1]); G
0 2
1 1
```

```python
sage: G.to_biword()
([1, 2, 2, 2], [2, 1, 1, 2])
```

```python
sage: RSK([[1, 2, 2, 2], [2, 1, 1, 2]])
[[[1, 2, 2, 2], [2]], [[1, 1, 2], [2]]]
```

to_word()

Return the filling as a word, if the shape is rectangular and there is at most one nonzero entry in each column, which must be 1.

EXAMPLES:

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: w = [3,3,2,4,1]; G = GrowthDiagram(RuleRSK, w)
sage: G
0 0 0 0 1
0 0 1 0 0
1 1 0 0 0
0 0 0 1 0
```

```python
sage: G.to_word()
[3, 3, 2, 4, 1]
```

class sage.combinat.growth.Rule

Bases: UniqueRepresentation

Generic base class for a rule for a growth diagram.

Subclasses may provide the following attributes:

- `zero` – the zero element of the vertices of the graphs
- `r` – (default: 1) the parameter in the equation $DU - UD = rI$
- `has_multiple_edges` – (default: False) if the dual graded graph has multiple edges and therefore edges are triples consisting of two vertices and a label.
- `zero_edge` – (default: 0) the zero label of the edges of the graphs used for degenerate edges. It is allowed to use this label also for other edges.

Subclasses may provide the following methods:

- `normalize_vertex` – a function that converts its input to a vertex.
- `vertices` – a function that takes a non-negative integer as input and returns the list of vertices on this rank.
• **rank** – the rank function of the dual graded graphs.

• **forward_rule** – a function with input \((y, t, x, \text{content})\) or \((y, e, t, f, x, \text{content})\) if `has_multiple_edges` is True. \((y, e, t)\) is an edge in the graph \(P\). \((t, f, x)\) an edge in the graph \(Q\). It should return the fourth vertex \(z\), or, if `has_multiple_edges` is True, the path \((g, z, h)\) from \(y\) to \(x\).

• **backward_rule** – a function with input \((y, z, x)\) or \((y, g, z, h, x)\) if `has_multiple_edges` is True. \((y, g, z)\) is an edge in the graph \(Q\). \((z, h, x)\) an edge in the graph \(P\). It should return the fourth vertex and the content \((t, \text{content})\), or, if `has_multiple_edges` is True, the path from \(y\) to \(x\) and the content as \((e, t, f, \text{content})\).

• **is_P_edge**, **is_Q_edge** – functions that take two vertices as arguments and return `True` or `False`, or, if multiple edges are allowed, the list of edge labels of the edges from the first vertex to the second in the respective graded graph. These are only used for checking user input and providing the dual graded graph, and are therefore not mandatory.

Note that the class **GrowthDiagram** is able to use partially implemented subclasses just fine. Suppose that **MyRule** is such a subclass. Then:

• **GrowthDiagram(MyRule, my_filling)** requires only an implementation of **forward_rule**, `zero` and possibly `has_multiple_edges`.

• **GrowthDiagram(MyRule, labels=my_labels, shape=my_shape)** requires only an implementation of **backward_rule** and possibly `has_multiple_edges`, provided that the labels `my_labels` are given as needed by **backward_rule**.

• **GrowthDiagram(MyRule, labels=my_labels)** additionally needs an implementation of **rank** to deduce the shape.

In particular, this allows to implement rules which do not quite fit Fomin’s notion of dual graded graphs. An example would be Bloom and Saracino’s variant of the RSK correspondence [BS2012], where a backward rule is not available.

Similarly:

• **MyRule.P_graph** only requires an implementation of **vertices**, **is_P_edge** and possibly `has_multiple_edges` is required, *mutatis mutandis* for **MyRule.Q_graph**.

• **MyRule._check_duality** requires **P_graph** and **Q_graph**.

In particular, this allows to work with dual graded graphs without local rules.

**P_graph**(\(n\))

Return the first \(n\) levels of the first dual graded graph.

The non-degenerate edges in the vertical direction come from this graph.

EXEMPLARY:

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.P_graph(3)
Finite poset containing 8 elements
```

**Q_graph**(\(n\))

Return the first \(n\) levels of the second dual graded graph.

The non-degenerate edges in the horizontal direction come from this graph.

EXEMPLARY:
```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: Q = Domino.Q_graph(3); Q
Finite poset containing 8 elements
sage: Q.upper_covers(Partition([1,1]))
[[1, 1, 1, 1], [3, 1], [2, 2]]
```

```python
has_multiple_edges = False

normalize_vertex(v)
Return v as a vertex of the dual graded graph.
This is a default implementation, returning its argument.

EXAMPLES:
```python
sage: from sage.combinat.growth import Rule
dsage: Rule().normalize_vertex("hello") == "hello"
True
```

```python
r = 1
zero_edge = 0

class sage.combinat.growth.RuleBinaryWord
Bases: Rule
A rule modelling a Schensted-like correspondence for binary words.

EXAMPLES:
```python
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: GrowthDiagram(BinaryWord, [3,1,2])
0 1 0 0 0 0 0 0 0
0 0 0 0 0 0 1 0 0
1 0 0
```

The vertices of the dual graded graph are binary words:
```python
sage: BinaryWord.vertices(3)
[word: 100, word: 101, word: 110, word: 111]
```

Note that, instead of passing the rule to `GrowthDiagram`, we can also use call the rule to create growth diagrams. For example:
```python
sage: BinaryWord([2,4,1,3]).P_chain()
[word: , word: 1, word: 10, word: 101, word: 1101]
sage: BinaryWord([2,4,1,3]).Q_chain()
[word: , word: 1, word: 11, word: 110, word: 1101]
```

The Kleitman Greene invariant is the descent word, encoded by the positions of the zeros:
```python
sage: pi = Permutation([4,1,8,3,6,5,2,7,9])
sage: G = BinaryWord(pi); G
0 1 0 0 0 0 0 0 0
0 0 0 0 0 1 0 0
```

(continues on next page)
backward_rule(y, z, x)

Return the content and the input shape.

• y, z, x – three binary words from a cell in a growth diagram, labelled as:

\[
\begin{align*}
    & x \\
    & y \\
    \end{align*}
\]

OUTPUT:

A pair (t, content) consisting of the shape of the fourth word and the content of the cell according to Viennot’s bijection [Vie1983].

forward_rule(y, t, x, content)

Return the output shape given three shapes and the content.

INPUT:

• y, t, x – three binary words from a cell in a growth diagram, labelled as:

\[
\begin{align*}
    & t \\
    & x \\
    & y \\
\end{align*}
\]

• content – 0 or 1; the content of the cell

OUTPUT:

The fourth binary word z according to Viennot’s bijection [Vie1983].

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()

sage: BinaryWord.forward_rule([], [], [], 1)
word: 1

sage: BinaryWord.forward_rule([1], [1], [1], 1)
word: 11

if x != y append last letter of x to y:

sage: BinaryWord.forward_rule([1,0], [1], [1,1], 0)
word: 101
```
if x == y != t append 0 to y:

```
sage: BinaryWord.forward_rule([1,1], [1], [1,1], 0)
word: 110
```

**is_P_edge**(*v*, *w*)
Return whether (*v*, *w*) is a $P$-edge of self.

(*v*, *w*) is an edge if *v* is obtained from *w* by deleting a letter.

**EXAMPLES:**

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: v = BinaryWord.vertices(2)[1]; v
word: 11
sage: [w for w in BinaryWord.vertices(3) if BinaryWord.is_P_edge(v, w)]
[word: 101, word: 110, word: 111]
sage: [w for w in BinaryWord.vertices(4) if BinaryWord.is_P_edge(v, w)]
[]
```

**is_Q_edge**(*v*, *w*)
Return whether (*v*, *w*) is a $Q$-edge of self.

(*w*, *v*) is an edge if *w* is obtained from *v* by appending a letter.

**EXAMPLES:**

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: v = BinaryWord.vertices(2)[0]; v
word: 10
sage: [w for w in BinaryWord.vertices(3) if BinaryWord.is_Q_edge(v, w)]
[word: 100, word: 101]
sage: [w for w in BinaryWord.vertices(4) if BinaryWord.is_Q_edge(v, w)]
[]
```

**normalize_vertex**(*v*)
Return *v* as a binary word.

**EXAMPLES:**

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.normalize_vertex([0,1]).parent()
Finite words over {0, 1}
```

**rank**(*v*)
Return the rank of *v*: number of letters of the word.

**EXAMPLES:**

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.rank(BinaryWord.vertices(3)[0])
3
```

**vertices**(*n*)
Return the vertices of the dual graded graph on level *n*.

**EXAMPLES:**
class sage.combinat.growth.RuleBurge

Bases: RulePartitions

A rule modelling Burge insertion.

EXAMPLES:

```python
sage: Burge = GrowthDiagram.rules.Burge()

sage: GrowthDiagram(Burge, labels=[[], [1, 1, 1], [2, 1, 1, 1], [2, 1, 1], [2, 1], [1, 1], []])

1 1
0 1
1 0
1 0
```

The vertices of the dual graded graph are integer partitions:

```python
sage: Burge.vertices(3)
```

Partitions of the integer 3

The local rules implemented provide Burge’s correspondence between matrices with non-negative integer entries and pairs of semistandard tableaux, the `P_symbol()` and the `Q_symbol()`. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams. For example:

```python
sage: m = matrix([[2, 0, 0, 1, 0], [1, 1, 0, 0, 0], [0, 0, 0, 0, 3]])

sage: G = Burge(m); G
```

```python
2 0 0 1 0
1 1 0 0 0
0 0 0 0 3
```

```python
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
```

```
[[ 1 2 3 1 2 5 ]
 [ 1 3 1 5 ]
 [ 1 3 1 5 ]
 [ 2 , 4 ]
```

For rectangular fillings, the Kleitman-Greene invariant is the shape of the `P_symbol()`. Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the transpose of the partition \((\mu_1, \ldots, \mu_n)\), where \(\mu_1 + \cdots + \mu_i\) is the maximal sum of entries in a collection of \(i\) pairwise disjoint sequences of cells with weakly decreasing row indices and weakly increasing column indices.

backward_rule\((y, z, x)\)

Return the content and the input shape.

See [Kra2006] \((B^4) - (B^4)\). (In the arXiv version of the article there is a typo: in the computation of carry in \((B^4)\), \(\rho\) must be replaced by \(\lambda\).)
• y, z, x – three partitions from a cell in a growth diagram, labelled as:

```
x
y z
```

OUTPUT:

A pair \((t, \text{content})\) consisting of the shape of the fourth partition according to the Burge correspondence and the content of the cell.

EXAMPLES:

```
sage: Burge = GrowthDiagram.rules.Burge()
sage: Burge.backward_rule([1,1,1],[2,1,1,1],[2,1,1])
([1, 1], 0)
```

\textbf{forward\_rule}(y, t, x, content)

Return the output shape given three shapes and the content.

See [Kra2006] \((F^40) - (F^42)\).

INPUT:

• y, t, x – three from a cell in a growth diagram, labelled as:

```
t x
y
```

• content – a non-negative integer; the content of the cell

OUTPUT:

The fourth partition according to the Burge correspondence.

EXAMPLES:

```
sage: Burge = GrowthDiagram.rules.Burge()
sage: Burge.forward_rule([2,1],[2,1],[2,1],1)
[3, 1]
sage: Burge.forward_rule([1],[],[2],2)
[2, 1, 1, 1]
```

class \texttt{sage.combinat.growth.RuleDomino}

\texttt{Bases: Rule}

A rule modelling domino insertion.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: GrowthDiagram(Domino, [[1,0,0],[0,0,1],[0,-1,0]])
1 0 0
0 0 1
0 -1 0
```

The vertices of the dual graded graph are integer partitions whose Ferrers diagram can be tiled with dominoes:

```
sage: Domino.vertices(2)
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```
Instead of passing the rule to \texttt{GrowthDiagram}, we can also call the rule to create growth diagrams. For example, let us check Figure 3 in [Lam2004]:

\begin{verbatim}
sage: G = Domino([[0,0,0,-1],[0,0,1,0],[-1,0,0,0],[0,1,0,0]]); G
0 0 0 -1
0 0 1 0
-1 0 0 0
0 1 0 0

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 4 1 2 2 ]
[ 1 2 4 1 3 3 ]
[ 3 3 , 4 4 ]
\end{verbatim}

The spin of a domino tableau is half the number of vertical dominoes:

\begin{verbatim}
sage: def spin(T):
    ...:
        return sum(2*len(set(row)) - len(row) for row in T)/4
\end{verbatim}

According to [Lam2004], the number of negative entries in the signed permutation equals the sum of the spins of the two associated tableaux:

\begin{verbatim}
sage: pi = [3,-1,2,4,-5]
sage: G = Domino(pi)
sage: list(G.filling().values()).count(-1) == spin(G.P_symbol()) + spin(G.Q_symbol())
True
\end{verbatim}

Negating all signs transposes all the partitions:

\begin{verbatim}
sage: G.P_symbol() == Domino([-e for e in pi]).P_symbol().conjugate()
True
\end{verbatim}

**\texttt{P\_symbol}(P\_chain)**

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) domino tableau.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: Domino = GrowthDiagram.rules.Domino()
sage: G = Domino([[0,1,0],[0,0,-1],[1,0,0]])
sage: G.P_symbol().pp()
1 1
2 3
2 3
\end{verbatim}

**\texttt{Q\_symbol}(P\_chain)**

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) domino tableau.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: Domino = GrowthDiagram.rules.Domino()
sage: G = Domino([[0,1,0],[0,0,-1],[1,0,0]])
sage: G.P_symbol().pp()
1 1
2 3
2 3
\end{verbatim}
forward_rule(y, t, x, content)

Return the output shape given three shapes and the content.

See [Lam2004] Section 3.1.

INPUT:

- y, t, x – three partitions from a cell in a growth diagram, labelled as:

```
  t x
  y
```

- content – −1, 0 or 1; the content of the cell

OUTPUT:

The fourth partition according to domino insertion.

EXAMPLES:

```sage
Domino = GrowthDiagram.rules.Domino()
```

Rule 1:

```sage
Domino.forward_rule([], [], [], 1)
[2]
```

```sage
Domino.forward_rule([1,1], [1,1], [1,1], 1)
[3, 1]
```

Rule 2:

```sage
Domino.forward_rule([1,1], [1,1], [1,1], -1)
[1, 1, 1, 1]
```

Rule 3:

```sage
Domino.forward_rule([1,1], [1,1], [2,2], 0)
[2, 2]
```

Rule 4:

```sage
Domino.forward_rule([2,2,2], [2,2], [3,3], 0)
[3, 3, 2]
```

```sage
Domino.forward_rule([2], [], [1,1], 0)
[2, 2]
```

```sage
Domino.forward_rule([1,1], [], [2], 0)
[2, 2]
```

```sage
Domino.forward_rule([2], [], [2], 0)
[2, 2]
```

```sage
Domino.forward_rule([4], [2], [4], 0)
[4, 2]
```
is_P_edge(v, w)
Return whether \((v, w)\) is a \(P\)-edge of \(self\).
\((v, w)\) is an edge if \(v\) is obtained from \(w\) by deleting a domino.

EXAMPLES:

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: v = Domino.vertices(2)[1]; ascii_art(v)
*** *
sage: ascii_art([w for w in Domino.vertices(3) if Domino.is_P_edge(v, w)])
[ *** ]
[ * ]
[ ***** *** * ]
[ * , ***, * ]
```

is_Q_edge(v, w)
Return whether \((v, w)\) is a \(P\)-edge of \(self\).
\((v, w)\) is an edge if \(v\) is obtained from \(w\) by deleting a domino.

EXAMPLES:

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: v = Domino.vertices(2)[1]; ascii_art(v)
*** *
sage: ascii_art([w for w in Domino.vertices(3) if Domino.is_P_edge(v, w)])
[ *** ]
[ * ]
[ ***** *** * ]
[ * , ***, * ]
```

normalize_vertex(v)
Return \(v\) as a partition.

EXAMPLES:

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.normalize_vertex([3,1]).parent()
Partitions
r = 2
**rank**\( (v) \)

Return the rank of \( v \).

The rank of a vertex is half the size of the partition, which equals the number of dominoes in any filling.

**EXAMPLES:**

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.rank(Domino.vertices(3)[0])
3
```

**vertices**\( (n) \)

Return the vertices of the dual graded graph on level \( n \).

**EXAMPLES:**

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.vertices(2)
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

**zero** = []

---

**class** **sage.combinat.growth.RuleLLMS**\( (k) \)

Bases: **Rule**

A rule modelling the Schensted correspondence for affine permutations.

**EXAMPLES:**

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: GrowthDiagram(LLMS3, [3,1,2])
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are **Cores**:

```python
sage: LLMS3.vertices(4)
3-Cores of length 4
```

Let us check example of Figure 1 in [LS2007]. Note that, instead of passing the rule to **GrowthDiagram**, we can also call the rule to create growth diagrams:

```python
sage: G = LLMS3([4,1,2,6,3,5]); G
0 1 0 0 0 0
0 0 1 0 0 0
0 0 0 0 1 0
1 0 0 0 0 0
0 0 0 0 0 1
0 0 0 1 0 0
```

The **P_symbol()** is a **StrongTableau**:

```python
sage: G.P_symbol().pp()
-1 -2 -3 -5
```

(continues on next page)
The \texttt{Q\_symbol()} is a \texttt{WeakTableau}:

\begin{verbatim}
sage: G.Q_symbol().pp()
1  3  4  5
2  5
3  6
5  6
\end{verbatim}

Let us also check Example 6.2 in [LLMSSZ2013]:

\begin{verbatim}
sage: G = LLMS3([4,1,3,2])
sage: G.P_symbol().pp()
-1 -2  3
-3
-4
sage: G.Q_symbol().pp()
1  3  4
2
3
\end{verbatim}

\texttt{P\_symbol}(\texttt{P\_chain})

Return the labels along the vertical boundary of a rectangular growth diagram as a skew \texttt{StrongTableau}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3,4,1,2])
sage: G.P_symbol().pp()
-1 -2
-3 -4
\end{verbatim}

\texttt{Q\_symbol}(\texttt{Q\_chain})

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew \texttt{WeakTableau}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3,4,1,2])
sage: G.Q_symbol().pp()
1  2
3  4
\end{verbatim}

\texttt{forward\_rule}(y, e, t, f, x, content)

Return the output path given two incident edges and the content.

See [LS2007] Section 3.4 and [LLMSSZ2013] Section 6.3.

\textbf{INPUT:}
• $y$, $e$, $t$, $f$, $x$ – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
t f x
  e
  y
```

• content $=$ 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition $g$, $z$, $h$ according to LLMS insertion.

EXAMPLES:

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: Z = LLMS3.zero
sage: LLMS3.forward_rule(Z, None, Z, None, Z, 0)
(None, [], None)
sage: LLMS3.forward_rule(Z, None, Z, None, Z, 1)
(None, [1], None)
sage: Y = Core([3,1,1], 3)
sage: LLMS3.forward_rule(Y, None, Y, None, Y, 1)
(None, [4, 2, 1, 1], 3)
```

if $x = y$:

```python
sage: Y = Core([1,1], 3); T = Core([1], 3); X = Core([2], 3)
sage: LLMS3.forward_rule(Y, -1, T, None, X, 0)
(None, [2, 1, 1], -1)
sage: Y = Core([2], 4); T = Core([1], 4); X = Core([1,1], 4)
sage: LLMS4.forward_rule(Y, 1, T, None, X, 0)
(None, [2, 1], 1)
```

if $x = y = t$:

```python
sage: Y = Core([1], 3); T = Core([], 3); X = Core([1], 3)
```

```python
sage: Y = Core([1], 4); T = Core([], 4); X = Core([1], 4)
```

```python
sage: Y = Core([2,1], 4); T = Core([1,1], 4); X = Core([2,1], 4)
```
has_multiple_edges = True

is_P_edge(v, w)

Return whether \((v, w)\) is a \(P\)-edge of \(self\).

For two \(k\)-cores \(v\) and \(w\) containing \(v\), there are as many edges as there are components in the skew partition \(w/v\). These components are ribbons, and therefore contain a unique cell with maximal content. We index the edge with this content.

EXAMPLES:

```python
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(2)[0]; v
[2]
sage: [(w, LLMS4.is_P_edge(v, w)) for w in LLMS4.vertices(3)]
[[[3], [2]], ([2, 1], [-1]), ([1, 1, 1], [])]
sage: all(LLMS4.is_P_edge(v, w) == [] for w in LLMS4.vertices(4))
True
```

is_Q_edge(v, w)

Return whether \((v, w)\) is a \(Q\)-edge of \(self\).

\((v, w)\) is an edge if \(w\) is a weak cover of \(v\), see \texttt{weak_covers()}. 

EXAMPLES:

```python
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(3)[1]; v
[2, 1]
sage: [w for w in LLMS4.vertices(4) if len(LLMS4.is_Q_edge(v, w)) > 0]
[[2, 2], [3, 1, 1]]
sage: all(LLMS4.is_Q_edge(v, w) == [] for w in LLMS4.vertices(5))
True
```

normalize_vertex(v)

Convert \(v\) to a \(k\)-core.

EXAMPLES:

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.normalize_vertex([3,1]).parent()
3-Cores of length 3
```

rank(v)

Return the rank of \(v\): the length of the core.

EXAMPLES:

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.rank(LLMS3.vertices(3)[0])
3
```

vertices(n)

Return the vertices of the dual graded graph on level \(n\).

EXAMPLES:
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.vertices(2)
3-Cores of length 2

zero_edge = None

class sage.combinat.growth.RulePartitions
Bases: Rule

A rule for growth diagrams on Young’s lattice on integer partitions graded by size.

P_symbol(P_chain)
Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.P_symbol().pp()
1 2 2
2
```

Q_symbol(Q_chain)
Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.Q_symbol().pp()
1 3 3
2
```

normalize_vertex(v)
Return v as a partition.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.normalize_vertex([3,1]).parent()
Partitions
```

rank(v)
Return the rank of v: the size of the partition.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.rank(RSK.vertices(3)[0])
3
```

vertices(n)
Return the vertices of the dual graded graph on level n.

EXAMPLES:
Combinatorics, Release 10.1

```python
sage: RSK = GrowthDiagram.rules.RSK
sage: RSK.vertices(3)
Partitions of the integer 3
```

```python
class sage.combinat.growth.RuleRSK

Bases: RulePartitions

A rule modelling Robinson-Schensted-Knuth insertion.

EXAMPLES:

```python
sage: RuleRSK = GrowthDiagram.rules.RSK
sage: GrowthDiagram(RuleRSK, [3,2,1,2,3])
0 0 1 0 0
0 1 0 1 0
1 0 0 0 1

The vertices of the dual graded graph are integer partitions:

```python
sage: RuleRSK.vertices(3)
Partitions of the integer 3
```

The local rules implemented provide the RSK correspondence between matrices with non-negative integer entries and pairs of semistandard tableaux, the `P_symbol()` and the `Q_symbol()`. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams. For example:

```python
sage: m = matrix([[0,0,0,0,1],[1,1,0,2,0], [0,3,0,0,0]])
sage: G = RuleRSK(m); G
0 0 0 0 1
1 1 0 2 0
0 3 0 0 0

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
```

```
[ 1 2 2 2 3 1 2 2 2 2 ]
[ 2 3 4 4 ]
[ 3 5 ]
```

For rectangular fillings, the Kleitman-Greene invariant is the shape of the `P_symbol()` (or the `Q_symbol()`). Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the partition \((\mu_1, \ldots, \mu_n)\), where \(\mu_1 + \cdots + \mu_i\) is the maximal sum of entries in a collection of \(i\) pairwise disjoint sequences of cells with weakly increasing coordinates.

For rectangular fillings, we could also use the (faster) implementation provided via `RSK()`. Because the of the coordinate conventions in `RSK()`, we have to transpose matrices:

```python
sage: [G.P_symbol(), G.Q_symbol()] == RSK(m.transpose())
True

sage: n = 5; l = [(pi, RuleRSK(pi)) for pi in Permutations(n)]
sage: all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True
```

(continues on next page)
sage: n = 5; l = [(w, RuleRSK(w)) for w in Words([1,2,3], 5)]
sage: all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True

backward_rule(y, z, x)
Return the content and the input shape.
See [Kra2006] (B₁₀) − (B¹²).
INPUT:
• y, z, x – three partitions from a cell in a growth diagram, labelled as:

```
x
y z
```

OUTPUT:
A pair (t, content) consisting of the shape of the fourth word according to the Robinson-Schensted-Knuth correspondence and the content of the cell.

forward_rule(y, t, x, content)
Return the output shape given three shapes and the content.
See [Kra2006] (F¹₀) − (F¹²).
INPUT:
• y, t, x – three partitions from a cell in a growth diagram, labelled as:

```
t x
y
```

• content – a non-negative integer; the content of the cell

OUTPUT:
The fourth partition according to the Robinson-Schensted-Knuth correspondence.

EXAMPLES:
```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: RuleRSK.forward_rule([2,1],[2,1],[2,1],1)
[3, 1]
sage: RuleRSK.forward_rule([1],[2],2)
[4, 1]
```

class sage.combinat.growth.RuleShiftedShapes
Bases: Rule
A class modelling the Schensted correspondence for shifted shapes.
This agrees with Sagan [Sag1987] and Worley’s [Wor1984], and Haiman’s [Hai1989] insertion algorithms, see Proposition 4.5.2 of [Fom1995].

EXAMPLES:
The vertices of the dual graded graph are shifted shapes:

```plaintext
growth: Shifted = GrowthDiagram.rules.ShiftedShapes()
growth: GrowthDiagram(Shifted, [3,1,2])
0 1 0
0 0 1
1 0 0
```

Let us check the example just before Corollary 3.2 in [Sag1987]. Note that, instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams:

```plaintext
growth: G = Shifted([2,6,5,1,7,4,3])
growth: G.P_chain()
[[], 0, [1], 0, [2], 0, [3], 0, [3,1], 0, [3,2], 0, [4,2], 0, [5,2]]
growth: G.Q_chain()
[[], 1, [1], 2, [2], 1, [2,1], 3, [3,1], 2, [4,1], 3, [4,2], 3, [5,2]]
```

\( \text{P}_\text{symbol}(P_{\text{chain}}) \)

Return the labels along the vertical boundary of a rectangular growth diagram as a shifted tableau.

EXAMPLES:

Check the example just before Corollary 3.2 in [Sag1987]:

```plaintext
growth: Shifted = GrowthDiagram.rules.ShiftedShapes()
growth: G = Shifted([2,6,5,1,7,4,3])
growth: G.P_symbol().pp()
1 2 3 6 7
4 5
```

Check the example just before Corollary 8.2 in [SS1990]:

```plaintext
growth: T = ShiftedPrimedTableau([[4],[1],[5]], skew=[3,1])
growth: T.pp()
. . . 4
. 1
5
growth: U = ShiftedPrimedTableau([[1],[3,5],[5]], skew=[3,1])
growth: U.pp()
. . . 1
. 4'
5
growth: Shifted = GrowthDiagram.rules.ShiftedShapes()
growth: labels = [\mu \text{ if } \text{is_even}(i) \text{ else } 0 \text{ for } i, \mu \text{ in enumerate}(T.to_chain()[:-1]) + U.to_chain()[1:]]
growth: G = Shifted({(1,2):1, (2,1):1}, shape=[5,5,5,5,5], labels=labels)
growth: G.P_symbol().pp()
. . . . 2
. . 1 3
. 4 5
```
**Q_symbol(Q_chain)**

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

**EXAMPLES:**

Check the example just before Corollary 3.2 in [Sag1987]:

```python
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2, 6, 5, 1, 7, 4, 3])
sage: G.Q_symbol().pp()
1 2 4' 5 7'
   3 6'
```

Check the example just before Corollary 8.2 in [SS1990]:

```python
sage: T = ShiftedPrimedTableau([[4], [1], [5]], skew=[3, 1])
sage: T.pp()
 . . . 4
  . 1
   5
sage: U = ShiftedPrimedTableau([[1], [3.5], [5]], skew=[3, 1])
sage: U.pp()
 . . . 1
  . 4'
   5
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: labels = [mu if is_even(i) else 0 for i, mu in enumerate(T.to_chain()[::-1])] + U.to_chain()[1:]
sage: G = Shifted({(1, 2): 1, (2, 1): 1}, shape=[5, 5, 5, 5, 5], labels=labels)
sage: G.Q_symbol().pp()
 . . . . 2
  . . 1 4'
   . 3' 5'
```

**backward_rule(y, g, z, h, x)**

Return the input path and the content given two incident edges.

See [Fom1995] Lemma 4.5.1, page 38.

**INPUT:**

* y, g, z, h, x – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
  x
  h
y g z
```

**OUTPUT:**

A tuple (e, t, f, content) consisting of the shape t of the fourth word, the colours of the incident edges and the content of the cell according to Sagan - Worley insertion.

**EXAMPLES:**

```python
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.backward_rule([], 1, [1], 0, [])
(continues on next page)"
sage: Shifted.backward_rule([1], 2, [2], 0, [1])
(0, [1], 0, 1)

if x != y:

sage: Shifted.backward_rule([3], 1, [3, 1], 0, [2,1])
(0, [2], 1, 0)
sage: Shifted.backward_rule([2,1], 2, [3, 1], 0, [3])
(0, [2], 2, 0)

if x == y != t:

sage: Shifted.backward_rule([3], 1, [3, 1], 0, [3])
(0, [2], 2, 0)
sage: Shifted.backward_rule([3,1], 2, [3, 2], 0, [3,1])
(0, [2, 1], 2, 0)
sage: Shifted.backward_rule([2,1], 3, [3, 1], 0, [2,1])
(0, [2], 1, 0)
sage: Shifted.backward_rule([3], 3, [4], 0, [3])
(0, [2], 3, 0)

\texttt{forward\_rule}(y, e, t, f, x, content)

Return the output path given two incident edges and the content.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

• y, e, t, f, x – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

\begin{verbatim}
 t f x
e
 y
\end{verbatim}

• content – 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition g, z, h according to Sagan-Worley insertion.

EXAMPLES:

sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.forward_rule([], 0, [], 0, [], 1)
(1, [1], 0)
sage: Shifted.forward_rule([1], 0, [1], 0, [1], 1)
(2, [2], 0)
if \( x \neq y \):

\[
\text{sage: Shifted.forward_rule([3], 0, [2], 1, [2,1], 0)}
\]

\( (1, [3, 1], 0) \)

\[
\text{sage: Shifted.forward_rule([2,1], 0, [2], 2, [3], 0)}
\]

\( (2, [3, 1], 0) \)

if \( x = y \neq t \):

\[
\text{sage: Shifted.forward_rule([3], 0, [2], 2, [3], 0)}
\]

\( (1, [3, 1], 0) \)

\[
\text{sage: Shifted.forward_rule([3,1], 0, [2,1], 2, [3,1], 0)}
\]

\( (2, [3, 2], 0) \)

\[
\text{sage: Shifted.forward_rule([2,1], 0, [2], 1, [2,1], 0)}
\]

\( (3, [3, 1], 0) \)

\[
\text{sage: Shifted.forward_rule([3], 0, [2], 3, [3], 0)}
\]

\( (3, [4], 0) \)

\[
\text{has_multiple_edges = True}
\]

\[
\text{is_P_edge}(v, w)
\]

Return whether \((v, w)\) is a \(P\)-edge of \(self\).

\((v, w)\) is an edge if \(w\) contains \(v\).

EXAMPLES:

\[
\text{sage: Shifted = GrowthDiagram.rules.ShiftedShapes()}
\]

\[
\text{sage: v = Shifted.vertices(2)[0]; v}
\]

\([2]\)

\[
\text{sage: [w for w in Shifted.vertices(3) if Shifted.is_P_edge(v, w)]}
\]

\([[[3], [2, 1]]]\)

\[
\text{is_Q_edge}(v, w)
\]

Return whether \((v, w)\) is a \(Q\)-edge of \(self\).

\((v, w)\) is an edge if \(w\) is obtained from \(v\) by adding a cell. It is a black (color 1) edge, if the cell is on the diagonal, otherwise it can be blue or red (color 2 or 3).

EXAMPLES:

\[
\text{sage: Shifted = GrowthDiagram.rules.ShiftedShapes()}
\]

\[
\text{sage: v = Shifted.vertices(2)[0]; v}
\]

\([2]\)

\[
\text{sage: [(w, Shifted.is_Q_edge(v, w)) for w in Shifted.vertices(3)]}
\]

\([[[[3], [2, 3]], ([2, 1], [1])]]\)

\[
\text{sage: all(Shifted.is_Q_edge(v, w) == [] for w in Shifted.vertices(4))}
\]

\(\text{True}\)

\[
\text{normalize_vertex}(v)
\]

Return \(v\) as a partition.

EXAMPLES:
rank(v)
Return the rank of v: the size of the shifted partition.

EXAMPLES:

```python
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.rank(Shifted.vertices(3)[0])
3
```

vertices(n)
Return the vertices of the dual graded graph on level n.

EXAMPLES:

```python
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.vertices(3)
```

zero = []

class `sage.combinat.growth.RuleSylvester`  
Bases: `Rule`  
A rule modelling a Schensted-like correspondence for binary trees.  

EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: GrowthDiagram(Sylvester, [3,1,2])
```

The vertices of the dual graded graph are *BinaryTrees*:

```python
sage: Sylvester.vertices(3)
```

The *P_graph()* is also known as the bracket tree, the *Q_graph()* is the lattice of finite order ideals of the infinite binary tree, see Example 2.4.6 in [Fom1994].

For a permutation, the *P_symbol()* is the binary search tree, the *Q_symbol()* is the increasing tree corresponding to the inverse permutation. Note that, instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. From [Nze2007]:

```python
sage: pi = Permutation([3,5,1,4,2,6]); G = Sylvester(pi); G
```

(continues on next page)
Combinatorics, Release 10.1

(continued from previous page)

```python
sage: ascii_art(G.P_symbol())
   ___3___
  /    \  \
1  5   \  \
  \    /  \
  2  4  6
sage: ascii_art(G.Q_symbol())
   ___1___
  /    \  \
3  2   \  \
  \    /  \
  5  4  6
```

```python
sage: all(Sylvester(pi).P_symbol() == pi.binary_search_tree() for pi in Permutations(5))
True
sage: all(Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree() for pi in Permutations(5))
True
```

**P_symbol** (*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the binary search tree.

**EXAMPLES:**

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).P_symbol())
   _2_
  / \  \
1  4   \  
  /  \
  3
sage: Sylvester(pi).P_symbol() == pi.binary_search_tree()
True
```

We can also do the skew version:

```python
sage: B = BinaryTree; E = B(); N = B([])
sage: ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).P_symbol())
   ___1___
  /    \  \
None  3   \  
  \    /  
   2
```

**Q_symbol** (*Q_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the increasing tree.

5.1. Comprehensive Module List 1173
EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).Q_symbol())
  _1_
  / \  
 4   2 
  /  
 3   1
sage: Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
True
```

We can also do the skew version:

```python
sage: B = BinaryTree; E = B(); N = B([])
sage: ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).Q_symbol())
  None_
  /   
 3   1
  / 
 2
```

**backward_rule**\((y, z, x)\)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

**INPUT:**

- \(y, z, x\) – three binary trees from a cell in a growth diagram, labelled as:

```
  x
 y z
```

**OUTPUT:**

A pair \((t, content)\) consisting of the shape of the fourth binary tree \(t\) and the content of the cell.

**EXAMPLES:**

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: B = BinaryTree; E = B(); N = B([]); L = B([[],None])
sage: R = B([None,[]]); T = B([[],[]])
```

```python
sage: ascii_art(Sylvester.backward_rule(E, E, E))
( , 0 )
sage: ascii_art(Sylvester.backward_rule(N, N, N))
( o, 0 )
```

**forward_rule**\((y, t, x, content)\)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

**INPUT:**
• \( y, t, x \) – three binary trees from a cell in a growth diagram, labelled as:

```
  t x
  y
```

• content – 0 or 1; the content of the cell

OUTPUT:
The fourth binary tree \( z \).

EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: B = BinaryTree; E = B(); N = B([]); L = B([[],None])
sage: R = B([None,[]]); T = B([[],[]])
```

```bash
sage: ascii_art(Sylvester.forward_rule(E, E, E, 1))
```

```bash
sage: ascii_art(Sylvester.forward_rule(N, N, N, 1))
```

```bash
sage: ascii_art(Sylvester.forward_rule(L, L, L, 1))
```

```bash
sage: ascii_art(Sylvester.forward_rule(R, R, R, 1))
```

If \( y \neq x \), obtain \( z \) from \( y \) adding a node such that deleting the right most gives \( x \):

```bash
sage: ascii_art(Sylvester.forward_rule(R, N, L, 0))
```

```bash
sage: ascii_art(Sylvester.forward_rule(L, N, R, 0))
```

If \( y = x \neq t \), obtain \( z \) from \( x \) by adding a node as left child to the right most node:

```bash
sage: ascii_art(Sylvester.forward_rule(N, E, N, 0))
```

```bash
sage: ascii_art(Sylvester.forward_rule(T, L, T, 0))
```

(continues on next page)
is_P_edge(v, w)
Return whether (v, w) is a P-edge of self.
(v, w) is an edge if v is obtained from w by deleting its right-most node.

EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
  o
 / 
 o  o
 / 
 o
sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_P_edge(v, w)])
[ o , o ]
[ / \ / ]
[ o o o ]
[ / ]
[ o ]
sage: [w for w in Sylvester.vertices(4) if Sylvester.is_P_edge(v, w)]
[]
```

is_Q_edge(v, w)
Return whether (v, w) is a Q-edge of self.
(v, w) is an edge if v is a sub-tree of w with one node less.

EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
  o
 / 
 o
sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_Q_edge(v, w)])
```

normalize_vertex(v)

Return v as a binary tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.normalize_vertex([[],[]]).parent()
Binary trees
```

rank(v)

Return the rank of v: the number of nodes of the tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.rank(Sylvester.vertices(3)[0])
3
```

vertices(n)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.vertices(3)
Binary trees of size 3
```

[0, 1, 0]
[0, 0, 1]
[1, 0, 0]

The vertices of the dual graded graph are Fibonacci words - compositions into parts of size at most two:

```
sage: YF.vertices(4)
[word: 22, word: 211, word: 121, word: 112, word: 1111]
```
Note that, instead of passing the rule to \textit{GrowthDiagram}, we can also use call the rule to create growth diagrams. For example:

\begin{verbatim}
sage: G = YF([2, 3, 7, 4, 1, 6, 5]); G
  0 0 0 0 1 0 0
  1 0 0 0 0 0 0
  0 1 0 0 0 0 0
  0 0 0 1 0 0 0
  0 0 0 0 0 1 0
  0 0 0 0 1 0 0
  0 0 1 0 0 0 0

The Kleitman Greene invariant is: take the last letter and the largest letter of the permutation and remove them. If they coincide write 1, otherwise write 2:

\begin{verbatim}
sage: G.P_chain()[-1]
word: 21211
\end{verbatim}

\texttt{backward\_rule}(y, z, x)

Return the content and the input shape.

See \cite{Fom1995} Lemma 4.4.1, page 35.

- \texttt{y, z, x} – three Fibonacci words from a cell in a growth diagram, labelled as:

\begin{verbatim}
x
y z
\end{verbatim}

\textbf{OUTPUT:}

A pair (t, content) consisting of the shape of the fourth word and the content of the cell.

\texttt{forward\_rule}(y, t, x, content)

Return the output shape given three shapes and the content.

See \cite{Fom1995} Lemma 4.4.1, page 35.

\textbf{INPUT:}

- \texttt{y, t, x} – three Fibonacci words from a cell in a growth diagram, labelled as:

\begin{verbatim}
t x
y
\end{verbatim}

- \texttt{content} – 0 or 1; the content of the cell

\textbf{OUTPUT:}

The fourth Fibonacci word.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.forward_rule([], [], [], 1)
word: 1
sage: YF.forward_rule([1], [1], [1], 1)
word: 11
\end{verbatim}
sage: YF.forward_rule([1,2], [1], [1,1], 0)
word: 21

sage: YF.forward_rule([1,1], [1], [1,1], 0)
word: 21

is_P_edge(v, w)
Return whether \((v, w)\) is a \(P\)-edge of self.
\((v, w)\) is an edge if \(v\) is obtained from \(w\) by deleting a 1 or replacing the left-most 2 by a 1.
EXAMPLES:

\[
\begin{align*}
\text{sage: } & YF = GrowthDiagram.rules.YoungFibonacci() \\
\text{sage: } & v = YF.vertices(5)[5]; v \\
& \text{word: 1121} \\
\text{sage: } & [w \text{ for } w \text{ in } YF.vertices(6) \text{ if } YF.is_P_edge(v, w)] \\
& [\text{word: 2121, word: 11121}] \\
\text{sage: } & [w \text{ for } w \text{ in } YF.vertices(7) \text{ if } YF.is_P_edge(v, w)] \\
& []
\end{align*}
\]

is_Q_edge(v, w)
Return whether \((v, w)\) is a \(P\)-edge of self.
\((v, w)\) is an edge if \(v\) is obtained from \(w\) by deleting a 1 or replacing the left-most 2 by a 1.
EXAMPLES:

\[
\begin{align*}
\text{sage: } & YF = GrowthDiagram.rules.YoungFibonacci() \\
\text{sage: } & v = YF.vertices(5)[5]; v \\
& \text{word: 1121} \\
\text{sage: } & [w \text{ for } w \text{ in } YF.vertices(6) \text{ if } YF.is_P_edge(v, w)] \\
& [\text{word: 2121, word: 11121}] \\
\text{sage: } & [w \text{ for } w \text{ in } YF.vertices(7) \text{ if } YF.is_P_edge(v, w)] \\
& []
\end{align*}
\]

normalize_vertex(v)
Return \(v\) as a word with letters 1 and 2.
EXAMPLES:

\[
\begin{align*}
\text{sage: } & YF = GrowthDiagram.rules.YoungFibonacci() \\
\text{sage: } & YF.normalize_vertex([1,2,1]).parent() \\
& \text{Finite words over \{1, 2\}}
\end{align*}
\]

rank(v)
Return the rank of \(v\): the size of the corresponding composition.
EXAMPLES:

\[
\begin{align*}
\text{sage: } & YF = GrowthDiagram.rules.YoungFibonacci() \\
\text{sage: } & YF.rank(YF.vertices(3)[0]) \\
& 3
\end{align*}
\]
vertices($n$)

Return the vertices of the dual graded graph on level $n$.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.vertices(3)
[word: 21, word: 12, word: 111]
```

zero = word:

5.1.118 Grossman-Larson Hopf Algebras

AUTHORS:

• Frédéric Chapoton (2017)

class sage.combinat.grossman_larson_algebras.GrossmanLarsonAlgebra($R$, names=None)

Bases: CombinatorialFreeModule

The Grossman-Larson Hopf Algebras are Hopf algebras with a basis indexed by forests of decorated rooted trees. They are the universal enveloping algebras of free pre-Lie algebras, seen as Lie algebras.

The Grossman-Larson Hopf algebra on a given set $E$ has an explicit description using rooted forests. The underlying vector space has a basis indexed by finite rooted forests endowed with a map from their vertices to $E$ (called the “labeling”). In this basis, the product of two (decorated) rooted forests $S \ast T$ is a sum over all maps from the set of roots of $T$ to the union of a singleton $\{\#\}$ and the set of vertices of $S$. Given such a map, one defines
a new forest as follows. Starting from the disjoint union of all rooted trees of $S$ and $T$, one adds an edge from every root of $T$ to its image when this image is not the fake vertex labelled #. The coproduct sends a rooted forest $T$ to the sum of all tensors $T_1 \otimes T_2$ obtained by splitting the connected components of $T$ into two subsets and letting $T_1$ be the forest formed by the first subset and $T_2$ the forest formed by the second. This yields a connected graded Hopf algebra (the degree of a forest is its number of vertices).

See [Pana2002] (Section 2) and [GroLar1]. (Note that both references use rooted trees rather than rooted forests, so think of each rooted forest grafted onto a new root. Also, the product is reversed, so they are defining the opposite algebra structure.)

**Warning:** For technical reasons, instead of using forests as labels for the basis, we use rooted trees. Their root vertex should be considered as a fake vertex. This fake root vertex is labelled ' #' when labels are present.

**EXAMPLES:**

```sage
sage: G = algebras.GrossmanLarson(QQ, 'xy')
sage: x, y = G.single_vertex_all()
sage: ascii_art(x*y)
B + B
#   #_
  | / /
 x x y
  |
 y

sage: ascii_art(x*x*x)
B + B + 3*B + B
#  #  #_ _#
  |  | / / / / /
 x x_ x x x x
  | / /   |
 x x x x
  |
 x
```

The Grossman-Larson algebra is associative:

```sage
sage: z = x * y
sage: x * (y * z) == (x * y) * z
True
```

It is not commutative:

```sage
sage: x * y == y * x
False
```

When `None` is given as input, unlabelled forests are used instead; this corresponds to a 1-element set $E$:

```sage
sage: G = algebras.GrossmanLarson(QQ, None)
sage: x = G.single_vertex_all()[0]
sage: ascii_art(x*x)
O + O
o o_
```

(continues on next page)
Note: Variables names can be None, a list of strings, a string or an integer. When None is given, unlabelled rooted forests are used. When a single string is given, each letter is taken as a variable. See sage.combinat.words.alphabet.build_alphabet().

Warning: Beware that the underlying combinatorial free module is based either on RootedTrees or on LabelledRootedTrees, with no restriction on the labellings. This means that all code calling the basis() method would not give meaningful results, since basis() returns many "chaff" elements that do not belong to the algebra.

REFERENCES:
  - [Pana2002]
  - [GroLar1]

an_element()
  Return an element of self.
  EXAMPLES:

  sage: A = algebras.GrossmanLarson(QQ, 'xy')
  sage: A.an_element()
  B[#[x[]]] + 2*B[#[x[x[]]]] + 2*B[#[x[], x[]]]

antipode_on_basis(x)
  Return the antipode of a forest.
  EXAMPLES:

  sage: G = algebras.GrossmanLarson(QQ,2)
  sage: x, y = G.single_vertex_all()
  sage: G.antipode(x)  # indirect doctest
  -B[#[0[]]]
  sage: G.antipode(y+x)  # indirect doctest
  B[#[0[1[]]]] + B[#[0[], 1[]]]

change_ring(R)
  Return the Grossman-Larson algebra in the same variables over R.
  INPUT:
  • R – a ring
  EXAMPLES:
sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.change_ring(QQ)
Grossman-Larson Hopf algebra on 3 generators ['f', 'g', 'h'] over Rational Field

coproduct_on_basis(x)

Return the coproduct of a forest.

EXAMPLES:

sage: G = algebras.GrossmanLarson(QQ,2)
sage: x, y = G.single_vertex_all()
sage: ascii_art(G.coproduct(x))  # indirect doctest
1 # B + B # 1
  #  
  |   
  0  0

sage: Delta_xy = G.coproduct(y*x)
sage: ascii_art(Delta_xy)  # random indirect doctest
1 # B + 1 # B + B # 1 + B # 1 + B # 1 + B # 1
  #_ # # # #_ # # #
  / / | | | / / | |
  0 1 1 0 1 0 1 1 0 1
  |   |
  0  0

counit_on_basis(x)

Return the counit on a basis element.

This is zero unless the forest $x$ is empty.

EXAMPLES:

sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: RT = A.basis().keys()
sage: x = RT([RT([[]], 'x')], '#')
sage: A.counit_on_basis(x)
0
sage: A.counit_on_basis(RT([[]], '#'))
1

degree_on_basis(r)

Return the degree of a rooted forest in the Grossman-Larson algebra.

This is the total number of vertices of the forest.

EXAMPLES:

sage: A = algebras.GrossmanLarson(QQ, '@')
sage: RT = A.basis().keys()
sage: A.degree_on_basis(RT([[[]]]))
1

one_basis()

Return the empty rooted forest.
Combinatorics, Release 10.1

EXEMPLARY:

```
sage: A = algebras.GrossmanLarson(QQ, 'ab')
sage: A.one_basis()
#[]
sage: A = algebras.GrossmanLarson(QQ, None)
sage: A.one_basis()
[]
```

**product_on_basis**(*x*, *y*)

Return the product of two forests *x* and *y*.

This is the sum over all possible ways for the components of the forest *y* to either fall side-by-side with components of *x* or be grafted on a vertex of *x*.

EXEMPLARY:

```
sage: A = algebras.GrossmanLarson(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([[]])])
sage: A.product_on_basis(x, x)
B[[[]]] + B[[[]], [[]]]
```

Check that the product is the correct one:

```
sage: A = algebras.GrossmanLarson(QQ, 'uv')
sage: RT = A.basis().keys()
sage: Tu = RT([RT([[]], 'u'), '#'])
sage: Tv = RT([RT([[]], 'v'), '#'])
sage: A.product_on_basis(Tu, Tv)
B[#[u[[]], v]] + B[#[u[], v[]]]
```

**single_vertex**(*i*)

Return the *i*-th rooted forest with one vertex.

This is the rooted forest with just one vertex, labelled by the *i*-th element of the label list.

See also:

**single_vertex_all**.

INPUT:

- *i* – a nonnegative integer

EXEMPLARY:

```
sage: F = algebras.GrossmanLarson(ZZ, 'xyz')
sage: F.single_vertex(0)
B[#[x[[]]]]
sage: F.single_vertex(4)
Traceback (most recent call last):
...
IndexError: argument i (= 4) must be between 0 and 2
```
single_vertex_all()

Return the rooted forests with one vertex in \texttt{self}.

They freely generate the Lie algebra of primitive elements as a pre-Lie algebra.

See also:

\texttt{single_vertex()}

EXAMPLES:

\begin{verbatim}
sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.single_vertex_all()
(B[#[f[]]], B[#[g[]]], B[#[h[]]])

sage: A = algebras.GrossmanLarson(QQ, ['x1', 'x2'])
sage: A.single_vertex_all()
(B[#[x1[]]], B[#[x2[]]])

sage: A = algebras.GrossmanLarson(ZZ, None)
sage: A.single_vertex_all()
(B[[]],)
\end{verbatim}

some_elements()

EXAMPLES:

\begin{verbatim}
sage: A = algebras.GrossmanLarson(QQ, None)
sage: A.some_elements()
[B[[]], B[] + B[[[]]] + B[[], []], 4*B[[[]]] + 4*B[[], []]]

With several generators:

\begin{verbatim}
sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: A.some_elements()
[B[#[x[]]], B[#[]] + B[#[x[x[]]]] + B[#[x], x[]],
B[#[x[x[]]]] + 3*B[#[x[y[]]]] + B[#[x], x[]] + 3*B[#[x], y[]]]
\end{verbatim}

variable_names()

Return the names of the variables.

This returns the set \(E\) (as a family).

EXAMPLES:

\begin{verbatim}
sage: R = algebras.GrossmanLarson(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}

sage: R = algebras.GrossmanLarson(QQ, ['a', 'b'])
sage: R.variable_names()
{'a', 'b'}

sage: R = algebras.GrossmanLarson(QQ, 2)
\end{verbatim}

(continues on next page)
5.1.119 Hall Polynomials

sage.combinat.hall_polynomial.hall_polynomial(nu, mu, la=q=None)

Return the (classical) Hall polynomial $P_{\mu,\lambda}^\nu$ (where $\nu$, $\mu$ and $\lambda$ are the inputs $nu$, $mu$ and $la$).

Let $\nu, \mu, \lambda$ be partitions. The Hall polynomial $P_{\mu,\lambda}^\nu(q)$ (in the indeterminate $q$) is defined as follows: Specialize $q$ to a prime power, and consider the category of $\mathbf{F}_q$-vector spaces with a distinguished nilpotent endomorphism. The morphisms in this category shall be the linear maps commuting with the distinguished endomorphisms. The type of an object in the category will be the Jordan type of the distinguished endomorphism; this is a partition. Now, if $N$ is any fixed object of type $\lambda$ such that the quotient object $N/L$ has type $\mu$. This determines the values of the polynomial $P_{\mu,\lambda}^\nu$ at infinitely many points (namely, at all prime powers), and hence $P_{\mu,\lambda}^\nu$ is uniquely determined. The degree of this polynomial is at most $n(\nu) - n(\lambda) - n(\mu)$, where $n(\kappa) = \sum (i - 1)\kappa_i$ for every partition $\kappa$. (If this is negative, then the polynomial is zero.)

These are the structure coefficients of the (classical) Hall algebra.

If $|\nu| \neq |\mu| + |\lambda|$, then we have $P_{\mu,\lambda}^\nu = 0$. More generally, if the Littlewood-Richardson coefficient $c_{\mu,\nu,\lambda}^\lambda$ vanishes, then $P_{\mu,\lambda}^\nu = 0$.

The Hall polynomials satisfy the symmetry property $P_{\mu,\lambda}^\nu = P_{\lambda,\mu}^\nu$.

ALGORITHM:

If $\lambda = (1^r)$ and $|\nu| = |\mu| + |\lambda|$, then we compute $P_{\mu,\lambda}^\nu$ as follows (cf. Example 2.4 in [Sch2006]):

First, write $\nu = (1^{l_1}, 2^{l_2}, \ldots, n^{l_n})$, and define a sequence $r = r_0 \geq r_1 \geq \cdots \geq r_n$ such that $\mu = (1^{l_1-r_0+2r_1-r_2}, 2^{l_2-r_1+2r_2-r_3}, \ldots, (n-1)^{l_{n-1}-r_{n-2}+2r_{n-1}-r_n}, n^{l_n-r_{n-1}+r_n})$.

Thus if $\mu = (1^{m_1}, \ldots, n^{m_n})$, we have the following system of equations:

\[
\begin{align*}
m_1 &= l_1 - r + 2r_1 - r_2, \\
m_2 &= l_2 - r_1 + 2r_2 - r_3, \\
&\vdots \\
m_{n-1} &= l_{n-1} - r_{n-2} + 2r_{n-1} - r_n, \\
m_n &= l_n - r_{n-1} + r_n
\end{align*}
\]

and solving for $r_j$ and back substituting we obtain the equations:

\[
\begin{align*}
r_n &= r_{n-1} + m_n - l_n, \\
r_{n-1} &= r_{n-2} + m_{n-1} - l_{n-1} + m_n - l_n, \\
&\vdots \\
r_1 &= r + \sum_{k=1}^{n} (m_k - l_k),
\end{align*}
\]
or in general we have the recursive equation:

\[ r_i = r_{i-1} + \sum_{k=i}^{n}(m_k - l_k). \]

This, combined with the condition that \( r_0 = r \), determines the \( r_i \) uniquely (recursively). Next we define

\[ t = (r_{n-2} - r_{n-1})(l_n - r_{n-1}) + (r_{n-3} - r_{n-2})(l_{n-1} + l_n - r_{n-2}) + \cdots + (r_0 - r_1)(l_2 + \cdots + l_n - r_1), \]

and with these notations we have

\[ P_{\mu, (1')}^\nu = q^t \left( \begin{array}{c} l_n \\ r_{n-1} \end{array} \right)_q \left( \begin{array}{c} l_{n-1} \\ r_{n-2} - r_{n-1} \end{array} \right)_q \cdots \left( \begin{array}{c} l_1 \\ r_0 - r_1 \end{array} \right)_q. \]

To compute \( P_{\mu, \lambda}^\nu \) in general, we compute the product \( I_{\mu} I_{\lambda} \) in the Hall algebra and return the coefficient of \( I_{\nu} \).

**EXAMPLES:**

```python
sage: from sage.combinat.hall_polynomial import hall_polynomial
sage: hall_polynomial([1,1],[1],[1])
q + 1
sage: hall_polynomial([2],[1],[1])
1
sage: hall_polynomial([2,1],[2],[1])
q
sage: hall_polynomial([2,2,1],[2,1],[1,1])
q^2 + q
sage: hall_polynomial([2,2,2,1],[2,2,1],[1,1])
q^4 + q^3 + q^2
sage: hall_polynomial([3,2,2,1], [3,2], [2,1])
q^6 + q^5
sage: hall_polynomial([4,2,1,1], [3,1,1], [2,1])
2*q^3 + q^2 - q - 1
sage: hall_polynomial([4,2], [2,1], [2,1], 0)
1
```

### 5.1.120 The Hillman-Grassl correspondence

This module implements weak reverse plane partitions and four correspondences on them: the Hillman-Grassl correspondence and its inverse, as well as the Sulzgruber correspondence and its inverse (the Pak correspondence).

Fix a partition \( \lambda \) (see `Partition()`). We draw all partitions and tableaux in English notation.

A \( \lambda \)-array will mean a tableau of shape \( \lambda \) whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape \( \lambda \) (short: \( \lambda \)-rpp) will mean a \( \lambda \)-array whose entries weakly increase along each row and weakly increase along each column. (The name “weak reverse plane partition” comes from Stanley in [EnumComb2] Section 7.22; other authors – such as Pak [Sulzgr2017], or Hillman and Grassl in [HilGra1976] – just call it a reverse plane partition.)

The Hillman-Grassl correspondence is a bijection from the set of \( \lambda \)-arrays to the set of \( \lambda \)-rpps. For its definition, see `hillman_grassl()`; for its inverse, see `hillman_grassl_inverse()`.

The Sulzgruber correspondence \( \Phi_\lambda \) and the Pak correspondence \( \xi_\lambda \) are two further mutually inverse bijections between the set of \( \lambda \)-arrays and the set of \( \lambda \)-rpps. They appear (sometimes with different definitions, but defining the same

---

**5.1. Comprehensive Module List**

---
maps) in [Pak2002], [Hopkins2017] and [Sulzgr2017]. For their definitions, see `sulzgruber_correspondence()` and `pak_correspondence()`.

EXAMPLES:
We construct a $\lambda$-rpp for $\lambda = (3, 3, 1)$ (note that $\lambda$ needs not be specified explicitly):

```python
sage: p = WeakReversePlanePartition([[0, 1, 3], [2, 4, 4], [3]])
sage: p
Weak Reverse Plane Partitions

([0, 1, 3], [2, 4, 4], [3])
```

(This is the example in Section 7.22 of [EnumComb2].)

Next, we apply the inverse of the Hillman-Grassl correspondence to it:

```python
sage: HGp = p.hillman_grassl_inverse(); HGp
[[1, 2, 0], [1, 0, 1], [1]]
sage: HGp
Tableaux
```

This is a $\lambda$-array, encoded as a tableau. We can recover our original $\lambda$-rpp from it using the Hillman-Grassl correspondence:

```python
sage: HGp.hillman_grassl() == p
True
```

We can also apply the Pak correspondence to our rpp:

```python
sage: Pp = p.pak_correspondence(); Pp
[[2, 0, 1], [0, 2, 0], [1]]
sage: Pp
Tableaux
```

This is undone by the Sulzgruber correspondence:

```python
sage: Pp.sulzgruber_correspondence() == p
True
```

These four correspondences can also be accessed as standalone functions (`hillman_grassl_inverse()`, `hillman_grassl()`, `pak_correspondence()` and `sulzgruber_correspondence()`) that transform lists of lists into lists of lists; this may be more efficient. For example, the above computation of HGp can also be obtained as follows:

```python
sage: from sage.combinat.hillman_grassl import hillman_grassl_inverse
sage: HGp_bare = hillman_grassl_inverse([[0, 1, 3], [2, 4, 4], [3]])
sage: HGp_bare
[[1, 2, 0], [1, 0, 1], [1]]
sage: isinstance(HGp_bare, list)
True
```

AUTHORS:
• Darij Grinberg and Tom Roby (2018): Initial implementation

class sage.combinat.hillman_grassl.WeakReversePlanePartition(parent, t)
    Bases: Tableau
    A weak reverse plane partition (short: rpp).
    A weak reverse plane partition is a tableau with nonnegative entries that are weakly increasing in each row and weakly increasing in each column.

    EXAMPLES:
    sage: x = WeakReversePlanePartition([[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3], [2]]); x
    [[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3], [2]]
    sage: x.pp()
    0 1 1
    0 1 3
    1 2 2
    1 2 3
    2
    sage: x.shape()
    [3, 3, 3, 3, 1]

    conjugate()
    Return the conjugate of self.

    EXAMPLES:
    sage: c = WeakReversePlanePartition([[1,1],[1,3],[2]]).conjugate(); c
    [[1, 1, 2], [1, 3]]
    sage: c.parent()
    Weak Reverse Plane Partitions

    hillman_grassl_inverse()
    Return the image of the \( \lambda \)-rpp self under the inverse of the Hillman-Grassl correspondence (as a Tableau).
    Fix a partition \( \lambda \) (see Partition()). We draw all partitions and tableaux in English notation.
    A \( \lambda \)-array will mean a tableau of shape \( \lambda \) whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)
    A weak reverse plane partition of shape \( \lambda \) (short: \( \lambda \)-rpp) will mean a \( \lambda \)-array whose entries weakly increase along each row and weakly increase along each column.
    The inverse \( H^{-1} \) of the Hillman-Grassl correspondence (see (hillman_grassl()) for the latter) sends a \( \lambda \)-rpp \( \pi \) to a \( \lambda \)-array \( H^{-1}(\pi) \) constructed recursively as follows:
    • If all entries of \( \pi \) are 0, then \( H^{-1}(\pi) = \pi \).
    • Otherwise, let \( s \) be the index of the leftmost column of \( \pi \) containing a nonzero entry. Write the \( \lambda \)-array \( M \) as \( (m_{i,j}) \).
    • Define a sequence \( ((i_1,j_1),(i_2,j_2),\ldots,(i_n,j_n)) \) of boxes in the diagram of \( \lambda \) (actually a lattice path made of northward and eastward steps) as follows: Let \( (i_1,j_1) \) be the bottommost box in the \( s \)-th
column of $\pi$. If $(i_k, j_k)$ is defined for some $k \geq 1$, then $(i_{k+1}, j_{k+1})$ is constructed as follows: If $q_{i_k-1,j_k}$ is well-defined and equals $q_{i_k,j_k}$, then we set $(i_{k+1}, j_{k+1}) = (i_k - 1, j_k)$. Otherwise, we set $(i_{k+1}, j_{k+1}) = (i_k, j_k + 1)$ if this is still a box of $\lambda$. Otherwise, the sequence ends here.

- Let $\pi'$ be the $\lambda$-rpp obtained from $\pi$ by subtracting 1 from the $(i_k, j_k)$-th entry of $\pi$ for each $k \in \{1, 2, \ldots, n\}$.
- Let $N'$ be the image $H^{-1}(\pi')$ (which is already constructed by recursion). Then, $H^{-1}(\pi)$ is obtained from $N'$ by adding 1 to the $(i_n, s)$-th entry of $N'$.

This construction appears in [HilGra1976] Section 6 (where $\lambda$-arrays are re-encoded as sequences of “hook number multiplicities”) and [EnumComb2] Section 7.22.

See also:

hillman_grassl_inverse() for the inverse of the Hillman-Grassl correspondence as a standalone function.

hillman_grassl() for the inverse map.

EXAMPLES:

```sage
sage: a = WeakReversePlanePartition([[2, 2, 4], [2, 3, 4], [3, 5]])
sage: a.hillman_grassl_inverse()
[[2, 1, 1], [0, 2, 0], [1, 1]]
```

Applying the inverse of the Hillman-Grassl correspondence to the transpose of a $\lambda$-rpp $M$ yields the same result as applying it to $M$ and then transposing the result ([Gans1981] Corollary 3.4):

```sage
sage: a = WeakReversePlanePartition([[1, 3, 5], [2, 4]])
sage: aic = a.hillman_grassl_inverse().conjugate()
sage: aic == a.conjugate().hillman_grassl_inverse()
True
```

pak_correspondence()  
Return the image of the $\lambda$-rpp self under the Pak correspondence (as a Tableau).

See hillman_grassl.

The Pak correspondence is the map $\xi_{\lambda}$ from [Sulzgr2017] Section 7, and is the map $\xi_{\lambda}$ from [Pak2002] Section 4. It is the inverse of the Sulzgruber correspondence (sulzgruber_correspondence()). The following description of the Pak correspondence follows [Hopkins2017] (which denotes it by $RSK^{-1}$):

Fix a partition $\lambda$ (see Partition()). We draw all partitions and tableaux in English notation.

A $\lambda$-array will mean a tableau of shape $\lambda$ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape $\lambda$ (short: $\lambda$-rpp) will mean a $\lambda$-array whose entries weakly increase along each row and weakly increase along each column.

We shall also use the following notation: If $(u, v)$ is a cell of $\lambda$, and if $\pi$ is a $\lambda$-rpp, then:

- the lower bound of $\pi$ at $(u, v)$ (denoted by $\pi_{<(u,v)}$) is defined to be $\max\{\pi_{u-1,v}, \pi_{u,v-1}\}$ (where $\pi_{0,v}$ and $\pi_{u,0}$ are understood to mean 0).
• the upper bound of \( \pi \) at \((u, v)\) (denoted by \( \pi_{(u,v)} \)) is defined to be \( \min\{\pi_{u+1,v}, \pi_{u,v+1}\} \) (where \( \pi_{i,j} \) is understood to mean \(+\infty\) if \((i, j)\) is not in \( \lambda \); thus, the upper bound at a corner cell is \(+\infty\).

• toggling \( \pi \) at \((u, v)\) means replacing the entry \( \pi_{u,v} \) of \( \pi \) at \((u, v)\) by \( \pi_{<(u,v)} + \pi_{(u,v)} \pi_{(u,v)} - \pi_{u,v} \) (this is well-defined as long as \((u, v)\) is not a corner of \( \lambda \)).

Note that every \( \lambda \)-rpp \( \pi \) and every cell \((u, v)\) of \( \lambda \) satisfy \( \pi_{<(u,v)} \leq \pi_{u,v} \leq \pi_{(u,v)} \). Note that toggling a \( \lambda \)-rpp (at a cell that is not a corner) always results in a \( \lambda \)-rpp. Also, toggling is an involution.

The Pak correspondence \( \Phi_\lambda \) sends a \( \lambda \)-array \( M = (m_{i,j}) \) to a \( \lambda \)-rpp \( \Phi_\lambda(M) \). It is defined by recursion on \( \lambda \) (that is, we assume that \( \Phi_\mu \) is already defined for every partition \( \mu \) smaller than \( \lambda \)), and its definition proceeds as follows:

• If \( \lambda = \emptyset \), then \( \Phi_\lambda \) is the obvious bijection sending the only \( \emptyset \)-array to the only \( \emptyset \)-rpp.

• Pick any corner \( c = (i, j) \) of \( \lambda \), and let \( \mu \) be the result of removing this corner \( c \) from the partition \( \lambda \). (The exact choice of \( c \) is immaterial.)

• Let \( M' \) be what remains of \( M \) when the corner cell \( c \) is removed.

• Let \( \pi' = \Phi_\mu(M') \).

• For each positive integer \( k \) such that \((i - k, j - k)\) is a cell of \( \lambda \), toggle \( \pi' \) at \((i - k, j - k)\). (All these togglings commute, so the order in which they are made is immaterial.)

• Extend the \( \mu \)-rpp \( \pi' \) to a \( \lambda \)-rpp \( \pi \) by adding the cell \( c \) and writing the number \( m_{i,j} - \pi'_{(i,j)} \) into this cell.

• Set \( \Phi_\lambda(M) = \pi \).

See also:

\( \text{pak_correspondence()} \) for the Pak correspondence as a standalone function.

\( \text{sulzgruber_correspondence()} \) for the inverse map.

EXAMPLES:

```sage
a = WeakReversePlanePartition([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
a = a.pak_correspondence(); A
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
a.pak_correspondence().conjugate() == a.conjugate().pak_correspondence()
True
```

Applying the Pak correspondence to the transpose of a \( \lambda \)-rpp \( M \) yields the same result as applying it to \( M \) and then transposing the result:

```sage
a = WeakReversePlanePartition([[1, 3, 5], [2, 4]])
acc = a.pak_correspondence().conjugate()
acc == a.conjugate().pak_correspondence()
True
```

class sage.combinat.hillman_grassl.WeakReversePlanePartitions

Bases: Tableaux

The set of all weak reverse plane partitions.

Element

alias of \( \text{WeakReversePlanePartition} \)

5.1. Comprehensive Module List
an_element()

Returns a particular element of the class.

sage.combinat.hillman_grassl.hillman_grassl(M)

Return the image of the \( \lambda \)-array \( M \) under the Hillman-Grassl correspondence.

The Hillman-Grassl correspondence is a bijection between the tableaux with nonnegative entries (otherwise arbitrary) and the weak reverse plane partitions with nonnegative entries. This bijection preserves the shape of the tableau. See hillman_grassl.

See hillman_grassl() for a description of this map.

See also:

hillman_grassl_inverse()

EXAMPLES:

```
sage: from sage.combinat.hillman_grassl import hillman_grassl
sage: hillman_grassl([[2, 1, 1], [0, 2, 0], [1, 1]])
[[2, 2, 4], [2, 3, 4], [3, 5]]
sage: hillman_grassl([[1, 2, 0], [1, 0, 1], [1]])
[[0, 1, 3], [2, 4, 4], [3]]
sage: hillman_grassl([[]])
[]
sage: hillman_grassl([[3, 1, 2]])
[[3, 4, 6]]
sage: hillman_grassl([[2, 2, 0], [1, 1, 1], [1]])
[[1, 2, 4], [3, 5, 5], [4]]
sage: hillman_grassl([[1, 1, 1, 1]*3])
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]
```
sage: from sage.combinat.hillman_grassl import pak_correspondence
sage: pak_correspondence([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
sage: pak_correspondence([[1, 1, 4], [2, 3, 4], [4, 4, 4]])
[[1, 1, 2], [0, 1, 0], [3, 0, 0]]
sage: pak_correspondence([[0, 2, 3], [1, 3, 3], [2, 4]])
[[1, 0, 2], [0, 2, 0], [1, 1]]
sage: pak_correspondence([[1, 2, 4], [1, 3], [3]])
[[0, 2, 2], [1, 1], [2]]

The Pak correspondence can actually be extended (by the same definition) to “rpps” of nonnegative reals rather than nonnegative integers. This implementation supports this:

sage: pak_correspondence([[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]])
[[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]]

sage.combinat.hillman_grassl.sulzgruber_correspondence(M)

Return the image of a \(\lambda\)-array \(M\) under the Sulzgruber correspondence.

The Sulzgruber correspondence is the map \(\Phi_\lambda\) from [Sulzgr2017] Section 7, and is the map \(\xi_\lambda^{-1}\) from [Pak2002] Section 5. It is denoted by \(\mathcal{RSK}\) in [Hopkins2017]. It is the inverse of the Pak correspondence (pak_correspondence()).

See sulzgruber_correspondence() for a description of this map.

EXAMPLES:

sage: from sage.combinat.hillman_grassl import sulzgruber_correspondence
sage: sulzgruber_correspondence([[1, 0, 2], [0, 2, 0], [1, 1, 0]])
[[1, 2, 3], [1, 2, 3], [2, 4, 4]]
sage: sulzgruber_correspondence([[1, 1, 2], [0, 1, 0], [3, 0, 0]])
[[1, 1, 4], [2, 3, 4], [4, 4, 4]]
sage: sulzgruber_correspondence([[1, 0, 2], [0, 2, 0], [1, 1]])
[[0, 2, 3], [1, 3, 3], [2, 4]]
sage: sulzgruber_correspondence([[0, 2, 2], [1, 1], [2]])
[[1, 2, 4], [1, 3], [3]]

(continues on next page)
The Sulzgruber correspondence can actually be extended (by the same definition) to arrays of nonnegative reals rather than nonnegative integers. This implementation supports this:

```
sage: sulzgruber_correspondence([[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]])
[[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]]
```

```
sage.combinat.hillman_grassl.transpose(M)
    Return the transpose of a \(\lambda\)-array.

    The transpose of a \(\lambda\)-array \((m_{i,j})\) is the \(\lambda^t\)-array \((m_{j,i})\) (where \(\lambda^t\) is the conjugate of the partition \(\lambda\)).
```

```
sage: from sage.combinat.hillman_grassl import transpose
sage: transpose([[1, 2, 3], [4, 5]])
[[1, 4], [2, 5], [3]]
sage: transpose([[5, 0, 3], [4, 1, 0], [7]])
[[5, 4, 7], [0, 1], [3, 0]]
```

5.1.121 Enumerated set of lists of integers with constraints: base classes

- **IntegerListsBackend**: base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.
- **Envelope**: a utility class for upper (lower) envelope of a function under constraints.

**class** ```sage.combinat.integer_lists.base.Envelope```

**Bases**: object

The (currently approximated) upper (lower) envelope of a function under the specified constraints.

**INPUT**:

- \(f\) – a function, list, or tuple; if \(f\) is a list, it is considered as the function \(f(i)=f[i]\), completed for larger \(i\) with \(f(i)=\maxpart\).
- \(\minpart, \maxpart, \minslope, \maxslope, ...\) as for IntegerListsLex (please consult for details).
- \(\text{sign} = (+1 \text{ or } -1)\) multiply the input values with \(\text{sign}\) and multiply the output with \(\text{sign}\). Setting this to \(-1\) can be used to implement a lower envelope.

The upper envelope \(U(f)\) of \(f\) is the (pointwise) largest function which is bounded above by \(f\) and satisfies the \(\maxpart\) and \(\maxslope\) conditions. Furthermore, for \(i, i+1<\minlength\), the upper envelope also satisfies the \minslope condition.

Upon computing \(U(f)(i)\), all the previous values for \(j \leq i\) are computed and cached; in particular \(f(i)\) will be computed at most once for each \(i\).

**Todo**:

- This class is a good candidate for Cythonization, especially to get the critical path in \verb+__call__+ super fast.
- To get full envelopes, we would want both the \minslope and \maxslope conditions to always be satisfied. This is only properly defined for the restriction of \(f\) to a finite interval 0, ..., \(k\), and depends on \(k\).
• This is the core “data structure” of IntegerListsLex. Improving the lookahead there essentially depends on having functions with a good complexity to compute the area below an envelope; and in particular how it evolves when increasing the length.

EXAMPLES:

```plaintext
sage: from sage.combinat.integer_lists import Envelope

Trivial upper and lower envelopes:

sage: f = Envelope([3,2,2])
sage: [f(i) for i in range(10)]
[3, 2, 2, inf, inf, inf, inf, inf, inf, inf]
sage: f = Envelope([3,2,2], sign=-1)
sage: [f(i) for i in range(10)]
[3, 2, 2, 0, 0, 0, 0, 0, 0, 0]

A more interesting lower envelope:

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

Currently, adding max_slope has no effect:

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

unless min_length is large enough:

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0, min_length=2)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0, min_length=4)
sage: [f(i) for i in range(10)]
[5, 5, 5, 4, 5, 4, 3, 2, 2, 2]

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0, min_length=5)
sage: [f(i) for i in range(10)]
[5, 5, 5, 5, 5, 4, 3, 2, 2, 2]

A non trivial upper envelope:

sage: f = Envelope([9,1,5,4], max_part=7, max_slope=2)
sage: [f(i) for i in range(10)]
[7, 1, 3, 4, 6, 7, 7, 7, 7, 7]

adapt(m, j)

Return this envelope adapted to an additional local constraint.
INPUT:

• m – a nonnegative integer (starting value)
• j – a nonnegative integer (position)

This method adapts this envelope to the additional local constraint imposed by having a part \( m \) at position \( j \). Namely, this returns a function which computes, for any \( i > j \), the minimum of the ceiling function and the value restriction given by the slope conditions.

EXAMPLES:

```python
sage: from sage.combinat.integer_lists import Envelope
sage: f = Envelope(3)
sage: g = f.adapt(1,1)
sage: g
True
sage: [g(i) for i in range(10)]
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3]

sage: f = Envelope(3, max_slope=1)
sage: g = f.adapt(1,1)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

Note that, in both cases above, the adapted envelope is only guaranteed to be valid for \( i > j \)! This is to leave potential room in the future for sharing similar adapted envelopes:

```python
sage: g = f.adapt(0,0)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
sage: g = f.adapt(2,2)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
sage: g = f.adapt(3,3)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

Now with a lower envelope:

```python
sage: f = Envelope(1, sign=-1, min_slope=-1)
sage: g = f.adapt(2,2)
sage: [g(i) for i in range(10)]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
sage: g = f.adapt(1,3)
sage: [g(i) for i in range(10)]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
```

limit()

Return a bound on the limit of \( \text{self} \).

OUTPUT: a nonnegative integer or \( \infty \)

This returns some upper bound for the accumulation points of this upper envelope. For a lower envelope, a lower bound is returned instead.
In particular this gives a bound for the value of \texttt{self} at \(i\) for \(i\) large enough. Special case: for a lower envelop, and when the limit is \(\infty\), the envelope is guaranteed to tend to \(\infty\) instead.

When \(s=\texttt{self.limit_start()}\) is finite, this bound is guaranteed to be valid for \(i > s\).

Sometimes it’s better to have a loose bound that starts early; sometimes the converse holds. At this point which specific bound and starting point is returned is not set in stone, in order to leave room for later optimizations.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit()
inf
sage: Envelope([4,1,5], max_part=2).limit()
2
sage: Envelope([4,1,5], max_slope=0).limit()
1
sage: Envelope(lambda x: 3, max_part=2).limit()
2
\end{verbatim}

Lower envelopes:

\begin{verbatim}
sage: Envelope(lambda x: 3, min_part=2, sign=-1).limit()
2
sage: Envelope([4,1,5], min_slope=0, sign=-1).limit()
5
sage: Envelope([4,1,5], sign=-1).limit()
0
\end{verbatim}

\textbf{See also:}

\begin{verbatim}
limit_start()
\end{verbatim}

\textbf{limit_start()}

Return from which \(i\) on the bound returned by \texttt{limit} holds.

\textbf{See also:}

\begin{verbatim}
limit() for the precise specifications.
\end{verbatim}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit_start()
3
sage: Envelope([4,1,5], sign=-1).limit_start()
3
sage: Envelope([4,1,5], max_part=2).limit_start()
3
sage: Envelope(4).limit_start()
0
sage: Envelope(4, sign=-1).limit_start()
0
\end{verbatim}

(continues on next page)
sage: Envelope(lambda x: 3).limit_start() == Infinity
True
sage: Envelope(lambda x: 3, max_part=2).limit_start() == Infinity
True
sage: Envelope(lambda x: 3, sign=-1, min_part=2).limit_start() == Infinity
True

class sage.combinat.integer_lists.base.IntegerListsBackend

Bases: object

Base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.

This base implements the basic operations, including checking for containment using _contains(), but not iteration. For iteration, subclass this class and implement an _iter() method.

EXAMPLES:

```
sage: from sage.combinat.integer_lists.base import IntegerListsBackend
sage: L = IntegerListsBackend(6, max_slope=-1)
sage: L._contains([3,2,1])
True
```

ceiling

floor

max_length

max_part

max_slope

max_sum

min_length

min_part

min_slope

min_sum
5.1.122 Enumerated set of lists of integers with constraints: front-end

- **IntegerLists**: class which models an enumerated set of lists of integers with certain constraints. This is a Python front-end where all user-accessible functionality should be implemented.

```python
class sage.combinat.integer_lists.lists.IntegerList
    Bases: ClonableArray

Element class for IntegerLists.

check()
    Check to make sure this is a valid element in its IntegerLists parent.

    EXAMPLES:
    sage: C = IntegerListsLex(4)
    sage: C([4]).check()
    True
    sage: C([5]).check()
    False
```

```python
class sage.combinat.integer_lists.lists.IntegerLists(*args, **kwds)
    Bases: Parent

Enumerated set of lists of integers with constraints.

Currently, this is simply an abstract base class which should not be used by itself. See IntegerListsLex for a class which can be used by end users.

IntegerLists is just a Python front-end, acting as a Parent, supporting element classes and so on. The attribute .backend which is an instance of sage.combinat.integer_lists.base.IntegerListsBackend is the Cython back-end which implements all operations such as iteration.

The front-end (i.e. this class) and the back-end are supposed to be orthogonal: there is no imposed correspondence between front-ends and back-ends.

For example, the set of partitions of 5 and the set of weakly decreasing sequences which sum to 5 might be implemented by the same back-end, but they will be presented to the user by a different front-end.

    EXAMPLES:
    sage: from sage.combinat.integer_lists import IntegerLists
    sage: L = IntegerLists(5)
    sage: L
    Integer lists of sum 5 satisfying certain constraints
    sage: IntegerListsLex(2, length=3, name="A given name")
    A given name
```

**Element**

alias of IntegerList

**backend = None**

**backend_class**

alias of IntegerListsBackend
5.1.123 Enumerated set of lists of integers with constraints, in inverse lexicographic order

- **IntegerListsLex**: the enumerated set of lists of nonnegative integers with specified constraints, in inverse lexicographic order.
- **IntegerListsBackend_invlex**: Cython back-end for `IntegerListsLex`.

**HISTORY:**
This generic tool was originally written by Hivert and Thiery in MuPAD-Combinat in 2000 and ported over to Sage by Mike Hansen in 2007. It was then completely rewritten in 2015 by Gillespie, Schilling, and Thiery, with the help of many, to deal with limitations and lack of robustness w.r.t. input.

**class** `sage.combinat.integer_lists.invlex.IntegerListsBackend_invlex`

**Bases**: `IntegerListsBackend`

Cython back-end of a set of lists of integers with specified constraints enumerated in inverse lexicographic order.

**check**

**class** `sage.combinat.integer_lists.invlex.IntegerListsLex(*args, **kwds)`

**Bases**: `IntegerLists`

Lists of nonnegative integers with constraints, in inverse lexicographic order.

An integer list is a list $l$ of nonnegative integers, its parts. The slope (at position $i$) is the difference $l[i+1]-l[i]$ between two consecutive parts.

This class allows to construct the set $S$ of all integer lists $l$ satisfying specified bounds on the sum, the length, the slope, and the individual parts, enumerated in inverse lexicographic order, that is from largest to smallest in lexicographic order. Note that, to admit such an enumeration, $S$ is almost necessarily finite (see **On finiteness and inverse lexicographic enumeration**).

The main purpose is to provide a generic iteration engine for all the enumerated sets like **Partitions**, **Compositions**, **IntegerVectors**. It can also be used to generate many other combinatorial objects like Dyck paths, Motzkin paths, etc. Mathematically speaking, this is a special case of set of integral points of a polytope (or union thereof, when the length is not fixed).

**INPUT:**

- **min_sum** – a nonnegative integer (default: 0): a lower bound on $\sum(l)$.
- **max_sum** – a nonnegative integer or $\infty$ (default: $\infty$): an upper bound on $\sum(l)$.
- **n** – a nonnegative integer (optional): if specified, this overrides min_sum and max_sum.
- **min_length** – a nonnegative integer (default: 0): a lower bound on $\text{len}(l)$.
- **max_length** – a nonnegative integer or $\infty$ (default: $\infty$): an upper bound on $\text{len}(l)$.
- **length** – an integer (optional): overrides min_length and max_length if specified;
- **min_part** – a nonnegative integer: a lower bounds on all parts: $\text{min_part} <= l[i]$ for $0 <= i < \text{len}(l)$.
- **floor** – a list of nonnegative integers or a function: lower bounds on the individual parts $l[i]$.

If floor is a list of integers, then $\text{floor} <= l[i]$ for $0 <= i < \min(\text{len}(l), \text{len}(floor))$. Similarly, if floor is a function, then $\text{floor}(i) <= l[i]$ for $0 <= i < \text{len}(l)$.
- **max_part** – a nonnegative integer or $\infty$: an upper bound on all parts: $l[i] <= \text{max_part}$ for $0 <= i < \text{len}(l)$.
• **ceiling** – upper bounds on the individual parts \(l[i]\); this takes the same type of input as **floor**, except that \(\infty\) is allowed in addition to integers, and the default value is \(\infty\).

• **min_slope** – an integer or \(-\infty\) (default: \(-\infty\)) \(\leq\) an lower bound on the slope between consecutive parts: \(\text{min}\_\text{slope} \leq l[i+1]-l[i] \text{ for } 0 \leq i < \text{len}(l)-1\)

• **max_slope** – an integer or \(+\infty\) (defaults: \(+\infty\)) \(\leq\) an upper bound on the slope between consecutive parts: \(l[i+1]-l[i] \leq \text{max}\_\text{slope} \text{ for } 0 \leq i < \text{len}(l)-1\)

• **category** – a category (default: **FiniteEnumeratedSets**)

• **check** – boolean (default: True): whether to display the warnings raised when functions are given as input to **floor** or **ceiling** and the errors raised when there is no proper enumeration.

• **name** – a string or **None** (default: **None**) if set, this will be passed down to **Parent.rename()** to specify the name of **self**. It is recommended to use rename method directly because this feature may become deprecated.

• **element_constructor** – a function (or callable) that creates elements of **self** from a list. See also **Parent**.

• **element_class** – a class for the elements of **self** (default: **ClonableArray**). This merely sets the attribute **self.Element**. See the examples for details.

**Note:** When several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is enumerated (and therefore counted). The others are still considered valid. See the examples below.

This feature is questionable. It is recommended not to rely on it, as it may eventually be discontinued.

**EXAMPLES:**

We create the enumerated set of all lists of nonnegative integers of length 3 and sum 2:

```python
sage: C = IntegerListsLex(2, length=3)
sage: C
Integer lists of sum 2 satisfying certain constraints
sage: C.cardinality()
6
sage: [p for p in C]
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
sage: [2, 0, 0] in C
True
sage: [2, 0, 1] in C
False
sage: "a" in C
False
sage: ["a"] in C
False
sage: C.first()
[2, 0, 0]
```

One can specify lower and upper bounds on each part:

```python
sage: list(IntegerListsLex(5, length=3, floor=[1,2,0], ceiling=[3,2,3]))
[[3, 2, 0], [2, 2, 1], [1, 2, 2]]
```

When the length is fixed as above, one can also use **IntegerVectors**:
Using the slope condition, one can generate integer partitions (but see *Partitions*):

```
sage: list(IntegerListsLex(4, max_slope=0))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The following is the list of all partitions of 7 with parts at least 2:

```
sage: list(IntegerListsLex(7, max_slope=0, min_part=2))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

**floor and ceiling conditions**

Next we list all partitions of 5 of length at most 3 which are bounded below by [2,1,1]:

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, floor=[2,1,1]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

Note that [5] is considered valid, because the floor constraints only apply to existing positions in the list. To obtain instead the partitions containing [2,1,1], one needs to use min_length or length:

```
sage: list(IntegerListsLex(5, max_slope=0, length=3, floor=[2,1,1]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

Here is the list of all partitions of 5 which are contained in [3,2,2]:

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, ceiling=[3,2,2]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

This is the list of all compositions of 4 (but see *Compositions*):

```
sage: list(IntegerListsLex(4, min_part=1))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

This is the list of all integer vectors of sum 4 and length 3:

```
sage: list(IntegerListsLex(4, length=3))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1], [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3], [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

For whatever it is worth, the floor and min_part constraints can be combined:

```
sage: L = IntegerListsLex(5, floor=[2,0,2], min_part=1)
sage: L.list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

This is achieved by updating the floor upon constructing L:

```
sage: [L.floor(i) for i in range(5)]
[2, 1, 2, 1, 1]
```
Similarly, the ceiling and max_part constraints can be combined:

```
sage: L = IntegerListsLex(4, ceiling=[2,3,1], max_part=2, length=3)
sage: L.list()
[[2, 2, 0], [2, 1, 1], [1, 2, 1]]
sage: [L.ceiling(i) for i in range(5)]
[2, 2, 1, 2, 2]
```

This can be used to generate Motzkin words (see Wikipedia article Motzkin_number):

```
sage: def motzkin_words(n):
    ....: return IntegerListsLex(length=n+1, min_slope=-1, max_slope=1,
    ....:                            ceiling=[0]+[+oo for i in range(n-1)]+[0])
sage: motzkin_words(4).list()
[[0, 1, 2, 1, 0],
 [0, 1, 1, 1, 0],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 0],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 0],
 [0, 0, 0, 1, 0],
 [0, 0, 0, 0, 0]]
sage: [motzkin_words(n).cardinality() for n in range(8)]
[1, 1, 2, 4, 9, 21, 51, 127]
sage: oeis(_)
# optional -- internet
0: A001006: Motzkin numbers: number of ways of drawing any number of nonintersecting chords joining n (labeled) points on a circle.
1: ...
2: ...
```

or Dyck words (see also DyckWords), through the bijection with paths from \((0, 0)\) to \((n, n)\) with left and up steps that remain below the diagonal:

```
sage: def dyck_words(n):
    ....: return IntegerListsLex(length=n, ceiling=list(range(n+1)), min_slope=0)
sage: dyck_words(3).list()
[[0, 1, 2], [0, 1, 1], [0, 0, 2], [0, 0, 1], [0, 0, 0]]
sage: [dyck_words(n).cardinality() for n in range(8)]
[1, 1, 2, 5, 14, 42, 132, 429]
sage: dyck_words(3).list()
[[0, 1, 2], [0, 1, 1], [0, 0, 2], [0, 0, 1], [0, 0, 0]]
```

**On finiteness and inverse lexicographic enumeration**

The set of all lists of integers cannot be enumerated in inverse lexicographic order, since there is no largest list (take \([n]\) for \(n\) as large as desired):

```
sage: IntegerListsLex().first()
Traceback (most recent call last):
...  
ValueError: could not prove that the specified constraints yield a finite set
```

Here is a variant which could be enumerated in lexicographic order but not in inverse lexicographic order:
Even when the sum is specified, it is not necessarily possible to enumerate all elements in inverse lexicographic order. In the following example, the list \([1, 1, 1]\) will never appear in the enumeration:

```
sage: IntegerListsLex(3).first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

If one wants to proceed anyway, one can sign a waiver by setting `check=False` (again, be warned that some valid lists may never appear):

```
sage: L = IntegerListsLex(3, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

In fact, being inverse lexicographically enumerable is almost equivalent to being finite. The only infinity that can occur would be from a tail of numbers 0, 1 as in the previous example, where the 1 moves further and further to the right. If there is any list that is inverse lexicographically smaller than such a configuration, the iterator would not reach it and hence would not be considered iterable. Given that the infinite cases are very specific, at this point only the finite cases are supported (without signing the waiver).

The finiteness detection is not complete yet, so some finite cases may not be supported either, at least not without disabling the checks. Practical examples of such are welcome.

### On trailing zeroes, and their caveats

As mentioned above, when several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is listed:

```
sage: L = IntegerListsLex(max_length=4, max_part=1)
sage: L.list()
[[1, 1, 1, 1],
 [1, 1, 1],
 [1, 1, 0, 1],
 [1, 1],
 [1, 0, 1, 1],
 [1, 0, 1],
 [1, 0, 0, 1],
 [1],
 [0, 1, 1, 1],
 [0, 1, 1],
 [0, 1, 0, 1],
 [0, 1],
 [0, 0, 1, 1],
 [0, 0, 1],
 [0, 0, 0, 1],
 [0, 0, 0, 0, 1],
 [0, 0, 0, 0, 0, 1]]
```
and counted:

\[
\text{sage: } L\text{.cardinality()}
\]
16

Still, the others are considered as elements of \(L\):

\[
\begin{align*}
\text{sage: } & L = \text{IntegerListsLex}(4, \text{min\_length}=3, \text{max\_length}=4) \\
\text{sage: } & L\text{.list()} \\
& [..., [2, 2, 0], ...] \\
\text{sage: } & [2, 2, 0] \text{ in } L \quad \# \text{ in } L\text{.list()} \\
& True \\
\text{sage: } & [2, 2, 0, 0] \text{ in } L \quad \# \text{ not in } L\text{.list()} ! \\
& True \\
\text{sage: } & [2, 2, 0, 0, 0] \text{ in } L \\
& False
\end{align*}
\]

### Specifying functions as input for the floor or ceiling

We construct all lists of sum 4 and length 4 such that \(l[i] \leq i\):

\[
\text{sage: } \text{list}(\text{IntegerListsLex}(4, \text{length}=4, \text{ceiling}=\lambda i: i, \text{check}=False))
\]
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]

**Warning:** When passing a function as floor or ceiling, it may become undecidable to detect improper inverse lexicographic enumeration. For example, the following example has a finite enumeration:

\[
\text{sage: } L = \text{IntegerListsLex}(3, \text{floor}=\lambda i: 1 \text{ if } i>=2 \text{ else } 0, \text{check}=False)
\]
[[3], [2, 1], [2, 0, 1], [1, 2], [1, 1, 1], [1, 0, 2], [1, 0, 1, 1], [0, 3], [0, 2, 1], [0, 1, 2], [0, 1, 1, 1], [0, 0, 3], [0, 0, 2, 1], [0, 0, 1, 2], [0, 0, 1, 1]]

but one cannot decide whether the following has an improper inverse lexicographic enumeration without computing the floor all the way to Infinity:

5.1. Comprehensive Module List
Combinatorics, Release 10.1

```
sage: L = IntegerListsLex(3, floor=lambda i: 0, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

Hence a warning is raised when a function is specified as input, unless the waiver is signed by setting check=False:

```
sage: L = IntegerListsLex(3, floor=lambda i: 1 if i>=2 else 0)
doctest:... A function has been given as input of the floor= [...] or ceiling= [...] arguments of IntegerListsLex. Please see the documentation for the caveats.
If you know what you are doing, you can set check=False to skip this warning.
```

Similarly, the algorithm may need to search forever for a solution when the ceiling is ultimately zero:

```
sage: L = IntegerListsLex(2, ceiling=lambda i: 0 if i<20 else 1, check=False)
sage: it = iter(L)
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1]
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1]
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1]
```

Tip: using disjoint union enumerated sets for additional flexibility

Sometimes, specifying a range for the sum or the length may be too restrictive. One would want instead to specify a list, or iterable $L$, of acceptable values. This is easy to achieve using a disjoint union of enumerated sets. Here we want to accept the values $n = 0, 2, 3$:

```
sage: C = DisjointUnionEnumeratedSets(Family([0,2,3],
.....: lambda n: IntegerListsLex(n, length=2)))
sage: C.list()
[[0, 0],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

The price to pay is that the enumeration order is now graded lexicographic instead of lexicographic: first choose the value according to the order specified by $L$, and use lexicographic order within each value. Here is we reverse $L$:

```
sage: DisjointUnionEnumeratedSets(Family([3,2,0],
.....: lambda n: IntegerListsLex(n, length=2))).list()
[[3, 0], [2, 1], [1, 2], [0, 3],
```

(continues on next page)
Note that if a given value appears several times, the corresponding elements will be enumerated several times, which may, or not, be what one wants:

```
sage: DisjointUnionEnumeratedSets(Family([2,2],
               ....: lambda n: IntegerListsLex(n, length=2))).list()
[[2, 0], [1, 1], [0, 2], [2, 0], [1, 1], [0, 2]]
```

Here is a variant where we specify acceptable values for the length:

```
sage: DisjointUnionEnumeratedSets(Family([0,1,3],
               ....: lambda l: IntegerListsLex(2, length=l))).list()
[[2],
  [2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

This technique can also be useful to obtain a proper enumeration on infinite sets by using a graded lexicographic enumeration:

```
sage: C = DisjointUnionEnumeratedSets(Family(NN,
               ....: lambda n: IntegerListsLex(n, length=2)))
sage: C
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
sage: it = iter(C)
sage: [next(it) for i in range(10)]
[[0, 0],
  [1, 0], [0, 1],
  [2, 0], [1, 1], [0, 2],
  [3, 0], [2, 1], [1, 2], [0, 3]]
```

### Specifying how to construct elements

This is the list of all monomials of degree 4 which divide the monomial $x^3y^1z^2$ (a monomial being identified with its exponent vector):

```
sage: R.<x,y,z> = QQ[]
sage: m = [3,1,2]
sage: def term(exponents):
    ....:     return x^exponents[0] * y^exponents[1] * z^exponents[2]
sage: list( IntegerListsLex(4, length=len(m), ceiling=m, element_constructor=term) )
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

Note the use of the `element_constructor` option to specify how to construct elements from a plain list.

A variant is to specify a class for the elements. With the default element constructor, this class should take as input the parent `self` and a list.

#### Warning:
The protocol for specifying the element class and constructor is subject to changes.

**ALGORITHM:**

5.1. Comprehensive Module List 1207
The iteration algorithm uses a depth first search through the prefix tree of the list of integers (see also *Lexico-graphic generation of lists of integers*). While doing so, it does some lookahead heuristics to attempt to cut dead branches.

In most practical use cases, most dead branches are cut. Then, roughly speaking, the time needed to iterate through all the elements of \( S \) is proportional to the number of elements, where the proportion factor is controlled by the length \( l \) of the longest element of \( S \). In addition, the memory usage is also controlled by \( l \), which is to say negligible in practice.

Still, there remains much room for efficiency improvements; see github issue #18055, github issue #18056.

**Note:** The generation algorithm could in principle be extended to deal with non-constant slope constraints and with negative parts.

### TESTS from comments on github issue #17979

Comment 191:

```python
sage: list(IntegerListsLex(1, min_length=2, min_slope=0, max_slope=0))
[]
```

Comment 240:

```python
sage: L = IntegerListsLex(min_length=2, max_part=0)
sage: L.list()
[[0, 0]]
```

### Tests on the element constructor feature and mutability

Internally, the iterator works on a single list that is mutated along the way. Therefore, you need to make sure that the `element_constructor` actually copies its input. This example shows what can go wrong:

```python
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_constructor=lambda _x: x)
sage: list(P)
[[], [], []]
```

However, specifying `list()` as constructor solves this problem:

```python
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_constructor=list)
sage: list(P)
[[3], [2, 1], [1, 1, 1]]
```

Same, step by step:

```python
sage: it = iter(P)
sage: a = next(it); a
[3]
sage: b = next(it); b
[2, 1]
sage: a
[3]
```
\texttt{sage: a is b}
False

Tests from \texttt{MuPAD-Combinat}:

\begin{verbatim}
\texttt{sage: IntegerListsLex(7, min_length=2, max_length=6, floor=[0,0,2,0,0,1],}
\texttt{ceiling=[3,2,3,2,1,2]).cardinality()}
83
\texttt{sage: IntegerListsLex(7, min_length=2, max_length=6, floor=[0,0,2,0,1,1],}
\texttt{ceiling=[3,2,3,2,1,2]).cardinality()}
53
\texttt{sage: IntegerListsLex(5, min_length=2, max_length=6, floor=[0,0,1,1,0,0],}
\texttt{ceiling=[2,2,2,2,2,2]).cardinality()}
30
\texttt{sage: IntegerListsLex(5, min_length=2, max_length=6, floor=[0,0,1,1,0,0],}
\texttt{ceiling=[2,2,2,2,2,2]).cardinality()}
43
\texttt{sage: IntegerListsLex(0, min_length=0, max_length=7, floor=[1,1,0,0,1,0],}
\texttt{ceiling=[4,3,2,3,2,2,1]).first()}
[]
\texttt{sage: IntegerListsLex(0, min_length=1, max_length=7, floor=[0,1,0,0,1,0],}

This used to hang (see comment 389 and fix in Envelope.__init__()):

sage: IntegerListsLex(7, max_part=0, ceiling=lambda i:i, check=False).list()
[]

backend_class
alias of IntegerListsBackend_invlex

class sage.combinat.integer_lists.invlex.IntegerListsLexIter(backend)
Bases: object

Iterator class for IntegerListsLex.

Let T be the prefix tree of all lists of nonnegative integers that satisfy all constraints except possibly for min_length and min_sum; let the children of a list be sorted decreasingly according to their last part.

The iterator is based on a depth-first search exploration of a subtree of this tree, trying to cut branches that do not contain a valid list. Each call of next iterates through the nodes of this tree until it finds a valid list to return.

Here are the attributes describing the current state of the iterator, and their invariants:

• backend – the IntegerListsBackend object this is iterating on;
• _current_list – the list corresponding to the current node of the tree;
• _j – the index of the last element of _current_list: self._j == len(self._current_list) - 1;
• _current_sum – the sum of the parts of _current_list;
• _search_ranges – a list of same length as _current_list: the range for each part.

Furthermore, we assume that there is no obvious contradiction in the constraints:

• self.backend.min_length <= self.backend.max_length;
• self.backend.min_slope <= self.backend.max_slope unless self.backend.min_length <= 1.

Along this iteration, next switches between the following states:

• LOOKAHEAD: determine whether the current list could be a prefix of a valid list;
• PUSH: go deeper into the prefix tree by appending the largest possible part to the current list;
• ME: check whether the current list is valid and if yes return it.
• DECREASE: decrease the last part;
• POP: pop the last part of the current list;
• STOP: the iteration is finished.

The attribute \_next_state contains the next state next should enter in.

## 5.1.124 Counting, generating, and manipulating non-negative integer matrices

Counting, generating, and manipulating non-negative integer matrices with prescribed row sums and column sums.

**AUTHORS:**

• Franco Saliola

```python
class sage.combinat.integer_matrices.IntegerMatrices(row_sums, column_sums)
    Bases: UniqueRepresentation, Parent

The class of non-negative integer matrices with prescribed row sums and column sums.

An integer matrix \( m \) with column sums \( c := (c_1, ..., c_k) \) and row sums \( l := (l_1, ..., l_n) \) where \( c_1 + ... + c_k \) is equal to \( l_1 + ... + l_n \), is a \( n \times k \) matrix \( m = (m_{i,j}) \) such that \( m_{1,j} + \cdots + m_{n,j} = c_j \), for all \( j \) and \( m_{i,1} + \cdots + m_{i,k} = l_i \), for all \( i \).

**EXAMPLES:**

There are 6 integer matrices with row sums \([3, 2, 2]\) and column sums \([2, 5]\):

```python
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
sage: IM.list()
[[2 1] [1 2] [1 2] [0 3] [0 3] [0 3]
 [0 2] [1 1] [0 2] [2 0] [1 1] [0 2]
 [0 2], [0 2], [1 1], [0 2], [1 1], [2 0]]
sage: IM.cardinality()

```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
This method computes the cardinality using symmetric functions. Below are the same examples, but computed by generating the actual matrices:

```python
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: len(IntegerMatrices([2,5], [3,2,2]).list())
6
sage: len(IntegerMatrices([1,1,1,1], [1,1,1,1]).list())
120
sage: len(IntegerMatrices([2,2,2,2], [2,2,2,2]).list())
282
sage: len(IntegerMatrices([4], [3]).list())
0
sage: len(IntegerMatrices([0], [0]).list())
1
```

column_sums()  
The column sums of the integer matrices in self.

OUTPUT:  
• Composition

EXAMPLES:

```python
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5])
sage: IM.column_sums()
[2, 5]
```

row_sums()  
The row sums of the integer matrices in self.

OUTPUT:  
• Composition

EXAMPLES:

```python
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5])
sage: IM.row_sums()
[3, 2, 2]
```

to_composition(x)  
The composition corresponding to the integer matrix.

This is the composition obtained by reading the entries of the matrix from left to right along each row, and reading the rows from top to bottom, ignore zeros.

INPUT:  
• x – matrix

EXAMPLES:

```python
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
```
sage: IM.list()
[
[2 1] [1 2] [1 2] [0 3] [0 3] [0 3]
[0 2] [1 1] [0 2] [2 0] [1 1] [0 2]
[0 2], [0 2], [1 1], [0 2], [1 1], [2 0]
]
sage: for m in IM: print(IM.to_composition(m))
[2, 1, 2, 2]
[1, 2, 1, 1, 2]
[1, 2, 2, 1, 1]
[3, 2, 2]
[3, 1, 1, 1, 1]
[3, 2, 2]

sage.combinat.integer_matrices.integer_matrices_generator(row_sums, column_sums)
Recursively generate the integer matrices with the prescribed row sums and column sums.

INPUT:
  • row_sums – list or tuple
  • column_sums – list or tuple

OUTPUT:
  • an iterator producing a list of lists

EXAMPLES:

sage: from sage.combinat.integer_matrices import integer_matrices_generator
sage: iter = integer_matrices_generator([3,2,2], [2,5]); iter
<generator object ...integer_matrices_generator at ...>
sage: for m in iter: print(m)
[[2, 1], [0, 2], [0, 2]]
[[1, 2], [1, 1], [0, 2]]
[[1, 2], [0, 2], [1, 1]]
[[0, 3], [2, 0], [0, 2]]
[[0, 3], [1, 1], [1, 1]]
[[0, 3], [0, 2], [2, 0]]

5.1.125 (Non-negative) Integer vectors

AUTHORS:
  • Mike Hansen (2007) - original module
  • Nathann Cohen, David Joyner (2009-2010) - Gale-Ryser stuff
  • Nathann Cohen, David Joyner (2011) - Gale-Ryser bugfix
  • Travis Scrimshaw (2012-05-12) - Updated doc-strings to tell the user of that the class’s name is a misnomer (that they only contains non-negative entries).
  • Federico Poloni (2013) - specialized rank()
  • Travis Scrimshaw (2013-02-04) - Refactored to use ClonableIntArray
class sage.combinat.integer_vector.IntegerVector

Bases: ClonableArray

An integer vector.

def check()
    Check to make sure this is a valid integer vector by making sure all entries are non-negative.

    EXAMPLES:
    sage: IV = IntegerVectors()
    sage: elt = IV([1,2,1])
    sage: elt.check()

    Check github issue #34510:

    sage: IV3 = IntegerVectors(n=3)
    sage: IV3([2,2])
    Traceback (most recent call last):
      ... ValueError: [2, 2] doesn't satisfy correct constraints
    sage: IVk3 = IntegerVectors(k=3)
    sage: IVk3([2,2])
    Traceback (most recent call last):
      ... ValueError: [2, 2] doesn't satisfy correct constraints
    sage: IV33 = IntegerVectors(n=3, k=3)
    sage: IV33([2,2])
    Traceback (most recent call last):
      ... ValueError: [2, 2] doesn't satisfy correct constraints

def specht_module(base_ring=None)
    Return the Specht module corresponding to self.

    EXAMPLES:
    sage: SM = IntegerVectors()([2,0,1,0,2]).specht_module(QQ); SM
    Specht module of [(0, 0), (0, 1), (2, 0), (4, 0), (4, 1)] over Rational Field
    sage: s = SymmetricFunctions(QQ).s()  # optional - sage.combinat
    sage: s(SM.frobenius_image())  # optional - sage.combinat
    s[2, 2, 1]

def specht_module_dimension(base_ring=None)
    Return the dimension of the Specht module corresponding to self.

    INPUT:
    - BR – (default: QQ) the base ring

    EXAMPLES:
sage: IntegerVectors()([2,0,1,0,2]).specht_module_dimension() # optional - sage.combinat
5
sage: IntegerVectors()([2,0,1,0,2]).specht_module_dimension(GF(2)) # optional - sage.combinat sage.rings.finite_rings
5

trim()

Remove trailing zeros from the integer vector.

EXAMPLES:

sage: IV = IntegerVectors()
sage: IV([5,3,5,1,0,0]).trim()
\[5, 3, 5, 1\]
sage: IV([5,0,5,1,0]).trim()
\[5, 0, 5, 1\]
sage: IV([4,3,3]).trim()
\[4, 3, 3\]
sage: IV([0,0,0]).trim()
\[
\]
sage: IV = IntegerVectors(k=4)
sage: v = IV([4,3,2,0]).trim(); v
\[4, 3, 2\]
sage: v.parent()
Integer vectors

class sage.combinat.integer_vector.IntegerVectors(category=None)

Bases: Parent

The class of (non-negative) integer vectors.

INPUT:

• \(n\) – if set to an integer, returns the combinatorial class of integer vectors whose sum is \(n\); if set to \(\text{None}\) (default), no such constraint is defined

• \(k\) – the length of the vectors; set to \(\text{None}\) (default) if you do not want such a constraint

Note: The entries are non-negative integers.

EXAMPLES:

If \(n\) is not specified, it returns the class of all integer vectors:

sage: IntegerVectors()
Integer vectors
sage: [] in IntegerVectors()
True
sage: [1,2,1] in IntegerVectors()
True
sage: [1, 0, 0] in IntegerVectors()
True
Entries are non-negative:

```
sage: [-1, 2] in IntegerVectors()
False
```

If \( n \) is specified, then it returns the class of all integer vectors which sum to \( n \):

```
sage: IV3 = IntegerVectors(3); IV3
Integer vectors that sum to 3
```

Note that trailing zeros are ignored so that \([3, 0]\) does not show up in the following list (since \([3]\) does):

```
sage: IntegerVectors(3, max_length=2).list() # optional - sage.combinat
[[3], [2, 1], [1, 2], [0, 3]]
```

If \( n \) and \( k \) are both specified, then it returns the class of integer vectors that sum to \( n \) and are of length \( k \):

```
sage: IV53 = IntegerVectors(5,3); IV53
Integer vectors of length 3 that sum to 5
sage: IV53.cardinality()
21
sage: IV53.first()
[5, 0, 0]
```

Further examples:

```
sage: IntegerVectors(-1, 0, min_part=1).list() []
sage: IntegerVectors(-1, 2, min_part=1).list() []
sage: IntegerVectors(0, 0, min_part=1).list() [[]]
sage: IntegerVectors(3, 0, min_part=1).list() []
sage: IntegerVectors(0, 1, min_part=1).list() []
sage: IntegerVectors(2, 2, min_part=1).list() [[1, 1]]
sage: IntegerVectors(2, 3, min_part=1).list() []
sage: IntegerVectors(4, 2, min_part=1).list() [[3, 1], [2, 2], [1, 3]]
sage: IntegerVectors(0, 3, outer=[0,0,0]).list() [[0, 0, 0]]
sage: IntegerVectors(1, 3, outer=[0,0,0]).list() []
sage: IntegerVectors(2, 3, outer=[0,2,0]).list() [[0, 2, 0]]
```
Combinatorics, Release 10.1

(continued from previous page)

```
sage: IntegerVectors(2, 3, outer=[1,2,1]).list()
[[1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1]]
sage: IntegerVectors(2, 3, outer=[1,1,1]).list()
[[1, 1, 0], [1, 0, 1], [0, 1, 1]]
sage: IntegerVectors(2, 5, outer=[1,1,1,1,1]).list()
[[1, 1, 0, 0, 0],
 [1, 0, 1, 0, 0],
 [1, 0, 0, 1, 0],
 [1, 0, 0, 0, 1],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 1],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 1],
 [0, 0, 0, 1, 1]]
```

```
sage: iv = [ IntegerVectors(n,k) for n in range(-2, 7) for k in range(7) ]
sage: all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
sage: essai = [[1,1,1], [2,5,6], [6,5,2]]
sage: iv = [ IntegerVectors(x[0], x[1], max_part = x[2]-1) for x in essai ]
sage: all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
```

An example showing the same output by using IntegerListsLex:

```
sage: IntegerVectors(4, max_length=2).list()
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
sage: list(IntegerListsLex(4, max_length=2))
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
```

See also:
```
sage.combinat.integer_lists.invlex.IntegerListsLex
Element
alias of IntegerVector
```

```
class sage.combinat.integer_vector.IntegerVectorsConstraints(n=None, k=None, **constraints)
```

Bases: IntegerVectors

Class of integer vectors subject to various constraints.

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: IntegerVectors(3, 3, min_part=1).cardinality()
1
sage: IntegerVectors(5, 3, min_part=1).cardinality()
```

(continues on next page)
```
→ optional - sage.combinat
6
sage: IntegerVectors(13, 4, max_part=4).cardinality()  #
→ optional - sage.combinat
20
sage: IntegerVectors(k=4, max_part=3).cardinality()  #
→ optional - sage.combinat
256
sage: IntegerVectors(k=3, min_part=2, max_part=4).cardinality()  #
→ optional - sage.combinat
27
sage: IntegerVectors(13, 4, min_part=2, max_part=4).cardinality()  #
→ optional - sage.combinat
16
```

**class** sage.combinat.integer_vector.IntegerVectors_all

Bases: UniqueRepresentation, IntegerVectors

Class of all integer vectors.

**class** sage.combinat.integer_vector.IntegerVectors_k(k)

Bases: UniqueRepresentation, IntegerVectors

Integer vectors of length $k$.

**class** sage.combinat.integer_vector.IntegerVectors_n(n)

Bases: UniqueRepresentation, IntegerVectors

Integer vectors that sum to $n$.

**class** sage.combinat.integer_vector.IntegerVectors_nk(n, k)

Bases: UniqueRepresentation, IntegerVectors

Integer vectors of length $k$ that sum to $n$.

**AUTHORS:**

- Martin Albrecht
- Mike Hansen

**rank(x)**

Return the rank of a given element.

**INPUT:**

- $x$ – a list with $\text{sum}(x) == n$ and $\text{len}(x) == k$

**class** sage.combinat.integer_vector.IntegerVectors_nnondescents(n, comp)

Bases: UniqueRepresentation, IntegerVectors

Integer vectors graded by two parameters.

The grading parameters on the integer vector $v$ are:

- $n$ – the sum of the parts of $v$,
- $c$ – the non descents composition of $v$. 

In other words: the length of \( v \) equals \( c_1 + \cdots + c_k \), and \( v \) is decreasing in the consecutive blocs of length \( c_1, \ldots, c_k \).

**INPUT:**
- \( n \) – the positive integer \( n \)
- \( \text{comp} \) – the composition \( c \)

Those are the integer vectors of sum \( n \) that are lexicographically maximal (for the natural left-to-right reading) in their orbit by the Young subgroup \( S_{c_1} \times \cdots \times S_{c_k} \). In particular, they form a set of orbit representative of integer vectors with respect to this Young subgroup.

```python
sage.combinat.integer_vector.gale_ryser_theorem(p1, p2, algorithm, solver, integrality_tolerance='gale')
```

Returns the binary matrix given by the Gale-Ryser theorem.

The Gale Ryser theorem asserts that if \( p_1, p_2 \) are two partitions of \( n \) of respective lengths \( k_1, k_2 \), then there is a binary \( k_1 \times k_2 \) matrix \( M \) such that \( p_1 \) is the vector of row sums and \( p_2 \) is the vector of column sums of \( M \), if and only if the conjugate of \( p_2 \) dominates \( p_1 \).

**INPUT:**
- \( p_1, p_2 \) – list of integers representing the vectors of row/column sums
- \( \text{algorithm} \) – two possible string values:
  - 'ryser' implements the construction due to Ryser [Ryser63].
  - 'gale' (default) implements the construction due to Gale [Gale57].
- \( \text{solver} \) – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method solve of the class MixedIntegerLinearProgram.
- \( \text{integrality_tolerance} \) – parameter for use with MILP solvers over an inexact base ring; see MixedIntegerLinearProgram.get_values().

**OUTPUT:**
A binary matrix if it exists, None otherwise.

Gale’s Algorithm:
(Gale [Gale57]): A matrix satisfying the constraints of its sums can be defined as the solution of the following Linear Program, which Sage knows how to solve.

\[
\forall i \sum_{j=1}^{k_2} b_{i,j} = p_{1,j} \\
\forall i \sum_{j=1}^{k_1} b_{j,i} = p_{2,j} \\
b_{i,j} \text{ is a binary variable}
\]

Ryser’s Algorithm:
(Ryser [Ryser63]): The construction of an \( m \times n \) matrix \( A = A_{r,s} \), due to Ryser, is described as follows. The construction works if and only if have \( s \leq r^* \).
