Sage enables computations with curves in affine and projective ambient spaces, curves over $\mathbb{C}$ as Riemann surfaces, and Jacobians of projective curves.
1.1 Curve constructor

Curves are constructed through the curve constructor, after an ambient space is defined either explicitly or implicitly.

EXAMPLES:

```python
sage: A.<x,y> = AffineSpace(QQ, 2)
 sage: Curve([y - x^2], A)
 Affine Plane Curve over Rational Field defined by -x^2 + y

>>> from sage.all import *

>>> A = AffineSpace(QQ, Integer(2), names=(x, y,)); (x, y,) = A._first_ngens(2)
>>> Curve([y - x**Integer(2)], A)
 Affine Plane Curve over Rational Field defined by -x^2 + y

sage: P.<x,y,z> = ProjectiveSpace(GF(5), 2)
 sage: Curve(y^2*z^7 - x^9 - x*z^8)
 Projective Plane Curve over Finite Field of size 5
 defined by -x^9 + y^2*z^7 - x*z^8

>>> from sage.all import *

>>> P = ProjectiveSpace(GF(Integer(5)), Integer(2), names=('x', 'y', 'z',)); (x, y, z, →) = P._first_ngens(3)
>>> Curve(y**Integer(2)*z**Integer(7) - x**Integer(9) - x*z**Integer(8))
 Projective Plane Curve over Finite Field of size 5
 defined by -x^9 + y^2*z^7 - x*z^8
```

AUTHORS:

- Grayson Jorgenson (2016-06)

`sage.schemes.curves.constructor.Curve(F, A=None)`

Return the plane or space curve defined by \( F \), where \( F \) can be either a multivariate polynomial, a list or tuple of polynomials, or an algebraic scheme.

If no ambient space is passed in for \( A \), and if \( F \) is not an algebraic scheme, a new ambient space is constructed.

Also not specifying an ambient space will cause the curve to be defined in either affine or projective space based on properties of \( F \). In particular, if \( F \) contains a nonhomogeneous polynomial, the curve is affine, and if \( F \) consists of homogeneous polynomials, then the curve is projective.
INPUT:

- \( F \) – a multivariate polynomial, or a list or tuple of polynomials, or an algebraic scheme
- \( A \) – (default: None) an ambient space in which to create the curve

EXAMPLES:

A projective plane curve:

```python
sage: x, y, z = QQ['x,y,z'].gens()
sage: C = Curve(x^3 + y^3 + z^3); C
Projective Plane Curve over Rational Field defined by x^3 + y^3 + z^3
sage: C.genus()
1
```

Affine plane curves.

```python
>>> from sage.all import *
>>> x, y, z = QQ['x,y,z'].gens()
>>> C = Curve(x**Integer(3) + y**Integer(3) + z**Integer(3)); C
Projective Plane Curve over Rational Field defined by x^3 + y^3 + z^3
>>> C.genus()
1
```

A projective space curve.

```python
>>> x, y, z, w = QQ['x,y,z,w'].gens()
>>> C = Curve([x^3 + y^3 - z^3 - w^3, x^5 - y^z^4]); C
Projective Curve over Rational Field defined by x^3 + y^3 - z^3 - w^3, x^5 - y*z^4
>>> C.genus()
13
```
An affine space curve.

```sage
x, y, z = QQ['x,y,z'].gens()
sage: C = Curve([y^2 + x^3 + x^10 + z^7, x^2 + y^2]); C
Affine Curve over Rational Field defined by x^10 + z^7 + x^3 + y^2, x^2 + y^2
sage: C.genus()
47
```

We can also make non-reduced non-irreducible curves.

```sage
x, y, z = QQ['x,y,z'].gens()
sage: Curve((x-y)*(x+y))
Projective Conic Curve over Rational Field defined by x^2 - y^2
sage: Curve((x-y)^2*(x+y)^2)
Projective Plane Curve over Rational Field defined by x^4 - 2*x^2*y^2 + y^4
```

A union of curves is a curve.

```sage
x, y, z = QQ['x,y,z'].gens()
sage: C = Curve(x^3 + y^3 + z^3)
sage: D = Curve(x^4 + y^4 + z^4)
sage: C.union(D)
Projective Plane Curve over Rational Field defined by x^7 + x^4*y^3 + x^3*y^4 + y^7 + x^4*z^3 + y^4*z^3 + x^3*z^4 + y^3*z^4 + z^7
```

The intersection is not a curve, though it is a scheme.

```sage
X = C.intersection(D); X
Closed subscheme of Projective Space of dimension 2 over Rational Field
defined by: x^3 + y^3 + z^3,
           x^4 + y^4 + z^4
```
Note that the intersection has dimension 0.

```
sage: X.dimension()
0
```

If only a polynomial in three variables is given, then it must be homogeneous such that a projective curve is constructed.

```
sage: x, y, z = QQ['x', 'y', 'z'].gens()
sage: Curve(x^2 + y^2)
Projective Conic Curve over Rational Field defined by x^2 + y^2
sage: Curve(x^2 + y^2 + z)
Traceback (most recent call last):
  ...TypeError: x^2 + y^2 + z is not a homogeneous polynomial
```

An ambient space can be specified to construct a space curve in an affine or a projective space.

```
sage: A.<x, y, z> = AffineSpace(QQ, 3)
sage: C = Curve([-x^2 + y, -x^3 + z], A)
sage: A == C.ambient_space()
True
```

(continues on next page)
The defining polynomial must be nonzero unless the ambient space itself is of dimension 1.

```python
sage: P1.<x,y> = ProjectiveSpace(1, GF(5))
sage: S = P1.coordinate_ring()
sage: Curve(S(0), P1)
Projective Line over Finite Field of size 5
sage: Curve(P1)
Projective Line over Finite Field of size 5
```

An affine line:

```python
sage: A1.<x> = AffineSpace(1, QQ)
sage: R = A1.coordinate_ring()
sage: Curve(R(0), A1)
Affine Line over Rational Field
sage: Curve(A1)
Affine Line over Rational Field
```

A projective line:

```python
sage: R.<x> = QQ[]
sage: N.<a> = NumberField(x^2 + 1)
sage: P1.<x,y> = ProjectiveSpace(N, 1)
sage: C = Curve(P1)
sage: C
Projective Line over Number Field in a with defining polynomial x^2 + 1
sage: C.geometric_genus()
0
sage: C.arithmetic_genus()
0
```
1.2 Base class of curves

This module defines the base class of curves in Sage.

Curves in Sage are reduced subschemes of dimension 1 of an ambient space. The ambient space is either an affine space or a projective space.

EXAMPLES:

```python
sage: A.<x,y,z> = AffineSpace(QQ, 3)
sage: C = Curve([x - y, z - 2])
sage: C
Affine Curve over Rational Field defined by x - y, z - 2
sage: C.dimension()
1
```

AUTHORS:

- William Stein (2005)

```
class sage.schemes.curves.curve.Curve_generic (A, polynomials, category=None)
```

Generic curve class.

EXAMPLES:

```python
sage: A.<x,y,z> = AffineSpace(QQ, 3)
sage: C = Curve([x - y, z - 2])
sage: loads(C.dumps()) == C
True
```

```python
>>> from sage.all import *

```
loads(C.dumps()) == C
True

change_ring$(R)$

Return a new curve which is this curve coerced to $\mathbb{R}$.

INPUT:

• $R$ – ring or embedding

OUTPUT: a new curve which is this curve coerced to $\mathbb{R}$

EXAMPLES:

```
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([x^2 - y^2, z*y - 4/5*w^2], P)
sage: C.change_ring(QuadraticField(-1))  # needs sage.rings.number_field
Projective Curve over Number Field in a with defining polynomial x^2 + 1
with a = 1*I defined by x^2 - y^2, y*z - 4/5*w^2
```

```
sage: from sage.all import *
```

```
P = ProjectiveSpace(QQ, Integer(3), names=(x, y, z, w,)); (x, y, z, w,) = P._first_ngens(4)
>>> C = Curve([x**Integer(2) - y**Integer(2), z*y - Integer(4)/Integer(5)*w**Integer(2)], P)
>>> C.change_ring(QuadraticField(-Integer(1)))  # needs sage.rings.number_field
Projective Curve over Number Field in a with defining polynomial x^2 + 1
with a = 1*I defined by x^2 - y^2, y*z - 4/5*w^2
```

```
sage: # needs sage.rings.number_field
sage: R.<a> = QQ[]
sage: K.<b> = NumberField(a**Integer(3) + a**Integer(2) - Integer(1), names=(b,)); (b,) = K._first_ngens(1)
>>> A.<x,y> = AffineSpace(K, Integer(2))
>>> C = Curve([K.gen(0)*x^Integer(2) - x + y^Integer(3) - Integer(11)], A)
>>> L = K.embeddings(QQbar)
>>> set_verbose(-Integer(1))  # suppress warnings for slow computation
>>> C.change_ring(L[Integer(0)])
Affine Plane Curve over Algebraic Field defined
by y^3 + (-0.8774388331233464? - 0.744861766619745?*I)*x^2 - x - 11
```

```
sage: # needs sage.rings.number_field
sage: from sage.all import *
```

```
# needs sage.rings.number_field
>>> R = QQ['a']; (a,) = R._first_ngens(1)
>>> K = NumberField(a**Integer(3) + a**Integer(2) - Integer(1), names=('b',)); (b,) = K._first_ngens(1)
>>> A = AffineSpace(K, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve([K.gen(0)*x**Integer(2) - x + y**Integer(3) - Integer(11)], A)
>>> L = K.embeddings(QQbar)
>>> set_verbose(-Integer(1))  # suppress warnings for slow computation
>>> C.change_ring(L[Integer(0)])
Affine Plane Curve over Algebraic Field defined
by y^3 + (-0.8774388331233464? - 0.744861766619745?*I)*x^2 - x - 11
```

1.2. Base class of curves
Plane and Space Curves, Release 10.4

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = P.curve([y*x - 18*x^2 + 17*z^2])
sage: C.change_ring(GF(17))
Projective Plane Curve over Finite Field of size 17 defined by -x^2 + x*y
```

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z'));
(,) = P._first_ngens(3)
>>> C = P.curve([y*x - Integer(18)*x**Integer(2) + Integer(17)*z**Integer(2)])
>>> C.change_ring(GF(Integer(17)))
Projective Plane Curve over Finite Field of size 17 defined by -x^2 + x*y
```

**defining_polynomial()**

Return the defining polynomial of the curve.

**EXAMPLES:**

```python
sage: x,y,z = PolynomialRing(QQ, 3, names='x,y,z').gens()
sage: C = Curve(y^2*z - x^3 - 17*x*z^2 + y*z^2)
sage: C.defining_polynomial()
-x^3 + y^2*z - 17*x*z^2 + y*z^2
```

```python
>>> from sage.all import *
>>> x,y,z = PolynomialRing(QQ, Integer(3), names='x,y,z').gens()
>>> C = Curve(y**Integer(2)*z - x**Integer(3) - Integer(17)*x*z**Integer(2) + y*z**Integer(2))
>>> C.defining_polynomial()
-x^3 + y^2*z - 17*x*z^2 + y*z^2
```

**dimension()**

Return the dimension of the curve.

Curves have dimension one by definition.

**EXAMPLES:**

```python
sage: x = polygen(QQ)
sage: C = HyperellipticCurve(x^7 + x^4 + x)
sage: C.dimension()
1
```

```python
>>> from sage.schemes.projective.projective_subscheme import *
>>> AlgebraicScheme_subscheme_projective
sage: AlgebraicScheme_subscheme_projective.dimension(C)
1
```

```python
>>> from sage.all import *
>>> x = polygen(QQ)
>>> C = HyperellipticCurve(x**Integer(7) + x**Integer(4) + x)
>>> C.dimension()
1
```

```python
>>> from sage.schemes.projective.projective_subscheme import AlgebraicScheme_subscheme_projective
>>> AlgebraicScheme_subscheme_projective.dimension(C)
1
```

**divisor(v, base_ring=None, check=True, reduce=True)**

Return the divisor specified by v.
**Warning:** The coefficients of the divisor must be in the base ring and the terms must be reduced. If you set `check=False` and/or `reduce=False` it is your responsibility to pass a valid object v.

**EXAMPLES:**

```python
sage: x, y, z = PolynomialRing(QQ, 3, names='x, y, z').gens()
sage: C = Curve(y^2*z - x^3 - 17*x*z^2 + y*z^2)
sage: p1 = C(0, -1, 1)
sage: p2 = C(0, 0, 1)
sage: p3 = C(0, 1, 0)
sage: C.divisor([(1, p1), (-1, p2), (2, p3)])
(x, y + z) - (x, y) + 2*(x, z)
```

```python
>>> from sage.all import *

```
geometric_genus()

Return the geometric genus of the curve.

EXAMPLES:

Examples of projective curves:

sage: P2 = ProjectiveSpace(2, GF(5), names=['x','y','z'])
sage: x, y, z = P2.coordinate_ring().gens()
sage: C = Curve(y^2*z - x^3 - 17*x*z^2 + y*z^2)
sage: C.geometric_genus()
1
sage: C = Curve(y^2*z - x^3)
sage: C.geometric_genus()
0
sage: C = Curve(x^10 + y^7*z^3 + z^10)
sage: C.geometric_genus()
3

Examples of affine curves:

sage: x, y = PolynomialRing(GF(5), 2, 'xy').gens()
sage: C = Curve(y^2 - x^3 - 17*x + y)
sage: C.geometric_genus()
1
sage: C = Curve(y^2 - x^3)
sage: C.geometric_genus()
0
sage: C = Curve(x^10 + y^7 + 1)
sage: C.geometric_genus()
3
>>> from sage.all import *
>>> x, y = PolynomialRing(GF(Integer(5)), Integer(2), 'xy').gens()
>>> C = Curve(y**Integer(2) - x**Integer(3) - Integer(17)*x + y)
>>> C.geometric_genus()
1
>>> C = Curve(y**Integer(2) - x**Integer(3))
>>> C.geometric_genus()
0
>>> C = Curve(x**Integer(10) + y**Integer(7) + Integer(1))
>>> C.geometric_genus()
3

**Warning:** Geometric genus is only defined for geometrically irreducible curve. This method does not check the condition. You may get a nonsensical result if the curve is not geometrically irreducible:

```
sage: P2.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x^2 + y^2, P2)
sage: C.geometric_genus()  # nonsense!
-1
```

**intersection_points** *(C, F=None)*

Return the points in the intersection of this curve and the curve C.

If the intersection of these two curves has dimension greater than zero, and if the base ring of this curve is not a finite field, then an error is returned.

**INPUT:**

- C – a curve in the same ambient space as this curve
- F – (default: None); field over which to compute the intersection points; if not specified, the base ring of this curve is used

**OUTPUT:** a list of points in the ambient space of this curve

**EXAMPLES:**

```
sage: # needs sage.rings.number_field
sage: R.<a> = QQ[]
sage: K.<b> = NumberField(a^2 + a + 1)
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([y^2 - w*z, w^3 - y^3], P)
sage: D = Curve([x*y - w*z, z^3 - y^3], P)
sage: C.intersection_points(D, F=K)
[(-b - 1 : -b - 1 : b : 1), (b : b : -b - 1 : 1),
 (1 : 0 : 0 : 0), (1 : 1 : 1 : 1)]
```

>>> from sage.all import *
>>> # needs sage.rings.number_field
intersects_at(C, P)

Return whether the point P is or is not in the intersection of this curve with the curve C.

INPUT:

- C – a curve in the same ambient space as this curve.
- P – a point in the ambient space of this curve.

EXAMPLES:
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([x^2 - z^2, y^3 - w*x^2], P)
sage: D = Curve([w^2 - 2*x*y + z^2, y^2 - w^2], P)
sage: Q1 = P([1,1,-1,1])
sage: C.intersects_at(D, Q1)
True
sage: Q2 = P([0,0,1,-1])
sage: C.intersects_at(D, Q2)
False

>>> from sage.all import *
>>> P = ProjectiveSpace(QQ, Integer(3), names=('x', 'y', 'z', 'w')); (x, y, z, w) = P._first_ngens(4)
>>> C = Curve([x**Integer(2) - z**Integer(2), y**Integer(3) - w*x**Integer(2)], P)
>>> D = Curve([w**Integer(2) - 2*x*y + z**Integer(2), y**Integer(2) - w**Integer(2)], P)
>>> Q1 = P([Integer(1),Integer(1),-Integer(1),Integer(1)])
>>> C.intersects_at(D, Q1)
True
>>> Q2 = P([Integer(0),Integer(0),Integer(1),-Integer(1)])
>>> C.intersects_at(D, Q2)
False

sage: A.<x,y> = AffineSpace(GF(13), 2)
sage: C = Curve([y + 12*x^5 + 3*x^3 + 7], A)
sage: D = Curve([y^2 + 7*x^2 + 8], A)
sage: Q1 = A([9,6])
sage: C.intersects_at(D, Q1)
True
sage: Q2 = A([3,7])
sage: C.intersects_at(D, Q2)
False

>>> from sage.all import *
>>> A = AffineSpace(GF(Integer(13)), Integer(2), names=('x', 'y')); (x, y) = A._first_ngens(2)
>>> C = Curve([y + Integer(12)*x^5 + Integer(3)*x^3 + Integer(7)], A)
>>> D = Curve([y^2 + Integer(7)*x^2 + Integer(8)], A)
>>> Q1 = A([Integer(9),Integer(6)])
>>> C.intersects_at(D, Q1)
True
>>> Q2 = A([Integer(3),Integer(7)])
>>> C.intersects_at(D, Q2)
False

is_singular(P=None)

Return whether \( P \) is a singular point of this curve, or if no point is passed, whether this curve is singular or not.

This just uses the is_smooth function for algebraic subschemes.

INPUT:
• \( P \) – (default: None) a point on this curve

OUTPUT:
A boolean. If a point \( P \) is provided, and if \( P \) lies on this curve, returns True if \( P \) is a singular point of this curve, and False otherwise. If no point is provided, returns True or False depending on whether this curve is or is not singular, respectively.

**EXAMPLES:**

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = P.curve([y^2 - x^2 - z^2, z - w])
sage: C.is_singular()
False
```

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(QQ, Integer(3), names=('x', 'y', 'z', 'w',)); (x, y, z, w,) = P._first_ngens(4)
>>> C = P.curve([y**Integer(2) - x**Integer(2) - z**Integer(2), z - w])
>>> C.is_singular()
False
```

```python
sage: A.<x,y,z> = AffineSpace(GF(11), 3)
sage: C = A.curve([y^3 - z^5, x^5 - y + 1])
sage: Q = A([Integer(7),Integer(0),Integer(0)])
sage: C.is_singular(Q)
True
```

```python
>>> from sage.all import *
>>> A = AffineSpace(GF(Integer(11)), Integer(3), names=('x', 'y', 'z',)); (x, y, z,) = A._first_ngens(3)
>>> C = Curve([y**Integer(3) - z**Integer(5), x**Integer(5) - y + Integer(1)])
>>> Q = A([Integer(7),Integer(0),Integer(0)])
>>> C.is_singular(Q)
True
```

`singular_points (F=None)`

Return the set of singular points of this curve.

**INPUT:**

- \( F \) – (default: None) field over which to find the singular points; if not given, the base ring of this curve is used

**OUTPUT:** a list of points in the ambient space of this curve

**EXAMPLES:**

```python
sage: A.<x,y,z> = AffineSpace(QQ, 3)
sage: C = Curve([y^2 - x^5, x - z], A)
sage: C.singular_points()
[(0, 0, 0)]
```

```python
>>> from sage.all import *
>>> A = AffineSpace(QQ, Integer(3), names=('x', 'y', 'z',)); (x, y, z,) = A._first_ngens(3)
>>> C = A.curve([y**Integer(3) - z**Integer(5), x**Integer(5) - y + Integer(1)])
>>> C.singular_points()
[(0, 0, 0)]
```
sage: # needs sage.rings.number_field
sage: R.<a> = QQ[]

sage: K.<b> = NumberField(a^8 - a^4 + 1)

sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)

sage: C = Curve([359/12*x*y^2*z^2 + 2*y*z^4 + 187/12*y^3*z^2 + x*z^4
.....:     + 67/3*x^2*y*z^2 + 117/4*x^5 + 9*x^5 + 6*x^3*z^2
.....:     + 393/4*x*y^4 + 145*x^2*y^3 + 115*x^3*y^2 + 49*x^4*y], P)

sage: sorted(C.singular_points(K), key=str)

[(-1/2*b^5 - 1/2*b^3 + 1/2*b - 1 : 1 : 0),
 (-2/3*b^4 + 1/3 : 0 : 1),
 (-b^6 : b^6 : 1),
 (1/2*b^5 + 1/2*b^3 - 1/2*b - 1 : 1 : 0),
 (2/3*b^4 - 1/3 : 0 : 1),
 (b^6 : -b^6 : 1)]

```

>>> from sage.all import *

# needs sage.rings.number_field

R = QQ['a']; (a,) = R._first_ngens(1)

(b,) = K._first_ngens(1)

P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z')); (x, y, z,) =

P._first_ngens(3)

C = Curve([Integer(359)/Integer(12)*x*y**Integer(2)*z**Integer(2) +
.....:  Integer(2)*y*z**Integer(4) + Integer(187)/
.....:  Integer(12)*y**Integer(3)*z**Integer(2) + x*z**Integer(4)
.....:     + Integer(67)/Integer(3)*x**Integer(2)*y*z**Integer(2) +
.....:  Integer(117)/Integer(4)*y**Integer(5) + Integer(9)*x**Integer(5) +
.....:  Integer(6)*x**Integer(3)*z**Integer(2)
.....:     + Integer(393)/Integer(4)*x*y**Integer(4) +
.....:  Integer(145)*x**Integer(2)*y**Integer(3) +
.....:  Integer(115)*x**Integer(3)*y**Integer(2) + Integer(49)*x**Integer(4)*y], P)

>>> sorted(C.singular_points(K), key=str)

[(-1/2*b^5 - 1/2*b^3 + 1/2*b - 1 : 1 : 0),
 (-2/3*b^4 + 1/3 : 0 : 1),
 (-b^6 : b^6 : 1),
 (1/2*b^5 + 1/2*b^3 - 1/2*b - 1 : 1 : 0),
 (2/3*b^4 - 1/3 : 0 : 1),
 (b^6 : -b^6 : 1)]

sage: # singular_subscheme

Return the subscheme of singular points of this curve.

OUTPUT:

• a subscheme in the ambient space of this curve.

EXAMPLES:

```

```

1.2. Base class of curves
```python
>>> from sage.all import *
>>> A = AffineSpace(CC, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve([y**Integer(4) - Integer(2)*x**Integer(5) - x**Integer(2)*y], A)
>>> C.singular_subscheme()
Closed subscheme of Affine Space of dimension 2 over Complex Field
with 53 bits of precision defined by:
(-2.0000000000000000000)*x^5 + y^4 - x^2*y,
(-10.0000000000000000000)*x^4 + (-2.0000000000000000000)*x*y,
4.0000000000000000000*y^3 - x^2

sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([y^8 - x^2*z*w^5, w^2 - 2*y^2 - x*z], P)
sage: C.singular_subscheme()
Closed subscheme of Projective Space of dimension 3
over Rational Field defined by:
y^8 - x^2*z*w^5,
-2*y^2 - x*z + w^2,
x^3*y*z^4 + 3*x^2*y*z^3*w^2 - 3*x*y*z^2*w^4 + 8*x*y*z*w^5 + y*z*w^6,
x^2*z*w^5,
-5*x^2*z^2*w^4 - 4*x*z*w^6,
x^4*y*z^3 - 3*x^3*y*z^2*w^2 + 3*x^2*y*z*w^4 - 4*x^2*y*w^5 - x*y*w^6,
-2*x^3*y*z^3*w + 6*x^2*y*z^2*w^3 - 20*x^2*y*z*w^4
- 6*x*y*z*w^5 + 2*y*w^7,
-5*x^3*z*w^4 - 2*x^2*z*w^6
```

```python
from sage.all import *

P = ProjectiveSpace(QQ, Integer(3), names=('x', 'y', 'z', 'w',)); (x, y, z, w,) = P._first_ngens(4)
P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
C = Curve([y**Integer(8) - x**Integer(2)*z*w**Integer(5), w**Integer(2) - Integer(2)*y**Integer(2) - x*z], P)
C.singular_subscheme()
Closed subscheme of Projective Space of dimension 3
over Rational Field defined by:
y^8 - x^2*z*w^5,
-2*y^2 - x*z + w^2,
x^3*y*z^4 + 3*x^2*y*z^3*w^2 - 3*x*y*z^2*w^4 + 8*x*y*z*w^5 + y*z*w^6,
x^2*z*w^5,
-5*x^2*z^2*w^4 - 4*x*z*w^6,
x^4*y*z^3 - 3*x^3*y*z^2*w^2 + 3*x^2*y*z*w^4 - 4*x^2*y*w^5 - x*y*w^6,
-2*x^3*y*z^3*w + 6*x^2*y*z^2*w^3 - 20*x^2*y*z*w^4
- 6*x*y*z*w^5 + 2*y*w^7,
-5*x^3*z*w^4 - 2*x^2*z*w^6
```

**union** (other)

Return the union of self and other.

**EXAMPLES:**

```python
sage: x,y,z = PolynomialRing(QQ, 3, names='x,y,z').gens()
sage: C1 = Curve(z - x)
sage: C2 = Curve(y - x)
sage: C1.union(C2).defining_polynomial()
x^2 - x*y - x*z + y*z
```

```python
from sage.all import *
```

(continues on next page)
1.3 Affine curves

Affine curves in Sage are curves in an affine space or an affine plane.

EXAMPLES:

We can construct curves in either an affine plane:

```python
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([y - x**2], A); C
Affine Plane Curve over Rational Field defined by -x^2 + y
```

or in higher dimensional affine space:

```python
sage: A.<x,y,z,w> = AffineSpace(QQ, 4)
sage: C = Curve([y - x**2, z - w**3, w - y**4], A); C
Affine Curve over Rational Field defined by -x^2 + y, -w^3 + z, -y^4 + w
```

1.3.1 Integral affine curves over finite fields

If the curve is defined over a finite field and integral, that is reduced and irreducible, its function field is tightly coupled with the curve so that advanced computations based on Sage’s global function field machinery are available.

EXAMPLES:

```python
sage: k.<a> = GF(2)
sage: A.<x,y,z> = AffineSpace(k, 3)
sage: C = Curve([(x**2 + x - y**3, y**4 - y - z**3], A)
sage: C.genus()
10
sage: C.function_field()
Function field in z defined by z^9 + x^8 + x^6 + x^5 + x^4 + x^3 + x
```
Closed points of arbitrary degree can be computed:

```python
sage: # long time
sage: C.closed_points()
[Point (x, y, z), Point (x + 1, y, z)]
```

The places at infinity correspond to the extra closed points of the curve’s projective closure:

```python
sage: C.places_at_infinity()
[Place (1/x, 1/x*z)]
```

It is easy to transit to and from the function field of the curve:

```python
sage: fx = C(x)
sage: fy = C(y)
sage: fx^2 + fx - fy^3
0
sage: fx.divisor()
-9*Place (1/x, 1/x*z) + 9*Place (x, z)
sage: p, = fx.zeros()
sage: C.place_to_closed_point(p)
Point (x, y, z)
```
1.3.2 Integral affine curves over $\mathbb{Q}$

An integral curve over $\mathbb{Q}$ is equipped also with the function field. Unlike over finite fields, it is not possible to enumerate closed points.

EXAMPLES:

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve(x^2 + y^2 -1)
sage: p = C(0,1)
sage: p
(0, 1)
sage: p.closed_point()
Point (x, y - 1)
sage: pl = _.place()
sage: C.parametric_representation(pl)
(s + ...), 1 - 1/2*s^2 - 1/8*s^4 - 1/16*s^6 + ...)
sage: sx, sy = _
sage: sx = sx.polynomial(10); sx
s
sage: sy = sy.polynomial(10); sy
-7/256*s^10 - 5/128*s^8 - 1/16*s^6 - 1/8*s^4 - 1/2*s^2 + 1
sage: s = var('s')
#-- needs sage.symbolic
sage: P1 = parametric_plot([sx, sy], (s, -1, 1), color='red')
#-- needs sage.plot sage.symbolic
sage: P2 = C.plot((x, -1, 1), (y, 0, 2)) # half circle
#-- needs sage.plot sage.symbolic
sage: P1 + P2
```
needs sage.plot sage.symbolic
Graphics object consisting of 2 graphics primitives

```
>>> from sage.all import *

>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y')); (x, y) = A._first_ngens(2)

>>> C = Curve(x**Integer(2) + y**Integer(2) - Integer(1))

>>> p = C(Integer(0), Integer(1))

>>> p
(0, 1)

>>> p.closed_point()
Point (x, y - 1)

>>> C.parametric_representation(p1)
(s + ..., 1 - 1/2*s^2 - 1/8*s^4 - 1/16*s^6 + ...)

>>> sx, sy = _

>>> sx = sx.polynomial(Integer(10)); sx
s

>>> sy = sy.polynomial(Integer(10)); sy
-7/256*s^10 - 5/128*s^8 - 1/16*s^6 - 1/8*s^4 - 1/2*s^2 + 1

>>> s = var('s')

>>> P1 = parametric_plot([sx, sy], (s, -Integer(1), Integer(1)), color=red)

>>> P2 = C.plot((x, -Integer(1), Integer(1)), (y, Integer(0), Integer(2)))

>>> P1 + P2
```

- Kwankyu Lee (2019-05): added integral affine curves

```python
class sage.schemes.curves.affine_curve.AffineCurve(A, X)

Bases: Curve_generic, AlgebraicScheme_subscheme_affine

Affine curves.

EXAMPLES:

```
```

(continues on next page)
>>> R = QQ['v']; (v,) = R._first_ngens(1)
>>> K = NumberField(v**Integer(2) + Integer(3), names=('u',)); (u,) = K._first_ngens(1)
>>> A = AffineSpace(K, Integer(3), names=('x', 'y', 'z',)); (x, y, z,) = A._first_ngens(3)
>>> C = Curve([z - u*x**Integer(2), y**Integer(2)], A); C
Affine Curve over Number Field in u with defining polynomial v^2 + 3
defined by (-u)*x^2 + z, y^2

sage: A.<x,y,z> = AffineSpace(GF(7), 3)
sage: C = Curve([x^2 - 8*x], A); C
Affine Curve over Finite Field of size 7 defined by x^2 - z, -x + z

>>> from sage.all import *

>>> A = AffineSpace(GF(Integer(7)), Integer(3), names=('x', 'y', 'z',)); (x, y, z,) = A._first_ngens(3)
>>> C = Curve([x**Integer(2) - z, z - Integer(8)*x], A); C
Affine Curve over Finite Field of size 7 defined by x^2 - z, -x + z

**projective_closure** (*i=0, PP=0*)

Return the projective closure of this affine curve.

**INPUT:**

- *i* – (default: 0) the index of the affine coordinate chart of the projective space that the affine ambient space of this curve embeds into.
- *PP* – (default: None) ambient projective space to compute the projective closure in. This is constructed if it is not given.

**OUTPUT:** A curve in projective space.

**EXAMPLES:**

sage: A.<x,y,z> = AffineSpace(QQ, 3)
sage: C = Curve([y-x^2,z-x^3], A)
sage: C.projective_closure()
Projective Curve over Rational Field defined by x1^2 - x0*x2,
x1*x2 - x0*x3, x2^2 - x1*x3

>>> from sage.all import *

>>> A = AffineSpace(QQ, Integer(3), names=('x', 'y', 'z',)); (x, y, z,) = A._first_ngens(3)
>>> C = Curve([y-x**Integer(2),z-x**Integer(3)], A)
>>> C.projective_closure()
Projective Curve over Rational Field defined by x1^2 - x0*x2,
x1*x2 - x0*x3, x2^2 - x1*x3

sage: A.<x,y,z> = AffineSpace(QQ, 3)
sage: C = Curve([y - x^2, z - x^3], A)
sage: C.projective_closure()
Projective Curve over Rational Field defined by x1^2 - x0*x2,
x1*x2 - x0*x3, x2^2 - x1*x3

>>> from sage.all import *

>>> A = AffineSpace(QQ, Integer(3), names=('x', 'y', 'z',)); (x, y, z,) = A._first_ngens(3)
>>> C = Curve([y-x**Integer(2),z-x**Integer(3)], A)
>>> C.projective_closure()
Projective Curve over Rational Field defined by x1^2 - x0*x2,
x1*x2 - x0*x3, x2^2 - x1*x3

(continues on next page)
class sage.schemes.curves.affine_curve.AffineCurve_field(A, X)

Bases: AffineCurve, AlgebraicScheme_subscheme_affine_field

Affine curves over fields.

blowup (P=None)

Return the blow up of this affine curve at the point P.

The blow up is described by affine charts. This curve must be irreducible.

INPUT:

- P – (default: None) a point on this curve at which to blow up; if None, then P is taken to be the origin.

OUTPUT: A tuple of

- a tuple of curves in affine space of the same dimension as the ambient space of this curve, which define the blow up in each affine chart.
- a tuple of tuples such that the jth element of the ith tuple is the transition map from the ith affine patch to the jth affine patch.
• a tuple consisting of the restrictions of the projection map from the blow up back to the original curve, restricted to each affine patch. There the ith element will be the projection from the ith affine patch.

EXAMPLES:

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([y**2 - x**3], A)
sage: C.blowup()

**plane_projection** *(AP=None)*

Return a projection of this curve into an affine plane so that the image of the projection is a plane curve.

**INPUT:**

- `AP` – (default: None) the affine plane to project this curve into. This space must be defined over the same base field as this curve, and must have dimension two. This space will be constructed if not specified.

**OUTPUT:** A tuple of

- a scheme morphism from this curve into an affine plane
- the plane curve that defines the image of that morphism

**EXAMPLES:**

```python
sage: A.<x,y,z,w> = AffineSpace(QQ, 4)
sage: C = Curve([x^2 - y*z*w, z^3 - w, w + x*y - 3*z^3], A)
sage: C.plane_projection()

sage: proj2 = C.plane_projection()
sage: proj2[1].ambient_space() is B
False

projection(indices, AS=None)

Return the projection of this curve onto the coordinates specified by indices.

INPUT:

- indices – a list or tuple of distinct integers specifying the indices of the coordinates to use in the projection. Can also be a list or tuple consisting of variables of the coordinate ring of the ambient space of this curve. If integers are used to specify the coordinates, 0 denotes the first coordinate. The length of indices must be between two and one less than the dimension of the ambient space of this curve,
Plane and Space Curves, Release 10.4

• AS – (default: None) the affine space the projected curve will be defined in. This space must be defined over the same base field as this curve, and must have dimension equal to the length of indices. This space is constructed if not specified.

OUTPUT: A tuple of

• a scheme morphism from this curve to affine space of dimension equal to the number of coordinates specified in indices

• the affine subscheme that is the image of that morphism. If the image is a curve, the second element of the tuple will be a curve.

EXAMPLES:

```python
sage: A.<x,y,z> = AffineSpace(QQ, 3)

\end{verbatim}

\texttt{resolution_of_singularities}(\texttt{extend=False})

Return a nonsingular model for this affine curve created by blowing up its singular points.

The nonsingular model is given as a collection of affine patches that cover it. If \texttt{extend} is \texttt{False} and if the base field is a number field, or if the base field is a finite field, the model returned may have singularities with coordinates not contained in the base field. An error is returned if this curve is already nonsingular, or if it has no singular points over its base field. This curve must be irreducible, and must be defined over a number field or finite field.

INPUT:

- \texttt{extend} – (default: \texttt{False}) specifies whether to extend the base field when necessary to find all singular points when this curve is defined over a number field. If \texttt{extend} is \texttt{False}, then only singularities with coordinates in the base field of this curve will be resolved. However, setting \texttt{extend} to \texttt{True} will slow down computations.

OUTPUT: A tuple of

- a tuple of curves in affine space of the same dimension as the ambient space of this curve, which represent affine patches of the resolution of singularities.
- a tuple of tuples such that the \(j\)th element of the \(i\)th tuple is the transition map from the \(i\)th patch to the \(j\)th patch.
- a tuple consisting of birational maps from the patches back to the original curve that were created by composing the projection maps generated from the blow up computations. There the \(i\)th element will be a map from the \(i\)th patch.

EXAMPLES:

\begin{verbatim}
sage: A.<\texttt{x},\texttt{y}> = \texttt{AffineSpace}((\texttt{QQ}, \texttt{2)})
sage: C = \texttt{Curve}([\texttt{y}^2 - \texttt{x}^3], \texttt{A})
sage: C.resolution_of_singularities()
((\texttt{Affine Plane Curve over Rational Field defined by \texttt{s1}^2 - \texttt{x}},
\texttt{Affine Plane Curve over Rational Field defined by \texttt{y}^\texttt{s0}^3 - 1}),
((\texttt{Scheme endomorphism of Affine Plane Curve over Rational Field}
continues on next page)
defined by $s_1^2 - x$
Defn: Defined on coordinates by sending $(x, s_1)$ to $(x, s_1)$,

Scheme morphism:
From: Affine Plane Curve over Rational Field defined by $s_1^2 - x$
To: Affine Plane Curve over Rational Field defined by $y^*s_0^3 - 1$
Defn: Defined on coordinates by sending $(x, s_1)$ to $(x*s_1, 1/s_1))$,

(Scheme morphism:
From: Affine Plane Curve over Rational Field defined by $y^*s_0^3 - 1$
To: Affine Plane Curve over Rational Field defined by $s_1^2 - x$

tangent_line(p)

Return the tangent line at the point p.

INPUT:

- p – a rational point of the curve

EXAMPLES:

```
sage: A3.<x,y,z> = AffineSpace(3, QQ)
sage: C = Curve([x + y + z, x^2 - y^2*z^2 + z^3])
sage: p = C(0,0,0)
sage: C.tangent_line(p)
Traceback (most recent call last):
...
ValueError: the curve is not smooth at (0, 0, 0)
sage: p = C(Integer(1),Integer(0),-Integer(1))
sage: C.tangent_line(p)
Affine Curve over Rational Field defined by x + y + z, 2*x + 3*z + 1
```

```
>>> from sage.all import *
>>> A3 = AffineSpace(Integer(3), QQ, names=('x', 'y', 'z')); (x, y, z) = A3._first_ngens(3)
>>> C = Curve([x + y + z, x**Integer(2) - y**Integer(2)*z**Integer(2) +
               z**Integer(3)])
>>> p = C(Integer(0),Integer(0),Integer(0))
>>> C.tangent_line(p)
Traceback (most recent call last):
...
ValueError: the curve is not smooth at (0, 0, 0)
>>> p = C(Integer(1),Integer(0),-Integer(1))
>>> C.tangent_line(p)
Affine Curve over Rational Field defined by x + y + z, 2*x + 3*z + 1
```

We check that the tangent line at p is the tangent space at p, translated to p.

```
sage: Tp = C.tangent_space(p)
sage: Tp
```

class sage.schemes.curves.affine_curve.AffinePlaneCurve(A, f)

Bases: AffineCurve

Affine plane curves.

divisor_of_function(r)

Return the divisor of a function on a curve.

INPUT: r is a rational function on X

OUTPUT:

• list – The divisor of r represented as a list of coefficients and points. (TODO: This will change to a more structural output in the future.)

EXAMPLES:

sage: F = GF(5)
sage: P2 = AffineSpace(2, F, names='xy')
sage: R = P2.coordinate_ring()
sage: x, y = R.gens()
sage: f = y^2 - x^9 - x
sage: C = Curve(f)
sage: K = FractionField(R)
sage: r = 1/x
sage: C.divisor_of_function(r)  # not implemented (broken)
[[-1, (0, 0, 1)]]
sage: r = 1/x^3
sage: C.divisor_of_function(r)  # not implemented (broken)
[[-3, (0, 0, 1)]]

(continues on next page)
is_ordinary_singularity($P$)

Return whether the singular point $P$ of this affine plane curve is an ordinary singularity.

The point $P$ is an ordinary singularity of this curve if it is a singular point, and if the tangents of this curve at $P$ are distinct.

**INPUT:**

- $P$ – a point on this curve

**OUTPUT:**

True or False depending on whether $P$ is or is not an ordinary singularity of this curve, respectively. An error is raised if $P$ is not a singular point of this curve.

**EXAMPLES:**

```python
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([y^2 - x^3], A)
sage: Q = A([0,0])
sage: C.is_ordinary_singularity(Q)
False
```

```python
from sage.all import *
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y')); (x, y) = A._first_ngens(2)
>>> C = Curve([y**Integer(2) - x**Integer(3)], A)
>>> Q = A([Integer(0),Integer(0)])
>>> C.is_ordinary_singularity(Q)
False
```

```python
sage: # needs sage.rings.number_field
sage: R.<a> = QQ[]
sage: K.<b> = NumberField(a^2 - Integer(3))
sage: A.<x,y> = AffineSpace(K, 2)
sage: C = Curve([(x^2 + y^2 - 2*x)^2 - x^2 - y^2], A)
sage: Q = A([0,0])
sage: C.is_ordinary_singularity(Q)
True
```

```python
from sage.all import *
>>> # needs sage.rings.number_field
>>> R = QQ['a']; (a,) = R._first_ngens(1)
>>> K = NumberField(a**Integer(2) - Integer(3), names=('b',)); (b,) = K._first_ngens(1)
```

(continues on next page)
A = AffineSpace(K, Integer(2), names=('x', 'y',)); (x, y,) = A._first_˓→ngens(2)

C = Curve([(x**Integer(2) + y**Integer(2) - Integer(2)*x)**Integer(2) -␣˓→x**Integer(2) - y**Integer(2)], A)

Q = A((Integer(0),Integer(0)))

C.is_ordinary_singularity(Q)

True

sage: from sage.all import *

sage: A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_˓→ngens(2)

sage: C = A.curve([x**Integer(2)*y - y**Integer(2)*x + y**Integer(2) +␣˓→x**Integer(3)])

sage: Q = A((-Integer(1),-Integer(1)))

sage: C.is_ordinary_singularity(Q)

Traceback (most recent call last):

  ...TypeError: (=(-1, -1)) is not a singular point of (=Affine Plane Curve

****

over Rational Field defined by x^3 + x^2*y - x*y^2 + y^2)

is_transverse(C, P)

Return whether the intersection of this curve with the curve C at the point P is transverse.

The intersection at P is transverse if P is a nonsingular point of both curves, and if the tangents of the curves at P are distinct.

INPUT:

• C – a curve in the ambient space of this curve.

• P – a point in the intersection of both curves.

OUTPUT: A boolean.

EXAMPLES:

sage: A.<x,y> = AffineSpace(QQ, 2)

sage: C = A.curve([x^2 + y^2 - 1], A)

sage: D = Curve([x - 1], A)

sage: Q = A((1,0))

sage: C.is_transverse(D, Q)

False

>>> from sage.all import *

>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_˓→ngens(2)

>>> C = Curve([x**Integer(2) + y**Integer(2) - Integer(1)], A)

>>> D = Curve([x - Integer(1)], A)

(continues on next page)
local_coordinates (pt, n)

Return local coordinates to precision n at the given point.

Behaviour is flaky - some choices of n are worst than others.

INPUT:

- pt – an F-rational point on X which is not a point of ramification for the projection (x, y) - x.
- n – the number of terms desired

OUTPUT: x = x0 + t y = y0 + power series in t

EXAMPLES:
multiplicity ($P$)

Return the multiplicity of this affine plane curve at the point $P$.

In the special case of affine plane curves, the multiplicity of an affine plane curve at the point $(0,0)$ can be computed as the minimum of the degrees of the homogeneous components of its defining polynomial. To compute the multiplicity of a different point, a linear change of coordinates is used.

This curve must be defined over a field. An error is raised if $P$ is not a point on this curve.

INPUT:

* $P$ – a point in the ambient space of this curve.

OUTPUT: An integer.

EXAMPLES:

```python
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([y^2 - x^3], A)
sage: Q1 = A([1,1])
sage: C.multiplicity(Q1)
1
sage: Q2 = A([0,0])
sage: C.multiplicity(Q2)
2
```
```python
sage: # needs sage.rings.number_field
sage: A.<x,y> = AffineSpace(QQbar,2)

sage: C = Curve([-x^7 + (-7)*x^6 + y^6 + (-21)*x^5 + 12*y^5 + (-35)*x^4 + 60*y^4 + (-35)*x^3 + 160*y^3 + (-21)*x^2 + 240*y^2 + (-7)*x + 192*y + 63], A)

sage: Q = A([-1,-2])

sage: C.multiplicity(Q)
6
```

```
from sage.all import *

>>> A = AffineSpace(QQbar,Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)

>>> C = Curve([-x**Integer(7) + (-Integer(7))*x**Integer(6) + y**Integer(6) + (-Integer(21))*x**Integer(5) + Integer(12)*y**Integer(5) + (-Integer(35))*x**Integer(4) + Integer(60)*y**Integer(4) + (-Integer(35))*x**Integer(3) + Integer(160)*y**Integer(3) + (-Integer(21))*x**Integer(2) + Integer(240)*y**Integer(2) + (-Integer(7))*x + Integer(192)*y + Integer(63)], A)

>>> Q = A([-Integer(1),-Integer(2)])

>>> C.multiplicity(Q)
6
```

```
sage: A.<x,y> = AffineSpace(QQ, 2)

sage: C = A.curve([y^3 - x^3 + x^6])

sage: Q = A([1,1])

sage: C.multiplicity(Q)
Traceback (most recent call last):
...
TypeError: (=1, 1) is not a point on (=Affine Plane Curve over Rational Field defined by x^6 - x^3 + y^3)
```

```
>>> from sage.all import *

>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)

>>> C = A.curve([y**Integer(3) - x**Integer(3) + x**Integer(6)])

>>> Q = A([Integer(1),Integer(1)])

>>> C.multiplicity(Q)
Traceback (most recent call last):
...
TypeError: (=1, 1) is not a point on (=Affine Plane Curve over Rational Field defined by x^6 - x^3 + y^3)
```

```
plot(*args, **kwds)

Plot the real points on this affine plane curve.

INPUT:

• *args – optional tuples (variable, minimum, maximum) for plotting dimensions

• **kwds – optional keyword arguments passed on to implicit_plot

EXAMPLES:

A cuspidal curve:

```python
sage: R.<x, y> = QQ[]

sage: C = Curve(x^3 - y^2)
```
```
A 5-nodal curve of degree 11. This example also illustrates some of the optional arguments:

```python
>>> from sage.all import *
>>> R = QQ['x', 'y']; (x, y,) = R._first_ngens(2)
>>> C = Curve(x**Integer(3) - y**Integer(2))
>>> C.plot()  # needs sage.plot
Graphics object consisting of 1 graphics primitive
```

```
R = ZZ['x', 'y']; (x, y,) = R._first_ngens(2)
C = Curve(Integer(32)*x**Integer(2) - Integer(2097152)*y**Integer(11) + Integer(1441792)*y**Integer(9) - Integer(360448)*y**Integer(7) + Integer(39424)*y**Integer(5) - Integer(1760)*y**Integer(3) + Integer(22)*y - Integer(1))
C.plot((x, -Integer(1), Integer(1)), (y, -Integer(1), Integer(1)), plot_points=Integer(400))
```

A line over RR:

```python
>>> from sage.all import *
>>> R = ZZ['x', 'y']; (x, y,) = R._first_ngens(2)
>>> C = Curve(R(y - sqrt(Integer(2))*x))
>>> C.plot()  # needs sage.plot
```

```
R = RR['x', 'y']; (x, y,) = R._first_ngens(2)
C = Curve(R(y - sqrt(Integer(2))*x))
C.plot()
Graphics object consisting of 1 graphics primitive
```

**rational_parameterization()**

Return a rational parameterization of this curve.

This curve must have rational coefficients and be absolutely irreducible (i.e. irreducible over the algebraic closure of the rational field). The curve must also be rational (have geometric genus zero).

The rational parameterization may have coefficients in a quadratic extension of the rational field.

**OUTPUT:**

- a birational map between $\mathbb{A}^1$ and this curve, given as a scheme morphism.

**EXAMPLES:**
```python
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([y^2 - x], A)
sage: C.rational_parameterization()
Scheme morphism:
  From: Affine Space of dimension 1 over Rational Field
  To:  Affine Plane Curve over Rational Field defined by y^2 - x
  Defn: Defined on coordinates by sending (t) to
        (t^2, t)

>>> from sage.all import *
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve((y**Integer(2) - x), A)
>>> C.rational_parameterization()
Scheme morphism:
  From: Affine Space of dimension 1 over Rational Field
  To:  Affine Plane Curve over Rational Field defined by y^2 - x
  Defn: Defined on coordinates by sending (t) to
        (t^2, t)

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([(x^2 + y^2 - 2*x)^2 - x^2 - y^2], A)
sage: C.rational_parameterization()
Scheme morphism:
  From: Affine Space of dimension 1 over Rational Field
  To:  Affine Plane Curve over Rational Field defined by x^4 + 2*x^2*y^2 + y^4 - 4*x^3 - 4*x*y^2 + 3*x^2 - y^2
  Defn: Defined on coordinates by sending (t) to
        ((-12*t^4 + 6*t^3 + 4*t^2 - 2*t)/(-25*t^4 + 40*t^3 - 26*t^2 + 8*t - 1), (-9*t^4 + 12*t^3 - 4*t + 1)/(-25*t^4 + 40*t^3 - 26*t^2 + 8*t - 1))

>>> from sage.all import *
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve([(x**Integer(2) + y**Integer(2) - Integer(2)*x)**Integer(2) - x**Integer(2) - y**Integer(2)], A)
>>> C.rational_parameterization()
Scheme morphism:
  From: Affine Space of dimension 1 over Rational Field
  To:  Affine Plane Curve over Rational Field defined by x^4 + 2*x^2*y^2 + y^4 - 4*x^3 - 4*x*y^2 + 3*x^2 - y^2
  Defn: Defined on coordinates by sending (t) to
        ((-12*t^4 + 6*t^3 + 4*t^2 - 2*t)/(-25*t^4 + 40*t^3 - 26*t^2 + 8*t - 1), (-9*t^4 + 12*t^3 - 4*t + 1)/(-25*t^4 + 40*t^3 - 26*t^2 + 8*t - 1))

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([x^2 + y^2 + 7], A)
sage: C.rational_parameterization()
Scheme morphism:
  From: Affine Space of dimension 1 over Number Field in a with defining polynomial a^2 + 7
  To:  Affine Plane Curve over Number Field in a with defining polynomial a^2 + 7 defined by x^2 + y^2 + 7
  Defn: Defined on coordinates by sending (t) to
        ((-7*t^2 + 7)/((-a)*t^2 + (-a)), 14*t/((-a)*t^2 + (-a)))
```

48 Chapter 1. Curves
```python
>>> from sage.all import *
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve([x**Integer(2) + y**Integer(2) + Integer(7)], A)
>>> C.rational_parameterization()
Scheme morphism:
  From: Affine Space of dimension 1 over Number Field in a with defining polynomial a^2 + 7
  To:  Affine Plane Curve over Number Field in a with defining polynomial a^2 + 7 defined by x^2 + y^2 + 7
  Defn: Defined on coordinates by sending (t) to
  ((-7*t^2 + 7)/((-a)*t^2 + (-a)), 14*t/((-a)*t^2 + (-a)))
```

### tangents \((P, \text{factor=}True\))

Return the tangents of this affine plane curve at the point \(P\).

The point \(P\) must be a point on this curve.

**INPUT:**

- \(P\) – a point on this curve
- \(\text{factor} = \) (default: True) whether to attempt computing the polynomials of the individual tangent lines over the base field of this curve, or to just return the polynomial corresponding to the union of the tangent lines (which requires fewer computations)

**OUTPUT:** A list of polynomials in the coordinate ring of the ambient space.

**EXAMPLES:**

```python
sage: # needs sage.rings.number_field
sage: set_verbose(-1)
sage: A.<x,y> = AffineSpace(QQbar, 2)
sage: C = Curve([x^5*y^3 + 2*x^4*y^4 + x^3*y^5 + 3*x^4*y^3 + 6*x^3*y^4 + 3*x^2*y^5 + 3*x^3*y^3 + 6*x^2*y^4 + 3*x*y^5 + x^5 + 10*x^4*y + 40*x^3*y^2 + 81*x^2*y^3 + 82*x*y^4 + 33*y^5], A)
```

```python
sage: Q = A([0,0])
sage: C.tangents(Q)
[x + 3.425299577684700?*y, x + (1.949159013086856? + 1.179307909383728?*I)*y, x + (1.949159013086856? - 1.179307909383728?*I)*y, x + (1.338191198070797? + 0.2560234251008043?*I)*y, x + (1.338191198070797? - 0.2560234251008043?*I)*y]
sage: C.tangents(Q, factor=False)
[120*x^5 + 1200*x^4*y + 4800*x^3*y^2 + 9720*x^2*y^3 + 9840*x*y^4 + 3960*y^5]
```

```python
>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> set_verbose(-Integer(1))
>>> A = AffineSpace(QQbar, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve([x**Integer(5)*y**Integer(3) + 2*x**Integer(4)*y**Integer(4) + x**Integer(3)*y**Integer(5) + 3*x**Integer(4)*y**Integer(3) + 6*x**Integer(3)*y**Integer(4) + 3*x**Integer(2)*y**Integer(5) + x**Integer(3)*y**Integer(3) + 6*x**Integer(2)*y**Integer(4) + 3*x*y**Integer(5) + x**Integer(5) + 10*x**Integer(4)*y + 40*x**Integer(3)*y**Integer(2) + 81*x**Integer(2)*y**Integer(3) + 82*x*y**Integer(4) + 33*y**Integer(5)], A)
```

```python
>>> # needs sage.rings.number_field
>>> A.<x,y> = AffineSpace(QQbar, 2)
>>> C = Curve([x**Integer(5)*y**Integer(3) + 2*x**Integer(4)*y**Integer(4) + x**Integer(3)*y**Integer(5) + 3*x**Integer(4)*y**Integer(3) + 6*x**Integer(3)*y**Integer(4) + 3*x**Integer(2)*y**Integer(5) + x**Integer(3)*y**Integer(3) + 6*x**Integer(2)*y**Integer(4) + 3*x*y**Integer(5) + x**Integer(5) + 10*x**Integer(4)*y + 40*x**Integer(3)*y**Integer(2) + 81*x**Integer(2)*y**Integer(3) + 82*x*y**Integer(4) + 33*y**Integer(5)], A)
```

---

**class** `sage.schemes.curves.affine_curve.AffinePlaneCurve_field(A, f)`

**Bases:** `AffinePlaneCurve`, `AffineCurve_field`

Affine plane curves over fields.

**braid_monodromy()**

Compute the braid monodromy of a projection of the curve.

**OUTPUT:**

A list of braids. The braids correspond to paths based in the same point; each of this paths is the conjugated of a loop around one of the points in the discriminant of the projection of self.

**Note:** The projection over the $x$ axis is used if there are no vertical asymptotes. Otherwise, a linear change of variables is done to fall into the previous case.

**Note:** This functionality requires the `sirocco` package to be installed.

**EXAMPLES:**

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = A.curve((x^2-y^3)*(x+3*y-5))
sage: C.braid_monodromy()  # needs sirocco
[s1*s0*(s1*s2)^2*s0*s2^2*s0^-1*1*(s2^-1*s1^-1)^2*s0^-1*s1^-1,
 s1*s0*(s1*s2)^2*(s2^-1*s1^-1)^2*s0^-1*s1^-1,
 s1*s0*(s1*s2)^2*s2*s1^-1*s2^-1*s0^-1*s1^-1,
 s1*s0*s2*s0^-1*s2^2*s1^-1]

sage: T.<t> = QQ[]

sage: K.<a> = NumberField(t^3 + 2, 'a')

sage: A.<x, y> = AffineSpace(K, 2)

sage: Curve(y^2 + a * x).braid_monodromy()

Traceback (most recent call last):
...

NotImplementedError: the base field must have an embedding to the algebraic_field
```

---

**(... continues on next page ...)**
>>> C = A.curve((x**Integer(2)-y**Integer(3))*(x+Integer(3)*y-Integer(5)))
>>> C.braid_monodromy()  # needs sirocco
[s1*s0*(s1*s2)^2*s0^2 s0^2*s0^1 s1^-1 1,
 s1*s0*(s1*s2)^2*(s0*s2^1*s1*s2*s1^-2)^2*(s2^-1*s1^-1)^2*s0^1 s1^-1,
 s1*s0*(s1*s2)^2*s2*s2^1*s2^-1*s1^-1 s0^1 s1^-1,
 s1*s0*s0^1 s2^1 s1^-1]  

>>> T = QQ['t']; (t,) = T._first_ngens(1)

>>> Curve(y**Integer(2) + a * x).braid_monodromy()
Traceback (most recent call last):
  ... Not Implemented Error: the base field must have an embedding to the algebraic...

fundamental_group (simplified=True, puiseux=True)

Return a presentation of the fundamental group of the complement of self.

INPUT:

- simplified – (default: True) boolean to simplify the presentation.
- puiseux – (default: True) boolean to decide if the presentation is constructed in the classical way or using Puiseux shortcut.

OUTPUT:

A presentation with generators \( x_1, \ldots, x_d \) and relations. If \( \text{puiseux} \) is False the relations are \((x_j \tau) x_j^{-1}\) for \( 1 \leq j < d \) and \( \tau \) a braid in the braid monodromy; finally the presentation is simplified. If \( \text{puiseux} \) is True, each \( \tau \) is decomposed as \( \alpha^{-1} \cdot \beta \cdot \alpha \), where \( \beta \) is a positive braid; the relations are \((x_j \beta) x_j^{-1} \cdot \alpha\) where \( j \) is an integer of the Tietze word of \( \beta \). This presentation is not simplified by default since it represents the homotopy type of the complement of the curve.

Note: The curve must be defined over the rationals or a number field with an embedding over \( \mathbb{Q} \). This functionality requires the sirocco package to be installed.

EXAMPLES:

```python
sage: # needs sirocco
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = A.curve(y^2 - x^3 - x^2)
sage: C.fundamental_group(puiseux=False)
Finitely presented group < x0 | >
sage: bm = C.braid_monodromy()
sage: g = C.fundamental_group(simplified=False)
sage: g.sorted_presentation()
Finitely presented group < x0, x1 | x1^-1*x0^-1*x1*x0, x1^-1*x0 >
sage: g.simplified()
Finitely presented group < x0, x1 | >
```

```python
>>> from sage.all import *

>>> # needs sirocco
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
```

(continues on next page)
In the case of number fields, they need to have an embedding to the algebraic field:

```python
sage: # needs sage.rings.number_field
sage: x = polygen(ZZ)
sage: a = QQ[x](x^2 + 5).roots(QQbar)[0][0]
sage: F = NumberField(a.minpoly(), 'a', embedding=a)
sage: F.inject_variables()
Defining a
sage: A.<x,y> = AffineSpace(F, 2)
sage: C = A.curve(y^2 - a*x^3 - x^2)
sage: C.fundamental_group()  # needs sirocco
Finitely presented group < x0 | >
```

```python
sage: C = A.curve(x * (x - 1))
sage: C.fundamental_group()  # needs sirocco
Finitely presented group < x0, x1 | >
```

### has_vertical_asymptote()

Check if the curve is not a line and has vertical asymptotes.

**EXAMPLES:**

```python
sage: A2.<x,y> = AffineSpace(2, QQ)
sage: Curve(x).has_vertical_asymptote()
False
sage: Curve(y^2 * x + x + y).has_vertical_asymptote()
True
```

```python
>>> from sage.all import *
```

```python
>>> A2 = AffineSpace(Integer(2), QQ, names=('x', 'y',)); (x, y,) = A2._first_  # needs sage.rings.number_field
>>> x = polygen(ZZ)
>>> a = QQ[x](x^2 + 5).roots(QQbar)[0][0]
>>> F = NumberField(a.minpoly(), 'a', embedding=a)
>>> F.inject_variables()
Defining a
>>> A = AffineSpace(F, Integer(2), names=('x', 'y',)); (x, y,) = A._first_
>>> C = A.curve(y**Integer(2) - a*x**Integer(3) - x**Integer(2))
>>> C.fundamental_group()  # needs sirocco
Finitely presented group < x0 | >
```

```python
>>> C = A.curve(x * (x - Integer(1)))
>>> C.fundamental_group()  # needs sirocco
Finitely presented group < x0, x1 | >
```

1.3. Affine curves 53
**is_vertical_line()**

Check if the curve is a vertical line.

**EXAMPLES:**

```python
sage: A2.<x, y> = AffineSpace(2, QQ)
sage: Curve(x - 1).is_vertical_line()
True
sage: Curve(x - y).is_vertical_line()
False
sage: Curve(y^2 * x + x + y).is_vertical_line()
False
```

```python
>>> from sage.all import *
```
• algorithm – possible choices:
  – 'enum’ – use very naive point enumeration to find all rational points on this curve over a finite field.
  – 'all’ – use all implemented algorithms and verify that they give the same answer, then return it

Note: The Brill-Noether package does not always work. When it fails, a RuntimeError exception is raised.

EXAMPLES:

```python
sage: x, y = (GF(5)[x,y]).gens()
sage: f = y^2 - x^9 - x
sage: C = Curve(f); C
Affine Plane Curve over Finite Field of size 5 defined by -x^9 + y^2 - x
sage: C.rational_points(algorithm='bn')
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
sage: C = Curve(x - y + 1)
sage: C.rational_points()
[(0, 1), (1, 2), (2, 3), (3, 4), (4, 0)]
```

We compare Brill-Noether and enumeration:

```python
>>> from sage.all import *
>>> x, y = (GF(Integer(5))[x,y]).gens()
>>> f = y**Integer(2) - x**Integer(9) - x
>>> C = Curve(f); C
Affine Plane Curve over Finite Field of size 5 defined by -x^9 + y^2 - x
>>> C.rational_points(algorithm='bn')
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
>>> C = Curve(x - y + 1)
>>> C.rational_points()
[(0, 1), (1, 2), (2, 3), (3, 4), (4, 0)]
```

(continues on next page)
>>> v = C.rational_points(algorithm='bn')
>>> w = C.rational_points(algorithm='enum')
>>> len(v)
20
>>> v == w
True

>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(Integer(2), GF(Integer(9), 'a'), names=('x', 'y',)); (x, y, →)
>>> C = Curve(x**Integer(2) + y**Integer(2) - Integer(1)); C
Affine Plane Curve over Finite Field in a of size 3^2
defined by x^2 + y^2 - 1
>>> C.rational_points()
[(0, 1), (0, 2), (1, 0), (2, 0), (a + 1, a + 1),
 (a + 1, 2*a + 2), (2*a + 2, a + 1), (2*a + 2, 2*a + 2)]

\textbf{riemann\_roch\_basis(D)}

Return a basis of the Riemann-Roch space of the divisor D.

This interfaces with Singular’s Brill-Noether command.

This curve is assumed to be a plane curve defined by a polynomial equation \( f(x, y) = 0 \) over a prime finite field \( F = GF(p) \) in 2 variables \( x, y \) representing a curve \( X : f(x, y) = 0 \) having \( n \) \( F \)-rational points (see the Sage function \( \text{places\_on\_curve} \)).

**INPUT:**

- D – an \( n \)-tuple of integers \( (d_1, \ldots, d_n) \) representing the divisor \( D = d_1 P_1 + \cdots + d_n P_n \), where \( X(F) = \{ P_1, \ldots, P_n \} \). The ordering is that dictated by \( \text{places\_on\_curve} \).

**OUTPUT:** A basis of \( L(D) \).

**EXAMPLES:**

\begin{verbatim}
sage: R = PolynomialRing(GF(5), 2, names="x","y")
sage: x, y = R.gens()
sage: f = y^2 - x^9 - x
sage: C = Curve(f)
sage: D = [6,0,0,0,0,0]
sage: C.riemann_roch_basis(D)
[1, (-x*z^5 + y^2*z^4)/x^6, (-x*z^6 + y^2*z^5)/x^7, (-x*z^7 + y^2*z^6)/x^8]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> R = PolynomialRing(GF(Integer(5)), Integer(2), names="x","y")
>>> x, y = R.gens()
>>> f = y**Integer(2) - x**Integer(9) - x
>>> C = Curve(f)
>>> D = [Integer(6),Integer(0),Integer(0),Integer(0),Integer(0),Integer(0)]
>>> C.riemann_roch_basis(D)
[1, (-x*z^5 + y^2*z^4)/x^6, (-x*z^6 + y^2*z^5)/x^7, (-x*z^7 + y^2*z^6)/x^8]
\end{verbatim}

\textbf{class sage.schemes.curves.affine_curve.IntegralAffineCurve(A, X)}

Bases: \texttt{AffineCurve\_field}

Base class for integral affine curves.
coordinate_functions()

Return the coordinate functions.

EXAMPLES:

```sage
# needs sage.rings.finite_rings
A.<x,y> = AffineSpace(GF(8), 2)
C = Curve(x^5 + y^5 + x*y + 1)
x, y = C.coordinate_functions()
x^5 + y^5 + x*y + 1
0
```

function(f)

Return the function field element coerced from f.

INPUT:

- f – an element of the fraction field of the coordinate ring of the ambient space or the coordinate ring of the curve

OUTPUT: An element of the function field of this curve.

EXAMPLES:

```sage
A.<x,y> = AffineSpace(GF(8), 2)
C = Curve(x^5 + y^5 + x*y + 1)
f = C.function(x/y)
f
(x/(x^5 + 1))*y^4 + x^2/(x^5 + 1)
```

```python
from sage.all import *
```
2*Place \((1/x, 1/x^4*y^4 + 1/x^3*y^3 + 1/x^2*y^2 + 1/x*y + 1)\) 
+ 2*Place \((1/x, 1/x*y + 1)\) 
- 2*Place \((x + 1, y)\) 
- 2*Place \((x^4 + x^3 + x^2 + x + 1, y)\)

**function_field()**

Return the function field of the curve.

**EXAMPLES:**

```python
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve(x^3 - y^2 - x^4 - y^4)
sage: C.function_field()
Function field in y defined by y^4 + y^2 + x^4 - x^3
```

```python
>>> from sage.all import *
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve(x**Integer(3) - y**Integer(2) - x**Integer(4) - y**Integer(4))
>>> C.function_field()
Function field in y defined by y^4 + y^2 + x^4 - x^3
```

```python
sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(8), 2)
sage: C = Curve(x^5 + y^5 + x*y + 1)
sage: C.function_field()
Function field in y defined by y^5 + x*y + x^5 + 1
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(GF(Integer(8)), Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve(x**Integer(5) + y**Integer(5) + x*y + Integer(1))
>>> C.function_field()
Function field in y defined by y^5 + x*y + x^5 + 1
```

**parametric_representation**(place, name=None)

Return a power series representation of the branch of the curve given by place.

**INPUT:**

- `place` – a place on the curve

**EXAMPLES:**

```python
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve(x^2 + y^2 -1)
sage: p = C(0,1)
sage: p.closed_point()
Point (x, y - 1)
sage: pl = _.place()
sage: C.parametric_representation(pl)
(s + ..., 1 - 1/2*s^2 - 1/8*s^4 - 1/16*s^6 + ...)
```

```python
>>> from sage.all import *
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve(x^2 + y^2 -1)
>>> p = C(0,1)
>>> p.closed_point()
Point (x, y - 1)
>>> pl = _.place()
>>> C.parametric_representation(pl)
(s + ..., 1 - 1/2*s^2 - 1/8*s^4 - 1/16*s^6 + ...)
```
Plane and Space Curves, Release 10.4

(continued from previous page)

```python
>>> gens(2)

```

```python
>>> C = Curve(x**Integer(2) + y**Integer(2) -Integer(1))
```

```python
>>> p = C(Integer(0), Integer(1))
```

```python
>>> p.closed_point()
```

```python
Point (x, y - 1)
```

```

```python
f = xs**2 - xs**4 - ys**4
```

```python
[f.coefficient(i) for i in range(Integer(5))] 
```

```python
[0, 0, 0, 0, 0]
```

place_to_closed_point (place)

Return the closed point on the place.

INPUT:

• place – a place of the function field of the curve

EXAMPLES:

```python
sage: # needs sage.rings.finite_rings
```

```python
sage: A.<x,y> = AffineSpace(GF(4), 2)
```

```python
sage: C = Curve(x^5 + y^5 + x*y + 1)
```

```python
sage: F = C.function_field() 
```

```python
sage: pls = F.places()
```

```python
sage: C.place_to_closed_point(pls[-1])
```

```python
Point (x + 1, y + 1)
```

```python
sage: C.place_to_closed_point(pls[-2])
```

```python
Point (x + 1, y + 1)
```

1.3. Affine curves 59
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(GF(Integer(4)), Integer(2), names=('x', 'y')); (x, y, ) = A._first_ngens(2)
>>> C = Curve(x**Integer(5) + y**Integer(5) + x*y + Integer(1))
>>> F = C.function_field()
>>> pls = F.places(Integer(1))
>>> C.place_to_closed_point(pls[-Integer(1)])
Point (x + 1, y + 1)
>>> C.place_to_closed_point(pls[-Integer(2)])
Point (x + 1, y + 1)

places_at_infinity()

Return the places of the curve at infinity.

EXAMPLES:

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve(x^3 - y^2 - x^4 - y^4)
sage: C.places_at_infinity()
[Place (1/x, 1/x^2*y, 1/x^3*y^2, 1/x^4*y^3)]

sage: from sage.all import *
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y')); (x, y, ) = A._first_ngens(2)
>>> C = Curve(x**Integer(3) - y**Integer(2) - x**Integer(4) - y**Integer(4))
>>> C.places_at_infinity()
[Place (1/x, 1/x^2*y, 1/x^3*y^2, 1/x^4*y^3)]

sage: # needs sage.rings.finite_rings
sage: F = GF(9)
sage: A2.<x,y> = AffineSpace(F, 2)
sage: C = A2.curve(y**3 + y - x**4)
sage: C.places_at_infinity()
[Place (1/x, 1/x^3*y^2)]

sage: from sage.all import *
>>> # needs sage.rings.finite_rings
>>> F = GF(Integer(9))
>>> A2 = AffineSpace(F, Integer(2), names=('x', 'y')); (x, y, ) = A2._first_ngens(2)
>>> C = A2.curve(y**Integer(3) + y - x**Integer(4))
>>> C.places_at_infinity()
[Place (1/x, 1/x^3*y^2)]

sage: A.<x,y,z> = AffineSpace(GF(11), 3)
sage: C = Curve([x*z - y^2, y - z^2, x - y*z], A)
sage: C.places_at_infinity()
[Place (1/x, 1/x*z^2)]

sage: from sage.all import *
>>> A = AffineSpace(GF(Integer(11)), Integer(3), names=('x', 'y', 'z')); (x, y, z, ) = A._first_ngens(3)
>>> C = Curve([x*z - y**Integer(2), y - z**Integer(2), x - y*z], A)
>>> C.places_at_infinity()
[Place (1/x, 1/x*z^2)]
places_on(point)

Return the places on the closed point.

INPUT:

- point – a closed point of the curve

OUTPUT: A list of the places of the function field of the curve.

EXAMPLES:

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve(x^3 - y^2 - x^4 - y^4)
sage: C.singular_closed_points()
[Point (x, y)]
sage: p, = _
sage: C.places_on(p)
[Place (x, y, y^2, 1/x*y^3 + 1/x*y)]
```

```
>>> from sage.all import *
>>> A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve(x**Integer(3) - y**Integer(2) - x**Integer(4) - y**Integer(4))
>>> C.singular_closed_points()
[Point (x, y)]
>>> p, = _
>>> C.places_on(p)
[Place (x, y, y^2, 1/x*y^3 + 1/x*y)]
```

```
sage: # needs sage.rings.finite_rings
sage: k.<a> = GF(9)
sage: A.<x,y> = AffineSpace(k, 2)
sage: C = Curve(y^2 - x^5 - x^4 - 2*x^3 - 2*x - 2)
sage: pts = C.closed_points()
sage: pts
[Point (x, y + (a + 1)),
 Point (x, y + (-a - 1)),
 Point (x + (a + 1), y + (a - 1)),
 Point (x + (a + 1), y + (-a + 1)),
 Point (x - 1, y + (a + 1)),
 Point (x - 1, y + (-a - 1)),
 Point (x + (-a - 1), y + a),
 Point (x + (-a - 1), y + (-a)),
 Point (x + 1, y + 1),
 Point (x + 1, y - 1)]
sage: p1, p2, p3 = pts[:3]
sage: C.places_on(p1)
[Place (x, y + a + 1)]
sage: C.places_on(p2)
[Place (x, y + 2*a + 2)]
sage: C.places_on(p3)
[Place (x + a + 1, y + a + 2)]
```

```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> k = GF(Integer(9), names=('a',)); (a,) = k._first_ngens(1)
>>> A = AffineSpace(k, Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
```

(continues on next page)
The code snippet provided demonstrates how to work with plane curves in a computational environment. It includes the definition of a curve, finding its closed points, and placing points on the curve. Additionally, there is a section that introduces working with a function field over a finite field and how to pull from a function field.

### pull_from_function_field(f)

Return the fraction corresponding to $f$.

**INPUT:**
- $f$ – an element of the function field

**OUTPUT:**
A fraction of polynomials in the coordinate ring of the ambient space of the curve.

**EXAMPLES:**

```python
sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(8), 2)
sage: C = Curve(x^5 + y^5 + x*y + 1)
sage: F = C.function_field()
sage: C.pull_from_function_field(F.gen())
y
sage: C.pull_from_function_field(F.one())
1
```
sage: C.pull_from_function_field(F.zero())
0
sage: f1 = F.gen()
sage: f2 = F.base_ring().gen()
sage: C.function(C.pull_from_function_field(f1)) == f1
True
sage: C.function(C.pull_from_function_field(f2)) == f2
True

>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(GF(Integer(8)), Integer(2), names=('x', 'y',)); (x, y,)
˓→A._first_ngens(2)
>>> C = Curve(x**Integer(5) + y**Integer(5) + x*y + Integer(1))
>>> F = C.function_field()
>>> C.pull_from_function_field(F.gen())
y
>>> C.pull_from_function_field(F.one())
1
>>> C.pull_from_function_field(F.zero())
0
>>> f1 = F.gen()
>>> f2 = F.base_ring().gen()
>>> C.function(C.pull_from_function_field(f1)) == f1
True
>>> C.function(C.pull_from_function_field(f2)) == f2
True

singular_closed_points()

Return the singular closed points of the curve.

EXAMPLES:

sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(7^2), 2)

```python
sage: C = Curve(x^2 - x^4 - y^4)
sage: C.singular_closed_points()
[Point (x, y)]
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(GF(Integer(7)**Integer(2)), Integer(2), names=('x', 'y',)); (x, y,)
˓→A._first_ngens(2)
>>> C = Curve(x**Integer(2) - x**Integer(4) - y**Integer(4))
```n

```python
>>> C.singular_closed_points()
[Point (x, y)]
```

```python
sage: A.<x,y,z> = AffineSpace(GF(11), 3)
sage: C = Curve([x*z - y^2, y - z^2, x - y*z], A)
sage: C.singular_closed_points()
[]
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(GF(Integer(11)), Integer(3), names=('x', 'y', 'z',)); (x,␣
˓→y, z,) = A._first_ngens(3)
```n

(continues on next page)
class sage.schemes.curves.affine_curve.IntegralAffineCurve_finite_field(A, X)

Bases: IntegralAffineCurve

Integral affine curves.

INPUT:

- A – an ambient space in which the curve lives
- X – list of polynomials that define the curve

EXAMPLES:

```python
sage: A.<x,y,z> = AffineSpace(GF(11), 3)
sage: C = Curve([x*z - y**2, y - z**2, x - y*z], A); C
Affine Curve over Finite Field of size 11
defined by -y^2 + x*z, -z^2 + y, -y*z + x
sage: C.function_field()
Function field in z defined by z^3 + 10*x
```

```python
>>> from sage.all import *

A = AffineSpace(GF(Integer(11)), Integer(2), names=(x, y, z,)); (x, y, z) = A._first_ngens(2)
>>> C = Curve(x**Integer(2) - y**Integer(2), y - z**Integer(2), x - y*z, A); C
Affine Curve over Finite Field of size 11
defined by -y^2 + x*z, -z^2 + y, -y*z + x
>>> C.function_field()
Function field in z defined by z^3 + 10*x
```

closed_points (degree=1)

Return a list of the closed points of degree of the curve.

INPUT:

- degree – a positive integer

EXAMPLES:

```python
sage: A.<x,y> = AffineSpace(GF(7), 2)
sage: C = Curve(x^2 - x^4 - y^4)
sage: C.closed_points()
[Point (x, y),
 Point (x + 1, y),
 Point (x + 2, y + 2),
 Point (x + 2, y - 2),
 Point (x - 2, y + 2),
 Point (x - 2, y - 2),
 Point (x - 1, y)]
```

```python
>>> from sage.all import *

A = AffineSpace(GF(Integer(7)), Integer(2), names=('x', 'y',)); (x, y) = A._first_ngens(2)
>>> C = Curve(x**Integer(2) - x**Integer(4) - y**Integer(4))
>>> C.closed_points()
```

places \( (\text{degree}=1) \)

Return all places on the curve of the degree.

INPUT:

- \( \text{degree} \) – positive integer

EXAMPLES:

```
sage: # needs sage.rings.finite_rings
sage: F = GF(9)
sage: A2.<x,y> = AffineSpace(F, 2)
sage: C = A2.curve(y^3 + y - x^4)
sage: C.places()
[Place (1/x, 1/x^3*y^2),
 Place (x, y),
 Place (x, y + z2 + 1),
 Place (x, y + 2*z2 + 2),
 Place (x + z2, y + 2),
 Place (x + z2, y + z2),
 Place (x + z2, y + 2*z2 + 1),
 Place (x + z2 + 1, y + 1),
 Place (x + z2 + 1, y + z2 + 2),
 Place (x + z2 + 1, y + 2*z2),
 Place (x + 2*z2 + 1, y + 2)*z2 + 1),
 Place (x + 2, y + 1),
 Place (x + 2, y + z2 + 2),
 Place (x + 2, y + 2*z2),
 Place (x + 2*z2, y + 2),
 Place (x + 2*z2, y + z2),
 Place (x + 2*z2, y + 2*z2 + 1),
 Place (x + 2*z2 + 2, y + 1),
 Place (x + 2*z2 + 2, y + z2 + 2),
 Place (x + 2*z2 + 2, y + 2*z2),
 Place (x + z2 + 2, y + 2),
 Place (x + z2 + 2, y + z2),
 Place (x + z2 + 2, y + 2*z2 + 1),
 Place (x + 1, y + 1),
 Place (x + 1, y + z2 + 2),
 Place (x + 1, y + 2*z2),
 Place (x + 1, y + 2*z2)]
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> F = GF(Integer(9))
>>> A2 = AffineSpace(F, Integer(2), names=('x', 'y')); (x, y,) = A2._first_ ngens(2)
>>> C = A2.curve(y**Integer(3) + y - x**Integer(4))
```
class sage.schemes.curves.affine_curve.IntegralAffinePlaneCurve(A, f)

Bases: IntegralAffineCurve, AffinePlaneCurve_field

class sage.schemes.curves.affine_curve.IntegralAffinePlaneCurve_finite_field(A, f)

Bases: AffinePlaneCurve_finite_field, IntegralAffineCurve_finite_field

Integral affine plane curve over a finite field.

EXAMPLES:

sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(8), 2)
sage: C = Curve(x^5 + y^5 + x*y + 1); C
Affine Plane Curve over Finite Field in z3 of size 2^3
defined by x^5 + y^5 + x*y + 1
sage: C.function_field()
Function field in y defined by y^5 + x*y + x^5 + 1

>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(GF(Integer(8)), Integer(2), names=('x', 'y',)); (x, y) = A._first_ngens(2)
>>> C = Curve(x**Integer(5) + y**Integer(5) + x*y + Integer(1)); C
Affine Plane Curve over Finite Field in z3 of size 2^3
defined by x^5 + y^5 + x*y + 1
1.4 Affine and Projective Plane Curve Arrangements

We create classes *AffinePlaneCurveArrangements* and *ProjectivePlaneCurveArrangements* following the properties of *HyperplaneArrangements*

```python
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: C = H(3*x + 2*y - x^2 + y^3 - 7); C
Arrangement (y^3 - x^2 + 3*x + 2*y - 7) in Affine Space of dimension 2 over Rational Field
```

The individual curves will be in *AffinePlaneCurve* or in *ProjectivePlaneCurve*:

```python
sage: C[0].parent()
<class 'sage.schemes.curves.affine_curve.IntegralAffinePlaneCurve_with_category'>
```

The default base field is $\mathbb{Q}$, the rational numbers. Number fields are also possible (also with fixed embeddings in $\mathbb{Q}$):

```python
sage: NF.<a> = NumberField(x^4 - 5 * x^2 + 5, embedding=1.90)
sage: H.<y,z> = AffinePlaneCurveArrangements(NF)
sage: A = H(y^2 - a * z, y^2 + a * z); A
Arrangement (y^2 + (-a)*z, y^2 + a*z) in Affine Space of dimension 2 over Number Field in a with defining polynomial x^4 - 5*x^2 + 5 with a = 1.902113032590308?
sage: A.base_ring()
Number Field in a with defining polynomial x^4 - 5*x^2 + 5 with a = 1.902113032590308?
```

(continues on next page)
over Number Field in a with defining polynomial
\(x^4 - 5x^2 + 5\) with \(a = 1.9021130325903082?\)

```python
>>> A.base_ring()
Number Field in a with defining polynomial \(x^4 - 5x^2 + 5\)
with \(a = 1.9021130325903082?\)
```

AUTHORS:

- Enrique Artal (2023-10): initial version

```python
class sage.schemes.curves.plane_curve_arrangement.AffinePlaneCurveArrangementElement(parent, curves, check=True):
    Bases: PlaneCurveArrangementElement
    An ordered affine plane curve arrangement.
```

**braid_monodromy** *(vertical=True)*

Return the braid monodromy of the complement of the union of affine plane curves in \(\mathbb{C}^2\). If there are vertical asymptotes a change of variable is done.

**INPUT:**

- **vertical** – boolean (default: True); if it is True, there are no vertical asymptotes, and there are vertical lines, then a simplified `braid_monodromy()` is computed.

**OUTPUT:**

A braid monodromy with dictionaries identifying strands with components and braids with vertical lines.

**Note:** This functionality requires the `sirocco` package to be installed.

**EXAMPLES:**

```python
sage: # needs sirocco
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: A = H(y^2 + x, y + x - 1, x)
sage: A.braid_monodromy(vertical=False)
[\text{s1}\text{s0}\text{s1}\text{s0}*(\text{s1}\text{s2}\text{s1})^2\text{s2}*(\text{s1}^-1\text{s2}^-1)^2\text{s1}^-1\text{s0}^-1\text{s1}^-1,
\text{s1}\text{s0}*(\text{s1}\text{s2})^2\text{s2}^1\text{s1}^-1\text{s2}^-1\text{s1}^-1\text{s0}^-1\text{s1}^-1,
\text{s1}\text{s0}\text{s1}\text{s2}^1\text{s0}\text{s1}\text{s2}\text{s1}^-1\text{s2}^-1\text{s1}^-3\text{s2}^1\text{s1}^-1\text{s2}^-1\text{s1}^-1\text{s0}^-1\text{s1}^-1,
\text{s1}\text{s0}\text{s1}\text{s2}^1\text{s1}^-1\text{s1}^-4\text{s2}^1\text{s1}^-1\text{s2}^-1\text{s1}^-1\text{s0}^-1\text{s1}^-1,
\text{s1}\text{s0}\text{s1}\text{s2}^1\text{s1}^-1\text{s2}^-1\text{s1}^-1\text{s2}^1\text{s0}^-1\text{s1}^-1]
sage: A.braid_monodromy(vertical=True)
[\text{s1}\text{s0}\text{s1}\text{s0}^-1\text{s1}^-1\text{s0}^-1, \text{s0}^-1\text{s1}\text{s0}\text{s1}^-1\text{s0}^-1, \text{s0}^-1\text{s1}^2\text{s0}^-1]
```

```python
>>> from sage.all import *
```

```python
>>> # needs sirocco
```

```python
>>> H = AffinePlaneCurveArrangements(QQ, names=(x, y)); (x, y) = H._first_ngens(2)
>>> A = H(y**Integer(2) + x, y + x - Integer(1), x)
>>> A.braid_monodromy(vertical=False)
[\text{s1}\text{s0}\text{s1}\text{s0}*(\text{s1}\text{s2}\text{s1})^2\text{s2}^1\text{s1}^-1\text{s2}^-1\text{s1}^-1\text{s0}^-1\text{s1}^-1,
\text{s1}\text{s0}\text{s1}\text{s2}^1\text{s0}\text{s1}\text{s2}\text{s1}^-1\text{s2}^-1\text{s1}^-1\text{s2}^-1\text{s1}^-1\text{s0}^-1\text{s1}^-1]
```

(continues on next page)
fundamental_group (simplified=True, vertical=True, projective=False)

Return the fundamental group of the complement of the union of affine plane curves in $\mathbb{C}^2$.

INPUT:

- vertical – boolean (default: True); if True, there are no vertical asymptotes, and there are vertical lines, then a simplified braid `braid_monodromy()` is used
- simplified – boolean (default: True); if it is True, the group is simplified
- projective – boolean (default: False); to be used in the method for projective curves

OUTPUT:

A finitely presented group.

Note: This functionality requires the sirocco package to be installed.

EXAMPLES:

```sage
sage: # needs sirocco
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: A = H(y^2 + x, y + x - 1, x)
sage: A.fundamental_group()
Finitely presented group
<x0, x1, x2 | x2*x0*x2^-1*x0^-1, x1*x0*x1^-1*x0^-1, (x2*x1)^2*(x2^-1*x1^-1)^-2 >
sage: A.meridians()
{0: [x1, x2*x1*x2^-1], 1: [x0], 2: [x2],
3: [x1^-1*x2^-1*x1^-1*x0^-1]}
sage: G = A.fundamental_group(simplified=False)
sage: G.sorted_presentation()
Finitely presented group
<x0, x1, x2, x3 | x3^-1*x2^-1*x3*x0*x1*x0^-1,
    x3^-1*x1^-1*x3*x0*x1*x0^-1*x2^-1*x0^-1*(x2*x0)^2*x1^-1*x0^-1
    x2^-1*x0^-1*x2*x0, x1^-1*x0^-1*x1*x0 >
sage: A.meridians(simplified=False)
{0: [x1, x2], 1: [x0], 2: [x3], 3: [x3^-1*x2^-1*x1^-1*x0^-1]}
sage: A.fundamental_group(vertical=False)
Finitely presented group
<x0, x1, x2 | x2^-1*x1^-1*x2*x1, x1*x0*x1^-1*x0^-1, (x0*x2)^2*(x0^-1*x2^-1)^-2 >
sage: A.meridians(vertical=False)
{0: [x2, x0*x2*x0^-1], 1: [x1], 2: [x0], 3: [x0*x2^-1*x0^-1*x2^-1*x1^-1*x0^-1]
    x1^-1}
sage: G = A.fundamental_group(simplified=False, vertical=False)
sage: G.sorted_presentation()
Finitely presented group
```

```
G.sorted_presentation()
Finitely presented group
< x0, x1, x2, x3 | x3^-1*x2^-1*x3*x2, x3^-1*x1^-1*x3*x1,
x3^-1*x0^-1*x3*x0, x2^-1*x1^-1*x2*x1,
x2^-1*x0^-1*x2*x0, x1^-1*x0^-1*x1*x0 >

meridians (simplified=True, vertical=True)
Return the meridians of each irreducible component.

OUTPUT:
A dictionary which associates the index of each curve with its meridians, including the line at infinity if it can be computed.

Note: This functionality requires the sirocco package to be installed and AffinePlaneCurveArrangements.fundamental_group() with the same options, where some examples are shown.

```sage
definitions:
# needs sirocco
H.<x, y> = AffinePlaneCurveArrangements(QQ)
A = H(x-1, y, x, y - 1)
A.fundamental_group()
Finitely presented group
< x0, x1, x2, x3 | x2*x0*x2^-1*x0^-1, x2*x1*x2^-1*x1^-1,
x3*x0*x3^-1*x0^-1, x3*x1*x3^-1*x1^-1 >
A.meridians()
{0: [x2], 1: [x0], 2: [x3], 3: [x1], 4: [x3^-1*x2^-1*x1^-1*x0^-1]}
```

strands()
Return the strands for each member of the arrangement.

OUTPUT:
A dictionary which associates to the index of each strand its associated component if the braid monodromy has been calculated with vertical=False.

Note: This functionality requires the sirocco package to be installed.

EXAMPLES:
vertical_lines_in_braid_monodromy()  
Return the vertical lines in the arrangement.

OUTPUT:
A dictionary which associates the index of a braid to the index of the vertical line associated to the braid.

**Note:** This functionality requires the `sirocco` package to be installed.

**EXAMPLES:**
```sage
sage: # needs sirocco
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: A = H(y^2 + x, y + x - 1, x)
sage: A.vertical_lines_in_braid_monodromy()
{1: 2}
sage: A.braid_monodromy(vertical=True)
[s1*s0*s1*s0^-1*s1^-1*s0, s0^-1*s1*s0*s1^-1*s0, s0^-1*s1^2*s0]
```

vertical_strands()  
Return the strands if the braid monodromy has been computed with the vertical option.

OUTPUT:
A dictionary which associates to the index of each strand its associated component if the braid monodromy has been calculated with `vertical=True`.

**Note:** This functionality requires the `sirocco` package to be installed.
EXAMPLES:

```python
sage: # needs sirocco
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
```

```python
sage: A = H(y^2 + x, y + x - 1, x)
```

```python
sage: A.vertical_strands()
{0: 1, 1: 0, 2: 0}
```

```python
sage: A.braid_monodromy(vertical=True)
[s1*s0*s1^-1*s1^-1*s0, s0^-1*s1*s0*s1^-1*s0, s0^-1*s1^2*s0]
```

```python
>>> from sage.all import *
```

```python
>>> H = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = H._first_ngens(2)
```

```python
>>> A = H(y**Integer(2) + x, y + x - Integer(1), x)
```

```python
>>> A.vertical_strands()
{0: 1, 1: 0, 2: 0}
```

```python
>>> A.braid_monodromy(vertical=True)
[s1*s0*s1^-1*s1^-1*s0, s0^-1*s1*s0*s1^-1*s0, s0^-1*s1^2*s0]
```

```python
class sage.schemes.curves.plane_curve_arrangement.AffinePlaneCurveArrangements(base_ring, names=())
```

Bases: `PlaneCurveArrangements`

Affine curve arrangements.

INPUT:

- `base_ring` – ring; the base ring
- `names` – tuple of strings; the variable names

EXAMPLES:

```python
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
```

```python
sage: H(x, y^2, x-1, y-1)
```

Arrangement (x, y^2, x - 1, y - 1) in Affine Space of dimension 2 over Rational Field

```python
>>> from sage.all import *
```

```python
>>> H = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = H._first_ngens(2)
```

```python
>>> H(x, y**Integer(2), x-Integer(1), y-Integer(1))
```

Arrangement (x, y^2, x - 1, y - 1) in Affine Space of dimension 2 over Rational Field

`Element`

alias of `AffinePlaneCurveArrangementElement`

`ambient_space()`

Return the ambient space.

EXAMPLES:

```python
sage: L.<x, y> = AffinePlaneCurveArrangements(QQ)
```

```python
sage: L.ambient_space()
```

Affine Space of dimension 2 over Rational Field
```python
>>> from sage.all import *
>>> L = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = L._
˓→first_ngens(2)
>>> L.ambient_space()
Affine Space of dimension 2 over Rational Field
```

```python
class sage.schemes.curves.plane_curve_arrangement.PlaneCurveArrangementElement (par-
ent, curves, check=True)
```

Bases: Element

An ordered plane curve arrangement.

**add_curves** *(other)*

The union of self with other.

**INPUT:**

- **other** – a curve arrangement or something that can be converted into a curve arrangement

**OUTPUT:**

A new curve arrangement.

**EXAMPLES:**

```python
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: h = H([x * y, x + y + 1, x^3 - y^5, x^2 * y^2 + x^5 + y^5, (x^2 + y^2)^ ˓→3 + (x^3 + y^3 - 1)^2])
sage: C = Curve(x^8 - y^8 -x^4 * y^4)
sage: h1 = h.union(C); h1
Arrangement of 6 curves in Affine Space of dimension 2 over Rational Field
sage: h1 == h1.union(C)
True
```

```python
>>> from sage.all import *
>>> H = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = H._
˓→first_ngens(2)
>>> h = H([x * y, x + y + Integer(1), x**Integer(3) - y**Integer(5),␣ ˓→x**Integer(2) * y**Integer(2) + x**Integer(5) + y**Integer(5),␣ ˓→(x**Integer(2) + y**Integer(2))**Integer(3) + (x**Integer(3) +␣ ˓→y**Integer(3) - Integer(1))**Integer(2)])
>>> C = Curve(x**Integer(8) - y**Integer(8) -x**Integer(4) * y**Integer(4))
>>> h1 = h.union(C); h1
Arrangement of 6 curves in Affine Space of dimension 2 over Rational Field
>>> h1 == h1.union(C)
True
```

**change_ring** *(base_ring)*

Return curve arrangement over the new base ring.

**INPUT:**

- **base_ring** – the new base ring; must be a field for curve arrangements

**OUTPUT:**

The curve arrangement obtained by changing the base field, as a new curve arrangement.

**EXAMPLES:**
Plane and Space Curves, Release 10.4

```python
sage: # needs sage.rings.number_field
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: A = H(y^2 - x^3, x, y, y^2 + x * y + x^2)
sage: K.<a> = CyclotomicField(3)
sage: A.change_ring(K)
Arrangement (-x^3 + y^2, x, y, x^2 + x*y + y^2) in Affine Space of
dimension 2 over Cyclotomic Field of order 3 and degree 2
```

```python
>>> from sage.all import *

>>> H = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,_) = H._first_ngens(2)
>>> A = H(y**Integer(2) - x**Integer(3), x, y, y**Integer(2) + x*y + x**Integer(2))
>>> K = CyclotomicField(Integer(3), names=('a',)); (a,) = K._first_ngens(1)
>>> A.change_ring(K)
Arrangement (-x^3 + y^2, x, y, x^2 + x*y + y^2) in Affine Space of
dimension 2 over Cyclotomic Field of order 3 and degree 2
```

**coordinate_ring()**

Return the coordinate ring of self.

**OUTPUT:**

The coordinate ring of the curve arrangement.

**EXAMPLES:**

```python
sage: L.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: C = L(x, y)
sage: C.coordinate_ring()
Multivariate Polynomial Ring in x, y over Rational Field
sage: P.<x, y, z> = ProjectivePlaneCurveArrangements(QQ)
sage: C = P(x, y)
sage: C.coordinate_ring()
Multivariate Polynomial Ring in x, y, z over Rational Field
```

```python
>>> from sage.all import *

>>> L = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,_) = L._first_ngens(2)
>>> C = L(x, y)
>>> C.coordinate_ring()
Multivariate Polynomial Ring in x, y over Rational Field
>>> P = ProjectivePlaneCurveArrangements(QQ, names=('x', 'y', 'z',)); (x, y,_,z,) = P._first_ngens(3)
>>> C = P(x, y)
>>> C.coordinate_ring()
Multivariate Polynomial Ring in x, y, z over Rational Field
```

**curves()**

Return the curves in the arrangement as a tuple.

**OUTPUT:**

A tuple.

**EXAMPLES:**

1.4. Affine and Projective Plane Curve Arrangements 75
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: h = H((x * y, x + y + 1))
sage: h.curves()
(Affine Plane Curve over Rational Field defined by x*y,
Affine Plane Curve over Rational Field defined by x + y + 1)

>>> from sage.all import *
>>> H = AffinePlaneCurveArrangements(QQ, names=('x', 'y')); (x, y,) = H._
˓→first_ngens(2)
>>> h = H((x * y, x + y + Integer(1)))
>>> h.curves()
(Affine Plane Curve over Rational Field defined by x*y,
Affine Plane Curve over Rational Field defined by x + y + 1)

Note that the curves can be indexed as if they were a list:

sage: h[1]
Affine Plane Curve over Rational Field defined by x + y + 1

>>> from sage.all import *
>>> h[Integer(1)]
Affine Plane Curve over Rational Field defined by x + y + 1

defining_polynomial(simplified=True)
Return the defining polynomial of the union of the curves in self.

EXAMPLES:

sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: A = H(y^2 + x^2, x, y)
sage: prod(A.defining_polynomials()) == A.defining_polynomial()
True

>>> from sage.all import *
>>> H = AffinePlaneCurveArrangements(QQ, names=('x', 'y')); (x, y,) = H._
˓→first_ngens(2)
>>> A = H(y**Integer(2) + x**Integer(2), x, y)
>>> prod(A.defining_polynomials()) == A.defining_polynomial()
True

defining_polynomials()
Return the defining polynomials of the elements of self.

EXAMPLES:

sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: A = H(y^2 - x^3, x, y, y^2 + x * y + x^2)
sage: A.defining_polynomials()
(-x^3 + y^2, x, y, x^2 + x*y + y^2)

>>> from sage.all import *
>>> H = AffinePlaneCurveArrangements(QQ, names=('x', 'y')); (x, y,) = H._
˓→first_ngens(2)
>>> A = H(y**Integer(2) - x**Integer(3), x, y, y**Integer(2) + x * y +
˓→x**Integer(2))

(continues on next page)
A defining polynomials()
(-x^3 + y^2, x, y, x^2 + x*y + y^2)

**deletion** *(curves)*

Return the curve arrangement obtained by removing curves.

**INPUT:**

- curves – a curve or curve arrangement

**OUTPUT:**

A new curve arrangement with the given curve(s) `h` removed.

**EXAMPLES:**

```python
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: h = H([x * y, x + y + 1, x^3 - y^5, x^2 * y^2 + x^5 + y^5, (x^2 + y^2)^3 + (x^3 + y^3 - 1)^2])
sage: C = h[-1]
sage: h.deletion(C)
Arrangement (x*y, x + y + 1, -y^5 + x^3, x^5 + y^5 + x^2*y^2)
in Affine Space of dimension 2 over Rational Field
sage: h.deletion(x)
Traceback (most recent call last):
... ValueError: curve is not in the arrangement
```

**have_common_factors** *

Check if the curves have common factors.

**EXAMPLES:**

```python
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: A = H(x * y, x^2 + x*y^3)
sage: A.have_common_factors()
True
sage: H(x * y, x + y^3).have_common_factors()
False
```
```python
>>> from sage.all import *
>>> H = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = H._
˓→first_ngens(2)
>>> A = H(x * y, x**Integer(2) + x*y**Integer(3))
>>> A.have_common_factors()
True
>>> H(x * y, x + y**Integer(3)).have_common_factors()
False
```

**ncurves()**

Return the number of curves in the arrangement.

**Output:**

An integer.

**Examples:**

```sage
sage: H.<x, y, z> = ProjectivePlaneCurveArrangements(QQ)
sage: h = H((x * y, x + y + z))
sage: h.ncurves()
2
sage: len(h) # equivalent
2
```

```python
>>> from sage.all import *
>>> H = ProjectivePlaneCurveArrangements(QQ, names=(x, y, z,)); (x, y,␣
˓→z,) = H._first_ngens(3)
>>> h = H((x * y, x + y + z))
>>> h.ncurves()
2
>>> len(h) # equivalent
2
```

**reduce** *(clean=False, verbose=False)*

Replace the curves by their reduction.

**Input:**

- clean – boolean (default: False); if False and there are common factors it returns None and a warning message. If True, the common factors are kept only in the first occurrence.

**Examples:**

```sage
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: A = H(y^2, (x + y)^3 * (x^2 + x * y + y^2))
sage: A.reduce()
Arrangement (y, x^3 + 2*x^2*y + 2*x*y^2 + y^3) in Affine Space
of dimension 2 over Rational Field
sage: C = H(x*y, x*(y + 1))
sage: C.reduce(verbose=True)
Some curves have common components
sage: C.reduce(clean=True)
Arrangement (x*y, y + 1) in Affine Space of dimension 2
over Rational Field
sage: C = H(x*y, x)
sage: C.reduce(clean=True)
Arrangement (x*y) in Affine Space of dimension 2 over Rational Field
```
union (other)

The union of self with other.

INPUT:

• other – a curve arrangement or something that can be converted into a curve arrangement

OUTPUT:

A new curve arrangement.

EXAMPLES:

sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: h = H([x * y, x + y + 1, x^3 - y^5, x^2 * y^2 + x^5 + y^5, (x^2 + y^2)^3 + (x^3 + y^3 - 1)^2])
sage: C = Curve(x^8 - y^8 -x^4 * y^4)
sage: h1 = h.union(C); h1
Arrangement of 6 curves in Affine Space of dimension 2 over Rational Field
sage: h1 == h1.union(C)
True

class sage.schemes.curves.plane_curve_arrangement.PlaneCurveArrangements(base_ring,
    names=())

Bases: UniqueRepresentation, Parent

Plane curve arrangements.
INPUT:

- `base_ring` – ring; the base ring
- `names` – tuple of strings; the variable names

EXAMPLES:

```sage
sage: H.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: H(x, y^2, x-1, y-1)
Arrangement (x, y^2, x - 1, y - 1) in Affine Space
of dimension 2 over Rational Field

>>> from sage.all import *

H = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = H._first_ngens(2)
H(x, y^Integer(2), x-Integer(1), y-Integer(1))
Arrangement (x, y^2, x - 1, y - 1) in Affine Space
of dimension 2 over Rational Field
```

Element

- **ambient_space()**
  
  Return the ambient space.

  EXAMPLES:

  ```sage
  sage: L.<x, y> = PlaneCurveArrangements(QQ)
  Traceback (most recent call last):
  ...\n  NotImplementedError: <abstract method ambient_space at 0x...>
  sage: L.<x, y> = AffinePlaneCurveArrangements(QQ)
  sage: L.ambient_space()
  Affine Space of dimension 2 over Rational Field
  sage: L.<x, y, z> = ProjectivePlaneCurveArrangements(QQ)
  sage: L.ambient_space()
  Projective Space of dimension 2 over Rational Field
  >>> from sage.all import *
  >>> L = PlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = L._first_ngens(2)
  Traceback (most recent call last):
  ...\n  NotImplementedError: <abstract method ambient_space at 0x...>
  >>> L = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = L._first_ngens(2)
  >>> L.ambient_space()
  Affine Space of dimension 2 over Rational Field
  >>> L = ProjectivePlaneCurveArrangements(QQ, names=('x', 'y', 'z',)); (x, y, z,) = L._first_ngens(3)
  >>> L.ambient_space()
  Projective Space of dimension 2 over Rational Field
  ```

`change_ring(base_ring)`

Return curve arrangements over a different base ring.

INPUT:

- `base_ring` – a ring; the new base ring.
OUTPUT:

A new `PlaneCurveArrangements` instance over the new base ring.

EXAMPLES:

```python
sage: L.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: L.change_ring(RR).base_ring()
Real Field with 53 bits of precision
```

```python
>>> from sage.all import *
>>> L = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = L._
˓→first_ngens(2)
>>> L.change_ring(RR).base_ring()
Real Field with 53 bits of precision
```

**coordinate_ring()**

Return the coordinate ring.

OUTPUT:

The coordinate ring of the curve arrangement.

EXAMPLES:

```python
sage: L.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: L.coordinate_ring()
Multivariate Polynomial Ring in x, y over Rational Field
```

```python
>>> from sage.all import *
>>>(x, y,) = L._
˓→first_ngens(2)
>>> L.coordinate_ring()
Multivariate Polynomial Ring in x, y over Rational Field
```

**gen (i)**

Return the $i$-th coordinate.

INPUT:

- $i$ – integer

OUTPUT:

A variable.

EXAMPLES:

```python
sage: L.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: L.gen(1)
y
sage: L.<x, y, z> = ProjectivePlaneCurveArrangements(QQ)
sage: L.gen(2)
z
```

```python
>>> from sage.all import *
>>>(x, y,) = L._
˓→first_ngens(2)
>>> L.gen(Integer(1))
y
```

(continues on next page)
Plane and Space Curves, Release 10.4

(continued from previous page)

```python
>>> L = ProjectivePlaneCurveArrangements(QQ, names=('x', 'y', 'z',)); (x, y, z) = L._first_ngens(3)
>>> L.gen(Integer(2))
z
```

**gens()**

Return the coordinates.

**OUTPUT:**

A tuple of linear expressions, one for each linear variable.

**EXAMPLES:**

```python
sage: L = AffinePlaneCurveArrangements(QQ, ('x', 'y'))
sage: L.gens()
(x, y)
sage: L = ProjectivePlaneCurveArrangements(QQ, ('x', 'y', 'z'))
sage: L.gens()
(x, y, z)
```

```python
>>> from sage.all import *

```  

```python
>>> L = AffinePlaneCurveArrangements(QQ, ('x', 'y'))
>>> L.gens()
(x, y)
>>> L = ProjectivePlaneCurveArrangements(QQ, ('x', 'y', 'z'))
>>> L.gens()
(x, y, z)
```

**ngens()**

Return the number of variables, i.e. 2 or 3, kept for completeness.

**OUTPUT:**

An integer, 2 or 3, depending if the arrangement is projective or affine.

**EXAMPLES:**

```python
sage: L.<x, y> = AffinePlaneCurveArrangements(QQ)
sage: L.ngens()
2
sage: L.<x, y, z> = ProjectivePlaneCurveArrangements(QQ)
sage: L.ngens()
3
```

```python
>>> from sage.all import *

```  

```python
>>> L.<x, y> = AffinePlaneCurveArrangements(QQ, names=('x', 'y',)); (x, y,) = L._first_ngens(2)
>>> L.ngens()
2
>>> L = ProjectivePlaneCurveArrangements(QQ, names=('x', 'y', 'z',)); (x, y, z,) = L._first_ngens(3)
>>> L.ngens()
3
```
Bases: `PlaneCurveArrangementElement`

An ordered projective plane curve arrangement.

**fundamental_group** *(simplified=True)*

Return the fundamental group of the complement of the union of an arrangement of projective plane curves in the projective plane.

**INPUT:**

- `simplified` – boolean (default: True); set if the group is simplified

**OUTPUT:**

A finitely presented group.

**Note:** This functionality requires the `sirocco` package to be installed.

**EXAMPLES:**

```python
sage: # needs sirocco
sage: H.<x, y, z> = ProjectivePlaneCurveArrangements(QQ)
sage: H(z).fundamental_group()
Finitely presented group < | >
sage: H(x*y).fundamental_group()
Finitely presented group < x | >
sage: A = H(y^2 + x*z, y + x - z, x)
sage: A.fundamental_group().sorted_presentation()
Finitely presented group < x0, x1 | x1^-1*x0^-1*x1*x0 >
sage: A.meridians()
{0: [x1], 1: [x0], 2: [x1^-1*x0^-1*x1^-1]}
sage: G = A.fundamental_group(simplified=False)
sage: G.sorted_presentation()
Finitely presented group < x0, x1, x2, x3 | x3^-1*x2^-1*x1^-1*x0^-1, x3^-1*x2^-1*x3*x0*x1*x0^-1*x2^-1*x0^-1*(x2*x0)^2*x1^-1*x0^-1,
    x3^-1*x0^-1*x3*x0*x1*x0^-1*x2^-1*x0^-1*x2*x0*x1^-1*x0^-1, x2^-1*x0^-1*x2*x0, x1^-1*x0^-1*x1*x0 >
sage: A.meridians(simplified=False)
{0: [x1, x2], 1: [x0], 2: [x3]}
sage: A = H(y^2 + x*z, z, x)
sage: A.fundamental_group()
Finitely presented group < x0, x1 | (x1*x0)^2*(x1^-1*x0^-1)^2 >
sage: A = H(y^2 + x*z, z*x, y)
sage: A.fundamental_group()
Finitely presented group < x0, x1 | x2*x0*x1*x0^-1*x2^-1*x1^-1,
    x1*(x2*x0)^2*x2^-1*x1^-1*x0^-1*x2^-1*x0^-1 >
```

```python
>>> from sage.all import *
>>> # needs sirocco
>>> H = ProjectivePlaneCurveArrangements(QQ, names=('x', 'y', 'z')); (x, y, z) = H._first_ngens(3)
>>> H(z).fundamental_group()
Finitely presented group < | >
>>> H(x*y).fundamental_group()
```
Finitely presented group < x | >
>>> A = H(y**Integer(2) + x*z, y + x - z, x)
>>> A.fundamental_group().sorted_presentation()
Finitely presented group < x0, x1 | x1^-1*x0^-1*x1*x0 >
>>> A.meridians()
{0: [x1], 1: [x0], 2: [x1^-1*x0^-1*x1^1-1]}
>>> G = A.fundamental_group(simplified=False)
>>> G.sorted_presentation()
Finitely presented group < x0, x1, x2, x3 | x3^-1*x2^-1*x1^-1*x0^-1, x3^1*x2^-1*x3*x0*x1*x0^-1, x3^-1*x1^-1*x3*x0*x1^-1*x2^-1*x0^-1*(x2*x0)^2*x1^-1*x0^-1 >
>>> A.meridians(simplified=False)
{0: [x1, x2], 1: [x0], 2: [x3]}
>>> A = H(y**Integer(2) + x*z, z, x)
>>> A.fundamental_group()
Finitely presented group < x0, x1 | (x1*x0)^2*(x1^-1*x0^-1)^2 >
>>> A.meridians()
{0: [x0, x1*x0*x1^-1*x1^-1], 1: [x0^-1*x1^-1*x0^-1*x2^-1*x1^-1],
 x2^-1*x0^-1*x2*x0, x1^-1*x0^-1*x1*x0 >

**meridians** *(simplified=True)*

Return the meridians of each irreducible component.

**OUTPUT:**

A dictionary which associates the index of each curve with its meridians, including the line at infinity if it can be computed.

**Note:** This function requires the *sirocco* package to be installed and ProjectivePlaneCurveArrangements.fundamental_group() with the same options, where some examples are shown.

**EXAMPLES:**

```python
sage: # needs sirocco
sage: H.<x, y, z> = ProjectivePlaneCurveArrangements(QQ)
sage: A = H(y^2 + x*z, y + x - z, x)
```

(continues on next page)
class sage.schemes.curves.plane_curve_arrangement.ProjectivePlaneCurveArrangements(base_ring, names=())

Bases: PlaneCurveArrangements

Projective curve arrangements.

INPUT:

• base_ring – ring; the base ring

• names – tuple of strings; the variable names

EXAMPLES:

sage: H.<x, y, z> = ProjectivePlaneCurveArrangements(QQ)

sage: H(x, y^2, x-z, y-z)

Arrangement (x, y^2, x - z, y - z) in Projective Space of dimension 2 over Rational Field

>>> from sage.all import *

>>> H = ProjectivePlaneCurveArrangements(QQ, names=('x', 'y', 'z',)); (x, y, z) = H._first_ngens(3)

>>> A = H(y^Integer(2) + x*z, y + x - z, x)

>>> A.fundamental_group().sorted_presentation()

Finitely presented group < x0, x1 | x1^-1*x0^-1*x1*x0 >

>>> A.meridians()

{0: [x1], 1: [x0], 2: [x1^-1*x0^-1*x1^-1^*1*x0^-1^*1*x0^1>}

Element

alias of ProjectivePlaneCurveArrangementElement

ambient_space()

Return the ambient space.

1.4. Affine and Projective Plane Curve Arrangements 85
1.5 Projective curves

Projective curves in Sage are curves in a projective space or a projective plane.

EXAMPLES:

We can construct curves in either a projective plane:

```sage
ten
P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([y*z^2 - x^3], P); C
Projective Plane Curve over Rational Field defined by -x^3 + y*z^2
```

or in higher dimensional projective spaces:

```sage
ten
P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([y*w^3 - x^4, z*w^3 - x^4], P); C
Projective Curve over Rational Field defined by -x^4 + y*w^3, -x^4 + z*w^3
```

1.5.1 Integral projective curves over finite fields

If the curve is defined over a finite field and integral, that is reduced and irreducible, its function field is tightly coupled with the curve so that advanced computations based on Sage’s global function field machinery are available.

EXAMPLES:

```sage
ten
k = GF(2)
sage: P.<x,y,z> = ProjectiveSpace(k, 2)
sage: C = Curve(x^2*z - y^3, P)
```

(continues on next page)
Closed points of arbitrary degree can be computed:

```
sage: C.closed_points()
[Point (x, y), Point (y, z), Point (x + z, y + z)]
sage: C.closed_points(2)
[Point (y^2 + y*z + z^2, x + z)]
sage: C.closed_points(3)
[Point (y^3 + y^2*z + z^3, x + y + z),
  Point (x^2 + y*z + z^2, x*y + x*z + y*z, y^2 + x*z + y*z + z^2)]
```

All singular closed points can be found:

```
sage: C.singular_closed_points()
[Point (x, y)]
sage: p = _[0]
sage: p.places()  # a unibranch singularity, that is, a cusp
[Place (1/y)]
sage: pls = _[0]
sage: C.place_to_closed_point(pls)
Point (x, y)
```

It is easy to transit to and from the function field of the curve:
1.5.2 Integral projective curves over Q

An integral curve over $\mathbb{Q}$ is also equipped with the function field. Unlike over finite fields, it is not possible to enumerate closed points.

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x^2*z^2 - x^4 - y^4, P)
sage: C.singular_closed_points()
[Point (x, y)]
sage: p, = _
sage: p.places()
[Place (1/y, 1/y^2*z - 1), Place (1/y, 1/y^2*z + 1)]
sage: fy = C.function(y/z)
sage: fy.divisor()
(continues on next page)
```
Place \((1/y, 1/y^2*z - 1)\) 
\(+\) Place \((1/y, 1/y^2*z + 1)\) 
\(+\) Place \((y, z - 1)\) 
\(+\) Place \((y, z + 1)\) 
\(-\) Place \((y^4 + 1, z)\)

\(\texttt{sage: supp = _.support()}
\texttt{sage: pl = supp[0]}
\texttt{sage: C.place_to_closed_point(pl)}\)

Point \((x, y)\)

\(\texttt{sage: pl = supp[1]}
\texttt{sage: C.place_to_closed_point(pl)}\)

Point \((x, y)\)

\(\texttt{sage: _.rational_point()}
\texttt{(0 : 0 : 1)}\)

\(\texttt{in C}\)

True

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._
˓→first_ngens(3)

>>> C = Curve(x**Integer(2)*z**Integer(2) - x**Integer(4) - y**Integer(4), P)

>>> C.singular_closed_points()

[Point (x, y)]

>>> p, = 

>>> p.places()

[Place (1/y, 1/y^2*z - 1), Place (1/y, 1/y^2*z + 1)]

>>> fy = C.function(y/z)

>>> fy.divisor()

Place (1/y, 1/y^2*z - 1) 
\(+\) Place (1/y, 1/y^2*z + 1) 
\(+\) Place \((y, z - 1)\) 
\(+\) Place \((y, z + 1)\) 
\(-\) Place \((y^4 + 1, z)\)

>>> supp = _.support()

>>> pl = supp[Integer(0)]

>>> C.place_to_closed_point(pl)

Point \((x, y)\)

>>> pl = supp[Integer(1)]

>>> C.place_to_closed_point(pl)

Point \((x, y)\)

>>> _.rational_point()

(0 : 0 : 1)

>>> _ in C

True
```

sage.schemes.curves.projective_curve.Hasse_bounds \(q, \text{genus}=1\)

Return the Hasse-Weil bounds for the cardinality of a nonsingular curve defined over \(\mathbb{F}_q\) of given \text{genus}.

**INPUT:**

- \(q\) (int) – a prime power
- \(\text{genus}\) (int, default 1) – a non-negative integer,

**OUTPUT:** A tuple. The Hasse bounds \((lb,ub)\) for the cardinality of a curve of genus \(\text{genus}\) defined over \(\mathbb{F}_q\).

**EXAMPLES:**

```python
sage: Hasse_bounds(2)
(1, 5)
sage: Hasse_bounds(next_prime(10^30))  # needs sage.libs.pari
(9999999999999980000000000058, 10000000000000020000000000058)
```

class sage.schemes.curves.projective_curve.IntegralProjectiveCurve(A, f)

Bases: ProjectiveCurve_field

Integral projective curve.

**coordinate_functions** \((i=\text{None})\)

Return the coordinate functions for the \(i\)-th affine patch.

If \(i\) is None, return the homogeneous coordinate functions.

**EXAMPLES:**

```python
sage: # needs sage.rings.finite_rings
sage: P.<x,y,z> = ProjectiveSpace(GF(4), 2)
sage: C = Curve(x^5 + y^5 + x*y*z^3 + z^5)
sage: C.coordinate_functions(0)
(y, z)
sage: C.coordinate_functions(1)
(1/y, 1/y*z)
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> P = ProjectiveSpace(GF(Integer(4)), Integer(2), names=('x', 'y', 'z'));...
>>> (x, y, z,) = P._first_ngens(3)
>>> C = Curve(x**Integer(5) + y**Integer(5) + x*y*z**Integer(3) +...
>>> z**Integer(5))
>>> C.coordinate_functions(Integer(0))
(y, z)
>>> C.coordinate_functions(Integer(1))
(1/y, 1/y*z)
```

**function** \((f)\)

Return the function field element corresponding to \(f\).
INPUT:

- $f$ – a fraction of homogeneous polynomials of the coordinate ring of the ambient space of the curve

OUTPUT: An element of the function field.

EXAMPLES:

```
sage: # needs sage.rings.finite_rings
sage: P.<x,y,z> = ProjectiveSpace(GF(4), 2)
sage: C = Curve(x^5 + y^5 + x*y*z^3 + z^5)
sage: f = C.function(x/y); f
1/y
sage: f.divisor()
Place (1/y, 1/y^2*z^2 + z2/y*z + 1)
 + Place (1/y, 1/y^2*z^2 + ((z2 + 1)/y)*z + 1)
 + Place (1/y, 1/y*z + 1)
 - Place (y, z^2 + z2*z + 1)
 - Place (y, z^2 + (z2 + 1)*z + 1)
 - Place (y, z + 1)
```

```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> P = ProjectiveSpace(GF(Integer(4)), Integer(2), names=(x, y, z,)); (x, y, z,) = P._first_ngens(3)
>>> C = Curve(x**Integer(5) + y**Integer(5) + x*y*z**Integer(3) + z**Integer(5))
>>> f = C.function(x/y); f
1/y
>>> f.divisor()
Place (1/y, 1/y^2*z^2 + z2/y*z + 1)
 + Place (1/y, 1/y^2*z^2 + ((z2 + 1)/y)*z + 1)
 + Place (1/y, 1/y*z + 1)
 - Place (y, z^2 + z2*z + 1)
 - Place (y, z^2 + (z2 + 1)*z + 1)
 - Place (y, z + 1)
```

```
function_field()
```

Return the function field of this curve.

EXAMPLES:

```
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x^2 + y^2 + z^2, P)
sage: C.function_field()
Function field in z defined by z^2 + y^2 + 1
```

```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z')); (x, y, z,) = P._first_ngens(3)
>>> C = Curve(x**Integer(2) + y**Integer(2) + z**Integer(2), P)
>>> C.function_field()
Function field in z defined by z^2 + y^2 + 1
```

```
sage: # needs sage.rings.finite_rings
sage: P.<x,y,z> = ProjectiveSpace(GF(4), 2)
sage: C = Curve(x^5 + y^5 + x*y*z^3 + z^5)
```

(continues on next page)
sage: C.function_field()
Function field in z defined by z^5 + y*z^3 + y^5 + 1

>> from sage.all import *
>> # needs sage.rings.finite_rings
>> P = ProjectiveSpace(GF(Integer(4)), Integer(2), names=('x', 'y', 'z'));
-> (x, y, z,) = P._first_ngens(3)
>> C = Curve(x**Integer(5) + y**Integer(5) + x*y*z**Integer(3) +
-> z**Integer(5))
>> C.function_field()
Function field in z defined by z^5 + y*z^3 + y^5 + 1

jacobian (model, base_div=None)

Return the Jacobian of this curve.

INPUT:

• model – model to use for arithmetic
• base_div – an effective divisor for the model

The degree of the base divisor should satisfy certain degree conditions corresponding to the model used. The following table lists these conditions. Let $g$ be the geometric genus of the curve.

• hess: ideal-based arithmetic; requires base divisor of degree $g$
• km_large: Khuri-Makdisi’s large model; requires base divisor of degree at least $2g + 1$
• km_medium: Khuri-Makdisi’s medium model; requires base divisor of degree at least $2g + 1$
• km_small: Khuri-Makdisi’s small model requires base divisor of degree at least $g + 1$

We assume the curve (or its function field) has a rational place. If a base divisor is not given, one is chosen using a rational place.

EXAMPLES:

sage: A.<x,y> = AffineSpace(GF(5), 2)
sage: C = Curve(y**2*(x**3 - 1) - (x**3 - 2)).projective_closure()
sage: J = C.jacobian(model='hess'); J
Jacobian of Projective Plane Curve over Finite Field of size 5
defined by 2*x0^5 - x0^2*x1^3 - x0^3*x2^2 + x1^3*x2^2 (Hess model)
sage: J.base_divisor().degree() == C.genus()
True

Place_to_closed_point (place)

Return the closed point at the place.

INPUT:
• place – a place of the function field of the curve

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(5), 2)
sage: C = Curve(y^2*z^7 - x^9 - x*z^8)
sage: pls = C.places()
sage: C.place_to_closed_point(pls[-1])
Point (x - 2*z, y - 2*z)
sage: pls2 = C.places(2)
sage: C.place_to_closed_point(pls2[0])
Point (y^2 + y*z + z^2, x + y)
```

places_on(point)

Return the places on the closed point.

INPUT:

• point – a closed point of the curve

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x*y*z^4 - x^6 - y^6)
sage: C.singular_closed_points()
[Point (x, y)]
sage: p, = _
sage: C.places_on(p)
[Place (1/y, 1/y^2*z, 1/y^3*z^2, 1/y^4*z^3),
 Place (y, y*z, y*z^2, y*z^3)]
sage: pl1, pl2 =_
sage: C.place_to_closed_point(pl1)
Point (x, y)
sage: C.place_to_closed_point(pl2)
Point (x, y)
```
\[
\text{C.place_to_closed_point}(\text{pl1}) \quad \text{Point } (x, y)
\]
\[
\text{C.place_to_closed_point}(\text{pl2}) \quad \text{Point } (x, y)
\]

```python
sage: \text{P.<x,y,z>} = \text{ProjectiveSpace}(\text{GF}(5), 2)
sage: \text{C = Curve}(x^2 * z - y^3)
sage: \text{[C.places_on(p) for p in C.closed_points() ]}
[[\text{Place } (1/y) ],
[\text{Place } (y) ],
[\text{Place } (y + 1)],
[\text{Place } (y + 2)],
[\text{Place } (y + 3)],
[\text{Place } (y + 4)]]
```

```python
>>> \text{from sage.all import *}
```  
```python
>>> \text{P = ProjectiveSpace}(\text{GF(Integer(5)), Integer(2), names=('x', 'y', 'z'))};␣
˓→\text{(x, y, z)} = \text{P.}_\text{first_ngens}(3)
>>> \text{C = Curve}(x**Integer(2)*z - y**Integer(3))
>>> \text{[C.places_on(p) for p in C.closed_points() ]}
[[\text{Place } (1/y) ],
[\text{Place } (y) ],
[\text{Place } (y + 1)],
[\text{Place } (y + 2)],
[\text{Place } (y + 3)],
[\text{Place } (y + 4)]]
```

**pull_from_function_field**\(f\)

Return the fraction corresponding to \(f\).

**INPUT:**

- \(f\) – an element of the function field

**OUTPUT:**

A fraction of homogeneous polynomials in the coordinate ring of the ambient space of the curve.

**EXAMPLES:**

```python
sage: # needs sage.rings.finite_rings
sage: \text{P.<x,y,z>} = \text{ProjectiveSpace}(\text{GF}(4), 2)
sage: \text{C = Curve}(x^5 + y^5 + x*y*z^3 + z^5)
sage: \text{F = C.function_field()}
sage: \text{C.pull_from_function_field(F.gen())}
\frac{z}{x}
sage: \text{C.pull_from_function_field(F.one())}
1
sage: \text{C.pull_from_function_field(F.zero())}
0
sage: f1 = F.gen()
sage: f2 = F.base_ring().gen()
sage: \text{C.function(C.pull_from_function_field(f1)) == f1}
\text{True}
sage: \text{C.function(C.pull_from_function_field(f2)) == f2}
\text{True}
```
```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> P = ProjectiveSpace(GF(Integer(4)), Integer(2), names=('x', 'y', 'z',));
→(x, y, z,) = P._first_ngens(3)
>>> C = Curve(x**Integer(5) + y**Integer(5) + x*y*z**Integer(3) +
→z**Integer(5))
>>> F = C.function_field()
>>> C.pull_from_function_field(F.gen())
z/x
>>> C.pull_from_function_field(F.one())
1
>>> C.pull_from_function_field(F.zero())
0
>>> f1 = F.gen()
>>> f2 = F.base_ring().gen()
>>> C.function(C.pull_from_function_field(f1)) == f1
True
>>> C.function(C.pull_from_function_field(f2)) == f2
True
```

`singular_closed_points()`

Return the singular closed points of the curve.

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(y^2*z - x^3, P)
sage: C.singular_closed_points()
[Point (x, y)]
```

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(5), 2)
sage: C = Curve(y^2*z^7 - x^9 - x*z^8)
sage: C.singular_closed_points()
[Point (x, z)]
```

```python
class sage.schemes.curves.projective_curve.IntegralProjectiveCurve Finite_field(A, f)
Bases: IntegralProjectiveCurve
Integral projective curve over a finite field.

INPUT:
- A – an ambient projective space
```
• $f$ – homogeneous polynomials defining the curve

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(5), 2)
sage: C = Curve(y^2*z^7 - x^9 - x*z^8)
sage: C.function_field()
Function field in z defined by z^8 + 4*y^2*z^7 + 1
sage: C.closed_points()
[Point (x, z),
 Point (x, y),
 Point (x - 2*z, y + 2*z),
 Point (x + 2*z, y + z),
 Point (x + 2*z, y - z),
 Point (x - 2*z, y - 2*z)]

>>> from sage.all import *
>>> P = ProjectiveSpace(GF(Integer(5)), Integer(2), names=('x', 'y', 'z'),); (x, y, z) = P._first_ngens(3)
>>> C = Curve(y**Integer(2)*z**Integer(7) - x**Integer(9) - x*z**Integer(8))
>>> C.function_field()
Function field in z defined by z^8 + 4*y^2*z^7 + 1
>>> C.closed_points()
[Point (x, z),
 Point (x, y),
 Point (x - 2*z, y + 2*z),
 Point (x + 2*z, y + z),
 Point (x + 2*z, y - z),
 Point (x - 2*z, y - 2*z)]
```

**L_polynomial** *(name='t')*

Return the L-polynomial of this possibly singular curve.

**INPUT:**

• name – (default: t) name of the variable of the polynomial

**EXAMPLES:**

```python
sage: A.<x,y> = AffineSpace(GF(3), 2)
sage: C = Curve(y^2 - x^5 - x^4 - 2*x^3 - 2*x - 2)
sage: Cbar = C.projective_closure()
sage: Cbar.L_polynomial()
9*t^4 - 3*t^3 + t^2 - t + 1

>>> from sage.all import *
>>> A = AffineSpace(GF(Integer(3)), Integer(2), names=('x', 'y'),); (x, y) = A._first_ngens(2)
>>> C = Curve(y**Integer(2) - x**Integer(5) - x**Integer(4) - 2*x**Integer(3) - 2*x - 2)
>>> Cbar = C.projective_closure()
>>> Cbar.L_polynomial()
9*t^4 - 3*t^3 + t^2 - t + 1
```

**closed_points** *(degree=1)*

Return a list of closed points of degree of the curve.

**INPUT:**

• degree – a positive integer
EXAMPLES:

```python
sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(9),2)
sage: C = Curve(y^2 - x^5 - x^4 - 2*x^3 - 2*x-2)
sage: Cp = C.projective_closure()
sage: Cp.closed_points()
[Point (x0, x1),
Point (x0 + (-z2 - 1)*x2, x1),
Point (x0 + (z2 + 1)*x2, x1),
Point (x0 + z2*x2, x1 + (z2 - 1)*x2),
Point (x0 + (-z2)*x2, x1 + (-z2 + 1)*x2),
Point (x0 + (z2 + 1)*x2, x1 + (z2 + 1)*x2),
Point (x0 + (z2 - 1)*x2, x1 + z2*x2),
Point (x0 + (-z2)*x2, x1 + (-z2)*x2),
Point (x0 + x2, x1 - x2),
Point (x0 - x2, x1 + x2)]
```

```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(GF(Integer(9)),Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve(y**Integer(2) - x**Integer(5) - x**Integer(4) - Integer(2)*x**Integer(3) - Integer(2)*x-Integer(2))
>>> Cp = C.projective_closure()
>>> Cp.closed_points()
[Point (x0, x1),
Point (x0 + (-z2 - 1)*x2, x1),
Point (x0 + (z2 + 1)*x2, x1),
Point (x0 + z2*x2, x1 + (z2 - 1)*x2),
Point (x0 + (-z2)*x2, x1 + (-z2 + 1)*x2),
Point (x0 + (z2 + 1)*x2, x1 + (z2 + 1)*x2),
Point (x0 + (z2 - 1)*x2, x1 + z2*x2),
Point (x0 + (-z2)*x2, x1 + (-z2)*x2),
Point (x0 + x2, x1 - x2),
Point (x0 - x2, x1 + x2)]
```

**number_of_rational_points** (*r*=1)

Return the number of rational points of the curve with constant field extended by degree *r*.

**INPUT:**

- *r* – positive integer (default: 1)

**EXAMPLES:**

```python
sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(3), 2)
sage: C = Curve(y^2 - x^5 - x^4 - 2*x^3 - 2*x - 2)
sage: Cbar = C.projective_closure()
sage: Cbar.number_of_rational_points(3)
21
sage: D = Cbar.change_ring(Cbar.base_ring().extension(3))
sage: D.base_ring()Finite Field in z3 of size 3^3
sage: len(D.closed_points())
21
```

1.5. Projective curves
places \( (\text{degree}=1) \)
Return all places on the curve of the degree.

INPUT:

\* degree \( \text{–} \) positive integer

EXAMPLES:

```
sage: P.<x,y,z> = ProjectiveSpace(GF(5), 2)
sage: C = Curve(x^2*z - y^3)
sage: C.places()
[Place (1/y),
 Place (y),
 Place (y + 1),
 Place (y + 2),
 Place (y + 3),
 Place (y + 4)]
sage: C.places(2)
[Place (y^2 + 2),
 Place (y^2 + 3),
 Place (y^2 + y + 1),
 Place (y^2 + y + 2),
 Place (y^2 + 2*y + 3),
 Place (y^2 + 2*y + 4),
 Place (y^2 + 3*y + 3),
 Place (y^2 + 3*y + 4),
 Place (y^2 + 4*y + 1),
 Place (y^2 + 4*y + 2)]
```
class sage.schemes.curves.projective_curve.IntegralProjectivePlaneCurve(A, f)
Bases: IntegralProjectiveCurve, ProjectivePlaneCurve_field

class sage.schemes.curves.projective_curve.IntegralProjectivePlaneCurve_finite_field(A, f)
Bases: IntegralProjectiveCurve_finite_field, ProjectivePlaneCurve_finite_field

Integral projective plane curve over a finite field.

INPUT:

- \( A \) – ambient projective plane
- \( f \) – a homogeneous equation that defines the curve

EXAMPLES:

```python
sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(9), 2)
sage: C = Curve(y^2 - x^5 - x^4 - 2*x^3 - 2*x - 2)
sage: Cb = C.projective_closure()
sage: Cb.singular_closed_points()
[Point (x0, x1)]
sage: Cb.function_field()
Function field in y defined by y^2 + 2*x^5 + 2*x^4 + x^3 + x + 1
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = AffineSpace(GF(Integer(9)), Integer(2), names=('x', 'y',)); (x, y,) = A._first_ngens(2)
>>> C = Curve(y**Integer(2) - x**Integer(5) - x**Integer(4) - 2*x**Integer(3) - 2*x - 2)
>>> Cb = C.projective_closure()
>>> Cb.singular_closed_points()
[Point (x0, x1)]
>>> Cb.function_field()
Function field in y defined by y^2 + 2*x^5 + 2*x^4 + x^3 + x + 1
```

class sage.schemes.curves.projective_curve.ProjectiveCurve(A, X, category=None)
Bases: Curve_generic, AlgebraicScheme_subscheme_projective

Curves in projective spaces.

INPUT:

- \( A \) – ambient projective space
- \( X \) – list of multivariate polynomials; defining equations of the curve
affine_patch(i, AA=None)

Return the i-th affine patch of this projective curve.

INPUT:

- i – affine coordinate chart of the projective ambient space of this curve to compute affine patch with respect to
- AA – (default: None) ambient affine space, this is constructed if it is not given

OUTPUT: A curve in affine space.

EXAMPLES:

sage: P.<x,y,z,w> = ProjectiveSpace(CC, 3)
sage: C = Curve([y*z - x^2, w^2 - x*y], P)
sage: C.affine_patch(0)
Affine Curve over Complex Field with 53 bits of precision defined by y*z - 1.000000000000000, w^2 - y

>>> from sage.all import *
>>> P = ProjectiveSpace(CC, Integer(3), names=('x', 'y', 'z', 'w', )); (x, y, z, w,) = P._first_ngens(4)
>>> C = Curve([y*z - x**Integer(2), w**Integer(2) - x*y], P)
>>> C.affine_patch(Integer(0))
Affine Curve over Complex Field with 53 bits of precision defined by y*z - 1.00000000000000, w^2 - y

```sage
P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x^3 - x^2*y + y^3 - x^2*z, P)
sage: C.affine_patch(1)
Affine Plane Curve over Rational Field defined by x^3 - x^2*z - x^2 + 1
```

```sage
A.<x,y> = AffineSpace(QQ, 2)
P.<u,v,w> = ProjectiveSpace(QQ, 2)
sage: C = Curve([u^2 - v^2], P)
sage: C.affine_patch(1, A).ambient_space() == A
True
```

```sage
from sage.all import *

P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z',))
(x, y, z,) = P._first_ngens(3)
C = Curve(x**Integer(3) - x**Integer(2)*y + y**Integer(3) - x**Integer(2)*z, P)
C.affine_patch(Integer(1))
Affine Plane Curve over Rational Field defined by x^3 - x^2*z - x^2 + 1
```

**plane_projection** *(PP=None)*

Return a projection of this curve into a projective plane.

**INPUT:**

- PP – (default: None) the projective plane the projected curve will be defined in. This space must be defined over the same base field as this curve, and must have dimension two. This space is constructed if not specified.

**OUTPUT:** A tuple of

- a scheme morphism from this curve into a projective plane
- the projective curve that is the image of that morphism

**EXAMPLES:**

```sage
P.<x,y,z,w,u,v> = ProjectiveSpace(QQ, 5)
sage: C = P.curve([x*u - z*v, w - y, w*y - x^2, y^3*u*2*z - w^4*w])
sage: L.<a,b,c> = ProjectiveSpace(QQ, 2)
sage: proj1 = C.plane_projection(PP=L)
sage: proj1
(Scheme morphism:
   From: Projective Curve over Rational Field
defined by x*u - z*v, -y + w, -x^2 + y*w, -w^5 + 2*y^3*z*u
   To:  Projective Space of dimension 2 over Rational Field
```
Defn: Defined on coordinates by sending $(x : y : z : w : u : v)$ to
$(x : -z + u : -z + v)$.
Projective Plane Curve over Rational Field defined by $a^8 + 6*a^7*b + 4*a^5*b^3 - 4*a^7*c - 2*a^6*b*c - 4*a^5*b^2*c + 2*a^6*c^2$)

```python
sage: proj1[1].ambient_space() is L
True
sage: proj2 = C.projection()
```
```python
sage: proj2[1].ambient_space() is L
False
```

```python
>>> from sage.all import *
```
```python
>>> P = ProjectiveSpace(QQ, Integer(5), names=('x', 'y', 'z', 'w', 'u', 'v',))
>>> (x, y, z, w, u, v,) = P._first_ngens(6)
>>> C = P.curve([x*u - z*v, w - y, w*y - x**Integer(2),
               y**Integer(3)*u*Integer(2)*z - w**Integer(4)*w])
>>> L = ProjectiveSpace(QQ, Integer(2), names=('a', 'b', 'c',)); (a, b, c,) =
               L._first_ngens(3)
>>> proj1 = C.plane_projection(PP=L)
>>> proj1
(Scheme morphism:
From: Projective Curve over Rational Field
defined by x*u - z*v, -y + w, -x^2 + y*w, -w^5 + 2*y^3*z*u
To: Projective Space of dimension 2 over Rational Field
Defn: Defined on coordinates by sending (x : y : z : w : u : v) to
(x : -z + u : -z + v),
Projective Plane Curve over Rational Field defined by $a^8 + 6*a^7*b + 4*a^5*b^3 - 4*a^7*c - 2*a^6*b*c - 4*a^5*b^2*c + 2*a^6*c^2$)
```
```python
>>> proj1[Integer(1)].ambient_space() is L
True
```
```python
>>> proj2 = C.projection()
```
```python
>>> proj2[Integer(1)].ambient_space() is L
False
```
```python
sage: P.<x,y,z,w,u> = ProjectiveSpace(GF(7), 4)
```
```python
sage: C = P.curve([x**Integer(2) - Integer(6)*y**Integer(2), w*z*u - y**Integer(3) + Integer(4)*y**Integer(2)*z, u**Integer(2) - x**Integer(2)])
```
```python
sage: C.plane_projection()
```
```python
(Scheme morphism:
From: Projective Curve over Finite Field of size 7
defined by $x^2 + y^2$, -y^3 - 3*y^2*z + z*w*u, -x^2 + u^2
To: Projective Space of dimension 2 over Finite Field of size 7
Defn: Defined on coordinates by sending (x : y : z : w : u) to
(x : z : -y + w),
Projective Plane Curve over Finite Field of size 7
defined by $x0^10 + 2*x0^8*x1^2 + 2*x0^6*x1^4 - 3*x0^6*x1^3*x2 + 2*x0^6*x1^2*x2^2 - 2*x0^4*x1^4*x2^2 + x0^2*x1^4*x2^4$
```
```python
>>> from sage.all import *
```
```python
>>> P = ProjectiveSpace(GF(Integer(7)), Integer(4), names=('x', 'y', 'z', 'w',
               '_u',)); (x, y, z, w, u,) = P._first_ngens(5)
>>> C = P.curve([x**Integer(2) - Integer(6)*y**Integer(2), w*z*u -
               y**Integer(3) + Integer(4)*y**Integer(2)*z, u**Integer(2) - x**Integer(2)])
>>> C.plane_projection()
```
```python
(Scheme morphism:
From: Projective Curve over Finite Field of size 7
defined by $x^2 + y^2$, -y^3 - 3*y^2*z + z*w*u, -x^2 + u^2
To: Projective Space of dimension 2 over Finite Field of size 7
```
```
Defn: Defined on coordinates by sending \((x : y : z : w : u)\) to 
\((x : z : -y + w)\),
Projective Plane Curve over Finite Field of size 7
defined by \(x0^{10} + 2*x0^8*x1^2 + 2*x0^6*x1^4 - 3*x0^6*x1^3*x2 + 2*x0^6*x1^2*x2^2 - 2*x0^4*x1^4*x2^2 + x0^2*x1^4*x2^4)\)

```sage
sage: P.<x,y,z> = ProjectiveSpace(GF(17), 2)
sage: C = P.curve(x^2 - y*z - z^2)
sage: C.plane_projection()
Traceback (most recent call last):
...TypeError: this curve is already a plane curve
```

```sage
from sage.all import *

>>> P = ProjectiveSpace(GF(Integer(17)), Integer(2), names=(x, y, z,));
˓→(x, y, z,) = P._first_ngens(3)
>>> C = P.curve(x**Integer(2) - y*z - z**Integer(2))
>>> C.plane_projection()
Traceback (most recent call last):
...TypeError: this curve is already a plane curve
```

**projection** \((P=None, PS=None)\)

Return a projection of this curve into projective space of dimension one less than the dimension of the ambient space of this curve.

This curve must not already be a plane curve. Over finite fields, if this curve contains all points in its ambient space, then an error will be returned.

**INPUT:**

- \(P\) – (default: None) a point not on this curve that will be used to define the projection map; this is constructed if not specified.
- \(PS\) – (default: None) the projective space the projected curve will be defined in. This space must be defined over the same base ring as this curve, and must have dimension one less than that of the ambient space of this curve. This space will be constructed if not specified.

**OUTPUT:** A tuple of

- a scheme morphism from this curve into a projective space of dimension one less than that of the ambient space of this curve
- the projective curve that is the image of that morphism

**EXAMPLES:**

```sage
sage: # needs sage.rings.number_field
sage: K.<a> = CyclotomicField(3)
sage: P.<x,y,z,w> = ProjectiveSpace(K, 3)
sage: C = Curve([y*w - x^2, z*w^2 - a*x^3], P)
sage: L.<a,b,c> = ProjectiveSpace(K, 2)
sage: proj1 = C.projection(PS=L)
sage: proj1
(Scheme morphism:  
  From: Projective Curve over Cyclotomic Field of order 3 and degree 2  
  defined by -x^2 + y*w, (-a)*x^3 + z*w^2  
  To: Projective Space of dimension 2)
```

(continues on next page)
over Cyclotomic Field of order 3 and degree 2

```

```python
class sage.schemes.curves.projective_curve.ProjectiveCurve_field(A, X,
category=\texttt{None})
```

Bases: \texttt{ProjectiveCurve}, \texttt{AlgebraicScheme_subscheme_projective_field}

Projective curves over fields.

\texttt{arithmetic_genus()}

Return the arithmetic genus of this projective curve.

This is the arithmetic genus \(p_a(C)\) as defined in [Har1977]. If \(P\) is the Hilbert polynomial of the defining ideal of this curve, then the arithmetic genus of this curve is \(1 - P(0)\).

EXAMPLES:

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = P.curve([w*z - x**2, w**2 + y**2 + z**2])
sage: C.arithmetic_genus()
1
```

1.5. Projective curves
is_complete_intersection()

Return whether this projective curve is a complete intersection.

EXAMPLES:

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([x*y - z*w, x^2 - y*w, y^2*z - x*z*w], P)
sage: C.is_complete_intersection()
False
```

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([y*w - x^2, z*w^2 - x^3], P)
sage: C.is_complete_intersection()
True
```

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([z^2 - y*z, y^2 - x*z], P)
sage: C.is_complete_intersection()
False
```

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([y*w - x^2, z*w^2 - x^3], P)
sage: C.is_complete_intersection()
True
```

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([z^2 - y*z, y^2 - x*z], P)
sage: C.is_complete_intersection()
False
```
P = ProjectiveSpace(QQ, Integer(3), names=('x', 'y', 'z', 'w',)); (x, y, z, w,) = P._first_ngens(4)
C = Curve([z**Integer(2) - y*w, y*z - x*w, y**Integer(2) - x*z], P)
C.is_complete_intersection()
False

tangent_line(p)
Return the tangent line at the point p.

INPUT:
• p – a rational point of the curve

EXAMPLES:
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([x*y - z*w, x^2 - y*w, y^2*w - x*z*w], P)
sage: p = C(Integer(1),Integer(1),Integer(1),Integer(1))
sage: C.tangent_line(p)
Projective Curve over Rational Field
defined by -2*x + y + w, -3*x + z + 2*w

class sage.schemes.curves.projective_curve.ProjectivePlaneCurve(A, f, category=None)
Bases: ProjectiveCurve
Curves in projective planes.

INPUT:
• A – projective plane
• f – homogeneous polynomial in the homogeneous coordinate ring of the plane

EXAMPLES:
A projective plane curve defined over an algebraic closure of Q:
sage: # needs sage.rings.number_field
sage: P.<x,y,z> = ProjectiveSpace(QQbar, 2)
sage: set_verbose(-1) # suppress warnings for slow computation
sage: C = Curve([y*z - x^2 - QQbar.gen()*z^2], P); C
Projective Plane Curve over Algebraic Field
defined by -x^2 + y*z + (-I)*z^2

from sage.all import *
>>> P = ProjectiveSpace(QQbar, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
A projective plane curve defined over a finite field:

```
sage: P.<x,y,z> = ProjectiveSpace(GF(5**2, 'v'), 2)
sage: C = Curve([y^2*z - x*z^2 - z^3], P); C
Projective Plane Curve over Finite Field in v of size 5^2
defined by y^2*z - x*z^2 - z^3
```

`degree()`
Return the degree of this projective curve.

For a plane curve, this is just the degree of its defining polynomial.

OUTPUT: An integer.

EXAMPLES:

```
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = P.curve([y^7 - x^2*z^5 + 7*z^7])
sage: C.degree()
7
```

`divisor_of_function(r)`
Return the divisor of a function on a curve.

INPUT: \( r \) is a rational function on \( X \)

OUTPUT: A list. The divisor of \( r \) represented as a list of coefficients and points. (TODO: This will change to a more structural output in the future.)

EXAMPLES:

```
sage: FF = FiniteField(5)
sage: P2 = ProjectiveSpace(2, FF, names=['x','y','z'])
sage: R = P2.coordinate_ring()
sage: x, y, z = R.gens()
```

(continues on next page)
sage: f = y^2*z^7 - x^9 - x*z^8
sage: C = Curve(f)
sage: K = FractionField(R)
sage: r = 1/x
sage: C.divisor_of_function(r)  # todo: not implemented !!!!!
[[−1, (0, 0, 1)]]
sage: r = 1/x^3
sage: C.divisor_of_function(r)  # todo: not implemented !!!!!
[[−3, (0, 0, 1)]]

>> from sage.all import *
>>> FF = FiniteField(Integer(5))
>>> P2 = ProjectiveSpace(Integer(2), FF, names=['x','y','z'])
>>> R = P2.coordinate_ring()
>>> x, y, z = R.gens()
>>> f = y**Integer(2)*z**Integer(7) - x**Integer(9) - x*z**Integer(8)
>>> C = Curve(f)
>>> K = FractionField(R)
>>> r = Integer(1)/x
>>> C.divisor_of_function(r)  # todo: not implemented !!!!!
[[−1, (0, 0, 1)]]
>>> r = Integer(1)/x**Integer(3)
>>> C.divisor_of_function(r)  # todo: not implemented !!!!!
[[−3, (0, 0, 1)]]

excellent_position(Q)

Return a transformation of this curve into one in excellent position with respect to the point Q.

Here excellent position is defined as in [Ful1989]. A curve $C$ of degree $d$ containing the point $(0 : 0 : 1)$ with multiplicity $r$ is said to be in excellent position if none of the coordinate lines are tangent to $C$ at any of the fundamental points $(1 : 0 : 0)$, $(0 : 1 : 0)$, and $(0 : 0 : 1)$, and if the two coordinate lines containing $(0 : 0 : 1)$ intersect $C$ transversally in $d - r$ distinct non-fundamental points, and if the other coordinate line intersects $C$ transversally at $d$ distinct, non-fundamental points.

INPUT:

• $Q$ – a point on this curve.

OUTPUT:

• a scheme morphism from this curve to a curve in excellent position that is a restriction of a change of coordinates map of the projective plane.

EXAMPLES:

sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([x*y - z^2], P)
sage: Q = P([1,1,1])
sage: C.excellent_position(Q)
Scheme morphism:
From: Projective Plane Curve over Rational Field defined by x*y - z^2
To: Projective Plane Curve over Rational Field
defined by -x^2 - 3*x*y - 4*y^2 - x*z - 3*y*z
Defn: Defined on coordinates by sending (x : y : z) to
(-x + 1/2*y + 1/2*z : -1/2*y + 1/2*z : x + 1/2*y - 1/2*z)
>>> from sage.all import *
>>> P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
>>> C = Curve([x*y - z**Integer(2)], P)
>>> Q = P([Integer(1),Integer(1),Integer(1)])
>>> C.excellent_position(Q)
Scheme morphism:
  From: Projective Plane Curve over Rational Field defined by x*y - z^2
  To:  Projective Plane Curve over Rational Field
defined by -x^2 - 3*x*y - 4*y^2 - x*z - 3*y*z
Defn: Defined on coordinates by sending (x : y : z) to
  (-x + 1/2*y + 1/2*z : -1/2*y + 1/2*z : x + 1/2*y - 1/2*z)

sage: # needs sage.rings.number_field
sage: R.<a> = QQ[]

sage: K.<b> = NumberField(a**Integer(2) - Integer(3), names=('b',)); (b,) = K._first_ngens(1)

sage: P.<x,y,z> = ProjectiveSpace(K, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)

sage: C = P.curve([z**2*y^3*x^4 - y^6*x^3 - 4*z^2*y^4*x^3 - 4*z^4*y^2*x^3
.....: + 3*y^7*x^2 + 10*z^2*y^5*x^2 + 9*z^4*y^3*x^2
.....: + 5*z^6*y^2*x - 3*y^8*x - 9*z^2*y^6*x - 11*z^4*y^4*x
.....: - 7*z^6*y^2*x + 2*z^8*x + y^9 + 2*z^2*y^7 + 3*z^4*y^5
.....: + 4*z^6*y^3 + 2*z^8*y])

sage: Q = P([1,0,0])

sage: C.excellent_position(Q)
Scheme morphism:
  From: Projective Plane Curve over Number Field in b with defining polynomial a^2 - 3

is_ordinary_singularity(P)

Return whether the singular point P of this projective plane curve is an ordinary singularity.

The point P is an ordinary singularity of this curve if it is a singular point, and if the tangents of this curve at P are distinct.

INPUT:

• P – a point on this curve.

OUTPUT:

• Boolean. True or False depending on whether P is or is not an ordinary singularity of this curve, respectively. An error is raised if P is not a singular point of this curve.

EXAMPLES:

sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([y^2*z^3 - x^5], P)
sage: Q = P([0,0,1])
sage: C.is_ordinary_singularity(Q)
False
```python
>>> Q = P([Integer(0),Integer(0),Integer(1)])
>>> C.is_ordinary_singularity(Q)
False
```

```python
sage: # needs sage.rings.number_field
sage: R.<a> = QQ[]
sage: K.<b> = NumberField(a^2 - 3)
```

```python
sage: P.<x,y,z> = ProjectiveSpace(K, 2)
```

```python
sage: C = P.curve([x^2*y^3*z^4 - y^6*z^3 - 4*x^2*y^4*z^3 - 4*x^4*y^2*z^3 + 3*y^7*z^2 + 10*x^2*y^5*z^2 + 9*x^4*y^3*z^2 + 5*x^6*y*z^2 - 3*y^8*z - 9*x^2*y^6*z - 11*x^4*y^4*z - 7*x^6*y^2*z - 2*x^8*z + y^9 + 2*x^2*y^7 + 3*x^4*y^5 + 4*x^6*y^3 + 2*x^8*y])
```

```python
sage: Q = P([0,1,1])
```

```python
sage: C.is_ordinary_singularity(Q)
True
```

```python

```
is_singular (P=None)

Return whether this curve is singular or not, or if a point P is provided, whether P is a singular point of this curve.

INPUT:

- P – (default: None) a point on this curve

OUTPUT:

If no point P is provided, return True or False depending on whether this curve is singular or not. If a point P is provided, return True or False depending on whether P is or is not a singular point of this curve.

EXAMPLES:

Over Q:

```
sage: F = QQ
sage: P2.<X,Y,Z> = ProjectiveSpace(F, 2)
sage: C = Curve(X^3 - Y^2*Z)
sage: C.is_singular()
True
```

```
>>> from sage.all import *
>>> F = QQ
>>> P2 = ProjectiveSpace(F, Integer(2), names=('X', 'Y', 'Z',)); (X, Y, Z,) = P2._first_ngens(3)
>>> C = Curve(X**Integer(3) - Y**Integer(2)*Z)
>>> C.is_singular()
True
```

Over a finite field:

```
sage: F = GF(19)
sage: P2.<X,Y,Z> = ProjectiveSpace(F, 2)
sage: C = Curve(X^3 + Y^3 + Z^3)
sage: C.is_singular()
False
sage: D = Curve(X^4 - X*Z^3)
sage: D.is_singular()
True
sage: E = Curve(X^5 + 19*Y^5 + Z^5)
sage: E.is_singular()
True
sage: E = Curve(X^5 + 9*Y^5 + Z^5)
sage: E.is_singular()
False
```
>>> from sage.all import *
>>> F = GF(19)
>>> P2 = ProjectiveSpace(F, Integer(2), names=('X', 'Y', 'Z',)); (X, Y, Z,) = P2._first_ngens(3)
>>> C = Curve(X**Integer(3) + Y**Integer(3) + Z**Integer(3))
>>> C.is_singular()
False
>>> D = Curve(X**Integer(4) - X*Z**Integer(3))
>>> D.is_singular()
True
>>> E = Curve(X**Integer(5) + Integer(19)*Y**Integer(5) + Z**Integer(5))
>>> E.is_singular()
True
>>> E = Curve(X**Integer(5) + Integer(9)*Y**Integer(5) + Z**Integer(5))
>>> E.is_singular()
False
Over C:

```python
sage: # needs sage.rings.function_field
sage: F = CC
sage: P2.<X,Y,Z> = ProjectiveSpace(F, 2)
sage: C = Curve(X)
sage: C.is_singular()
False
sage: D = Curve(Y**Integer(2)*Z - X**Integer(3))
>>> D.is_singular()
True
sage: E = Curve(Y**Integer(2)*Z - X**Integer(3) + Z**Integer(3))
>>> E.is_singular()
False
```

Showing that Issue #12187 is fixed:

```python
sage: F.<X,Y,Z> = GF(2)[]
sage: G = Curve(X**2 + Y*Z)
sage: G.is_singular()
False
```

(continues on next page)
is_transverse \( (C, P) \)

Return whether the intersection of this curve with the curve \( C \) at the point \( P \) is transverse.

The intersection at \( P \) is transverse if \( P \) is a nonsingular point of both curves, and if the tangents of the curves at \( P \) are distinct.

**INPUT:**

- \( C \) – a curve in the ambient space of this curve.
- \( P \) – a point in the intersection of both curves.

**OUTPUT:** A boolean.

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([x^2 - y^2], P)
sage: D = Curve([x - y], P)
sage: Q = P([1,1,0])
sage: C.is_transverse(D, Q)
False
```

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([x^2 - y^2], P)
sage: D = Curve([x - y], P)
sage: Q = P([1,1,0])
sage: C.is_transverse(D, Q)
False
```
local_coordinates$(pt, n)$

Return local coordinates to precision $n$ at the given point.

Behaviour is flaky - some choices of $n$ are worse than others.

**INPUT:**

- **pt** – a rational point on $X$ which is not a point of ramification
  for the projection $(x, y) \to x$.
- **n** – the number of terms desired

**OUTPUT:** $x = x0 + t, y = y0 +$ power series in $t$

**EXAMPLES:**

```
sage: FF = FiniteField(5)
sage: P2 = ProjectiveSpace(2, FF, names=['x', 'y', 'z'])
sage: x, y, z = P2.coordinate_ring().gens()  
sage: C = Curve(y^2*z^7 - x^9 - x*z^8)
sage: pt = C([2, 3, 1])  
sage: C.local_coordinates(pt, 9)       # todo: not implemented !!!!
[2 + t, 
 3 + 3*t^2 + t^3 + 3*t^4 + 3*t^6 + 3*t^7 + t^8 + 2*t^9 + 3*t^11 + 3*t^12]
```
>>> from sage.all import *
>>> FF = FiniteField(Integer(5))
>>> P2 = ProjectiveSpace(Integer(2), FF, names=['x', 'y', 'z'])
>>> x, y, z = P2.coordinate_ring().gens()
>>> C = Curve(y**Integer(2)*z**Integer(7) - x**Integer(9) - x*z**Integer(8))
>>> pt = C([Integer(2), Integer(3), Integer(1)])
>>> C.local_coordinates(pt, Integer(9))  # todo: not implemented !!!!
[2 + t,
 3 + 3*t^2 + t^3 + 3*t^4 + 3*t^6 + 3*t^7 + t^8 + 2*t^9 + 3*t^11 + 3*t^12]

ordinary_model()

Return a birational map from this curve to a plane curve with only ordinary singularities.

Currently only implemented over number fields. If not all of the coordinates of the non-ordinary singularities of this curve are contained in its base field, then the domain and codomain of the map returned will be defined over an extension. This curve must be irreducible.

OUTPUT:

• a scheme morphism from this curve to a curve with only ordinary singularities that defines a birational map between the two curves.

EXAMPLES:

sage: # needs sage.rings.number_field
sage: set_verbose(-1)

sage: K = QuadraticField(3)

sage: P.<x,y,z> = ProjectiveSpace(K, 2)

sage: C = Curve([x^5 - K.0*y*z^4], P)

sage: C.ordinary_model()

\texttt{plot (*args, **kwds)}

Plot the real points of an affine patch of this projective plane curve.

INPUT:

\begin{itemize}
\item \texttt{self} – an affine plane curve
\item \texttt{patch} – (optional) the affine patch to be plotted; if not specified, the patch corresponding to the last projective coordinate being nonzero
\item \texttt{*args} – optional tuples (variable, minimum, maximum) for plotting dimensions
\item \texttt{**kwds} – optional keyword arguments passed on to \texttt{implicit_plot}
\end{itemize}

EXAMPLES:

A cuspidal curve:

\texttt{sage: R.<x, y, z> = \texttt{QQ}[x, y, z]}
\texttt{sage: C = Curve(x^3 - y^2*z)}
\texttt{sage: C.plot()}

\texttt{# needs sage.plot}

Graphics object consisting of 1 graphics primitive

\texttt{from sage.all import *}
\texttt{R = \texttt{QQ}['x, y, z']; (x, y, z,) = R._first_ngens(3)}
\texttt{C = Curve(x**Integer(3) - y**Integer(2)*z)}
\texttt{C.plot()}

\texttt{# needs sage.plot}

Graphics object consisting of 1 graphics primitive

The other affine patches of the same curve:

\texttt{sage: # needs sage.plot}
\texttt{sage: C.plot(patch=0)}

Graphics object consisting of 1 graphics primitive

\texttt{sage: C.plot(patch=1)}

Graphics object consisting of 1 graphics primitive

\texttt{from sage.all import *}
\texttt{C.plot(patch=Integer(0))}

Graphics object consisting of 1 graphics primitive
\texttt{C.plot(patch=Integer(1))}

Graphics object consisting of 1 graphics primitive

An elliptic curve:
A hyperelliptic curve:

```
sage: # needs sage.plot
sage: P.<x> = QQ[]
sage: f = 4*x^5 - 30*x^3 + 45*x - 22
sage: C = HyperellipticCurve(f)
sage: C.plot()
Graphics object consisting of 1 graphics primitive
```

The `quadratic_transform()` method

Return a birational map from this curve to the proper transform of this curve with respect to the standard Cremona transformation.

The standard Cremona transformation is the birational automorphism of $\mathbb{P}^2$ defined $(x : y : z) \mapsto (yz : xz : xy)$.

**OUTPUT:**
- a scheme morphism representing the restriction of the standard Cremona transformation from this curve to the proper transform.
EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x^3*y - z^4 - z^2*x^2, P)
sage: C.quadratic_transform()
Scheme morphism:
  From: Projective Plane Curve over Rational Field
defined by x^3*y - x^2*z^2 - z^4
  To:  Projective Plane Curve over Rational Field
defined by -x^3*y - x*y*z^2 + z^4
  Defn: Defined on coordinates by sending (x : y : z) to
          (y*z : x*z : x*y)
```

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(17), 2)
sage: C = P.curve([y^7*z^2 - 16*x^9 + x*y*z^7 + 2*z^9])
sage: C.quadratic_transform()
Scheme morphism:
  From: Projective Plane Curve over Finite Field of size 17
defined by x^9 + y^7*z^2 + x*y*z^7 + 2*z^9
  To:  Projective Plane Curve over Finite Field of size 17
defined by 2*x^9*y^7 + x^8*y^6*z^2 + x^9*z^7 + y^7*z^9
  Defn: Defined on coordinates by sending (x : y : z) to
          (y*z : x*z : x*y)
```

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
>>> C = Curve(x**Integer(3)*y - z**Integer(4) - z**Integer(2)*x**Integer(2), P)
>>> C.quadratic_transform()
Scheme morphism:
  From: Projective Plane Curve over Rational Field
defined by x^3*y - x^2*z^2 - z^4
  To:  Projective Plane Curve over Rational Field
defined by -x^3*y - x*y*z^2 + z^4
  Defn: Defined on coordinates by sending (x : y : z) to
          (y*z : x*z : x*y)
```

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(17), 2)
sage: C = P.curve([y**Integer(7)*z**Integer(2) - Integer(16)*x**Integer(9) + x*y*z**Integer(7) + Integer(2)*z**Integer(9)])
sage: C.quadratic_transform()
Scheme morphism:
  From: Projective Plane Curve over Finite Field of size 17
defined by x^9 + y^7*z^2 + x*y*z^7 + 2*z^9
  To:  Projective Plane Curve over Finite Field of size 17
defined by 2*x^9*y^7 + x^8*y^6*z^2 + x^9*z^7 + y^7*z^9
  Defn: Defined on coordinates by sending (x : y : z) to
          (y*z : x*z : x*y)
```

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(GF(Integer(17)), Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
>>> C = P.curve([y**Integer(7)*z**Integer(2) - Integer(16)*x**Integer(9) + x*y*z**Integer(7) + Integer(2)*z**Integer(9)])
>>> C.quadratic_transform()
Scheme morphism:
  From: Projective Plane Curve over Finite Field of size 17
defined by x^9 + y^7*z^2 + x*y*z^7 + 2*z^9
  To:  Projective Plane Curve over Finite Field of size 17
defined by 2*x^9*y^7 + x^8*y^6*z^2 + x^9*z^7 + y^7*z^9
  Defn: Defined on coordinates by sending (x : y : z) to
          (y*z : x*z : x*y)
```

`tangents (P, factor=True)`

Return the tangents of this projective plane curve at the point \( P \).

These are found by homogenizing the tangents of an affine patch of this curve containing \( P \). The point \( P \) must be a point on this curve.
INPUT:

- \( P \) – a point on this curve.
- \( \text{factor} \) – (default: True) whether to attempt computing the polynomials of the individual tangent lines over the base field of this curve, or to just return the polynomial corresponding to the union of the tangent lines (which requires fewer computations).

OUTPUT:

A list of polynomials in the coordinate ring of the ambient space of this curve.

EXAMPLES:

```python
sage: # needs sage.rings.number_field
sage: set_verbose(-1)

sage: P.<x,y,z> = ProjectiveSpace(QQbar, 2)

sage: C = Curve([x^3*y + 2*x^2*y^2 + x*y^3 + x^3*z
       + 7*x^2*y*z + 14*x*y^2*z + 9*y^3*z], P)

sage: Q = P([0,0,1])

sage: C.tangents(Q)

[4.147899035704788?*y,
 x + (1.426050482147607? + 0.3689894074818041?*I)*y,
 x + (1.426050482147607? - 0.3689894074818041?*I)*y]

sage: C.tangents(Q, factor=False)

[6*x^3 + 42*x^2*y + 84*x*y^2 + 54*y^3]

sage: P.<x,y,z> = ProjectiveSpace(QQbar, 2)

sage: C = Curve([x*y^3*z^4 - y^6*z^3 - 4*x^2*y^4*z^3 - 4*x^4*y^2*z^3
       + 3*y^7*z^2 + 10*x^2*y^5*z^2 + 9*x^4*y^3*z^2 + 5*x^6*y*z^2
       - 3*y^8*z - 9*x^2*y^6*z - 11*x^4*y^4*z - 7*x^6*y^2*z

sage: x,y,z = PolynomialRing(GF(5), 3, 'xyz').gens()
sage: C = Curve(y^2*z^7 - x^9 - x*z^8); C
Projective Plane Curve over Finite Field of size 5
defined by -x^9 + y^2*z^7 - x*z^8
sage: C.arithmetic_genus()
28
sage: C.genus() # geometric
4

>>> from sage.all import *

P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([y^3*x - x^2*y*z - 7*z^4])
sage: C.arithmetic_genus()
3

fundamental_group()

Return a presentation of the fundamental group of the complement of self.

Note: The curve must be defined over the rationals or a number field with an embedding over \( \overline{\mathbb{Q}} \).

Note: This functionality requires the sirocco package to be installed.

EXAMPLES:

sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = P.curve(x^2*z - y^3)
sage: C.fundamental_group() # needs sirocco
Finitely presented group < x0 | x0^3 >

sage: P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z'));
(x, y, z) = P._first_ngens(3)
sage: C = Curve([y**Integer(3)*x - x**Integer(2)*y*z -
Integer(7)*z**Integer(4)])
>>> C.arithmetic_genus() 3

(continues on next page)
In the case of number fields, they need to have an embedding into the algebraic field:

```python
sage: # needs sage.rings.number_field
sage: a = QQ[x](x^2 + 5).roots(QQbar)[0][0]
sage: a
-2.236067977499790?*I
sage: F = NumberField(a.minpoly(), 'a', embedding=a)
sage: P.<x,y,z> = ProjectiveSpace(F, 2)
sage: F.inject_variables()
Defining a
sage: C = P.curve(x^2 + a * y^2)
sage: C.fundamental_group()  # needs sirocco
Finitely presented group < x0 | >
```

```
>>> from sage.all import *
```

```

(continues on next page)
riemann_surface(**kwargs)

Return the complex Riemann surface determined by this curve

OUTPUT: A RiemannSurface object.

EXAMPLES:

```python
sage: R.<x,y,z> = QQ[]
sage: C = Curve(x^3 + 3*y^3 + 5*z^3)
sage: C.riemann_surface()
Riemann surface defined by polynomial f = x^3 + 3*y^3 + 5 = 0, with 53 bits of precision
```

```python
>>> from sage.all import *
>>> R = QQ[x, y, z]; (x, y, z,) = R._first_ngens(3)
>>> C = Curve(x**Integer(3) + Integer(3)*y**Integer(3) + Integer(5)*z**Integer(3))
>>> C.riemann_surface()
Riemann surface defined by polynomial f = x^3 + 3*y^3 + 5 = 0, with 53 bits of precision
```

class sage.schemes.curves.projective_curve.ProjectivePlaneCurve_finite_field(A, f, category=None)

Bases: ProjectivePlaneCurve_field

Projective plane curves over finite fields

rational_points(algorithm='enum', sort=True)

Return the rational points on this curve.

INPUT:

- algorithm – one of
  - 'enum' – straightforward enumeration
  - 'bn' – via Singular's brnoeth package.

- sort – boolean (default: True); whether the output points should be sorted. If False, the order of the output is non-deterministic.

OUTPUT: A list of all the rational points on the curve, possibly sorted.

Note: The Brill-Noether package does not always work (i.e., the 'bn' algorithm. When it fails a Run-timeError exception is raised.

EXAMPLES:

```python
sage: x, y, z = PolynomialRing(GF(5), 3, 'xyz').gens()
sage: f = y^2*z^7 - x^9 - x^z^8
sage: C = Curve(f); C
```
### Projective Plane Curve over Finite Field of size 5

Defined by 
\[-x^9 + y^2z^7 - xz^8\]

```
from sage.all import *
F = GF(Integer(7))
P2.<X,Y,Z> = ProjectiveSpace(F, 2)
C = Curve(X^7 + 7*Y^6*Z + Z^4*X^2*Y*89)
len(C.rational_points())
```

1.5. Projective curves
```python
>>> from sage.all import *
>>> F = GF(Integer(1237))
>>> P2 = ProjectiveSpace(F, Integer(2), names=('X', 'Y', 'Z'));
>>> (X, Y, Z, ) = P2._first_ngens(3)
>>> C = Curve(X**Integer(7) + Integer(7)*Y**Integer(6)*Z +
             Z**Integer(4)*X**Integer(2)*Y*Integer(89))
>>> len(C.rational_points())
1237
```

```python
sage: # needs sage.rings.finite_rings
sage: F = GF(2^6,a)
sage: P2.<X,Y,Z> = ProjectiveSpace(F, 2)
sage: C = Curve(X^5 + 11*X*Y*Z^3 + X^2*Y^3 - 13*Y^2*Z^3)
sage: len(C.rational_points())
104
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> F = GF(Integer(2)**Integer(6),a)
>>> P2 = ProjectiveSpace(F, Integer(2), names=('X', 'Y', 'Z'));
>>> (X, Y, Z, ) = P2._first_ngens(3)
>>> C = Curve(X**Integer(5) + Integer(11)*X*Y*Z**Integer(3) +
             X**Integer(2)*Y**Integer(3) - Integer(13)*Y**Integer(2)*Z**Integer(3))
>>> len(C.rational_points())
104
```

```python
R.<x,y,z> = GF(2)[]
sage: f = x^3*y + y^3*z + x*z^3
sage: C = Curve(f); pts = C.rational_points()
sage: pts
[(0 : 0 : 1), (0 : 1 : 0), (1 : 0 : 0)]
```

```python
>>> from sage.all import *
>>> R = GF(Integer(2))['x, y, z']; (x, y, z, ) = R._first_ngens(3)
>>> f = x**Integer(3)*y + y**Integer(3)*z + x*z**Integer(3)
>>> C = Curve(f); pts = C.rational_points()
>>> pts
[(0 : 0 : 1), (0 : 1 : 0), (1 : 0 : 0)]
```

**rational_points_iterator()**

Return a generator object for the rational points on this curve.

**INPUT:**

- `self` - a projective curve

**OUTPUT:**

A generator of all the rational points on the curve defined over its base field.

**EXAMPLES:**

```python
sage: F = GF(37)
sage: P2.<X,Y,Z> = ProjectiveSpace(F, 2)
sage: C = Curve(X^7 + Y*X*Z^5*55 + Y^7*12)
sage: len(list(C.rational_points_iterator()))
37
```
```python
>>> from sage.all import *

from sage.all import *

```

```python
F = GF(Integer(37))

P2 = ProjectiveSpace(F, Integer(2), names=('X', 'Y', 'Z',)); (X, Y, Z,) = P2._first_ngens(3)

C = Curve(X**Integer(7) + Y*X*Z**Integer(5)*Integer(55) + Y**Integer(7)*Integer(12))

len(list(C.rational_points_iterator()))

37
```

```python
sage: F = GF(2)
sage: P2.<X,Y,Z> = ProjectiveSpace(F, 2)
sage: C = Curve(X*Y*Z)

Traceback (most recent call last):
riemann_roch_basis($D$)
Return a basis for the Riemann-Roch space corresponding to $D$.
This uses Singular's Brill-Noether implementation.

INPUT:
- $D$ – a divisor

OUTPUT: A list of function field elements that form a basis of the Riemann-Roch space.

EXAMPLES:

```sage
definitions:
    sage: R.<x,y,z> = GF(2)[]
sage: f = x^3*y + y^3*z + x*z^3
sage: C = Curve(f); pts = C.rational_points()
sage: D = C.divisor([ (4, pts[0]), (4, pts[2]) ])
sage: C.riemann_roch_basis(D)
[x/y, 1, z/y, z^2/y^2, z/x, z^2/(x*y)]
```

```sage
>>> from sage.all import *
>>> R = GF(Integer(2))[x, y, z]; (x, y, z,) = R._first_ngens(3)
>>> f = x**Integer(3)*y + y**Integer(3)*z + x*z**Integer(3)
>>> C = Curve(f); pts = C.rational_points()
>>> D = C.divisor([ (Integer(4), pts[Integer(0)]), (Integer(4),
                   pts[Integer(2)]) ])
>>> C.riemann_roch_basis(D)
[x/y, 1, z/y, z^2/y^2, z/x, z^2/(x*y)]
```

```sage
definitions:
    sage: R.<x,y,z> = GF(5)[]
sage: f = x^7 + y^7 + z^7
sage: C = Curve(f); pts = C.rational_points()
sage: D = C.divisor([ (3, pts[0]), (-1,pts[1]), (10, pts[5]) ])
sage: C.riemann_roch_basis(D)
[(-2*x + y)/(x + y), (-x + z)/(x + y)]
```

```sage
>>> from sage.all import *
>>> R = GF(Integer(5))[x, y, z]; (x, y, z,) = R._first_ngens(3)
>>> f = x**Integer(7) + y**Integer(7) + z**Integer(7)
>>> C = Curve(f); pts = C.rational_points()
>>> D = C.divisor([ (Integer(3), pts[Integer(0)]), (-Integer(1),
                   pts[Integer(1)]), (Integer(10), pts[Integer(5)]) ])
>>> C.riemann_roch_basis(D)
[(-2*x + y)/(x + y), (-x + z)/(x + y)]
```

**Note:** Currently this only works over prime field and divisors supported on rational points.
1.6 Rational points of curves

We can create points on projective curves:

\begin{verbatim}
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([x^3 - 2*x*z^2 - y^3, z^3 - w^3 - x*y*z], P)
sage: Q = C([1,1,0,0])
sage: Q.parent()
Set of rational points of Projective Curve over Rational Field
defined by x^3 - y^3 - 2*x*z^2, -x*y*z + z^3 - w^3
\end{verbatim}

or on affine curves:

\begin{verbatim}
sage: A.<x,y> = AffineSpace(GF(23), 2)
sage: C = Curve([y - y^4 + 17*x^2 - 2*x + 22], A)
sage: Q = C([22,21])
sage: Q.parent()
Set of rational points of Affine Plane Curve over Finite Field of size 23
defined by -y^4 - 6*x^2 - 2*x + y - 1
\end{verbatim}

AUTHORS:

• Grayson Jorgenson (2016-6): initial version

\begin{verbatim}
class sage.schemes.curves.point.AffineCurvePoint_field(X, v, check=True)
    Bases: SchemeMorphism_point_affine_field
    is_singular()
       Return whether this point is a singular point of the affine curve it is on.

EXAMPLES:
\end{verbatim}
>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> K = QuadraticField(-Integer(1))
>>> A = AffineSpace(K, Integer(3), names=('x', 'y', 'z'))
>>> (x, y, z) = A._first_ngens(3)
>>> C = Curve([(x**Integer(4) + Integer(2)*z + Integer(2))*y, z - y + Integer(1)])
>>> Q1 = C([Integer(0), Integer(0), -Integer(1)])
>>> Q1.is_singular()
True
>>> Q2 = C([-K.gen(), Integer(0), -Integer(1)])
>>> Q2.is_singular()
False

1.6. Rational points of curves 139
is_transverse(D)

Return whether the intersection of the curve D at this point with the curve this point is on is transverse or not.

INPUT:

• D – a curve in the same ambient space as the curve this point is on.

EXAMPLES:

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([y - x^2], A)
sage: D = Curve([y], A)
sage: Q = C([0,0])
sage: Q.is_transverse(D)
False

sage: R.<a> = QQ[]
sage: K.<b> = NumberField(a^2 - 2)
sage: A.<x,y> = AffineSpace(K, 2)
sage: C = Curve([y^2 + x^2 - 1], A)
sage: D = Curve([y - x], A)
sage: Q = C([-1/2*b, -1/2*b])
sage: Q.is_transverse(D)
True

(continues on next page)
>>> Q.is_transverse(D)
True

**multiplicity()**

Return the multiplicity of this point with respect to the affine curve it is on.

**EXAMPLES:**

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = A.curve((2*x^7 - 3*x^6*y + x^5*y^2 + 31*x^6 - 40*x^5*y +
.....: 13*x^4*y^2 - x^3*y^3 + 207*x^5 - 228*x^4*y + 70*x^3*y^2 - 7*x^2*y^3
.....: + 775*x^4 - 713*x^3*y + 193*x^2*y^2 - 19*x*y^3 + y^4 + 1764*x^3 -
.....: 1293*x^2*y + 277*x*y^2 - 22*y^3 + 2451*x^3 - 1297*x*y + 172*y^2 +
.....: + 1935*x - 570*y + 675))
sage: Q = C([-2,1])
sage: Q.multiplicity()
4
```

```
>>> from sage.all import *
```  

```
A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_
˓→ngens(2)
>>> C = A.curve([Integer(2)*x**Integer(7) - Integer(3)*x**Integer(6)*y +␣
˓→Integer(13)*x**Integer(4)*y**Integer(2) + Integer(207)*x**Integer(5)*y +␣
˓→Integer(70)*x**Integer(3)*y**Integer(2) - Integer(7)*x**Integer(2)*y**Integer(3)
˓→+ Integer(775)*x**Integer(4) - Integer(713)*x**Integer(3)*y +␣
˓→Integer(193)*x**Integer(2)*y**Integer(2) - Integer(19)*x*y**Integer(3) +␣
˓→y**Integer(4) + Integer(1764)*x**Integer(3) -
˓→Integer(1293)*x**Integer(2)*y + Integer(277)*x*y**Integer(2) -␣
˓→Integer(22)*y**Integer(3) + Integer(2451)*x**Integer(2)*y - Integer(1297)*x*y␣
˓→+ Integer(172)*y**Integer(2) +
˓→Integer(1935)*x - Integer(570)*y + Integer(675))
>>> Q = C([-Integer(2),Integer(1)])
>>> Q.multiplicity()
4
```

**tangents()**

Return the tangents at this point of the affine plane curve this point is on.

**OUTPUT:** a list of polynomials in the coordinate ring of the ambient space of the curve this point is on.

**EXAMPLES:**

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = A.curve((x^5 - x^3*y^2 + 5*x^4 - x^3*y - 3*x^2*y^2 +
.....: x*y^3 + 10*x^3 - 3*x^2*y + y^3 + 10*x^2 - 3*x*y - y^2 +
.....: 5*x - y + 1))
sage: Q = C([-1,0])
sage: Q.tangents()
[y, x + 1, x - y + 1, x + y + 1]
```

```
>>> from sage.all import *
```  

```
A = AffineSpace(QQ, Integer(2), names=('x', 'y',)); (x, y,) = A._first_

```

```
class sage.schemes.curves.point.AffinePlaneCurvePointFiniteField(X, v, check=True)

Bases: AffinePlaneCurvePointField, SchemeMorphism_point_affine_finite_field

Point of an affine plane curve over a finite field.

class sage.schemes.curves.point.IntegralAffineCurvePoint(X, v, check=True)

Bases: AffineCurvePointField

Point of an integral affine curve.

closed_point()

Return the closed point that corresponds to this rational point.

EXAMPLES:

```
sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(8), 2)
sage: C = Curve(x^5 + y^5 + x*y + 1)
sage: p = C([1,1])
sage: p.closed_point()
Point (x + 1, y + 1)
```

place()

Return a place on this point.

EXAMPLES:

```
sage: A.<x,y> = AffineSpace(GF(2), 2)
sage: C = Curve(x^5 + y^5 + x*y + 1)
sage: p = C([-1,-1])
sage: p = p.closed_point()
Point (x + 1, y + 1)
```

(continues on next page)
Problem: Given a curve defined by a polynomial equation, find all places at which the curve is defined.

Solution:

```python
from sage.all import *

A = AffineSpace(GF(Integer(2)), Integer(2), names=('x', 'y'),); (x, y,)
C = Curve(x**Integer(5) + y**Integer(5) + x*y + Integer(1))
p = C(-Integer(1),-Integer(1))
p
p.closed_point()
_.place()
```

Result:

```
(1, 1)
Point (x + 1, y + 1)
Place (x + 1, (1/(x^5 + 1))*y^4 + ((x^5 + x^4 + 1)/(x^5 + 1))*y^3
+ ((x^5 + x^3 + 1)/(x^5 + 1))*y^2 + (x^2/(x^5 + 1))*y)
```

---

**class sage.schemes.curves.point.IntegralAffineCurvePoint_finite_field**($X$, $v$, check=True)

**Bases:** IntegralAffineCurvePoint

Point of an integral affine curve over a finite field.

**class sage.schemes.curves.point.IntegralAffinePlaneCurvePoint**($X$, $v$, check=True)

**Bases:** IntegralAffineCurvePoint, AffinePlaneCurvePoint_field

---

1.6. Rational points of curves
Point of an integral affine plane curve.

```python
class sage.schemes.curves.point.IntegralAffinePlaneCurvePoint_finite_field(X, v, check=True):
    Bases: AffinePlaneCurvePoint_finite_field, IntegralAffineCurvePoint_finite_field

Point of an integral affine plane curve over a finite field.

```python
class sage.schemes.curves.point.IntegralProjectiveCurvePoint(X, v, check=True):
    Bases: ProjectiveCurvePoint_field

closed_point()
    Return the closed point corresponding to this rational point.

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(17), 2)
sage: C = Curve([x^4 - 16*y^3*z], P)
sage: C.singular_points()
[(0 : 0 : 1)]
sage: p = _[0]
sage: p.closed_point()
Point (x, y)
```

place()
    Return a place on this point.

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(17), 2)
sage: C = Curve([x^4 - 16*y^3*z], P)
sage: C.singular_points()
[(0 : 0 : 1)]
sage: p = _[0]
sage: p.place()
Place (y)
```
places()

Return all places on this point.

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(17), 2)
sage: C = Curve([x^4 - 16*y^3*z], P)
sage: C.singular_points()
[(0 : 0 : 1)]
sage: p = _[0]
sage: p.places()
[Place (y)]
```

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(GF(Integer(17)), Integer(2), names=(x, y, z,));
   (x, y, z,) = P._first_ngens(3)
>>> C = Curve([x**Integer(4) - Integer(16)*y**Integer(3)*z], P)
>>> C.singular_points()
[(0 : 0 : 1)]
>>> p = _[Integer(0)]
>>> p.places()
[Place (y)]
```

class sage.schemes.curves.point.IntegralProjectiveCurvePoint_finite_field(X, v, check=True)

Bases: IntegralProjectiveCurvePoint

Point of an integral projective curve over a finite field.

class sage.schemes.curves.point.IntegralProjectivePlaneCurvePoint_finite_field(X, v, check=True)

Bases: IntegralProjectiveCurvePoint, ProjectivePlaneCurvePoint_field

Point of an integral projective plane curve over a field.

class sage.schemes.curves.point.IntegralProjectivePlaneCurvePoint_finite_field(X, v, check=True)

Bases: ProjectivePlaneCurvePoint_finite_field, IntegralProjectiveCurvePoint_finite_field

Point of an integral projective plane curve over a finite field.

class sage.schemes.curves.point.ProjectiveCurvePoint_field(X, v, check=True)

Bases: SchemeMorphism_point_projective_field

Point of a projective curve over a field.

is_singular()

Return whether this point is a singular point of the projective curve it is on.

EXAMPLES:

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: C = Curve([x^2 - y^2, z - w], P)
sage: Q1 = C([0,0,1,1])
sage: Q1.is_singular()
True
(continues on next page)```
sage: Q2 = C([1,1,1,1])
sage: Q2.is_singular()
False

```python
>>> from sage.all import *
>>>
P = ProjectiveSpace(QQ, Integer(4), names=('x', 'y', 'z', 'w',)); (x, y, z, w,) = P._first_ngens(4)
>>> C = Curve([x**Integer(2) - y**Integer(2), z - w], P)
>>> Q1 = C([Integer(0),Integer(0),Integer(1),Integer(1)])
>>> Q1.is_singular()
True
>>> Q2 = C([Integer(1),Integer(1),Integer(1),Integer(1)])
>>> Q2.is_singular()
False
```

class sage.schemes.curves.point.ProjectivePlaneCurvePoint_field(X, v, check=True)

Point of a projective plane curve over a field.

**is_ordinary_singularity()**

Return whether this point is an ordinary singularity of the projective plane curve it is on.

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([z^6 - x^6 - x^3*z^3 - x^3*y^3])
sage: Q = C([0,1,0])
sage: Q.is_ordinary_singularity()
False
```

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
>>> C = Curve([z**Integer(6) - x**Integer(6) - x**Integer(3)*z**Integer(3) - x**Integer(3)*y**Integer(3) - z**Integer(3)*y**Integer(3)], P)
>>> Q = C([Integer(0),Integer(1),Integer(0)])
>>> Q.is_ordinary_singularity()
False
```

```python
sage: # needs sage.rings.number_field
sage: R.<a> = QQ[]
sage: K.<b> = NumberField(a^2 - 3)
sage: P.<x,y,z> = ProjectiveSpace(K, 2)
sage: C = P.curve([x^2*y^3*z^4 - y^6*z^3 - 4*x^2*y^4*z^3 - 4*x^4*y^2*z^3 + 3*y^7*z^2 + 9*x^4*y^3*z^2 + 3*y^8*z - 9*x^2*y^6*z - 11*x^4*y^4*z - 7*x^6*y^2*z - 2*x^8*z + y^9 + 2*x^2*y^7 + 3*x^4*y^5 + 4*x^6*y^3 + 2*x^8*y])
sage: Q = C([-1/2, 1/2, 1])
sage: Q.is_ordinary_singularity()
True
```

```python
>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> R = QQ['a']; (a,) = R._first_ngens(1)
```
is_transverse($D$)

Return whether the intersection of the curve $D$ at this point with the curve this point is on is transverse or not.

INPUT:

- $D$ – a curve in the same ambient space as the curve this point is on

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([x^2 - 2*y^2 - 2*z^2], P)
sage: D = Curve([y - z], P)
sage: Q = C([2,1,1])
sage: Q.is_transverse(D)
True
```

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(17), 2)
sage: C = Curve([x^4 - 16*y^3*z], P)
sage: D = Curve([y^2 - z*x], P)
sage: Q = C([0,0,1])
sage: Q.is_transverse(D)
False
```
```python
>>> from sage.all import *
>>> P = ProjectiveSpace(GF(Integer(17)), Integer(2), names=('x', 'y', 'z',));
(x, y, z,) = P._first_ngens(3)
>>> C = Curve([x**Integer(4) - Integer(16)*y**Integer(3)*z], P)
>>> D = Curve([y**Integer(2) - z*x], P)
>>> Q = C([Integer(0),Integer(0),Integer(1)])
>>> Q.is_transverse(D)
False
```

**multiplicity()**

Return the multiplicity of this point with respect to the projective curve it is on.

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(17), 2)
sage: C = Curve([y^3*z - 16*x^4], P)
sage: Q = C([0,0,1])
sage: Q.multiplicity()
3
```

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(GF(Integer(17)), Integer(2), names=('x', 'y', 'z',));
(x, y, z,) = P._first_ngens(3)
>>> C = Curve([y**Integer(3)*z - Integer(16)*x**Integer(4)], P)
>>> Q = C([Integer(0),Integer(0),Integer(1)])
>>> Q.multiplicity()
3
```

**tangents()**

Return the tangents at this point of the projective plane curve this point is on.

**OUTPUT:**

A list of polynomials in the coordinate ring of the ambient space of the curve this point is on.

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: C = Curve([y^2*z^3 - x^5 + 18*y*x*z^3])
sage: Q = C([0,0,1])
sage: Q.tangents()
[y, 18*x + y]
```

```python
>>> from sage.all import *
>>> P = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) =
P._first_ngens(3)
>>> C = Curve([y**Integer(2)*z**Integer(3) - x**Integer(5) +
Integer(18)*y*x*z**Integer(3)])
>>> Q = C([Integer(0),Integer(0),Integer(1)])
>>> Q.tangents()
[y, 18*x + y]
```

class sage.schemes.curves.point.ProjectivePlaneCurvePoint_finite_field(X, v, check=True)

**Bases:** ProjectivePlaneCurvePoint_field, SchemeMorphism_point_projective_finite_field

Point of a projective plane curve over a finite field.
1.7 Closed points of integral curves

A rational point of a curve in Sage is represented by its coordinates. If the curve is defined over finite field and integral, that is reduced and irreducible, then it is empowered by the global function field machinery of Sage. Thus closed points of the curve are computable, as represented by maximal ideals of the coordinate ring of the ambient space.

EXAMPLES:

```python
sage: F.<a> = GF(2)
sage: P.<x,y> = AffineSpace(F, 2)
sage: C = Curve(y^2 + y - x^3)
sage: C.closed_points()
[Point (x, y), Point (x, y + 1)]
sage: C.closed_points(2)
[Point (y^2 + y + 1, x + 1),
 Point (y^2 + y + 1, x + y),
 Point (y^2 + y + 1, x + y + 1)]
sage: C.closed_points(3)
[Point (x^2 + x + y, x*y + 1, y^2 + x + 1),
 Point (x^2 + x + y + 1, x*y + x + 1, y^2 + x)]

>>> from sage.all import *

>>> F = GF(Integer(2), names=('a',)); (a,) = F._first_ngens(1)
>>> P = AffineSpace(F, Integer(2), names=('x', 'y',)); (x, y,) = P._first_ngens(2)
>>> C = Curve(y**Integer(2) + y - x**Integer(3))
>>> C.closed_points()
[Point (x, y), Point (x, y + 1)]
>>> C.closed_points(Integer(2))
[Point (y^2 + y*z + z^2, x + y + z)]
>>> C.closed_points(Integer(3))
[Point (y^3 + y^2*z + z^3, x + y + z)]
```

Closed points of projective curves are represented by homogeneous maximal ideals:

```python
sage: F.<a> = GF(2)
sage: P.<x,y,z> = ProjectiveSpace(F, 2)
sage: C = Curve(x^3*y + y^3*z + x*z^3)
sage: C.closed_points()
[Point (x, z), Point (x, y), Point (y, z)]
sage: C.closed_points(2)
[Point (y^2 + y*z + z^2, x + y + z)]
sage: C.closed_points(3)
[Point (x^2 + x*y + x^2 + y^2 + z^2, x*y + x*z + y*z),
 Point (x^2 + y*z + z^2, x*y + x*z + y*z),
 Point (x^2 + y*z + z^2, x*y + x*z + y*z, y^2 + x*z + y*z + z^2),
 Point (x^2 + y*z + z^2, x*y + x*z + y*z, y^2 + x*z + y*z + z^2),
 Point (x^2 + y*z + z^2, x*y + x*z + y*z, y^2 + x*z + y*z + z^2),
 Point (x^2 + y*z + z^2, x*y + x*z + y*z, y^2 + x*z + y*z + z^2),
 Point (x^2 + y*z + z^2, x*y + x*z + y*z, y^2 + x*z + y*z + z^2)]

>>> from sage.all import *

>>> F = GF(Integer(2), names=('a',)); (a,) = F._first_ngens(1)
>>> P = ProjectiveSpace(F, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
```

(continues on next page)
C = Curve(x**Integer(3)*y + y**Integer(3)*z + x*z**Integer(3))
>>> C.closed_points()
[Point (x, z), Point (x, y), Point (y, z)]
>>> C.closed_points(Integer(2))
[Point (y**2 + y*z + z**2, x + y + z)]
>>> C.closed_points(Integer(3))
[Point (y^3 + y^2*z + z^3, x + y),
 Point (y^3 + y^2*z^2 + z^3, x + z),
 Point (x^2 + x*z + y*z + z^2, x*y + x*z + z^2, y^2 + x*z),
 Point (x^2 + y*z, x*y + x*z + z^2, y^2 + x*z + y*z),
 Point (x^3 + x*z^2 + z^3, y + z),
 Point (x^2 + y*z + z^2, x*y + x*z + y*z, y^2 + x*z + y*z + z^2),
 Point (x^2 + y*z + z^2, x*y + z^2, y^2 + x*z + y*z)]

Rational points are easily converted to closed points and vice versa if the closed point is of degree one:

```python
sage: F.<a> = GF(2)
sage: P.<x,y,z> = ProjectiveSpace(F, 2)
sage: C = Curve(x^3*y + y^3*z + x*z^3)
sage: p1, p2, p3 = C.closed_points()
sage: p1.rational_point()
(0 : 1 : 0)
sage: p2.rational_point()
(0 : 0 : 1)
sage: p3.rational_point()
(1 : 0 : 0)
sage: _.closed_point()
Point (y, z)
sage: _ == p3
True
```

AUTHORS:

- Kwankyu Lee (2019-03): initial version

```python
>>> from sage.all import *
>>> F = GF(Integer(2), names=('a',)); (a,) = F._first_ngens(1)
>>> P = ProjectiveSpace(F, Integer(2), names=('x', 'y', 'z',)); (x, y, z) = P._first_ngens(3)
>>> C = Curve(x**Integer(3)*y + y**Integer(3)*z + x*z**Integer(3))
>>> p1, p2, p3 = C.closed_points()
>>> p1.rational_point()
(0 : 1 : 0)
>>> p2.rational_point()
(0 : 0 : 1)
>>> p3.rational_point()
(1 : 0 : 0)
>>> _.closed_point()
Point (y, z)
>>> _ == p3
True
```

```python
class sage.schemes.curves.closed_point.CurveClosedPoint(S, P, check=False)
    Bases: SchemeTopologicalPoint
    Base class of closed points of curves.
```
class sage.schemes.curves.closed_point.IntegralAffineCurveClosedPoint(curve, prime_ideal, degree)

Bases: IntegralCurveClosedPoint

Closed points of affine curves.

projective (i=0)

Return the point in the projective closure of the curve, of which this curve is the i-th affine patch.

INPUT:

• i – an integer

EXAMPLES:

```python
sage: F.<a> = GF(2)
sage: A.<x,y> = AffineSpace(F, 2)
sage: C = Curve(y^2 + y - x^3, A)
sage: p1, p2 = C.closed_points()
sage: p1
Point (x, y)
sage: p2
Point (x, y + 1)
sage: p1.projective()
Point (x1, x2)
sage: p2.projective(0)
Point (x1, x0 + x2)
sage: p2.projective(1)
Point (x0, x1 + x2)
sage: p2.projective(2)
Point (x0, x1 + x2)
```

rational_point()

Return the rational point if this closed point is of degree 1.

EXAMPLES:

```python
sage: # needs sage.rings.finite_rings
sage: A.<x,y> = AffineSpace(GF(3^2), 2)
```

(continues on next page)
sage: C = Curve(y^2 - x^5 - x^4 - 2*x^3 - 2*x - 2)
sage: C.closed_points()
[Point (x, y + (z2 + 1)),
 Point (x, y + (-z2 - 1)),
 Point (x + (z2 + 1), y + (z2 - 1)),

>>> set(_) == set(C.rational_points())
True
class sage.schemes.curves.closed_point.IntegralCurveClosedPoint (curve, prime_ideal, degree)

Bases: CurveClosedPoint

Closed points of integral curves.

INPUT:

- curve – the curve to which the closed point belongs
- prime_ideal – a prime ideal
- degree – degree of the closed point

EXAMPLES:

```python
sage: # needs sage.rings.finite_rings
sage: F.<a> = GF(4)
sage: P.<x,y> = AffineSpace(F, 2)
sage: C = Curve(y^2 + y - x^3)
sage: C.closed_points()
[Point (x, y),
  Point (x, y + 1),
  Point (x + a, y + a),
  Point (x + a, y + (a + 1)),
  Point (x + (a + 1), y + a),
  Point (x + (a + 1), y + (a + 1)),
  Point (x + 1, y + a),
  Point (x + 1, y + (a + 1))]
```

```python
>>> from sage.all import *

>>> # needs sage.rings.finite_rings

>>> F = GF(Integer(4), names=(a,)); (a,) = F._first_ngens(1)

>>> P = AffineSpace(F, Integer(2), names=(x, y,)); (x, y,) = P._first_ngens(2)

>>> C = Curve(y**Integer(2) + y - x**Integer(3))

>>> C.closed_points()
[Point (x, y),
  Point (x, y + 1),
  Point (x + a, y + a),
  Point (x + a, y + (a + 1)),
  Point (x + (a + 1), y + a),
  Point (x + (a + 1), y + (a + 1)),
  Point (x + 1, y + a),
  Point (x + 1, y + (a + 1))]
```

curve()

Return the curve to which this point belongs.

EXAMPLES:

```python
sage: # needs sage.rings.finite_rings
sage: F.<a> = GF(4)
sage: P.<x,y> = AffineSpace(F, 2)
sage: C = Curve(y^2 + y - x^3)
sage: pts = C.closed_points()
sage: p = pts[0]
sage: p.curve()
Affine Plane Curve over Finite Field in a of size 2^2 defined by x^3 + y^2 + y
```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> F = GF(Integer(4), names=('a',)); (a,) = F._first_ngens(1)
>>> P = AffineSpace(F, Integer(2), names=('x', 'y')); (x, y,) = P._first_ngens(2)
>>> C = Curve(y**Integer(2) + y - x**Integer(3))
>>> pts = C.closed_points()
>>> p = pts[Integer(0)]
>>> p.curve()
Affine Plane Curve over Finite Field in a of size 2^2 defined by x^3 + y^2 + y

degree()
Return the degree of the point.

EXAMPLES:

sage: # needs sage.rings.finite_rings
sage: F.<a> = GF(4)
sage: P.<x,y> = AffineSpace(F, 2)
sage: C = Curve(y^2 + y - x^3)
sage: pts = C.closed_points()
sage: p = pts[0]
sage: p.degree()
1

place()
Return a place on this closed point.
If there are more than one, arbitrary one is chosen.

EXAMPLES:

sage: # needs sage.rings.finite_rings
sage: F.<a> = GF(4)
sage: P.<x,y> = AffineSpace(F, 2)
sage: C = Curve(y^2 + y - x^3)
sage: pts = C.closed_points()
sage: p = pts[0]
sage: p.place()
Place (x, y)
```python
>>> C = Curve(y**Integer(2) + y - x**Integer(3))
>>> pts = C.closed_points()
>>> p = pts[Integer(0)]
>>> p.place()
Place (x, y)
```

**places()**

Return all places on this closed point.

**EXAMPLES:**

```python
sage: # needs sage.rings.finite_rings
sage: F.<a> = GF(4)
sage: P.<x,y> = AffineSpace(F, 2)
sage: C = Curve(y^2 + y - x^3)
sage: pts = C.closed_points()
sage: p = pts[0]
sage: p.places()
[Place (x, y)]
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> F = GF(Integer(4), names=(a,)); (a,) = F._first_ngens(1)
>>> P = AffineSpace(F, Integer(2), names=(x, y,)); (x, y,) = P._first_˓→ngens(2)
>>> C = Curve(y**Integer(2) + y - x**Integer(3))
>>> pts = C.closed_points()
>>> p = pts[Integer(0)]
>>> p.places()
[Place (x, y)]
```

```python
class sage.schemes.curves.closed_point.IntegralProjectiveCurveClosedPoint (curve, prime_ideal, degree)

Bases: IntegralCurveClosedPoint

Closed points of projective plane curves.

**affine** (i=None)

Return the point in the i-th affine patch of the curve.

**INPUT:**

- i – an integer; if not specified, it is chosen automatically.

**EXAMPLES:**

```python
sage: F.<a> = GF(2)
sage: P.<x,y,z> = ProjectiveSpace(F, 2)
sage: C = Curve(x^3*y + y^3*z + x*z^3)
sage: p1, p2, p3 = C.closed_points()
sage: p1.affine()
Point (x, z)
sage: p2.affine()
Point (x, y)
sage: p3.affine()
```

(continues on next page)
Point \( (y, z) \)
sage: p3.affine(0)
Point \( (y, z) \)
sage: p3.affine(1)
Traceback (most recent call last):
...
ValueError: not in the affine patch

```python
>>> from sage.all import *
>>> F = GF(Integer(2), names=('a',)); (a,) = F._first_ngens(1)
>>> P = ProjectiveSpace(F, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
>>> C = Curve(x**Integer(3)*y + y**Integer(3)*z + x*z**Integer(3))
>>> p1, p2, p3 = C.closed_points()
>>> p1.affine()
Point \( (x, z) \)
>>> p2.affine()
Point \( (x, y) \)
>>> p3.affine()
Point \( (y, z) \)
>>> p3.affine(Integer(0))
Point \( (y, z) \)
>>> p3.affine(Integer(1))
Traceback (most recent call last):
...
ValueError: not in the affine patch
```

rational_point()

Return the rational point if this closed point is of degree 1.

EXAMPLES:

```python
sage: # needs sage.rings.finite_rings
sage: F.<a> = GF(4)
sage: P.<x,y,z> = ProjectiveSpace(F, 2)
sage: C = Curve(x^3*y + y^3*z + x*z^3)
sage: C.closed_points()
[Point \( (x, z) \),
Point \( (x, y) \),
Point \( (y, z) \),
Point \( (x + a*z, y + (a + 1)*z) \),
Point \( (x + (a + 1)*z, y + a*z) \)]
sage: [p.rational_point() for p in _]
[(0 : 1 : 0), (0 : 0 : 1), (1 : 0 : 0), (a : a + 1 : 1), (a + 1 : a : 1)]
sage: set(_) == set(C.rational_points())
True
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> F = GF(Integer(4), names=('a',)); (a,) = F._first_ngens(1)
>>> P = ProjectiveSpace(F, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
>>> C = Curve(x**Integer(3)*y + y**Integer(3)*z + x*z**Integer(3))
>>> C.closed_points()
[Point \( (x, z) \),
Point \( (x, y) \),
Point \( (y, z) \),
Point \( (x + a*z, y + (a + 1)*z) \),
Point \( (x + (a + 1)*z, y + a*z) \)]
```
1.8 Zariski-Van Kampen method implementation

This file contains functions to compute the fundamental group of the complement of a curve in the complex affine or projective plane, using Zariski-Van Kampen approach. It depends on the package sirocco.

The current implementation allows to compute a presentation of the fundamental group of curves over the rationals or number fields with a fixed embedding on \( \mathbb{Q} \).

Instead of computing a representation of the braid monodromy, we choose several base points and a system of paths joining them that generate all the necessary loops around the points of the discriminant. The group is generated by the free groups over these points, and braids over these paths give relations between these generators. This big group presentation is simplified at the end.

AUTHORS:

• Miguel Marco (2015-09-30): Initial version

EXAMPLES:

```python
sage: from sage.schemes.curves.zariski_vankampen import fundamental_group, braid_monodromy

sage: f = y^3 + x^3 - 1

sage: braid_monodromy(f)
([s1*s0, s1*s0, s1*s0], {0: 0, 1: 0, 2: 0}, {}, 3)

sage: fundamental_group(f)
Finitely presented group < x0 | >
```

```
>>> from sage.all import *

>>> from sage.schemes.curves.zariski_vankampen import fundamental_group, braid_monodromy

>>> R = QQ['x, y']; (x, y) = R._first_ngens(2)

>>> f = y**Integer(3) + x**Integer(3) - Integer(1)

>>> braid_monodromy(f)
([s1*s0, s1*s0, s1*s0], {0: 0, 1: 0, 2: 0}, {}, 3)

>>> fundamental_group(f)
Finitely presented group < x0 | >
```

`sage.schemes.curves.zariski_vankampen.braid2rels(L)`

Return a minimal set of relations of the group \( F / [(b * F([j])) / F([j]) \text{ for } j \text{ in } (1..d)] \) where \( F = \text{FreeGroup}(d) \) and \( b \) is a conjugate of a positive braid. One starts from the non-trivial relations determined by the positive braid and transform them in relations determined by \( b \).

INPUT:

• \( L \) – a tuple whose first element is a positive braid and the second element is a list of permutation braids.
OUTPUT:

A list of Tietze words for a minimal set of relations of $F / [(g * b) / g$ for $g$ in $F.gens()]$.

EXAMPLES:

```python
sage: from sage.schemes.curves.zariski_vankampen import braid2rels
sage: B.<s0, s1, s2> = BraidGroup(4)
sage: L = ((s1*s0)^2, [s2])
```

```python
sage: braid2rels(L)
[[(4, 1, -2, -1), (2, -4, -2, 1)]
```

```python
>>> from sage.all import *
>>> from sage.schemes.curves.zariski_vankampen import braid2rels
>>> B = BraidGroup(Integer(4), names=('s0', 's1', 's2'),); (s0, s1, s2,) = B._first_ngens(3)
>>> L = ((s1*s0)**Integer(2), [s2])
>>> braid2rels(L)
[[(4, 1, -2, -1), (2, -4, -2, 1)]
```

`sage.schemes.curves.zariski_vankampen.braid_from_piecewise(strands)`

Compute the braid corresponding to the piecewise linear curves strands.

**INPUT:**

- `strands` – a list of lists of tuples $(t, c_1, c_2)$, where $t$ is a number between 0 and 1, and $c_1$ and $c_2$ are rationals or algebraic reals.

**OUTPUT:**

The braid formed by the piecewise linear strands.

**EXAMPLES:**

```python
sage: # needs sirocco
sage: from sage.schemes.curves.zariski_vankampen import braid_from_piecewise
sage: paths = [[(0, 0, 1), (0.2, -1, -0.5), (0.8, -1, 0), (1, 0, -1)],
            [(0, -1, 0), (0.5, 0, -1), (1, 1, 0)],
            [(0, 1, 0), (0.5, 1, 1), (1, 0, 1)]
```

```python
sage: braid_from_piecewise(paths)
s0*s1
```

```python
>>> from sage.all import *
>>> # needs sirocco
>>> from sage.schemes.curves.zariski_vankampen import braid_from_piecewise
>>> paths = [((Integer(0), Integer(0), Integer(1)), (RealNumber('0.2'),
           -Integer(1)), -RealNumber('0.5'),) , (RealNumber('0.8'), -Integer(1), Integer(0)),
           (Integer(1), Integer(0), -Integer(1)),
           ...
           [(Integer(0), -Integer(1), Integer(0)), (RealNumber('0.5'),
           -Integer(1), Integer(1)), (Integer(1), Integer(0), Integer(0))],
           ...
           [(Integer(0), Integer(1), Integer(0)), (RealNumber('0.5'),
           -Integer(1), Integer(1)), (Integer(1), Integer(0), Integer(1))]
```

```python
>>> braid_from_piecewise(paths)
s0*s1
```

`sage.schemes.curves.zariski_vankampen.braid_monodromy(f, arrangement=(), vertical=False)`

Compute the braid monodromy of a projection of the curve defined by a polynomial.

**INPUT:**
• \( f \) - a polynomial with two variables, over a number field with an embedding in the complex numbers

• \( \text{arrangement} \) - tuple (default: \((\))): an optional tuple of polynomials whose product equals \( f \)

• \( \text{vertical} \) - boolean (default: \(\text{False} \)); if set to `\text{True}` arrangements contains more than one polynomial, some of them are of degree 1 in \( x \) and degree 0 in \( y \), and none of the other components have vertical asymptotes, then these components are marked as \text{vertical} and not used for the computation of the braid monodromy. The other ones are marked as \text{horizontal}. If a vertical component does not pass through a singular points of the projection of the horizontal components a trivial braid is added to the list.

**OUTPUT:**

• A list of braids, images by the braid monodromy of a geometric basis of the complement of the discriminant of \( f \) in \( \mathbb{C} \).

• A dictionary: \( i \), index of a strand is sent to the index of the corresponding factor in \( \text{arrangement} \).

• Another dictionary \( dv \), only relevant if \( \text{vertical} \) is \(\text{True} \). If \( j \) is the index of a braid corresponding to a vertical line with index \( i \) in \( \text{arrangement} \), then \( dv[j] = i \).

• A non-negative integer: the number of strands of the braids, only necessary if the list of braids is empty.

**Note:** The projection over the \( x \) axis is used if there are no vertical asymptotes. Otherwise, a linear change of variables is done to fall into the previous case except if the only vertical asymptotes are lines and \( \text{vertical}=\text{True} \).

**EXAMPLES:**

```python
sage: # needs sirocco
sage: from sage.schemes.curves.zariski_vankampen import braid_monodromy
sage: R.<x, y> = QQ[]

sage: f = (x^2 - y^3) * (x + 3*y - 5)

sage: bm = braid_monodromy(f); bm
([s1*s0*(s1*s2)^2*s0^2*s2^2*s0^2-1*(s2^-1*s1^-1)^2*s0^-1*s1^-1,
  s1*s0*(s1*s2)^2*(s0^-2-1)*s1^2*s1^-2*s1^-1)^2*(s2^1-s1^-1)^2*s0^-1*s1^-1,
  s1*s0*(s1*s2)^2*s2^2*s1^-1*s2^-1*s1^-1*s0^-1*s1^-1,
  s1*s0*s2^-1-1*s2^2*s1^-1],[0: 0, 1: 0, 2: 0, 3: 0], {}, 4)

sage: flist = (x^2 - y^3, x + 3*y - 5)

sage: bm1 = braid_monodromy(f, arrangement=flist)

sage: bm1[0] == bm[0]
True

sage: bm1[1]
{0: 0, 1: 1, 2: 0, 3: 0}

sage: braid_monodromy(R(1))
([], {}, {}, 0)

sage: braid_monodromy(x*y^2 - 1)
([s0^1*s0^-1-1*s1^2*s0^-1*s0^2-1, s0^1*s0^-1, s0], {0: 0, 1: 0, 2: 0}, {}, 3)

sage: L = [x, y, x - 1, x - y]

sage: braid_monodromy(prod(L), arrangement=L, vertical=True)
([s^2, 1], {0: 1, 1: 3}, {0: 0, 1: 2}, 2)

>>> from sage.all import *
>>> # needs sirocco
>>> from sage.schemes.curves.zariski_vankampen import braid_monodromy

>>> R = QQ['x', 'y']; (x, y) = R._first_ngens(2)

>>> f = (x**Integer(2) - y**Integer(3)) * (x + Integer(3)*y - Integer(5))

>>> bm = braid_monodromy(f); bm
([s1*s0*(s1*s2)^2*s0^2*s2^2*s0^2-1*(s2^-1*s1^-1)^2*s0^-1*s1^-1,
  s1*s0*(s1*s2)^2*(s0^-2-1)*s1^2*s1^-2*s1^-1)^2*(s2^1-s1^-1)^2*s0^-1*s1^-1,
  s1*s0*(s1*s2)^2*s2^2*s1^-1*s2^-1*s1^-1*s0^-1*s1^-1,
  s1*s0*s2^-1-1*s2^2*s1^-1],[0: 0, 1: 0, 2: 0, 3: 0], {}, 4)
```

(continues on next page)
\[
\begin{align*}
s1*s0*(s1*s2)^2*s2*s1^-1*s2^-1*s1^-1*s0^-1*s1^-1, \\
s1*s0*s2*s0^-1*s2*s1^-1), \{0: 0, 1: 0, 2: 0, 3: 0, \}, 4)
\end{align*}
\]

```python
>>> flist = (x**Integer(2) - y**Integer(3), x + Integer(3)*y - Integer(5))

```  

```python
>>> bm1 = braid_monodromy(f, arrangement=flist)

```  

```python
>>> bm1[Integer(0)] == bm[Integer(0)]
True
```

```python
>>> bm1[Integer(1)]
{0: 0, 1: 1, 2: 0, 3: 0}
```  

```python
>>> braid_monodromy(R(Integer(1)))
([], {}, {}, 0)
```  

```python
>>> braid_monodromy(x*y**Integer(2) - Integer(1))
([s0*s1*s0^-1*s1*s0*s1^-1*s0^-1, s0*s1*s0^-1, s0], {0: 0, 1: 0, 2: 0}, {}, 3)
```  

```
>>> L = [x, y, x - Integer(1), x -y]

```  

```python
>>> braid_monodromy(prod(L), arrangement=L, vertical=True)
([s^2, 1], {0: 1, 1: 3}, {0: 0, 1: 2}, 2)
```  

\[
\text{sage.schemes.curves.zariski_vankampen.\texttt{conjugate_positive_form}(braid)}
\]

For a braid which is conjugate to a product of disjoint positive braids a list of such decompositions is given.

**INPUT:**

- braid – a braid \(\sigma\)

**OUTPUT:**

A list of \(r\) lists. Each such list is another list with two elements, a positive braid \(\alpha_i\) and a list of permutation braids \(\gamma_1, \ldots, \gamma_n\), such that if \(\gamma_i = \prod_{j=1}^n \gamma_j^i\) then the braids \(\tau_i = \gamma_i \alpha_i \gamma_i^{-1}\) pairwise commute and \(\alpha = \prod_{i=1}^r \tau_i\).

**EXAMPLES:**

```python
sage: from sage.schemes.curves.zariski_vankampen import conjugate_positive_form
sage: B = BraidGroup(4)
sage: t = B((1, 3, 2, -3, 1, 1))
sage: conjugate_positive_form(t)
[[[s1*s0]^2, [s2]]]
```

```python
sage: B = BraidGroup(5)
sage: t = B((1, 2, 3, 4, -1, -2, 3, 3, 2, -4))
sage: conjugate_positive_form(t)  # L
[[s1^2, [s3*s2]], [s1*s2, [s0]]]
```

```python
sage: s = B.one()
sage: for a, l in L:
....: b = prod(l)
....: s *= b * a / b
sage: s == t
True
```

```python
sage: s1 = B.gen(1)^3
sage: conjugate_positive_form(s1)
[[s1^3, []]]
```

```python
>>> from sage.all import *

>>> from sage.schemes.curves.zariski_vankampen import conjugate_positive_form

>>> B = BraidGroup(Integer(4))

```  

```python
>>> t = B((Integer(1), Integer(3), Integer(2), -Integer(3), Integer(1),-
...

```  

```python
>>> conjugate_positive_form(t)
[[s1*s0]^2, [s2]]
```  

```python
>>> B = BraidGroup(Integer(5))

```  

```python
>>> t = B((Integer(1), Integer(2), Integer(3), Integer(4), -Integer(1),-

```  

(continues on next page)
sage.schemes.curves.zariski_vankampen.corrected_voronoi_diagram()

Compute a Voronoi diagram of a set of points with rational coordinates. The given points are granted to lie one in each bounded region.

INPUT:

- points – a tuple of complex numbers

OUTPUT:

A Voronoi diagram constructed from rational approximations of the points, with the guarantee that each bounded region contains exactly one of the input points.

EXAMPLES:

```python
sage: from sage.schemes.curves.zariski_vankampen import corrected_voronoi_diagram
sage: points = (2, I, 0.000001, 0, 0.000001*I)
sage: V = corrected_voronoi_diagram(points)
sage: V
The Voronoi diagram of 9 points of dimension 2 in the Rational Field
sage: V.regions()
(P(-7, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 4 vertices and 2 rays,
P(0, -7): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 4 vertices and 2 rays,
P(0, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 4 vertices,
P(0, 1): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices,
P(0, 1/1000000): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 4 vertices,
P(0, 7): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 3 vertices and 2 rays,
P(1/1000000, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices,
P(2, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices,
P(7, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 2 vertices and 2 rays)
```
The Voronoi diagram of 9 points of dimension 2 in the Rational Field

>>> V.regions()

(P(-7, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 4 → vertices and 2 rays,
P(0, -7): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 4 → vertices and 2 rays,
P(0, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 4 → vertices,
P(0, 1): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 → vertices,
P(0, 1/1000000): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 4 → vertices,
P(0, 7): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 3 → vertices and 2 rays,
P(1/1000000, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 → vertices,
P(2, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 → vertices,
P(7, 0): A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 2 → vertices and 2 rays)

sage.schemes.curves.zariski_vankampen.discrim(pols)

Return the points in the discriminant of the product of the polynomials of a list or tuple pols.

The result is the set of values of the first variable for which two roots in the second variable coincide.

INPUT:

• pols – a list or tuple of polynomials in two variables with coefficients in a number field with a fixed embedding in \( \mathbb{Q} \).

OUTPUT:

A tuple with the roots of the discriminant in \( \mathbb{Q} \).

EXAMPLES:

```python
>>> from sage.schemes.curves.zariski_vankampen import discrim
>>> R.<x, y> = QQ[]
>>> flist = (y^3 + x^3 - 1, 2 * x + y)
>>> sorted((discrim(flist)))
[-0.522757958574711?, -0.500000000000000? - 0.866025403784439?*I,
 -0.500000000000000? + 0.866025403784439?*I,
 0.2613789792873551? - 0.4527216721561923?*I,
 0.2613789792873551? + 0.4527216721561923?*I,
 1]
```

```python
>>> from sage.all import *
>>> from sage.schemes.curves.zariski_vankampen import discrim
>>> R = QQ['x', y']; (x, y,) = R._first_ngens(2)
>>> flist = (y**Integer(3) + x**Integer(3) - Integer(1), Integer(2) * x + y)
>>> sorted((discrim(flist)))
[-0.522757958574711?, -0.500000000000000? - 0.866025403784439?*I,
 -0.500000000000000? + 0.866025403784439?*I,
 0.2613789792873551? - 0.4527216721561923?*I,
 0.2613789792873551? + 0.4527216721561923?*I,
 1]
```
Return the (either double or trivial) extension of a number field which contains $I$.

**INPUT:**

- `field` – a number field with an embedding in $\bar{\mathbb{Q}}$.

**OUTPUT:**

The extension $F$ of $\text{field}$ containing $I$ with an embedding in $\bar{\mathbb{Q}}$.

**EXAMPLES:**

```python
sage: from sage.schemes.curves.zariski_vankampen import fieldI
sage: fieldI(F0)
Number Field in prim with defining polynomial
    x^10 + 5*x^8 + 14*x^6 - 2*x^5 - 10*x^4 + 20*x^3 - 11*x^2 - 14*x + 10
    with prim = 0.4863890359345430? + 1.000000000000000?*I
```

```
>>> from sage.all import *
>>> from sage.schemes.curves.zariski_vankampen import fieldI
>>> p = QQ[x](x**Integer(5) + Integer(2) * x + Integer(1))
>>> a0 = p.roots(QQbar, multiplicities=False)[Integer(0)]
>>> F0 = NumberField(p, embedding=a0, names=('a',)); (a,) = F0._first_ngens(1)
>>> fieldI(F0)
Number Field in prim with defining polynomial
    x^10 + 5*x^8 + 14*x^6 - 2*x^5 - 10*x^4 + 20*x^3 - 11*x^2 - 14*x + 10
    with prim = 0.4863890359345430? + 1.000000000000000?*I
```

If $I$ is already in the field, the result is the field itself:
sage: from sage.schemes.curves.zariski_vankampen import fieldI
sage: p = QQ[x](x^4 + 1)
Sage: a0 = p.roots(QQbar, multiplicities=False)[0]
Sage: F0.<a> = NumberField(p, embedding=a0)
Sage: F1 = fieldI(F0)
Sage: F0 == F1
True
Sage: QuadraticField(-1) == fieldI(QuadraticField(-1))
True

sage.schemes.curves.zariski_vankampen.followstrand(f, factors, x0, x1, y0a, prec=53)

Return a piecewise linear approximation of the homotopy continuation of the root y0a from x0 to x1.

INPUT:

- \( f \) – an irreducible polynomial in two variables
- \( \text{factors} \) – a list of irreducible polynomials in two variables
- \( x0 \) – a complex value, where the homotopy starts
- \( x1 \) – a complex value, where the homotopy ends
- \( y0a \) – an approximate solution of the polynomial \( F(y) = f(x0, y) \)
- \( \text{prec} \) – the precision to use

OUTPUT:
A list of values \((t, y_{tr}, y_{ti})\) such that:

- \( t \) is a real number between zero and one
- \( f(t \cdot x1 + (1-t) \cdot x0, y_{tr} + I \cdot y_{ti}) \) is zero (or a good enough approximation)
- the piecewise linear path determined by the points has a tubular neighborhood where the actual homotopy continuation path lies, and no other root of \( f \), nor any root of the polynomials in \( \text{factors} \), intersects it.

EXAMPLES:

sage: # needs sirocco
sage: from sage.schemes.curves.zariski_vankampen import followstrand
sage: R.<x, y> = QQ[]
Sage: f = x^2 + y^3
Sage: x0 = CC(1, 0)
Sage: x1 = CC(1, 0.5)

\end{align*}
\]

sage.schemes.curves.zariski_vankampen.fundamental_group(\(f\), simplified=True, projective=False, puiseux=True)

Return a presentation of the fundamental group of the complement of the algebraic set defined by the polynomial \(f\).

INPUT:

- \(f\) – a polynomial in two variables, with coefficients in either the rationals or a number field with a fixed embedding in \(\mathbb{Q}\)
- simplified – boolean (default: True); if set to True the presentation will be simplified (see below)
- projective – boolean (default: False); if set to True, the fundamental group of the complement of the projective completion of the curve will be computed, otherwise, the fundamental group of the complement in the affine plane will be computed
- puiseux – boolean (default: True); if set to True, a presentation of the fundamental group with the homotopy type of the complement of the affine curve is computed. If the Euler characteristic does not match, the homotopy type is obtained with a wedge of 2-spheres. One relation is added if projective is set to True.

If projective` is False and puiseux is True, a Zariski-VanKampen presentation is returned.

OUTPUT:

A presentation of the fundamental group of the complement of the curve defined by \(f\).

EXAMPLES:
It is also possible to have coefficients in a number field with a fixed embedding in $\mathbb{Q}$:

```
sage: from sage.schemes.curves.zariski_vankampen import fundamental_group
sage: zeta = QQbar['x']('x^2 + x + 1').roots(multiplicities=False)[0]
sage: zeta
-0.5000000000000000? - 0.866025403784439?*I
sage: F = NumberField(zeta.minpoly(), 'zeta', embedding=zeta)
sage: F.inject_variables()
```

(continues on next page)
Defining zeta

```python
sage: R.<x, y> = F[]
sage: f = y^3 + x^3 + zeta * x + 1
sage: fundamental_group(f)  # needs sirocco
Finitely presented group < x0 | >
```

```python
>>> from sage.all import *
>>> from sage.schemes.curves.zariski_vankampen import fundamental_group
>>> zeta = QQbar['x']('x^2 + x+ 1').roots(multiplicities=False)[Integer(0)]
>>> zeta
-0.5000000000000000? - 0.866025403784439?*I
>>> F = NumberField(zeta.minpoly(), 'zeta', embedding=zeta)
>>> F.inject_variables()
Defining zeta
```  

We compute the fundamental group of the complement of a quartic using the `puiseux` option:

```python
sage: # optional - sirocco
sage: from sage.schemes.curves.zariski_vankampen import fundamental_group
sage: R.<x, y> = QQ[]
sage: f = x^2 * y^2 + x^2 + y^2 - 2 * x * y * (x + y + 1)
sage: g = fundamental_group(f); g.sorted_presentation()
Finitely presented group < x0, x1 | x1^-2*x0^2, (x1^-1*x0)^3 >
>>> g = fundamental_group(f, projective=True)
>>> g.order(), g.abelian_invariants()
(12, (4,))
```  

```python
>>> from sage.all import *
>>> # optional - sirocco
>>> from sage.schemes.curves.zariski_vankampen import fundamental_group
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> f = x**Integer(2) * y**Integer(2) + x**Integer(2) + y**Integer(2) - x^-2*x0^2, (x1^-1*x0)^3 >
>>> g = fundamental_group(f, projective=True)
>>> g.order(), g.abelian_invariants()
(12, (4,))
```  

```python
sage.schemes.curves.zariski_vankampen.fundamental_group_arrangement (flist, simplified=True, projective=False, puiseux=True, vertical=False, braid_data=None)
```

Compute the fundamental group of the complement of a curve defined by a list of polynomials with the extra information about the correspondence of the generators and meridians of the elements of the list.
INPUT:

- **flist** – a tuple of polynomial with two variables, over a number field with an embedding in the complex numbers
- **simplified** – boolean (default: True); if set to True the presentation will be simplified (see below)
- **projective** – boolean (default: False); if set to True, the fundamental group of the complement of the projective completion of the curve will be computed, otherwise, the fundamental group of the complement in the affine plane will be computed
- **puiseux** – boolean (default: True); if set to True a presentation of the fundamental group with the homotopy type of the complement of the affine curve will be computed, adding one relation if projective is set to True.
- **vertical** – boolean (default: False); if set to True, whenever no curve has vertical asymptotes the computation of braid monodromy is simpler if some lines are vertical
- **braid_data** – tuple (default: None); if it is not the default it is the output of fundamental_group_from_braid_mon previously computed

OUTPUT:

- A list of braids. The braids correspond to paths based in the same point; each of this paths is the conjugated of a loop around one of the points in the discriminant of the projection of f.
- A dictionary attaching to j a tuple a list of elements of the group which are meridians of the curve in position j. If projective is False and the y-degree of the horizontal components coincide with the total degree, another key is added to give a meridian of the line at infinity.

EXAMPLES:

```python
sage: # needs sirocco
sage: from sage.schemes.curves.zariski_vankampen import braid_monodromy
sage: from sage.schemes.curves.zariski_vankampen import fundamental_group_arrangement
sage: R.<x, y> = QQ[]
sage: flist = [x^2 - y^3, x + 3 * y - 5]
```
```python
sage: g, dic = fundamental_group_arrangement(flist)
sage: g.sorted_presentation()
```
```
Finitely presented group
< x0, x1, x2 | x2^-1*x1^-1*x2*x1, x2^-1*x0^-1*x2^-1*x0*x2*x0, x1^-1*x0^-1*x1*x0 >
```
```python
sage: dic
{0: [x0, x2], 1: [x1], 2: [x0^-1*x2^-1*x1^-1*x0^-1]}
```
```python
sage: g, dic = fundamental_group_arrangement(flist, simplified=False, puiseux=False)
sage: g.sorted_presentation(), dic
```
```
(Finitely presented group < x0, x1, x2, x3 | 1, 1, 1, 1, 1, 1, x3^-1*x2^-1*x1^-1*x2*x3*x2^-1*x1*x2, x3^-1*x2^-1*x1^-1*x0^-1*x1*x2*x3*x2, x3^-1*x2^-1*x1^-1*x0^-1*x1*x2*x1^-1*x0*x1*x2, x3^-1*x2^-1*x1^-1*x2*x3*x2^-1*x1*x2, x3^-1*x1^-1*x0*x1, x1^-1*x0^-1*x1*x0, x1^-1*x0^-1*x1*x0, x1^-1*x0^-1*x1*x0, x1^-1*x0^-1*x1*x0, x1^-1*x0^-1*x1*x0, x1^-1*x0^-1*x1*x0 >,
{0: [x0, x2, x3], 1: [x1], 2: [x3^-1*x2^-1*x1^-1*x0^-1]})
```
```python
sage: fundamental_group_arrangement(flist, projective=True)
```
```python
(Finitely presented group < x | >, {0: [x], 1: [x^-3]})
```
```python
sage: fundamental_group_arrangement([])
```
```python
```
(continues on next page)
1.8. Zariski-Van Kampen method implementation

```python
>>> from sage.all import *
>>> # needs sirocco
>>> from sage.schemes.curves.zariski_vankampen import braid_monodromy
>>> from sage.schemes.curves.zariski_vankampen import fundamental_group_arrangement
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> flist = [x**Integer(2) - y**Integer(3), x + Integer(3) * y - Integer(5)]
>>> g, dic = fundamental_group_arrangement(flist)
>>> g.sorted_presentation()
Finitely presented group < x0, x1, x2 | x2^-1*x1^-1*x2*x1, x2^-1*x0^-1*x2*x0,
        x1^-1*x0^-1*x1*x0 >
>>> dic
{0: [x0, x2, x3], 1: [x1], 2: [x0^-1*x2^-1*x1^-1*x0^-1]}

(Finitely presented group < | >, {})
sage.schemes.curves.zariski_vankampen.fundamental_group_from_braid_mon(bm, degree=None, simplified=True, projective=False, puiseux=True, vertical=[])  

Return a presentation of the fundamental group computed from a braid monodromy.

INPUT:

- `bm` – a list of braids
- `degree` – integer (default: None); only needed if the braid monodromy is an empty list.
- `simplified` – boolean (default: True); if set to True the presentation will be simplified (see below)
- `projective` – boolean (default: False); if set to True, the fundamental group of the complement of the projective completion of the curve will be computed, otherwise, the fundamental group of the complement in the affine plane will be computed
- `puiseux` – boolean (default: True); if set to True a presentation of the fundamental group with the homotopy type of the complement of the affine curve will be computed, adding one relation if `projective` is set to True.
- `vertical` – list of integers (default: []); the indices in `[0 .. r - 1]` of the braids that surround a vertical line

If `projective` is `False` and `puiseux` is `True`, a Zariski-VanKampen presentation is returned.

OUTPUT:

A presentation of the fundamental group of the complement of the union of the curve with some vertical lines from its braid monodromy.

EXAMPLES:
Plane and Space Curves, Release 10.4

1.8. Zariski-Van Kampen method implementation

```python
sage: from sage.schemes.curves.zariski_vankampen import fundamental_group_from_braid_mon

sage: B.<s0, s1, s2> = BraidGroup(4)
sage: bm = [s1*s2*s0*s1*s0^-1*s1^-1*s0^-1,
....:     s0*s1^2*s0*s1*(s0^-1*s1^-1)*2*s0^-1,
....:     (s0*s1)^2]
sage: g = fundamental_group_from_braid_mon(bm, projective=True); g
# needs sirocco
Finitely presented group
< x1, x3 | x3^2*x1^2, x1^-1*x3^-1*x1*x3^-1*x1^-1*x3^-1 >
sage: print(g.order(), g.abelian_invariants())
# needs sirocco
12 (4,)
sage: B2 = BraidGroup(2)
sage: bm = [B2(3 * [1])]
sage: g = fundamental_group_from_braid_mon(bm, vertical=[0]); g
# needs sirocco
Finitely presented group
< x0, x1, x2 | x2*x0*x1*x2^-1*x1^-1*x0^-1,
           x2*x0*x1*x0*x1^-1*x2^-1*x1^-1 >
sage: fundamental_group_from_braid_mon([]) is None
# needs sirocco
True
sage: fundamental_group_from_braid_mon([], degree=Integer(2))
(continues on next page)
```
### geometric_basis

Return a geometric basis, based on a vertex.

**INPUT:**

- \( G \) – a graph with the bounded edges of a Voronoi Diagram
- \( E \) – a subgraph of \( G \) which is a cycle containing the bounded edges touching an unbounded region of a Voronoi Diagram
- \( EC_0 \) – A counterclockwise orientation of the vertices of \( E \)
- \( p \) – a vertex of \( E \)
- \( \text{dual_graph} \) – a dual graph for a plane embedding of \( G \) such that \( E \) is the boundary of the non-bounded component of the complement. The edges are labelled as the dual edges and the vertices are labelled by a tuple whose first element is the an integer for the position and the second one is the cyclic ordered list of vertices in the region
- \( \text{vertical_regions} \) – dictionary (default: ); its keys are the vertices of \( \text{dual_graph} \) to fix regions associated with vertical lines

**OUTPUT:** A geometric basis and a dictionary.

The geometric basis is formed by a list of sequences of paths. Each path is a list of vertices, that form a closed path in \( G \), based at \( p \), that goes to a region, surrounds it, and comes back by the same path it came. The concatenation of all these paths is equivalent to \( E \).

The dictionary associates to each vertical line the index of the generator of the geometric basis associated to it.

**EXAMPLES:**

```python
sage: from sage.schemes.curves.zariski_vankampen import geometric_basis,

\[ \text{from sage.schemes.curves.zariski_vankampen import geometric_basis, } \]
\[ \text{corrected_voronoi_diagram, voronoi_cells} \]
sage: points = (0, -1, I, 1, -I)
sage: V = corrected_voronoi_diagram(points)
sage: G, E, p, EC, DG, VR = voronoi_cells(V, vertical_lines=frozenset((0 .. 4)))
sage: gb, vd = geometric_basis(G, E, EC, p, DG, vertical_regions=VR)
sage: gb
\[
[[\text{A vertex at } (5/2, -5/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (-5/2, 5/2), \text{A vertex at } (-1/2, 1/2), \text{A vertex at } (-5/2, -5/2)],
[\text{A vertex at } (5/2, -5/2), \text{A vertex at } (1/2, -1/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (-1/2, 1/2), \text{A vertex at } (-5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (-1/2, 1/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (-1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), \text{A vertex at } (1/2, 1/2), \text{A vertex at } (5/2, 5/2), ]
```

(continues on next page)
>>> from sage.all import *
>>> from sage.schemes.curves.zariski_vankampen import geometric_basis, corrected_voronoi_diagram, voronoi_diagram, voronoi_cells
>>> points = (Integer(0), -Integer(1), I, Integer(1), -I)
>>> V = corrected_voronoi_diagram(points)
>>> G, E, EC, DG, VR = voronoi_cells(V, vertical_lines=frozenset((ellipsis_iter(Integer(0), Ellipsis, Integer(4)))))
>>> gb, vd = geometric Basis(G, E, EC, p, DG, vertical_regions=VR)

sage.schemes.curves.zariski_vankampen.newton(f, x0, I0)

Return the interval Newton operator.

INPUT:

• $f$ – a univariate polynomial

• $x_0$ – a number

• $I_0$ – an interval

OUTPUT:

The interval $x_0 = \frac{f(x_0)}{f'(I_0)}$

EXAMPLES:

sage: from sage.schemes.curves.zariski_vankampen import newton
sage: R.<x> = QQbar[]
sage: f = x^3 + x
sage: x0 = 1/10
sage: I0 = RIF((-1/5, 1/5))
sage: n = newton(f, x0, I0)
sage: n
0.0?

sage: n.real().endpoints()
(-0.0460743801652894, 0.0291454081632654)

sage: n.imag().endpoints()
(0.000000000000000, -0.000000000000000)
Reverse a circuit if it goes clockwise; otherwise leave it unchanged.

INPUT:

- **circuit** – a circuit in the graph of a Voronoi Diagram, given by a list of edges
- **convex** – boolean (default: False); if set to True a simpler computation is made
- **precision** – bits of precision (default: 53)
- **verbose** – boolean (default: False); for testing purposes

OUTPUT:

The same circuit if it goes counterclockwise, and its reversed otherwise, given as the ordered list of vertices with identical extremities.

EXAMPLES:

```python
sage: from sage.schemes.curves.zariski_vankampen import orient_circuit
sage: points = [(-4, 0), (4, 0), (0, 4), (0, -4), (0, 0)]
```

(continues on next page)
sage: orient_circuit(cirinv) == cir_oriented
True
sage: cir_oriented == orient_circuit(cir, convex=True)

(A vertex at (2, 2), A vertex at (2, -2), None),
(A vertex at (2, -2), A vertex at (-2, -2), None)]
>>> orient_circuit(cirinv) == cir_oriented
True
>>> cir_oriented == orient_circuit(cir, convex=True)
True
>>> P0=[(Integer(1),Integer(1)/Integer(2)),(Integer(0),Integer(1)),(Integer(1),)
sage.schemes.curves.zariski_vankampen.populate_roots_interval_cache(inputs)

Call roots_interval() to the inputs that have not been computed previously, and cache them.

INPUT:

- inputs - a list of tuples (f, x0)

EXAMPLES:

```python
sage: from sage.schemes.curves.zariski_vankampen import populate_roots_interval_cache, roots_interval_cache, fieldI

sage: R.<x,y> = QQ[]
sage: K=fieldI(QQ)
sage: f = y^5 - x^2
sage: f = f.change_ring(K)
sage: (f, 3) in roots_interval_cache
False
sage: populate_roots_interval_cache([(f, 3)])
sage: (f, 3) in roots_interval_cache
True
sage: roots_interval_cache[(f, 3)]
{-1.255469441943070? - 0.9121519421827974?*I: -2.? - 1.?*I,
 -1.255469441943070? + 0.9121519421827974?*I: -2.? + 1.?*I,
 0.4795466549853897? - 1.475892845355996?*I: 1.? - 2.?*I,
 0.4795466549853897? + 1.475892845355996?*I: 1.? + 2.?*I,
 14421467174121563/9293107134194871: 2.? + 0.?*I}
```

(continues on next page)
sage.schemes.curves.zariski_vankampen.roots_interval_cached(f, x0)
Cached version of roots_interval().

sage.schemes.curves.zariski_vankampen.strand_components(f, pols, p1)
Compute only the assignment from strands to elements of flist.

INPUT:
• f – a reduced polynomial with two variables, over a number field with an embedding in the complex numbers
• pols – a list of polynomials with two variables whose product equals f
• p1 – a Gauss rational

OUTPUT:
• A list and a dictionary. The first one is an ordered list of pairs consisting of \((z, i)\) where \(z\) is a root of \(f(p_1, y)\) and \(i\) is the position of the polynomial in the list whose root is \(z\). The second one attaches a number \(i\) (strand) to a number \(j\) (a polynomial in the list).

EXAMPLES:

```
sage: from sage.schemes.curves.zariski_vankampen import strand_components
sage: R.<x, y> = QQ[]
sage: flist = [x^2 - y^3, x + 3 * y - 5]
sage: strand_components(prod(flist), flist, 1)
([(-0.500000000000000? - 0.866025403784439?*I, 0),
  (-0.500000000000000? + 0.866025403784439?*I, 0),
  (1, 0), (1.333333333333334?, 1)], {0: 0, 1: 0, 2: 0, 3: 1})
```

sage.schemes.curves.zariski_vankampen.vertical_lines_in_braidmon(pols)
Return the vertical lines in pols, unless one of the other components has a vertical asymptote.

INPUT:
• pols – a list of polynomials with two variables whose product equals f

OUTPUT:
A list with the indices of the vertical lines in flist if there is no other component with vertical asymptote; otherwise it returns an empty list.

EXAMPLES:
sage: from sage.schemes.curves.zariski_vankampen import vertical_lines_in_braidmon
sage: R.<x, y> = QQ[]

sage: flist = [x^2 - y^3, x, x + 3*y - 5, 1 - x]

sage: vertical_lines_in_braidmon(flist)
[1, 3]

sage: flist += [x*y - 1]

sage: vertical_lines_in_braidmon(flist)
[]

sage: vertical_lines_in_braidmon([])
[]

sage.schemes.curves.zariski_vankampen.voronoi_cells(V, vertical_lines=frozenset())
Compute the graph, the boundary graph, a base point, a positive orientation of the boundary graph, and the dual
graph of a corrected Voronoi diagram.

INPUT:

• V – a corrected Voronoi diagram

• vertical_lines – frozenset (default: frozenset()); indices of the vertical lines

OUTPUT:

• G – the graph of the 1-skeleton of V

• E – the subgraph of the boundary

• p – a vertex in E

• EC – a list of vertices (representing a counterclockwise orientation of E) with identical first and last elements)

• DG – the dual graph of V, where the vertices are labelled by the compact regions of V and the edges by their
dual edges.

• vertical_regions – dictionary for the regions associated with vertical lines

EXAMPLES:

sage: from sage.schemes.curves.zariski_vankampen import corrected_voronoi_diagram,
       voronoi_cells
sage: points = (2, I, 0.000001, 0, 0.000001*I)

sage: V = corrected_voronoi_diagram(points)

sage: G, E, p, EC, DG, VR = voronoi_cells(V, vertical_lines=frozenset({1,}))

sage: Gv = G.vertices(sort=True)

sage: Ge = G.edges(sort=True)

sage: len(Gv), len(Ge)
(12, 16)
sage: Ev = E.vertices(sort=True); Ev

CHAPTER TWO

PLANE CONICS

2.1 Plane conic constructor

AUTHORS:
• Marco Streng (2010-07-20)
• Nick Alexander (2008-01-08)

sage.schemes.plane_conics.constructor.Conic(base_field, F=None, names=None, unique=True)

Return the plane projective conic curve defined by $F$ over $base_field$.

The input form Conic$(F, names=None)$ is also accepted, in which case the fraction field of the base ring of $F$ is used as base field.

INPUT:
• $base_field$ – The base field of the conic.
• $names$ – a list, tuple, or comma separated string of three variable names specifying the names of the coordinate functions of the ambient space $\mathbb{P}^3$. If not specified or read off from $F$, then this defaults to '$x, y, z$'.
• $F$ – a polynomial, list, matrix, ternary quadratic form, or list or tuple of 5 points in the plane.
  - If $F$ is a polynomial or quadratic form, then the output is the curve in the projective plane defined by $F = 0$.
  - If $F$ is a polynomial, then it must be a polynomial of degree at most 2 in 2 variables, or a homogeneous polynomial in of degree 2 in 3 variables.
  - If $F$ is a matrix, then the output is the zero locus of $(x, y, z)F(x, y, z)^t$.
  - If $F$ is a list of coefficients, then it has length 3 or 6 and gives the coefficients of the monomials $x^2, y^2, z^2$ or all 6 monomials $x^2, xy, xz, y^2, yz, z^2$ in lexicographic order.
  - If $F$ is a list of 5 points in the plane, then the output is a conic through those points.
• $unique$ – Used only if $F$ is a list of points in the plane. If the conic through the points is not unique, then raise ValueError if and only if unique is True

OUTPUT:
A plane projective conic curve defined by $F$ over a field.

EXAMPLES:
Conic curves given by polynomials
Plane and Space Curves, Release 10.4

Conic curves given by matrices

```python
sage: Conic(matrix(QQ, [[1, 2, 0], [4, 0, 0], [7, 0, 9]], [x,y,z])
Projective Conic Curve over Rational Field defined by x^2 + 6*x*y + 7*x*z + 9*z^2
```

```python
sage: x,y,z = GF(11)[x,y,z].gens()
sage: C = Conic(x^2 + y^2 - 2*z^2); C
Projective Conic Curve over Finite Field of size 11 defined by x^2 + y^2 - 2*z^2
```

```python
sage: Conic(C.symmetric_matrix(), x,y,z)
Projective Conic Curve over Finite Field of size 11 defined by x^2 + y^2 - 2*z^2
```

Conics given by coefficients

```python
sage: Conic(QQ, [1,2,3])
Projective Conic Curve over Rational Field defined by x^2 + 2*y^2 + 3*z^2
```

```python
sage: Conic(GF(7), [1,2,3,4,5,6], 'X')
Projective Conic Curve over Finite Field of size 7 defined by X0^2 + 2*X0*X1 + 3*X1^2 + 3*X0*X2 + 2*X1*X2 - X2^2
```

```python
sage: from sage.all import *

>>> Conic(matrix(QQ, [[Integer(1), Integer(2), Integer(0)], [Integer(4), Integer(0), Integer(0)], [Integer(7), Integer(0), Integer(9)]], [x,y,z])
Projective Conic Curve over Rational Field defined by x^2 + 6*x*y + 7*x*z + 9*z^2
```

```python
>>> x,y,z = GF(Integer(11))[x,y,z].gens()

>>> C = Conic(x^2 + y^2 - Integer(2)*z^2); C
Projective Conic Curve over Finite Field of size 11 defined by x^2 + y^2 - 2*z^2
```

```python
>>> Conic(C.symmetric_matrix(), [x,y,z])
Projective Conic Curve over Finite Field of size 11 defined by x^2 + y^2 - 2*z^2
```

The conic through a set of points

```python
sage: X,Y,Z = QQ['X,Y,Z'].gens()
sage: Conic(X^2 - X*Y + Y^2 - Z^2)
Projective Conic Curve over Rational Field defined by X^2 - X*Y + Y^2 - Z^2
```

```python
sage: x,y = GF(7)['x,y'].gens()
sage: Conic(x^2 - x + Integer(2)*y^2 - Integer(3), U,V,W)
Projective Conic Curve over Finite Field of size 7 defined by U^2 + 2*V^2 - U*W - 3*W^2
```

```python
>>> from sage.all import *

>>> X,Y,Z = QQ['X,Y,Z'].gens()

>>> Conic(X^Integer(2) - X*Y + Y^Integer(2) - Z^Integer(2))
Projective Conic Curve over Rational Field defined by X^2 - X*Y + Y^2 - Z^2
```

```python
>>> x,y,z = GF(Integer(7))[x,y,z].gens()

>>> Conic(x^Integer(2) - x + Integer(2)*y^Integer(2) - Integer(3), U,V,W)
Projective Conic Curve over Finite Field of size 7 defined by U^2 + 2*V^2 - U*W - 3*W^2
```

Conics given by coefficients

```python
sage: Conic(QQ, [1,2,3])
Projective Conic Curve over Rational Field defined by x^2 + 2*y^2 + 3*z^2
```

```python
sage: Conic(GF(7), [1,2,3,4,5,6], 'X')
Projective Conic Curve over Finite Field of size 7 defined by X0^2 + 2*X0*X1 + 3*X1^2 + 3*X0*X2 + 2*X1*X2 - X2^2
```

```python
>>> from sage.all import *

>>> Conic(QQ, [Integer(1), Integer(2), Integer(3)])
Projective Conic Curve over Rational Field defined by x^2 + 2*y^2 + 3*z^2
```

```python
>>> Conic(GF(Integer(7)), [Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(6)], 'X')
Projective Conic Curve over Finite Field of size 7 defined by X0^2 + 2*X0*X1 + 3*X1^2 + 3*X0*X2 + 2*X1*X2 - X2^2
```
2.2 Projective plane conics over a field

AUTHORS:

- Marco Streng (2010-07-20)
- Nick Alexander (2008-01-08)

class sage.schemes.plane_conics.con_field.ProjectiveConic_field(A, f)

Bases: ProjectivePlaneCurve_field

Create a projective plane conic curve over a field. See Conic for full documentation.

EXAMPLES:

sage: K = FractionField(PolynomialRing(QQ, 't'))
sage: P.<X, Y, Z> = K[

sage: Conic(X**Integer(2) + Y**Integer(2) - Z**Integer(2))

Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Rational Field defined by X^2 + Y^2 - Z^2

>>> from sage.all import *
>>> K = FractionField(PolynomialRing(QQ, 't'))
>>> P = K['X, Y, Z']; (X, Y, Z,) = P._first_ngens(3)
>>> Conic(X**Integer(2) + Y**Integer(2) - Z**Integer(2))

Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Rational Field defined by X^2 + Y^2 - Z^2

base_extend (S)

Return the conic over S given by the same equation as self.
EXAMPLES:

```python
sage: c = Conic([1, 1, 1]); c
Projective Conic Curve over Rational Field defined by x^2 + y^2 + z^2
sage: c.has_rational_point()  # needs sage.libs.pari
False
sage: d = c.base_extend(QuadraticField(-1, 'i')); d  # needs sage.rings.number_field
Projective Conic Curve over Number Field in i with defining polynomial x^2 + 1 with i = 1*I defined by x^2 + y^2 + z^2
sage: d.rational_point(algorithm='rnfisnorm')  # needs sage.rings.number_field
(i : 1 : 0)
```

```python
>>> from sage.all import *
>>> c = Conic([Integer(1), -Integer(1), Integer(1)]); c
Projective Conic Curve over Rational Field defined by x^2 + y^2 + z^2
>>> c.has_rational_point()  # needs sage.libs.pari
False
>>> d = c.base_extend(QuadraticField(-Integer(1), 'i')); d  # needs sage.rings.number_field
Projective Conic Curve over Number Field in i with defining polynomial x^2 + 1 with i = 1*I defined by x^2 + y^2 + z^2
>>> d.rational_point(algorithm='rnfisnorm')  # needs sage.rings.number_field
(i : 1 : 0)
```

`cache_point(p)`

Replace the point in the cache of `self` by `p` for use by `rational_point()` and `parametrization()`.

EXAMPLES:

```python
sage: c = Conic([1, -1, 1])
sage: c.point([15, 17, 8])
(15/8 : 17/8 : 1)
sage: c.rational_point()
(15/8 : 17/8 : 1)
```
coefficients()  
Gives the 6 coefficients of the conic self in lexicographic order.

EXAMPLES:

```sage
sage: Conic(QQ, [1,2,3,4,5,6]).coefficients()
[1, 2, 3, 4, 5, 6]
```

```sage
sage: P.<x,y,z> = GF(13)[]
sage: a = Conic(x^2 + 5*x*y + y^2 + z^2).coefficients(); a
[1, 5, 0, 1, 0, 1]
sage: Conic(a)
Projective Conic Curve over Finite Field of size 13
defined by x^2 + 5*x*y + y^2 + z^2
```

derivative_matrix()  
Gives the derivative of the defining polynomial of the conic self, which is a linear map, as a 3 × 3 matrix.

EXAMPLES:

In characteristic different from 2, the derivative matrix is twice the symmetric matrix:

```sage
sage: c = Conic(QQ, [1,1,1,1,1,0])
sage: c.symmetric_matrix()
[ 1 1/2 1/2]
[1/2 1 1/2]
[1/2 1/2 0]
sage: c.derivative_matrix()
[2 1 1]
[1 2 1]
[1 1 0]
```

```sage
>>> from sage.all import *
>>> c = Conic(QQ, [Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(0)])
>>> c.symmetric_matrix()
[ 1 1/2 1/2]
[1/2 1 1/2]
[1/2 1/2 0]
>>> c.derivative_matrix()
[2 1 1]
[1 2 1]
[1 1 0]
```

An example in characteristic 2:
```python
def determinant()
    Return the determinant of the symmetric matrix that defines the conic self.
    
    This is defined only if the base field has characteristic different from 2.
    
    EXAMPLES:

    sage: C = Conic([1,2,3,4,5,6])
    sage: C.determinant()
    41/4
    sage: C.symmetric_matrix().determinant()
    41/4

    >>> from sage.all import *
    >>> C = Conic([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
                 Integer(6)])
    >>> C.determinant()
    41/4
    >>> C.symmetric_matrix().determinant()
    41/4

    Determinants are only defined in characteristic different from 2:

    sage: C = Conic(GF(2), [1, 1, 1, 1, 1, 0])
    sage: C.is_smooth()
    True
    sage: C.determinant()
    Traceback (most recent call last):
    ...  
    ValueError: The conic self (= Projective Conic Curve over Finite Field
    (continues on next page)
```
of size 2 defined by \(x^2 + x*y + y^2 + x*z + y*z\) has no symmetric matrix because the base field has characteristic 2.

```python
>>> from sage.all import *

>>> C = Conic(GF(Integer(2)), [Integer(1), Integer(1), Integer(1), Integer(1), Integer(1), Integer(0)])

>>> C.is_smooth()
True

>>> C.determinant()
Traceback (most recent call last):
...
ValueError: The conic self (= Projective Conic Curve over Finite Field of size 2 defined by \(x^2 + x*y + y^2 + x*z + y*z\)) has no symmetric matrix because the base field has characteristic 2.
```

diagonal_matrix()

Return a diagonal matrix \(D\) and a matrix \(T\) such that \(T^t A T = D\) holds, where \((x, y, z)A(x, y, z)^t\) is the defining polynomial of the conic \(self\).

**EXAMPLES:**

```python
sage: c = Conic(QQ, [1,2,3,4,5,6])

sage: d, t = c.diagonal_matrix(); d, t
([1 0 0], [1 -1 -7/6]
[0 3 0], [0 1 -1/3]
[0 0 41/12], [0 0 1])

sage: t.transpose()*c.symmetric_matrix()*t

>>> from sage.all import *

>>> c = Conic(GF(4, a), [0, 1, 1, 1, 1, 1])

>>> c.is_smooth()
True

>>> c.diagonal_matrix()
Traceback (most recent call last):
...
ValueError: The conic self (= Projective Conic Curve over Finite Field of size 2 defined by \(x^2 + x*y + y^2 + x*z + y*z\)) has no symmetric matrix because the base field has characteristic 2.
```

Diagonal matrices are only defined in characteristic different from 2:

```python
sage: # needs sage.rings.finite_rings

sage: c = Conic(GF(4, 'a'), [0, 1, 1, 1, 1])

sage: c.is_smooth()
True

sage: c.diagonal_matrix()
Traceback (most recent call last): ...
```

(continues on next page)
diagonalization (names=None)

Return a diagonal conic $C$, an isomorphism of schemes $M : C \rightarrow \text{self}$ and the inverse $N$ of $M$.

EXAMPLES:

```python
>>> Conic(GF(5), [1,0,1,1,0,1]).diagonalization()
(Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + 2z^2$,
 Scheme morphism:
 From: Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + 2z^2$
 To: Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + xz + z^2$
 Defn: Defined on coordinates by sending $(x : y : z)$ to $(x + 2z : y : z)$,
 Scheme morphism:
 From: Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + xz + z^2$
 To: Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + 2z^2$
 Defn: Defined on coordinates by sending $(x : y : z)$ to $(x - 2z : y : z)$)
```

```python
>>> Conic(GF(Integer(5)), [Integer(1),Integer(0),Integer(1),Integer(1),
 Integer(0),Integer(1)]).diagonalization()
(Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + 2z^2$,
 Scheme morphism:
 From: Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + 2z^2$
 To: Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + xz + z^2$
 Defn: Defined on coordinates by sending $(x : y : z)$ to $(x + 2z : y : z)$,
 Scheme morphism:
 From: Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + xz + z^2$
 To: Projective Conic Curve over Finite Field of size 5 defined by $x^2 + y^2 + 2z^2$
 Defn: Defined on coordinates by sending $(x : y : z)$ to $(x - 2z : y : z)$)
```

The diagonalization is only defined in characteristic different from 2:
sage: Conic(GF(2), [1,1,1,1,1,0]).diagonalization()
Traceback (most recent call last):
...
ValueError: The conic self (= Projective Conic Curve over Finite Field
of size 2 defined by x^2 + x*y + y^2 + x*z + y*z) has no symmetric matrix
because the base field has characteristic 2

>>> from sage.all import *
>>> Conic(GF(Integer(2)), [Integer(1),Integer(1),Integer(1),Integer(1),
˓→Integer(1),Integer(0)]).diagonalization()
Traceback (most recent call last):
...
ValueError: The conic self (= Projective Conic Curve over Finite Field
of size 2 defined by x^2 + x*y + y^2 + x*z + y*z) has no symmetric matrix
because the base field has characteristic 2

An example over a global function field:

sage: K = FractionField(PolynomialRing(GF(7), 't'))
sage: (t,) = K.gens()
sage: C = Conic(K, [t/2,0, 1, 2, 0, 3])
sage: C.diagonalization()
( Projective Conic Curve over Fraction Field of Univariate
  Polynomial Ring in t over Finite Field of size 7
  defined by (-3*t)*x^2 + 2*y^2 + (3*t + 3)/t*z^2,
  Scheme morphism:
  From: Projective Conic Curve over Fraction Field of Univariate
  Polynomial Ring in t over Finite Field of size 7
  defined by (-3*t)*x^2 + 2*y^2 + (3*t + 3)/t*z^2
  To:   Projective Conic Curve over Fraction Field of Univariate
  Polynomial Ring in t over Finite Field of size 7
  defined by (-3*t)*x^2 + 2*y^2 + x*z + 3*z^2
  Defn: Defined on coordinates by sending (x : y : z) to (x - 1/t*z : y : z),
  Scheme morphism:
  From: Projective Conic Curve over Fraction Field of Univariate
  Polynomial Ring in t over Finite Field of size 7
  defined by (-3*t)*x^2 + 2*y^2 + x*z + 3*z^2
  To:   Projective Conic Curve over Fraction Field of Univariate
  Polynomial Ring in t over Finite Field of size 7
  defined by (-3*t)*x^2 + 2*y^2 + (3*t + 3)/t*z^2
  Defn: Defined on coordinates by sending (x : y : z) to (x + 1/t*z : y : z))

>>> from sage.all import *
>>> K = FractionField(PolynomialRing(GF(Integer(7)), 't'))
>>> (t,) = K.gens()
>>> C = Conic(K, [t/Integer(2),Integer(0), Integer(1), Integer(2), Integer(0),
˓→ Integer(3)])
>>> C.diagonalization()
(Projective Conic Curve over Fraction Field of Univariate
  Polynomial Ring in t over Finite Field of size 7
  defined by (-3*t)*x^2 + 2*y^2 + (3*t + 3)/t*z^2,
  Scheme morphism:
  From: Projective Conic Curve over Fraction Field of Univariate
  Polynomial Ring in t over Finite Field of size 7
  defined by (-3*t)*x^2 + 2*y^2 + x*z + 3*z^2
  To:   Projective Conic Curve over Fraction Field of Univariate
  Polynomial Ring in t over Finite Field of size 7
  defined by (-3*t)*x^2 + 2*y^2 + (3*t + 3)/t*z^2
  Defn: Defined on coordinates by sending (x : y : z) to (x + 1/t*z : y : z))

(continues on next page)
Defined by \((-3t)x^2 + 2y^2 + xz + 3z^2\)

Defn: Defined on coordinates by sending \((x : y : z)\) to \((x - 1/tz : y : z)\).

Scheme morphism:

From: Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Finite Field of size 7

defined by \((-3t)x^2 + 2y^2 + xz + 3z^2\)

To: Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Finite Field of size 7

defined by \((-3t)x^2 + 2y^2 + (3t + 3)/tz^2\)

Defn: Defined on coordinates by sending \((x : y : z)\) to \((x + 1/tz : y : z)\)

gens()

Return the generators of the coordinate ring of self.

EXAMPLES:

```
sage: P.<x,y,z> = QQ()
sage: c = Conic(x^2 + y^2 + z^2)
sage: c.gens()  # needs sage.libs.singular
(xbar, ybar, zbar)
sage: c.defining_polynomial()(c.gens())  # needs sage.libs.singular
0
```

The function `gens()` is required for the following construction:

```
sage: C.<a,b,c> = Conic(GF(3), [1, 1, 1]); C  # needs sage.libs.singular
Projective Conic Curve over Finite Field of size 3 defined by a^2 + b^2 + c^2
```

```
sage: C = Conic(GF(Integer(3)), [Integer(1), Integer(1), Integer(1)], names=('a', 'b', 'c')); (a, b, c) = C._first_ngens(3); C
# needs sage.libs.singular
Projective Conic Curve over Finite Field of size 3 defined by a^2 + b^2 + c^2
```

has_rational_point(point=False, algorithm='default', read_cache=True)

Return True if and only if the conic self has a point over its base field \(B\).

If \(point\) is True, then returns a second output, which is a rational point if one exists.

Points are cached whenever they are found. Cached information is used if and only if \(read_cache\) is True.

ALGORITHM:
The parameter algorithm specifies the algorithm to be used:

- 'default' – If the base field is real or complex, use an elementary native Sage implementation.
- 'magma' (requires Magma to be installed) – delegates the task to the Magma computer algebra system.

**EXAMPLES:**

```python
sage: Conic(RR, [1, 1, 1]).has_rational_point()
False
sage: Conic(CC, [1, 1, 1]).has_rational_point()
True
sage: Conic(RR, [1, 2, -3]).has_rational_point(point = True)
(True, (1.73205080756888 : 0.000000000000000 : 1.000000000000000))
```

```python
>>> from sage.all import *

>>> R = QQ[t]; (t,) = R._first_ngens(1)
>>>
>>> C = Conic([-Integer(2), t**Integer(2) + Integer(1), t**Integer(2) - Integer(1)])
>>> C.has_rational_point()
(True, (-t : 1 : 1))
```

Conics over polynomial rings can be solved internally:

```python
sage: C = Conic([-2, t^2 + 1, t^2 - 1])
sage: C.has_rational_point()  # needs sage.libs.pari
True
```

And they can also be solved with Magma:

```python
sage: C.has_rational_point(algorithm='magma')  # optional - magma
True
sage: C.has_rational_point(algorithm='magma', point=True)  # optional - magma
(True, (-t : 1 : 1))
```

(continues on next page)
has_singular_point (point=False)

Return True if and only if the conic self has a rational singular point.

If point is True, then also return a rational singular point (or None if no such point exists).

EXAMPLES:

```
sage: c = Conic(QQ, [1,0,1]); c
Projective Conic Curve over Rational Field defined by x^2 + z^2
sage: c.has_singular_point(point = True)
(True, (0 : 1 : 0))
sage: P.<x,y,z> = GF(7)[]
sage: e = Conic((x+y+z)*(x-y+2*z)); e
Projective Conic Curve over Finite Field of size 7 defined by x^2 - y^2 + 3*x*z + y*z + 2*z^2
sage: e.has_singular_point(point = True)
(True, (2 : 4 : 1))
sage: Conic([1, 1, -1]).has_singular_point()
False
sage: Conic([1, 1, -1]).has_singular_point(point=True)
(False, None)
```

has_singular_point is not implemented over all fields of characteristic 2. It is implemented over finite fields.

```
sage: F.<a> = FiniteField(8)  # needs sage.rings.finite_rings
sage: Conic([a, a + 1, 1]).has_singular_point(point=True)  # needs sage.rings.finite_rings
(True, (a + 1 : 0 : 1))
```
sage: P.<t> = GF(2)[]
sage: C = Conic(P, [t,t,1]); C
Projective Conic Curve over Fraction Field of Univariate Polynomial Ring
in t over Finite Field of size 2... defined by t*x^2 + t*y^2 + z^2
sage: C.has_singular_point(point=False)
Traceback (most recent call last):
... NotImplementedError: Sorry, find singular point on conics not implemented
over all fields of characteristic 2.

>>> from sage.all import *
>>> F = FiniteField(Integer(8), names=('a',)); (a,) = F._first_ngens(1)
#
˓→ needs sage.rings.finite_rings
>>> Conic([a, a + Integer(1), Integer(1)]).has_singular_point(point=True)
˓→ # needs sage.rings.finite_rings
(True, (a + 1 : 0 : 1))
>>> P = GF(Integer(2))[t]; (t,) = P._first_ngens(1)
>>> C = Conic(P, [t,t,Integer(1)]); C
Projective Conic Curve over Fraction Field of Univariate Polynomial Ring
in t over Finite Field of size 2... defined by t*x^2 + t*y^2 + z^2
>>> C.has_singular_point(point=False)
Traceback (most recent call last):
... NotImplementedError: Sorry, find singular point on conics not implemented
over all fields of characteristic 2.

hom(x, Y=None)

Return the scheme morphism from self to Y defined by x. Here x can be a matrix or a sequence of
polynomials. If Y is omitted, then a natural image is found if possible.

EXAMPLES:

Here are a few morphisms given by matrices. In the first example, Y is omitted, in the second example, Y is
specified.

sage: c = Conic([-1, 1, 1])
sage: h = c.hom(Matrix([[1,1,0], [0,1,0], [1,0,0]]), d); h
Scheme morphism:
  From: Projective Conic Curve over Rational Field defined by -x^2 + y^2 + z^2
  To: Projective Conic Curve over Rational Field defined by 4*x^2 + y^2 - z^2
  Defn: Defined on coordinates by sending (x : y : z) to (1/2*z : y : x)

2.2. Projective plane conics over a field 193
from sage.all import *
c = Conic([-Integer(1), Integer(1), Integer(1)])
h = c.hom(Matrix([[Integer(1), Integer(1), Integer(0)],
                 [-Integer(1), Integer(0), Integer(0)],
                 [Integer(0), Integer(0), Integer(1)]])); h
Scheme morphism:
  From: Projective Conic Curve over Rational Field defined by -x^2 + y^2 + z^2
  To:   Projective Conic Curve over Rational Field defined by -x^2 + 2*x*y + z^2
  Defn: Defined on coordinates by sending (x : y : z) to (x + y : y : z)

h([-Integer(1), Integer(1), Integer(0)]) # needs sage.libs.singular
(0 : 1 : 0)

c = Conic([-Integer(1), Integer(1), Integer(1)])
d = Conic([Integer(4), Integer(1), -Integer(1)])
h = c.hom(Matrix([[Integer(0), Integer(0), Integer(1)/Integer(2)],
                 [Integer(0), Integer(1), Integer(0)],
                 [Integer(1), Integer(0), Integer(0)]]), d)
Scheme morphism:
  From: Projective Conic Curve over Rational Field defined by -x^2 + y^2 + z^2
  To:   Projective Conic Curve over Rational Field defined by 4*x^2 + y^2 - z^2
  Defn: Defined on coordinates by sending (x : y : z) to (1/2*z : y : x)

ValueError is raised if the wrong codomain Y is specified:
sage: c = Conic([-1, 1, 1])
sage: c.hom(Matrix([[0, 0, 1/2], [0, 1, 0], [1, 0, 0]]), c)
Traceback (most recent call last):
... ValueError: The matrix x (= [ 0 0 1/2]
   [ 0 1 0]
   [ 1 0 0]) does not define a map from self (= Projective Conic Curve over Rational Field defined by -x^2 + y^2 + z^2) to Y (= Projective Conic Curve over Rational Field defined by -x^2 + y^2 + z^2)

from sage.all import *
c = Conic([-Integer(1), Integer(1), Integer(1)])
h = c.hom(Matrix([[Integer(0), Integer(0), Integer(1)/Integer(2)],
                 [Integer(0), Integer(1), Integer(0)],
                 [Integer(1), Integer(0), Integer(0)]]), c)
Traceback (most recent call last):
... ValueError: The matrix x (= [ 0 0 1/2]
   [ 0 1 0]
   [ 1 0 0]) does not define a map from self (= Projective Conic Curve over Rational Field defined by -x^2 + y^2 + z^2) to Y (= Projective Conic Curve over Rational Field defined by -x^2 + y^2 + z^2)

The identity map between two representations of the same conic:
sage: C = Conic([1,2,3,4,5,6])
sage: D = Conic([2,4,6,8,10,12])
sage: C.hom(identity_matrix(3), D)
Scheme morphism:
From: Projective Conic Curve over Rational Field
defined by \(x^2 + 2xy + 4y^2 + 3xz + 5yz + 6z^2\)
To: Projective Conic Curve over Rational Field
defined by \(2x^2 + 4xy + 8y^2 + 6xz + 10yz + 12z^2\)
Defn: Defined on coordinates by sending \((x : y : z)\) to \((x : y : z)\)

\[
\begin{align*}
\text{from sage.all import } &* \\
\text{C = Conic([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),} \\
\text{Integer(6)])} \\
\text{D = Conic([Integer(2),Integer(4),Integer(6),Integer(8),Integer(10),} \\
\text{Integer(12)])} \\
\text{C.hom(identity_matrix(Integer(3)), D)} \\
\text{Scheme morphism:} \\
\text{From: Projective Conic Curve over Rational Field} \\
\text{defined by } x^2 + 2xy + 4y^2 + 3xz + 5yz + 6z^2 \\
\text{To: Projective Conic Curve over Rational Field} \\
\text{defined by } 2x^2 + 4xy + 8y^2 + 6xz + 10yz + 12z^2 \\
\text{Defn: Defined on coordinates by sending } (x : y : z) \text{ to } (x : y : z)
\end{align*}
\]

An example not over the rational numbers:

sage: P.<t> = QQ[]
sage: C = Conic([1,0,0,t,0,1/t])
sage: D = Conic([1/t^2, 0, -2/t^2, t, 0, (t + 1)/t^2])
sage: T = Matrix([[t,0,1], [0,1,0], [0,0,1]])
sage: C.hom(T, D)
Scheme morphism:
From: Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Rational Field
defined by \(x^2 + ty^2 + 1/tz^2\)
To: Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Rational Field
defined by \(1/(t^2)x^2 + ty^2 - 2/(t^2)xz + (t + 1)/(t^2)z^2\)
Defn: Defined on coordinates by sending \((x : y : z)\) to \((t^2x + z : y : z)\)

\[
\begin{align*}
\text{from sage.all import } &* \\
\text{P = QQ['t']; (t,) = P._first_ngens(1)} \\
\text{C = Conic([Integer(1),Integer(0),Integer(0),t,Integer(0),Integer(1)/t])} \\
\text{D = Conic([Integer(1)/t**Integer(2), Integer(0), -Integer(2)/} \\
\text{t**Integer(2), t, Integer(0), (t + Integer(1))/t**Integer(2)])} \\
\text{T = Matrix([[t,Integer(0),Integer(1)]}, [Integer(0),Integer(1),Integer(0),} \\
\text{Integer(0),Integer(0),Integer(1)])} \\
\text{C.hom(T, D)} \\
\text{Scheme morphism:} \\
\text{From: Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Rational Field} \\
\text{defined by } x^2 + t*y^2 + 1/t^2 \\
\text{To: Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Rational Field} \\
\text{defined by } 1/(t^2)*x^2 + t*y^2 - 2/(t^2)*x*z + (t + 1)/(t^2)*z^2 \\
\text{Defn: Defined on coordinates by sending } (x : y : z) \text{ to } (t^2x + z : y : z)
\end{align*}
\]

is_diagonal()

Return True if and only if the conic has the form \(ax^2 + by^2 + cz^2\).
EXAMPLES:

```python
sage: c = Conic([1,1,0,1,0,1]); c
Projective Conic Curve over Rational Field defined by x^2 + x*y + y^2 + z^2
sage: d, t = c.diagonal_matrix()
sage: c.is_diagonal()
False
sage: c.diagonalization()[0].is_diagonal()
True
```

```python
>>> from sage.all import *

>>> c = Conic([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(1)]); c
Projective Conic Curve over Rational Field defined by x^2 + x*y + y^2 + z^2
>>> d, t = c.diagonal_matrix()
>>> c.is_diagonal()
False
>>> c.diagonalization()[Integer(0)].is_diagonal()
True
```

`is_smooth()`

Return True if and only if self is smooth.

EXAMPLES:

```python
sage: Conic([1,-1,0]).is_smooth()
False
sage: Conic(GF(2),[1,1,1,1,1,0]).is_smooth()
True
```

```python
>>> from sage.all import *

>>> Conic([Integer(1),-Integer(1),Integer(0)]).is_smooth()
False
>>> Conic(GF(Integer(2)),[Integer(1),Integer(1),Integer(1),Integer(1),
Integer(1),Integer(0)]).is_smooth()
True
```

`matrix()`

Return a matrix $M$ such that $(x, y, z)^t M (x, y, z)^t$ is the defining equation of self.

The matrix $M$ is upper triangular if the base field has characteristic 2 and symmetric otherwise.

EXAMPLES:

```python
sage: R.<x, y, z> = QQ[]
sage: C = Conic(x^2 + x*y + y^2 + z^2)
sage: C.matrix()
[ 1 1/2 0]
[1/2 1 0]
[ 0  0 1]
sage: R.<x, y, z> = GF(2)[]
sage: C = Conic(x^2 + x*y + y^2 + x*z + z^2)
sage: C.matrix()
[1 1 1]
[0 1 0]
[0 0 1]
```
parametrization (point=None, morphism=True)

Return a parametrization $f$ of self together with the inverse of $f$.

If point is specified, then that point is used for the parametrization. Otherwise, use rational_point() to find a point.

If morphism is True, then $f$ is returned in the form of a Scheme morphism. Otherwise, it is a tuple of polynomials that gives the parametrization.

EXAMPLES:

An example over a finite field

```python
sage: # needs sage.libs.pari
sage: c = Conic(GF(2), [1,1,1,1,1,0])
```

```python
sage: f, g = c.parametrization(); f, g
(Scheme morphism:  
  From: Projective Space of dimension 1 over Finite Field of size 2  
  To:  Projective Conic Curve over Finite Field of size 2  
  defined by x^2 + x*y + y^2 + x*z + y*z  
  Defn: Defined on coordinates by sending (x : y) to ...,  
Scheme morphism:  
  From: Projective Conic Curve over Finite Field of size 2  
  defined by x^2 + x*y + y^2 + x*z + y*z  
  To:  Projective Space of dimension 1 over Finite Field of size 2  
  Defn: Defined on coordinates by sending (x : y : z) to ...)
```

```python
sage: set(f(p) for p in f.domain())
{(0 : 0 : 1), (0 : 1 : 1), (1 : 0 : 1)}
```

(continues on next page)
Defn: Defined on coordinates by sending \((x : y : z)\) to ...

```python
>>> set(f(p) for p in f.domain())
{(0 : 0 : 1), (0 : 1 : 1), (1 : 0 : 1)}
```

Verification of the example

```python
sage: # needs sage.libs.pari
sage: h = g*f; h
Scheme endomorphism of Projective Space of dimension 1
  over Finite Field of size 2
  Defn: Defined on coordinates by sending \((x : y)\) to ...

sage: h[0]/h[1]
x/y
sage: h.is_one()  # known bug (see :issue:`#31892`)
True
sage: (x,y,z) = c.gens()

sage: x.parent()
Quotient of Multivariate Polynomial Ring in x, y, z
  over Finite Field of size 2 by the ideal \((x^2 + x*y + y^2 + x*z + y*z)\)

sage: k = f*g

sage: k[0]*z-k[2]*x
0
sage: k[1]*z-k[2]*y
0
```

The morphisms are mathematically defined in all points, but don’t work completely in SageMath (see Issue #31892)

```python
sage: # needs sage.libs.pari
sage: f, g = c.parametrization([0,0,1])
sage: g([0,1,1])
(1 : 0)
sage: f([1,0])
(0 : 1 : 1)
sage: f([1,1])
(0 : 0 : 1)
```
An example with morphism = False

```python
sage: # needs sage.libs.pari
sage: R.<x,y,z> = QQ[]
sage: C = Curve(7*x^2 + 2*y*z + z^2)
sage: (p, i) = C.parametrization(morphism=False); (p, i)
([-2*x*y, x^2 + 7*y^2, -2*x^2], [-1/2*x, 1/7*y + 1/14*z])
sage: C.defining_polynomial()(p)
0
sage: i[0](p) / i[1](p)
x/y
```

A `ValueError` is raised if `self` has no rational point

```python
sage: # needs sage.libs.pari
sage: C = Conic(x^2 + y^2 + 7*z^2)
sage: C.parametrization()
Traceback (most recent call last):
...
ValueError: Conic Projective Conic Curve over Rational Field defined by x^2 + y^2 + 7*z^2 has no rational points over Rational Field!
```

```python
sage: # needs sage.libs.pari
sage: C = Conic(x**2 + y**2 + 7*z**2)
sage: C.parametrization()
Traceback (most recent call last):
...
ValueError: Conic Projective Conic Curve over Rational Field defined by x^2 + y^2 + 7*z^2 has no rational points over Rational Field!
```
A `ValueError` is raised if `self` is not smooth.

```
sage: # needs sage.libs.pari
sage: C = Conic(x^2 + y^2)
Traceback (most recent call last):
  ... 
ValueError: The conic self (=Projective Conic Curve over Rational Field
defined by x^2 + y^2) is not smooth, hence does not have a parametrization.
```

```
>>> from sage.all import *
>>> # needs sage.libs.pari
>>> C = Conic(x**Integer(2) + y**Integer(2))
Traceback (most recent call last):
  ... 
ValueError: The conic self (=Projective Conic Curve over Rational Field
defined by x^2 + y^2) is not smooth, hence does not have a parametrization.
```

```
>>> from sage.all import *
>>> C = Conic([Integer(1), -Integer(1), Integer(1)])
>>> C.point([Integer(15), Integer(17), Integer(8)])
(15/8 : 17/8 : 1)
>>> C.rational_point() #...
(-1 : 1 : 0)
```

```
>>> from sage.all import *
>>> C = Conic([Integer(1), -Integer(1), Integer(1)])
>>> C.point([Integer(15), Integer(17), Integer(8)])
(15/8 : 17/8 : 1)
>>> C.rational_point() #...
(-1 : 1 : 0)
```

`random_rational_point(*args1, **args2)`

Return a random rational point of the conic `self`.

**ALGORITHM:**

1. Compute a parametrization \( f \) of `self` using `parametrization()`.
2. Computes a random point \((x : y)\) on the projective line.
3. Output \( f(x : y) \).
The coordinates $x$ and $y$ are computed using $\text{B.random_element}$, where $\text{B}$ is the base field of $\text{self}$ and additional arguments to $\text{random_rational_point}$ are passed to $\text{random_element}$.

If the base field is a finite field, then the output is uniformly distributed over the points of $\text{self}$.

**EXAMPLES:**

```python
sage: # needs sage.libs.pari
sage: c = Conic(GF(2), [1,1,1,1,0])

sage: [c.random_rational_point() for i in range(10)]  # random
[(1 : 0 : 1), (1 : 0 : 1), (1 : 0 : 1), (0 : 1 : 1), (1 : 0 : 1),
 (0 : 1 : 1), (1 : 0 : 1), (0 : 1 : 1), (1 : 0 : 1)]

sage: d = Conic(QQ, [1, 1, -1])

sage: d.random_rational_point(den_bound=1, num_bound=5)  # random
(-24/25 : 7/25 : 1)

sage: Conic(QQ, [1, 1, 1]).random_rational_point()
Traceback (most recent call last):
...
ValueError: Conic Projective Conic Curve over Rational Field defined by
x^2 + y^2 + z^2 has no rational points over Rational Field!
```

`rational_point(algorithm='default', read_cache=True)`

Return a point on $\text{self}$ defined over the base field.

This raises a `ValueError` if no rational point exists.

See $\text{self}.\text{has_rational_point}$ for the algorithm used and for the use of the parameters $\text{algorithm}$ and $\text{read_cache}$.

**EXAMPLES:**

Examples over $\mathbb{Q}$

```python
sage: R.<x,y,z> = QQ[]

sage: # needs sage.libs.pari
sage: C = Conic(7*x^2 + 2*y*z + z^2)

sage: C.rational_point()
(0 : 1 : 0)

sage: C = Conic(x^2 + 2*y^2 + z^2)

sage: C.rational_point()
```

(continues on next page)
Examples over number fields

```python
sage: # needs sage.rings.number_field
sage: P.<x> = QQ[]
sage: L.<b> = NumberField(x^3 - 5)
sage: C = Conic(L, [3, 2, -b])
sage: p = C.rational_point(algorithm='rnfisnorm')
sage: p
# output is random
(1/3*b^2 - 4/3*b + 4/3 : b^2 - 2 : 1)
sage: C.defining_polynomial()(list(p))
0

sage: K.<i> = QuadraticField(-1)       # needs sage.rings.number_field
sage: D = Conic(K, [3, 2, 5])         # needs sage.rings.number_field
sage: D.rational_point(algorithm='rnfisnorm')  # output is random
(-3 : 4*i : 1)
sage: # needs sage.libs.pari sage.rings.number_field
sage: L.<s> = QuadraticField(2)
sage: Conic(QQ, [1, 1, -3]).has_rational_point()
```

(continues on next page)
Currently Magma is better at solving conics over number fields than Sage, so it helps to use the algorithm ‘magma’ if Magma is installed:

```python
sage: # optional - magma, needs sage.rings.number_field
sage: q = C.rational_point(algorithm='magma',
.....: read_cache=False)

sage: k = Conic(QQ, [Integer(1), Integer(1), -Integer(3)]).has_rational_point()
False

sage: E = Conic(L, [Integer(1), Integer(1), -Integer(3)])

sage: q = E.rational_point(algorithm='magma',
.....: read_cache=False)

sage: F = Conic([L.gen(), 30, -20])

sage: q = F.rational_point(algorithm='magma')
```

(continues on next page)
(-10/7*s + 40/7 : 5/7*s - 6/7 : 1)
sage: p = F.rational_point(read_cache=False)

with 53 bits of precision defined by \( x^2 + y^2 + z^2 \) has  
o no rational points over Real Field with 53 bits of precision!
```

`singular_point()`  

Return a singular rational point of \( \text{self} \).

EXAMPLES:

```
sage: Conic(GF(2), [1,1,1,1,1,1]).singular_point()  
(1 : 1 : 1)
```

```
from sage.all import *

>>> Conic(GF(Integer(2)), [Integer(1),Integer(1),Integer(1),Integer(1),  
Integer(1),Integer(1)]).singular_point()  
(1 : 1 : 1)
```

`ValueError` is raised if the conic has no rational singular point

```
sage: Conic(QQ, [1,1,1,1,1,1]).singular_point()  
Traceback (most recent call last):  
...  
ValueError: The conic self (= Projective Conic Curve over Rational Field  
defined by \( x^2 + x*y + y^2 + x*z + y*z + z^2 \)) has no rational singular point
```

```
from sage.all import *

>>> Conic(QQ, [Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),  
Integer(1)]).singular_point()  
```

(continues on next page)
Traceback (most recent call last):
...
ValueError: The conic self (= Projective Conic Curve over Rational Field
defined by x^2 + x*y + y^2 + x*z + y*z + z^2) has no rational singular point

**symmetric_matrix()**

The symmetric matrix $M$ such that $(xyz)M(\text{xyz})^t$ is the defining equation of `self`.

**EXAMPLES:**

```
sage: R.<x, y, z> = QQ[]
sage: C = Conic(x^2 + x*y/2 + y^2 + z^2)
sage: C.symmetric_matrix()
[ 1 1/4 0]
[1/4 1 0]
[ 0 0 1]
```

```
sage: C = Conic(x^2 + 2*x*y + y^2 + 3*x*z + z^2)
sage: v = vector([x, y, z])
sage: v * C.symmetric_matrix() * v
x^2 + 2*x*y + y^2 + 3*x*z + z^2
```

```
from sage.all import *
>>> R = QQ['x, y, z']; (x, y, z,) = R._first_ngens(3)
>>> C = Conic(x**Integer(2) + x*y/Integer(2) + y**Integer(2) + z**Integer(2))
>>> C.symmetric_matrix()
[ 1 1/4 0]
[1/4 1 0]
[ 0 0 1]
```

```
>>> C = Conic(x**Integer(2) + 2*x*y + y**Integer(2) + Integer(3)*x*z + z**Integer(2))
>>> v = vector([x, y, z])
>>> v * C.symmetric_matrix() * v
x^2 + 2*x*y + y^2 + 3*x*z + z^2
```

**upper_triangular_matrix()**

The upper-triangular matrix $M$ such that $(xyz)M(\text{xyz})^t$ is the defining equation of `self`.

**EXAMPLES:**

```
sage: R.<x, y, z> = QQ[]
sage: C = Conic(x^2 + x*y + y^2 + z^2)
sage: C.upper_triangular_matrix()
[1 1 0]
[0 1 0]
[0 0 1]
```

```
sage: C = Conic(x^2 + 2*x*y + y^2 + 3*x*z + z^2)
sage: v = vector([x, y, z])
sage: v * C.upper_triangular_matrix() * v
x^2 + 2*x*y + y^2 + 3*x*z + z^2
```

```
from sage.all import *
>>> R = QQ['x, y, z']; (x, y, z,) = R._first_ngens(3)
>>> C = Conic(x**Integer(2) + x*y + y**Integer(2) + z**Integer(2))
```

(continues on next page)
variable_names()

Return the variable names of the defining polynomial of self.

EXAMPLES:

```
sage: c = Conic([1,1,0,0,1], 'x,y,z')
sage: c.variable_names()
('x', 'y', 'z')
sage: c.variable_name()
'x'
```

The function `variable_names()` is required for the following construction:

```
sage: C.<p,q,r> = Conic(QQ, [1, 1, 1]); C #_needs sage.libs.singular
Projective Conic Curve over Rational Field defined by p^2 + q^2 + r^2
```

```
sage: C.<p,q,r> = Conic(QQ, [1, 1, 1], names=('p','q', 'r', 'z')); (p, q, r) = C._first_ngens(3); C #_needs sage.libs.singular
Projective Conic Curve over Rational Field defined by p^2 + q^2 + r^2
```

2.3 Projective plane conics over a number field

AUTHORS:

- Marco Streng (2010-07-20)

```python
class sage.schemes.plane_conics.con_number_field.ProjectiveConic_number_field(A, f)
```

Create a projective plane conic curve over a number field. See `Conic` for full documentation.

EXAMPLES:
sage: K.<a> = NumberField(x^3 - 2, 'a')
sage: P.<X, Y, Z> = K[]
sage: Conic(X^2 + Y^2 - a*Z^2)
Projective Conic Curve over Number Field in a with defining polynomial x^3 - 2
defined by X^2 + Y^2 + (-a)*Z^2

>>> from sage.all import *
>>> K = NumberField(x**Integer(3) - Integer(2), 'a', names=('a',)); (a,) = K._first_ngens(1)
>>> P = K['X, Y, Z']; (X, Y, Z,) = P._first_ngens(3)
>>> Conic(X**Integer(2) + Y**Integer(2) - a*Z**Integer(2))
Projective Conic Curve over Number Field in a with defining polynomial x^3 - 2
defined by X^2 + Y^2 + (-a)*Z^2

has_rational_point (point=False, obstruction=False, algorithm='default', read_cache=True)

Return True if and only if self has a point defined over its base field B.

If point and obstruction are both False (default), then the output is a boolean out saying whether self has a rational point.

If point or obstruction is True, then the output is a pair (out, S), where out is as above and:

• if point is True and self has a rational point, then S is a rational point,

• if obstruction is True, self has no rational point, then S is a prime or infinite place of B such that no rational point exists over the completion at S.

Points and obstructions are cached whenever they are found. Cached information is used for the output if available, but only if read_cache is True.

ALGORITHM:

The parameter algorithm specifies the algorithm to be used:

• 'rnfisnorm' – Use PARI's rnfisnorm (cannot be combined with obstruction = True)

• 'local' – Check if a local solution exists for all primes and infinite places of B and apply the Hasse principle. (Cannot be combined with point = True.)

• 'default' – Use algorithm 'rnfisnorm' first. Then, if no point exists and obstructions are requested, use algorithm 'local' to find an obstruction.

• 'magma' (requires Magma to be installed) – delegates the task to the Magma computer algebra system.

EXAMPLES:

An example over Q

sage: C = Conic(QQ, [1, 113922743, -310146482690273725409])
sage: C.has_rational_point(point=True)
(113922743, -310146482690273725409)

>>> from sage.all import *
>>> C = Conic(QQ, [Integer(1), Integer(113922743), -Integer(310146482690273725409)])
>>> C.has_rational_point(point=True)
(113922743, -310146482690273725409)
Examples over number fields:

```python
sage: K.<i> = QuadraticField(-1)
sage: C = Conic(K, [1, 3, -5])
sage: C.has_rational_point(point=True, obstruction=True)
(False, Fractional ideal (-i - 2))
sage: C.has_rational_point(algorithm="rnfisnorm")
False
sage: C.has_rational_point(algorithm="rnfisnorm", obstruction=True, read_cache=False)
Traceback (most recent call last):
  ...:
ValueError: Algorithm rnfisnorm cannot be combined with obstruction = True in has_rational_point

sage: P.<x> = QQ[]
sage: L.<b> = NumberField(x^3 - 5)
sage: C = Conic(L, [1, 2, -3])
sage: C.has_rational_point(point=True, algorithm='rnfisnorm')
(True, (5/3 : -1/3 : 1))
sage: K.<a> = NumberField(x^4 + 2)
sage: Conic(QQ, [4, 5, 6]).has_rational_point()
False
sage: Conic(K, [4, 5, 6]).has_rational_point()
True
sage: Conic(K, [4, 5, 6]).has_rational_point(algorithm='magma', # optional --
                                            magma
                                             ....:
                                              read_cache=False)
True

sage: P.<a> = QuadraticField(2)
sage: C = Conic(P, [1,1,1])
sage: C.has_rational_point()
False
sage: C.has_rational_point(point=True)
(False, None)
```

```python
>>> from sage.all import *
>>> K = QuadraticField(Integer(1), names=('i',)); (i,) = K._first_ngens(1)
>>> C = Conic(K, [Integer(1), Integer(3), -Integer(5)])
>>> C.has_rational_point(point=True, obstruction=True)
(False, Fractional ideal (-i - 2))
```

(continues on next page)
is_locally_solvable(p)

Return True if and only if self has a solution over the completion of the base field $B$ of self at $p$. Here $p$ is a finite prime or infinite place of $B$.

EXAMPLES:

```
sage: P.<x> = QQ[]  
sage: K.<a> = NumberField(x^3 + 5)  
sage: C = Conic(K, [1, 2, 3 - a])  
sage: [p1, p2] = K.places()  
```
sage: C.is_locally_solvable(p1)
False
sage: C.is_locally_solvable(p2)
True
sage: f = (2*K).factor()
\n\[\begin{align*}
\text{sage: } \text{C.is_locally_solvable}(f[0][0]) & \quad \text{True} \\
\text{sage: } \text{C.is_locally_solvable}(f[1][0]) & \quad \text{False}
\end{align*}\]

Local obstructions are cached. The parameter read_cache specifies whether to look at the cache before computing anything.

**EXAMPLES:**

```
sage: K.<i> = QuadraticField(-1)
sage: Conic(K, [1, 2, 3]).local_obstructions()
[]
sage: L.<a> = QuadraticField(5)
sage: Conic(L, [1, 2, 3]).local_obstructions()
[Ring morphism:
  From: Number Field in a with defining polynomial x^2 - 5
  with a = 2.236067977499790?
  To:   Algebraic Real Field
```
2.4 Projective plane conics over \( \mathbb{Q} \)

AUTHORS:

- Marco Streng (2010-07-20)
- Nick Alexander (2008-01-08)

```
class sage.schemes.plane_conics.con_rational_field.ProjectiveConic_rational_field(A, f)
```

Create a projective plane conic curve over \( \mathbb{Q} \).

See Conic for full documentation.

EXAMPLES:

```
sage: P.<X, Y, Z> = QQ[]
sage: Conic(X^2 + Y^2 - 3*Z^2)
```

```
Projective Conic Curve over Rational Field defined by X^2 + Y^2 - 3*Z^2
```

```
>>> from sage.all import *
>>> P = QQ['X, Y, Z']; (X, Y, Z,) = P._first_ngens(3)
>>> Conic(X**Integer(2) + Y**Integer(2) - Integer(3)*Z**Integer(2))
```

```
Projective Conic Curve over Rational Field defined by X^2 + Y^2 - 3*Z^2
```

```
has_rational_point(point=False, obstruction=False, algorithm='default', read_cache=True)
```

Return True if and only if self has a point defined over \( \mathbb{Q} \).
If point and obstruction are both False (default), then the output is a boolean out saying whether 
self has a rational point.

If point or obstruction is True, then the output is a pair (out, S), where out is as above and the 
following holds:

- if point is True and self has a rational point, then S is a rational point,
- if obstruction is True and self has no rational point, then S is a prime such that no rational point
  exists over the completion at S or −1 if no point exists over \( \mathbb{R} \).

Points and obstructions are cached, whenever they are found. Cached information is used if and only if 
read_cache is True.

ALGORITHM:

The parameter algorithm specifies the algorithm to be used:

- 'qfsolve' – Use PARI/GP function pari:qfsolve
- 'rnfisnorm' – Use PARI's function pari:rnfisnorm (cannot be combined with obstruction = True)
- 'local' – Check if a local solution exists for all primes and infinite places of \( \mathbb{Q} \) and apply the Hasse principle (cannot be combined with point = True)
- 'default' – Use 'qfsolve'
- 'magma' (requires Magma to be installed) – delegates the task to the Magma computer algebra system.

EXAMPLES:

```python
sage: # needs sage.libs.pari
sage: C = Conic(QQ, [1, 2, -3])
sage: C.has_rational_point(point=True)
(True, (1 : 1 : 1))
sage: D = Conic(QQ, [1, 3, -5])
sage: D.has_rational_point(point=True)
(False, 3)
sage: P.<X,Y,Z> = QQ[]
sage: E = Curve(X^2 + Y^2 + Z^2); E
Projective Conic Curve over Rational Field defined by X^2 + Y^2 + Z^2
sage: E.has_rational_point(obstruction=True)
(False, -1)

>>> from sage.all import *
>>> # needs sage.libs.pari
>>> C = Conic(QQ, [Integer(1), Integer(2), -Integer(3)])
>>> C.has_rational_point(point=True)
(True, (1 : 1 : 1))
>>> D = Conic(QQ, [Integer(1), Integer(3), -Integer(5)])
>>> D.has_rational_point(point=True)
(False, 3)
>>> P = QQ('X, Y, Z'); (X, Y, Z,) = P._first_ngens(3)
>>> E = Curve(X**Integer(2) + Y**Integer(2) + Z**Integer(2)); E
Projective Conic Curve over Rational Field defined by X^2 + Y^2 + Z^2
>>> E.has_rational_point(obstruction=True)
(False, -1)
```

The following would not terminate quickly with algorithm = 'rnfisnorm'
C = Conic(QQ, \([1, 113922743, -310146482690273725409]\))

C.has_rational_point(point=True)  # needs sage.libs.pari
(True, (-76842858034579/5424 : -5316144401/5424 : 1))

C.has_rational_point(algorithm='local', read_cache=False)
True

C.has_rational_point(point=True, algorithm='magma',  # optional ~
magma
...: read_cache=False)
(True, (30106379962113/7913 : 12747947692/7913 : 1))

is_locally_solvable\( (p) \)

Return True if and only if self has a solution over the \( p \)-adic numbers.

Here \( p \) is a prime number or equals \(-1\), infinity, or \( \mathbb{R} \) to denote the infinite place.

EXAMPLES:
False
>>> D = Conic(QQ, [Integer(1), Integer(2), -Integer(3)])
>>> D.is_locally_solvable(infinity)
True
>>> D.is_locally_solvable(RR)
True

local_obstructions (finite=True, infinite=True, read_cache=True)

Return the sequence of finite primes and/or infinite places such that self is locally solvable at those primes and places.

The infinite place is denoted \(-1\).

The parameters finite and infinite (both True by default) are used to specify whether to look at finite and/or infinite places.

Note that finite = True involves factorization of the determinant of self, hence may be slow.

Local obstructions are cached. The parameter read_cache specifies whether to look at the cache before computing anything.

EXAMPLES:

```python
sage: # needs sage.libs.pari
sage: Conic(QQ, [1, 1, 1]).local_obstructions()
[2, -1]
sage: Conic(QQ, [1, 2, -3]).local_obstructions()
[]
sage: Conic(QQ, [1, 2, 3, 4, 5, 6]).local_obstructions()
[41, -1]
```

```python
>>> from sage.all import *

```

```python
>>> Conic(QQ, [Integer(1), Integer(1), Integer(1)]).local_obstructions()
[2, -1]

```

```python
>>> Conic(QQ, [Integer(1), Integer(2), -Integer(3)]).local_obstructions()
[]

```

```python
>>> Conic(QQ, [Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(6)]).local_obstructions()
[41, -1]
```

parametrization (point=None, morphism=True)

Return a parametrization \(f\) of self together with the inverse of \(f\).

If point is specified, then that point is used for the parametrization. Otherwise, use self.rational_point() to find a point.

If morphism is True, then \(f\) is returned in the form of a Scheme morphism. Otherwise, it is a tuple of polynomials that gives the parametrization.

ALGORITHM:

Uses the PARI/GP function pari:qfparam.

EXAMPLES:

```python
sage: # needs sage.libs.pari
sage: c = Conic([1,1,-1])
sage: c.parametrization()
```
An example with morphism = False

```
sage: # needs sage.libs.pari
sage: R.<x,y,z> = QQ[]
sage: C = Curve(7*x^2 + 2*y*z + z^2)
sage: (p, i) = C.parametrization(morphism=False); (p, i)
([-2*x*y, x^2 + 7*y^2, -2*x^2], [-1/2*x, 1/7*y + 1/14*z])
sage: C.defining_polynomial()(p)
0
sage: i[0](p) / i[1](p)
x/y
```

A ValueError is raised if self has no rational point

```
sage: # needs sage.libs.pari
sage: C = Conic(x^2 + 2*y^2 + z^2)
sage: C.parametrization()  # doctest: +ELLIPSIS
Traceback (most recent call last):
  ... AttributeError: ...
```

(continues on next page)
A `ValueError` is raised if `self` is not smooth

```python
>>> from sage.all import *
>>> # needs sage.libs.pari
>>> C = Conic(x**Integer(2) + y**Integer(2))
>>> C.parametrization()
Traceback (most recent call last):
...
ValueError: The conic self (=Projective Conic Curve over Rational Field defined by x^2 + y^2) is not smooth, hence does not have a parametrization.
```

### 2.5 Projective plane conics over finite fields

**AUTHORS:**
- Marco Streng (2010-07-20)

**class** `sage.schemes.plane_conics.con_finite_field.ProjectiveConic_finite_field(A, f)`

**Bases:** `ProjectiveConic_field, ProjectivePlaneCurve_finite_field`

Create a projective plane conic curve over a finite field.

See `Conic` for full documentation.

**EXAMPLES:**

```python
sage: K.<a> = FiniteField(9, 'a')
sage: P.<X, Y, Z> = K[]
sage: Conic(X^2 + Y^2 - a*Z^2)
Projective Conic Curve over Finite Field in a of size 3^2 defined by X^2 + Y^2 + (-a)*Z^2
```
>>> from sage.all import *
>>> K = FiniteField(Integer(9), 'a', names=('a',)); (a,) = K._first_ngens(1)
>>> P = K['X, Y, Z']; (X, Y, Z,) = P._first_ngens(3)
>>> Conic(X**Integer(2) + Y**Integer(2) - a*Z**Integer(2))
Projective Conic Curve over Finite Field in a of size 3^2
defined by X^2 + Y^2 + (-a)*Z^2

 sage: P.<X, Y, Z> = FiniteField(5)[]
sage: Conic(X^2 + Y^2 - 2*Z^2)
Projective Conic Curve over Finite Field of size 5 defined by X^2 + Y^2 - 2*Z^2

>>> from sage.all import *
>>> P = FiniteField(Integer(5))['X, Y, Z']; (X, Y, Z,) = P._first_ngens(3)
>>> Conic(X**Integer(2) + Y**Integer(2) - Integer(2)*Z**Integer(2))
Projective Conic Curve over Finite Field of size 5 defined by X^2 + Y^2 - 2*Z^2

**count_points** *(n)*

If the base field \( B \) of \( \text{self} \) is finite of order \( q \), then returns the number of points over \( F_q, \ldots, F_{q^n} \).

**EXAMPLES:**

 sage: P.<x,y,z> = GF(3)[]
sage: c = Curve(x^2+y^2+z^2); c
Projective Conic Curve over Finite Field of size 3 defined by x^2 + y^2 + z^2
 sage: c.count_points(4)
[4, 10, 28, 82]

>>> from sage.all import *
>>> P = GF(Integer(3))['x, y, z']; (x, y, z,) = P._first_ngens(3)
>>> c = Curve(x**Integer(2)+y**Integer(2)+z**Integer(2)); c
Projective Conic Curve over Finite Field of size 3 defined by x^2 + y^2 + z^2
>>> c.count_points(Integer(4))
[4, 10, 28, 82]

**has_rational_point** *(point=False, read_cache=True, algorithm='default')*

Always returns True because \( \text{self} \) has a point defined over its finite base field \( B \).

If point is True, then returns a second output \( S \), which is a rational point if one exists.

Points are cached. If read_cache is True, then cached information is used for the output if available. If no cached point is available or read_cache is False, then random \( y \)-coordinates are tried if \( \text{self} \) is smooth and a singular point is returned otherwise.

**EXAMPLES:**

 sage: Conic(FiniteField(37), [1, 2, 3, 4, 5, 6]).has_rational_point()
True

 sage: C = Conic(FiniteField(2), [1, 1, 1, 1, 1, 0]); C
Projective Conic Curve over Finite Field of size 2
defined by x^2 + x*y + y^2 + x*z + y*z
 sage: C.has_rational_point(point = True)  # output is random
(True, (0 : 0 : 1))

 sage: p = next_prime(10^50)
sage: F = FiniteField(p)
sage: C = Conic(F, [1, 2, 3]); C

 : 1))
```
2.6 Projective plane conics over a rational function field

The class `ProjectiveConic_rational_function_field` represents a projective plane conic over a rational function field $F(t)$, where $F$ is any field. Instances can be created using `Conic()`.

AUTHORS:
- Lennart Ackermans (2016-02-07): initial version

EXAMPLES:

Create a conic:

```python
sage: K = FractionField(PolynomialRing(QQ, 't'))
sage: P.<X, Y, Z> = K[

sage: Conic(X^2 + Y^2 - Z^2)
```

Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Rational Field defined by $X^2 + Y^2 - Z^2$

Points can be found using `has_rational_point()`:

```python
sage: K.<t> = FractionField(QQ[t])
sage: C = Conic([1, -t, t])
sage: C.has_rational_point(point=True) # needs sage.libs.singular
(True, (0 : 1 : 1))
```

```python
>>> from sage.all import *
>>> K = FractionField(QQ[t], names=(t,)); (t,) = K._first_ngens(1)
>>> C = Conic([Integer(1), -t, t])
>>> C.has_rational_point(point=True) # needs sage.libs.singular
(True, (0 : 1 : 1))
```
Plane and Space Curves, Release 10.4

```python
>>> from sage.all import *

>>> P = QQ['X, Y, Z']; (X, Y, Z,) = P._first_ngens(3)
>>> Conic(X**Integer(2) + Y**Integer(2) - Z**Integer(2))

Projective Conic Curve over Fraction Field of Univariate Polynomial Ring in t over Rational Field defined by X^2 + Y^2 - Z^2
```

REFERENCES:

- [HC2006]
- [Ack2016]

**find_point** (*supports*, *roots*, *case*, *solution=0*)

Given a solubility certificate like in [HC2006], find a point on `self`. Assumes `self` is in reduced form (see [HC2006] for a definition).

If you don’t have a solubility certificate and just want to find a point, use the function `has_rational_point()` instead.

**INPUT:**

- `self` – conic in reduced form.
- `supports` – 3-tuple where `supports[i]` is a list of all monic irreducible \( p \in F[t] \) that divide the \( i \)th of the 3 coefficients.
- `roots` – 3-tuple containing lists of roots of all elements of `supports[i]`, in the same order.
- `case` – 1 or 0, as in [HC2006].
- `solution` – (default: 0) a solution of (5) in [HC2006], if `case = 0`, 0 otherwise.

**OUTPUT:**

A point \((x, y, z) \in F(t)\) of `self`. Output is undefined when the input solubility certificate is incorrect.

**ALGORITHM:**

The algorithm used is the algorithm `FindPoint` in [HC2006], with a simplification from [Ack2016].

**EXAMPLES:**

```python
sage: K.<t> = FractionField(QQ['t'])
sage: C = Conic(K, [t**2 - 2, 2*t**3, -2*t**3 - 13*t**2 - 2*t + 18])
sage: C.has_rational_point(point=True) # indirect test
needs sage.libs.singular
(1, -3, (t + 1)/t : 1)
```

```python
>>> K = FractionField(QQ['t'], names=('t',)); (t,) = K._first_ngens(1)
>>> C = Conic(K, [t**2 - Integer(2), Integer(2)*t**3, -Integer(2)*t**3 - Integer(13)*t**2 - Integer(2)*t + Integer(18)])
>>> C.has_rational_point(point=True) # indirect test
needs sage.libs.singular
(1, -3, (t + 1)/t : 1)
```

Different solubility certificates give different points:
has_rational_point (point=False, algorithm='default', read_cache=True)

Returns True if and only if the conic self has a point over its base field $F(t)$, which is a field of rational functions.

If point is True, then returns a second output, which is a rational point if one exists.

Points are cached whenever they are found. Cached information is used if and only if read_cache is True.

The default algorithm does not (yet) work for all base fields $F$. In particular, sage is required to have:

- an algorithm for finding the square root of elements in finite extensions of $F$;
- a factorization and gcd algorithm for $F[t]$;
- an algorithm for solving conics over $F$.

ALGORITHM:

The parameter algorithm specifies the algorithm to be used:

- 'default' – use a native Sage implementation, based on the algorithm Conic in [HC2006].
• 'magma' (requires Magma to be installed) – delegates the task to the Magma computer algebra system.

EXAMPLES:

We can find points for function fields over (extensions of) $\mathbb{Q}$ and finite fields:

```python
sage: K.<t> = FractionField(PolynomialRing(QQ, 't'))
sage: C = Conic(K, [t^2 - 2, 2*t^3, -2*t^3 - 13*t^2 - 2*t + 18])
sage: C.has_rational_point(point=True)  # needs sage.libs.singular
(True, (-3 : (t + 1)/t : 1))
```

```python
sage: R.<t> = FiniteField(23)[]
sage: C = Conic([2, t^2 + 1, t^2 + 5])
sage: C.has_rational_point()  # needs sage.libs.singular
True
```

```python
sage: F.<i> = QuadraticField(-1)
sage: R.<t> = F[]
sage: C = Conic([1, i*t, -t^2 + 4])
sage: C.has_rational_point(point=True)  # needs sage.libs.singular
(True, (-t - 2*i : -2*i : 1))
```

It works on non-diagonal conics as well:
Plane and Space Curves, Release 10.4

```python
sage: K.<t> = QQ[]
sage: C = Conic([4, -4, 8, 1, -4, t + 4])
sage: C.has_rational_point(point=True) # needs sage.libs.singular
(True, (1/2 : 1 : 0))
```

```python
>>> from sage.all import *

>>> K = QQ['t']; (t,) = K._first_ngens(1)

>>> C = Conic([Integer(4), -Integer(4), Integer(8), Integer(1), -Integer(4), t + Integer(4)])

>>> C.has_rational_point(point=True) # needs sage.libs.singular
(True, (1/2 : 1 : 0))
```

If no point exists output still depends on the argument `point`:

```python
sage: K.<t> = QQ[]
sage: C = Conic(K, [t^2, (t-1), -2*(t-1)])
sage: C.has_rational_point() # needs sage.libs.singular
False
sage: C.has_rational_point(point=True) # needs sage.libs.singular
(False, None)
```

```python
>>> from sage.all import *

>>> K = QQ['t']; (t,) = K._first_ngens(1)

>>> C = Conic(K, [t**Integer(2), (t-Integer(1)), -Integer(2)*(t-Integer(1))])

>>> C.has_rational_point() # needs sage.libs.singular
False
```

Due to limitations in Sage of algorithms we depend on, it is not yet possible to find points on conics over multivariate function fields (see the requirements above):

```python
sage: F.<t1> = FractionField(QQ['t1'])
sage: K.<t2> = FractionField(F['t2'])
sage: a = K(1)
sage: b = 2*t2^2 + 2*t1*t2 - t1^2
sage: c = -3*t2^4 - 4*t1*t2^3 + 8*t1^2*t2^2 + 16*t1^3 - t2 - 48*t1^4
sage: C = Conic([a,b,c])
sage: C.has_rational_point() # needs sage.libs.singular
Traceback (most recent call last):
...
NotImplementedError: is_square() not implemented for elements of Univariate Quotient Polynomial Ring in tbar over Fraction Field of Univariate Polynomial Ring in t1 over Rational Field with modulus tbar^2 + t1*tbar - 1/2*t1^2
```

```python
>>> from sage.all import *

>>> F = FractionField(QQ['t1'], names=('t1',)); (t1,) = F._first_ngens(1)

>>> K = FractionField(F['t2'], names=('t2',)); (t2,) = K._first_ngens(1)
```

(continues on next page)
In some cases, the algorithm requires us to be able to solve conics over $F$. In particular, the following does not work:

```python
sage: P.<u> = QQ[]
sage: E = P.fraction_field()
sage: Q.<Y> = E[]
sage: F.<v> = E.extension(Y^2 - u^3 - 1)
sage: R.<t> = F[]
sage: K = R.fraction_field()
# needs sage.rings.function_field
sage: C = Conic(K, [u, v, 1])
# needs sage.rings.function_field
sage: C.has_rational_point()  # needs sage.rings.function_field
Traceback (most recent call last):
... NotImplementedError: has_rational_point not implemented for conics over base field Univariate Quotient Polynomial Ring in v over Fraction Field of Univariate Polynomial Ring in u over Rational Field with modulus v^2 - u^3 - 1
```

```python
>>> from sage.all import *
>>> P = QQ['u']; (u,) = P._first_ngens(1)
>>> E = P.fraction_field()
>>> Q = E['Y']; (Y,) = Q._first_ngens(1)
>>> F = E.extension(Y**Integer(2) - u**Integer(3) - Integer(1), names=('v',));
>>> (v,) = F._first_ngens(1)
>>> R = F['t']; (t,) = R._first_ngens(1)
>>> K = R.fraction_field()
# needs sage.rings.function_field
>>> C = Conic(K, [u, v, Integer(1)])
# needs sage.rings.function_field
>>> C.has_rational_point()  # needs sage.rings.function_field
Traceback (most recent call last):
... NotImplementedError: has_rational_point not implemented for conics over base field Univariate Quotient Polynomial Ring in v over Fraction Field of Univariate Polynomial Ring in u over Rational Field with modulus v^2 - u^3 - 1
```
CHAPTER THREE

PLANE QUARTICS

3.1 Quartic curve constructor

Return the quartic curve defined by the polynomial \( F \).

**INPUT:**

- \( F \) – a polynomial in three variables, homogeneous of degree 4
- \( PP \) – a projective plane (default: None)
- \( \text{check} \) – whether to check for smoothness or not (default: False)

**EXAMPLES:**

```python
sage: x, y, z = PolynomialRing(QQ, ['x', 'y', 'z']).gens()
sage: QuarticCurve(x**4 + y**4 + z**4)
Quartic Curve over Rational Field defined by x^4 + y^4 + z^4
```

3.2 Plane quartic curves over a general ring

These are generic genus 3 curves, as distinct from hyperelliptic curves of genus 3.

**EXAMPLES:**

```python
sage: PP.<X,Y,Z> = ProjectiveSpace(2, QQ)
sage: f = X**4 + Y**4 + Z**4 - 3*X*Y*Z*(X+Y+Z)
sage: C = QuarticCurve(f); C
Quartic Curve over Rational Field defined by X^4 + Y^4 - 3*X^2*Y*Z - 3*X*Y^2*Z - 3*X*Y*Z^2 + Z^4
```

(continues on next page)
class sage.schemes.plane_quartics.quartic_generic.QuarticCurve_generic(A, f, category=None)

Bases: ProjectivePlaneCurve

genus()

Return the genus of self.

EXAMPLES:

```sage
sage: x, y, z = PolynomialRing(QQ, ['x', 'y', 'z']).gens()
sage: Q = QuarticCurve(x**4 + y**4 + z**4)
sage: Q.genus()
3
```

```python
>>> from sage.all import *
>>> x, y, z = PolynomialRing(QQ, ['x', 'y', 'z']).gens()
>>> Q = QuarticCurve(x**Integer(4) + y**Integer(4) + z**Integer(4))
>>> Q.genus()
3
```

sage.schemes.plane_quartics.quartic_generic.is_QuarticCurve(C)

Check whether C is a Quartic Curve.

EXAMPLES:

```sage
sage: from sage.schemes.plane_quartics.quartic_generic import is_QuarticCurve
sage: x, y, z = PolynomialRing(QQ, ['x', 'y', 'z']).gens()
sage: Q = QuarticCurve(x**4 + y**4 + z**4)
sage: is_QuarticCurve(Q)
doctest:warning...
DeprecationWarning: The function is_QuarticCurve is deprecated; use 'isinstance(., QuarticCurve_generic)' instead.
See https://github.com/sagemath/sage/issues/38022 for details.
True
```

```python
>>> from sage.all import *
>>> from sage.schemes.plane_quartics.quartic_generic import is_QuarticCurve

>>> x, y, z = PolynomialRing(QQ, ['x', 'y', 'z']).gens()
>>> Q = QuarticCurve(x**Integer(4) + y**Integer(4) + z**Integer(4))
>>> is_QuarticCurve(Q)
doctest:warning...
DeprecationWarning: The function is_QuarticCurve is deprecated; use 'isinstance(., QuarticCurve_generic)' instead.
See https://github.com/sagemath/sage/issues/38022 for details.
True
```
4.1 Riemann matrices and endomorphism rings of algebraic Riemann surfaces

This module provides a class, `RiemannSurface`, to model the Riemann surface determined by a plane algebraic curve over a subfield of the complex numbers.

A homology basis is derived from the edges of a Voronoi cell decomposition based on the branch locus. The pull-back of these edges to the Riemann surface provides a graph on it that contains a homology basis.

The class provides methods for computing the Riemann period matrix of the surface numerically, using a certified homotopy continuation method due to [Kr2016].

The class also provides facilities for computing the endomorphism ring of the period lattice numerically, by determining integer (near) solutions to the relevant approximate linear equations.

One can also calculate the Abel-Jacobi map on the Riemann surface, and there is basic functionality to interface with divisors of curves to facilitate this.

AUTHORS:

- Alexandre Zotine, Nils Bruin (2017-06-10): initial version
- Nils Bruin, Jeroen Sijsling (2018-01-05): algebraization, isomorphisms
- Linden Disney-Hogg, Nils Bruin (2021-06-23): efficient integration
- Linden Disney-Hogg, Nils Bruin (2022-09-07): Abel-Jacobi map

EXAMPLES:

We compute the Riemann matrix of a genus 3 curve:

```
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
```

```
sage: f = x^4-x^3*y+2*x^3+2*x^2*y+2*x^2-2*x*y^2+4*x*y-y^3+3*y^2+2*y+1
sage: S = RiemannSurface(f, prec=100)
```

```
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
```

```python
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
```
We test the usual properties, i.e., that the period matrix is symmetric and that the imaginary part is positive definite:

```python
sage: all(abs(a) < 1e-20 for a in (M-M.T).list())
True
sage: iM = Matrix(RDF,3,3,[a.imag_part() for a in M.list()])

sage: iM.is_positive_definite()
True
```
We can read off the output of `places_at_branch_locus` to choose our divisor, and we can calculate the canonical divisor using curve functionality:

```
sage: P0 = 1*BL[0]
sage: from sage.schemes.curves.constructor import Curve
sage: C = Curve(f)
sage: F = C.function_field()
sage: K = (F(x).differential()).divisor() - F(f.derivative(y)).divisor()
sage: Pinf, Pinf_prime = C.places_at_infinity()
sage: if K-3*Pinf-1*Pinf_prime: Pinf, Pinf_prime = (Pinf_prime, Pinf);
sage: D = P0 + 2*Pinf - Pinf_prime
```

Note we could check using exact techniques that \(2D = K\):

```
sage: Z = K - 2*D
sage: (Z.degree() == 0, len(Z.basis_differential_space()) == S.genus, len(Z.basis_function_space()) == 1)
(True, True, True)
```

We can also check this using our Abel-Jacobi functions:

```
sage: avoid = C.places_at_infinity()
sage: Zeq, _ = S.strong_approximation(Z, avoid)
sage: Zlist = S.divisor_to_divisor_list(Zeq)
sage: AJ = S.abel_jacobi(Zlist)  # long time (1 second)
sage: S.reduce_over_period_lattice(AJ).norm() < 1e-10  # long time
True
```

(continues on next page)
REFERENCES:
The initial version of this code was developed alongside [BSZ2019].

exception sage.schemes.riemann_surfaces.riemann_surface.ConvergenceError
Bases: ValueError

Error object suitable for raising and catching when Newton iteration fails.

EXAMPLES:

```python
from sage.all import *
from sage.schemes.riemann_surfaces.riemann_surface import
raise ConvergenceError("test")
```

```
Traceback (most recent call last):
  ... ConvergenceError: test
isinstance(ConvergenceError(),ValueError)
```

```python
from sage.schemes.riemann_surfaces.riemann_surface import
raise ConvergenceError("test")
```

```
Traceback (most recent call last):
  ... ConvergenceError: test
isinstance(ConvergenceError(),ValueError)
```

class sage.schemes.riemann_surfaces.riemann_surface.RiemannSurface(f, prec=53, certification=True, differentials=None, integration_method='rigorous')

Bases: object

Construct a Riemann Surface. This is specified by the zeroes of a bivariate polynomial with rational coefficients \( f(z, w) = 0 \).

**INPUT:**

- \( f \) – a bivariate polynomial with rational coefficients. The surface is interpreted as the covering space of the coordinate plane in the first variable.
- \( \text{prec} \) – the desired precision of computations on the surface in bits (default: 53)
- \( \text{certification} \) – a boolean (default: True) value indicating whether homotopy continuation is certified or not. Uncertified homotopy continuation can be faster.
- \( \text{differentials} \) – (default: None). If specified, provides a list of polynomials \( h \) such that \( h/(df/dw)dz \) is a regular differential on the Riemann surface. This is taken as a basis of the regular differentials, so the genus is assumed to be equal to the length of this list. The results from the homology basis computation are checked against this value. Providing this parameter makes the computation independent from Singular. For a nonsingular plane curve of degree \( d \), an appropriate set is given by the monomials of degree up to \( d - 3 \).
• \textit{integration_method}—\textit{(default: 'rigorous')} String specifying the integration method to use when calculating the integrals of differentials. The options are 'heuristic' and 'rigorous', the latter of which is often the most efficient.

**EXAMPLES:**

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
Riemann surface defined by polynomial \( f = -z^3 + w^2 + 1 = 0 \), with 53 bits of...
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ[z, w]; (z, w,) = R._first_ngens(2)
>>> f = w**Integer(2) - z**Integer(3) + Integer(1)
>>> RiemannSurface(f)
Riemann surface defined by polynomial \( f = -z^3 + w^2 + 1 = 0 \), with 53 bits of...
```

Another Riemann surface with 100 bits of precision:

```python
sage: S = RiemannSurface(f, prec=Integer(100)); S
```

We can also work with Riemann surfaces that are defined over fields with a complex embedding, but since the current interface for computing genus and regular differentials in Singular presently does not support extensions of \( \mathbb{Q} \), we need to specify a description of the differentials ourselves. We give an example of a CM elliptic curve:

```python
sage: Qt.<t> = QQ[]
sage: K.<a> = NumberField(t^Integer(2)-t+Integer(3),embedding=CC(RealNumber(0.5+1.6*I)), names=(a,)); (a,) = K._first_ngens(1)
```

(continues on next page)
The 'heuristic' integration method uses the method integrate_vector defined in sage.numerical.gauss_legendre to compute integrals of differentials. As mentioned there, this works by iteratively doubling the number of nodes used in the quadrature, and uses a heuristic based on the rate at which the result is seemingly converging to estimate the error. The 'rigorous' method uses results from [Neu2018], and bounds the algebraic integrands on circular domains using Cauchy's form of the remainder in Taylor approximation coupled to Fujiwara's bound on polynomial roots (see Bruin-DisneyHogg-Gao, in preparation). Note this method of bounding on circular domains is also implemented in _compute_delta(). The net result of this bounding is that one can know (an upper bound on) the number of nodes required to achieve a certain error. This means that for any given integral, assuming that the same number of nodes is required by both methods in order to achieve the desired error (not necessarily true in practice), approximately half the number of integrand evaluations are required. When the required number of nodes is high, e.g. when the precision required is high, this can make the 'rigorous' method much faster. However, the 'rigorous' method does not benefit as much from the caching of the nodes method over multiple integrals. The result of this is that, for calls of matrix_of_integral_values() if the computation is 'fast', the heuristic method may outperform the rigorous method, but for slower computations the rigorous method can be much faster:

sage: f = z*w^3 + z^3 + w
sage: p = 53
sage: Sh = RiemannSurface(f, prec=p, integration_method='heuristic')
sage: Sr = RiemannSurface(f, prec=p, integration_method='rigorous')

```sage
>>> from sage.numerical.gauss_legendre import nodes
>>> import time

>>> nodes.cache.clear()
... ct = time.time()
>>> Rh = Sh.riemann_matrix()
... ct1 = time.time()-ct
>>> nodes.cache.clear()
... ct = time.time()
>>> Rr = Sr.riemann_matrix()

1.2429363969691192
```

(continues on next page)
ct2 = time.time() - ct
ct2/ct1  # random
1.2429363969691192

Note that for the above curve, the branch points are evenly distributed, and hence the implicit assumptions in the heuristic method are more sensible, meaning that a higher precision is required to see the heuristic method being significantly slower than the rigorous method. For a worse conditioned curve, this effect is more pronounced:

```python
sage: q = 1 / 10
sage: f = y^2 - (x^2 - 2*x + 1 + q^2) * (x^2 + 2*x + 1 + q^2)

sage: Rh = Sh.riemann_matrix()  # long time (8 seconds)
sage: Rr = Sr.riemann_matrix()  # long time (1 seconds)
```

This disparity in timings can get increasingly worse, and testing has shown that even for random quadrics the heuristic method can be as bad as 30 times slower.

`abel_jacobi` *(divisor, verbose=False)*

Return the Abel-Jacobi map of `divisor`.

Return a representative of the Abel-Jacobi map of a divisor with basepoint `self._basepoint`.

**INPUT:**

- `divisor` – list. A list with each entry a tuple of the form \((v, P)\), where \(v\) is the valuation of the divisor at point \(P\), \(P\) as per the input to `_aj_based()`.
- `verbose` – logical (default: False). Whether to report the progress of the computation, in terms of how many elements of the list `divisor` have been completed.

**OUTPUT:** A vector of length `self.genus`.

**EXAMPLES:**

We can test that the Abel-Jacobi map between two branchpoints of a superelliptic curve of degree \(p\) is a \(p\)-torsion point in the Jacobian:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
sage: p = 4
sage: S = RiemannSurface(y^p-x^4+1, prec=100)
sage: divisor = [(-1, (-1, 0)), (1, (1, 0))]
```
Plane and Space Curves, Release 10.4

sage: AJ = S.abel_jacobi(divisor)  # long time (15 seconds)
sage: AJxp = [p*z for z in AJ]  # long time
sage: bool(S.reduce_over_period_lattice(AJxp).norm()<1e-7)  # long time
True

>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> p = Integer(4)
>>> S = RiemannSurface(y**p-x**Integer(4)+Integer(1), prec=Integer(100))
>>> divisor = [(-Integer(1), (-Integer(1), Integer(0))), (Integer(1),
→(Integer(1), Integer(0)))]
>>> AJ = S.abel_jacobi(divisor)  # long time (15 seconds)
>>> AJxp = [p*z for z in AJ]  # long time
>>> bool(S.reduce_over_period_lattice(AJxp).norm()<RealNumber('1e-7'))  # long time
True

cohomology_basis (option=1)

Compute the cohomology basis of this surface.

INPUT:

• option – Presently, this routine uses Singular's adjointIdeal and passes the option parameter on. Legal values are 1, 2, 3, 4, where 1 is the default. See the Singular documentation for the meaning. The backend for this function may change, and support for this parameter may disappear.

OUTPUT:

This returns a list of polynomials \( g \) representing the holomorphic differentials \( g/(df/dw)dz \), where \( f(z, w) = 0 \) is the equation specifying the Riemann surface.

EXAMPLES:

sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
sage: f = z^3*w + w^3 + z
sage: S = RiemannSurface(f)
sage: S.cohomology_basis()
[1, w, z]

curve ()

Return the curve from which this Riemann surface is obtained.

Riemann surfaces explicitly obtained from a curve return that same object. For others, the curve is constructed and cached, so that an identical curve is returned upon subsequent calls.

OUTPUT: Curve from which Riemann surface is obtained.

EXAMPLES:
sage: R.<x,y> = QQ[]
sage: C = Curve( y^3+x^3-1)
sage: S = C.riemann_surface()
sage: S.curve() is C
True

```python
>>> from sage.all import *
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> C = Curve( y**Integer(3)+x**Integer(3)-Integer(1))
>>> S = C.riemann_surface()
>>> S.curve() is C
True
```

divisor_to_divisor_list(divisor, eps=None)

Turn a divisor into a list for abel_jacobi().

Given divisor in Curve(self.f).function_field().divisor_group(), consisting of places above finite points in the base, return an equivalent divisor list suitable for input into abel_jacobi().

INPUT:

- divisor – an element of Curve(self.f).function_field().divisor_group()
- eps – real number (optional); tolerance used to determine whether a complex number is close enough to a root of a polynomial

OUTPUT:

A list with elements of the form \((v, (z, w))\) representing the finite places.

EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
sage: S = RiemannSurface(y^2-x^3+1)
sage: D = sum(S.places_at_branch_locus())
sage: S.divisor_to_divisor_list(D)
[(1, (1.000000000000000, 0.000000000000000)),
 (1, (-0.500000000000000 - 0.866025403784439*I, 0.000000000000000)),
 (1, (-0.500000000000000 + 0.866025403784439*I, 0.000000000000000))]
```

Todo: Currently this method can only handle places above finite points in the base. It would be useful to extend this to allow for places at infinity.

downstairs_edges()

Compute the edgeset of the Voronoi diagram.

4.1. Riemann matrices and endomorphism rings of algebraic Riemann surfaces 237
OUTPUT:

A list of integer tuples corresponding to edges between vertices in the Voronoi diagram.

EXAMPLES:

Form a Riemann surface, one with a particularly simple branch locus:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
sage: f = w^2 + z^3 - z^2
sage: S = RiemannSurface(f)
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ[z, w]; (z, w,) = R._first_ngens(2)
>>> f = w**Integer(2) + z**Integer(3) - z**Integer(2)
>>> S = RiemannSurface(f)
```

Compute the edges:

```python
sage: S.downstairs_edges()
[(0, 1), (0, 5), (1, 4), (2, 3), (2, 4), (3, 5), (4, 5)]
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ[z, w]; (z, w,) = R._first_ngens(2)
>>> f = w**Integer(2) - z**Integer(4) + Integer(1)
>>> S = RiemannSurface(f)
>>> S.downstairs_graph()
Graph on 11 vertices
```

This now gives an edgset which one could use to form a graph.

Note: The numbering of the vertices is given by the Voronoi package.

`downstairs_graph()`

Return the Voronoi decomposition as a planar graph.

The result of this routine can be useful to interpret the labelling of the vertices. See also `upstairs_graph()`.

OUTPUT:

The Voronoi decomposition as a graph, with appropriate planar embedding.

EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
sage: f = w^2 - z^4 + 1
sage: S = RiemannSurface(f)
sage: S.downstairs_graph()
Graph on 11 vertices
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ[z, w]; (z, w,) = R._first_ngens(2)
>>> f = w**Integer(2) - z**Integer(4) + Integer(1)
>>> S = RiemannSurface(f)
>>> S.downstairs_graph()
Graph on 11 vertices
```
**edge_permutations()**

Compute the permutations of branches associated to each edge.

Over the vertices of the Voronoi decomposition around the branch locus, we label the fibres. By following along an edge, the lifts of the edge induce a permutation of that labelling.

**OUTPUT:**

A dictionary with as keys the edges of the Voronoi decomposition and as values the corresponding permutations.

**EXAMPLES:**

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
sage: f = w^2 + z^2+1
sage: S = RiemannSurface(f)
sage: S.edge_permutations()
{(0, 2): (),
 (0, 4): (),
 (1, 2): (),
 (1, 3): (0,1),
 (1, 6): ()
 (2, 0): (),
 (2, 1): (),
 (2, 5): (0,1),
 (3, 1): (0,1),
 (3, 4): (),
 (4, 0): (),
 (4, 3): (),
 (5, 2): (0,1),
 (5, 7): (),
 (6, 1): (),
 (6, 7): (),
 (7, 5): (),
 (7, 6): ()}
```

```
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ[\[z, w\]]; (z, w,) = R._first_ngens(2)
>>> f = w**Integer(2) + z**Integer(2)+Integer(1)
>>> S = RiemannSurface(f)
>>> S.edge_permutations()
{(0, 2): (),
 (0, 4): (),
 (1, 2): (),
 (1, 3): (0,1),
 (1, 6): ()
 (2, 0): (),
 (2, 1): (),
 (2, 5): (0,1),
 (3, 1): (0,1),
 (3, 4): (),
 (4, 0): (),
 (4, 3): (),
 (5, 2): (0,1),
 (5, 7): (),
 (6, 1): (),
 (6, 7): (),
 (7, 5): (),
 (7, 6): ()}
```

(continues on next page)
endomorphism_basis \( (b=None, r=None) \)
Numerically compute a \( \mathbb{Z} \)-basis for the endomorphism ring.

Let \( (I|M) \) be the normalized period matrix \( (M \) is the \( g \times g \) \text{riemann_matrix}()\). We consider the system of matrix equations \( MA + C = (MB + D)M \) where \( A, B, C, D \) are \( g \times g \) integer matrices. We determine small integer (near) solutions using LLL reductions. These solutions are returned as \( 2g \times 2g \) integer matrices obtained by stacking \((D|B)\) on top of \((C|A)\).

INPUT:

- \( b \) – integer (default provided). The equation coefficients are scaled by \( 2^b \) before rounding to integers.
- \( r \) – integer (default: \( b/4 \)). Solutions that have all coefficients smaller than \( 2^r \) in absolute value are reported as actual solutions.

OUTPUT:
A list of \( 2g \times 2g \) integer matrices that, for large enough \( r \) and \( b-r \), generate the endomorphism ring.

EXAMPLES:

```
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface/nsage: R.<x,y> = QQ[]
sage: S = RiemannSurface(x^3 + y^3 + 1)
sage: B = S.endomorphism_basis(); B  # random
[ [1 0] [ 0 -1]
 [0 1], [ 1 1]
]
sage: sorted([b.minpoly().disc() for b in B])
[-3, 1]
```

```
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ['x, y']; (x, y) = R._first_ngens(2)
>>> S = RiemannSurface(x**Integer(3) + y**Integer(3) + Integer(1))
>>> B = S.endomorphism_basis(); B  # random
[ [1 0] [ 0 -1]
 [0 1], [ 1 1]
]
>>> sorted([b.minpoly().disc() for b in B])
[-3, 1]
```

homology_basis()
Compute the homology basis of the Riemann surface.

OUTPUT:
A list of paths \( L = [P_1, \ldots, P_n] \). Each path \( P_i \) is of the form \((k, [p_1 \ldots p_m, p_1])\), where \( k \) is the number of times to traverse the path (if negative, to traverse it backwards), and the \( p_i \) are vertices of the upstairs graph.

EXAMPLES:
In this example, there are two paths that form the homology basis:
In order to check that the answer returned above is reasonable, we test some basic properties. We express the faces of the downstairs graph as \(\mathbb{Z} \mathbb{Z}\)-linear combinations of the edges and check that the projection of the homology basis upstairs projects down to independent linear combinations of an even number of faces:

```python
sage: dg = S.downstairs_graph()
sage: edges = dg.edges(sort=True)
sage: E = \mathbb{Z}^2 * len(edges)
sage: edge_to_E = { e[:2]: E.gen(i) for i,e in enumerate(edges) }
sage: edge_to_E.update({ (e[1],e[0]): -E.gen(i) for i,e in enumerate(edges) })
sage: face_span = E.submodule([sum(edge_to_E[e] for e in f) for f in dg.faces()])
sage: def path_to_E(path): ...
  k,P = path ...
  return k*sum(edge_to_E[(P[i][0],P[i+1][0])] for i in range(len(P)-1))
sage: hom_basis = [sum(path_to_E(p) for p in loop) for loop in S.homology_basis()]
sage: face_span.submodule(hom_basis).rank() 2
sage: [sum(face_span.coordinate_vector(b))%2 for b in hom_basis]
[0, 0]
```

(continues on next page)
hom_basis = [sum(path_to_E(p) for p in loop) for loop in S.homology_\rightarrow basis()]

>>> face_span.submodule(hom_basis).rank()
2
>>> [sum(face_span.coordinate_vector(b))%Integer(2) for b in hom_basis]
[0, 0]

homomorphism_basis (other, b=None, r=None)

Numerically compute a \(\mathbb{Z}\)-basis for module of homomorphisms to a given complex torus.

Given another complex torus (given as the analytic Jacobian of a Riemann surface), numerically compute a basis for the homomorphism module. The answer is returned as a list of \(2g \times 2g\) integer matrices \(T = (D, B; C, A)\) such that if the columns of \((I|M_1)\) generate the lattice defining the Jacobian of the Riemann surface and the columns of \((I|M_2)\) do this for the codomain, then approximately we have \((I|M_2)T = (D + M_2C)(I|M_1)\), i.e., up to a choice of basis for \(\mathbb{C}^g\) as a complex vector space, we we realize \((I|M_1)\) as a sublattice of \((I|M_2)\).

INPUT:

- \(b\) – integer (default provided). The equation coefficients are scaled by \(2^b\) before rounding to integers.
- \(r\) – integer (default: \(b/4\)). Solutions that have all coefficients smaller than \(2^r\) in absolute value are reported as actual solutions.

OUTPUT:

A list of \(2g \times 2g\) integer matrices that, for large enough \(r\) and \(b-r\), generate the homomorphism module.

EXAMPLES:

sage: S1 = EllipticCurve("11a1").riemann_surface()
sage: S2 = EllipticCurve("11a3").riemann_surface()
sage: [m.det() for m in S1.homomorphism_basis(S2)]
[5]

homotopy_continuation (edge)

Perform homotopy continuation along an edge of the Voronoi diagram using Newton iteration.

INPUT:

- edge – a tuple \((z_{\text{start}}, z_{\text{end}})\) indicating the straight line over which to perform the homotopy continuation

OUTPUT:

A list containing the initialised continuation data. Each entry in the list contains: the \(t\) values that entry corresponds to, a list of complex numbers corresponding to the points which are reached when continued along the edge when traversing along the direction of the edge, and a value \(\epsilon\) giving the minimum distance between the fibre values divided by 3. The ordering of these points indicates how they have been permuted due to the weaving of the curve.

EXAMPLES:
We check that continued values along an edge correspond (up to the appropriate permutation) to what is stored. Note that the permutation was originally computed from this data:

```sage
from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
R.<z,w> = QQ[]
f = z^3*w + w^3 + z
S = RiemannSurface(f)
sigma = S.edge_permutations()[edge1]
sigma = S.w_values(S._vertices[edge1[1]])
all(abs(continued_values[i]-stored_values[sigma(i)]) < 1e-8 for i in range(3))
```

```
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ['z, w']; (z, w,) = R._first_ngens(2)
>>> f = z**Integer(3)*w + w**Integer(3) + z
>>> S = RiemannSurface(f)
>>> edge1 = sorted(S.edge_permutations())[Integer(0)]
>>> edge = [S._vertices[i] for i in edge1]
>>> continued_values = S.homotopy_continuation(edge)[-Integer(1)][Integer(1)]
>>> stored_values = S.w_values(S._vertices[edge1[1]])
>>> all(abs(continued_values[i]-stored_values[sigma]) < RealNumber('1e-8'))
```

make_zw_interpolator (upstairs_edge, initial_continuation=None)

Given a downstairs edge for which continuation data has been initialised, return a function that computes \( z(t), w(t) \), where \( t \) in \([0, 1]\) is a parametrization of the edge.

**INPUT:**

- `upstairs_edge` – tuple \(((z_{\text{start}}, sb), (z_{\text{end}},))\) giving the start and end values of the base coordinate along the straight-line path and the starting branch
- `initial_continuation` – list (optional); output of `homotopy_continuation` initialising the continuation data

**OUTPUT:**

A tuple \((g, d)\), where \(g\) is the function that computes the interpolation along the edge and \(d\) is the difference of the \(z\)-values of the end and start point.

**EXAMPLES:**

```sage
from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
R.<z,w> = QQ[]
f = w^2 - z^4 + 1
S = RiemannSurface(f)
_h = S.homology_basis()
_u_edge = [(0, 0), (1, 0)]
_d_edge = tuple(u[0] for u in _u_edge)
_u_edge = [(S._vertices[i], j) for i, j in _u_edge]
_initial_continuation = S._L[d_edge]
```
Note: The interpolator returned by this method can effectively hang if either \texttt{z\_start} or \texttt{z\_end} are branchpoints. In these situations it is better to take a different approach rather than continue to use the interpolator.

\textbf{matrix\_of\_integral\_values} \texttt{(differentials, integration\_method='heuristic')}  

Compute the path integrals of the given differentials along the homology basis.

The returned answer has a row for each differential. If the Riemann surface is given by the equation \( f(z, w) = 0 \), then the differentials are encoded by polynomials \( g \), signifying the differential \( \frac{g(z, w)}{(df/dw)dz} \).

\textbf{INPUT:}  
\begin{itemize}  
  \item \texttt{differentials} – a list of polynomials.  
  \item \texttt{integration\_method} – (default: 'heuristic'). String specifying the integration method to use. The options are 'heuristic' and 'rigorous'.  
\end{itemize}

\textbf{OUTPUT:}  
A matrix, one row per differential, containing the values of the path integrals along the homology basis of the Riemann surface.

\textbf{EXAMPLES:}  

\begin{verbatim}
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
sage: S = RiemannSurface(x^3 + y^3 + 1)
sage: B = S.cohomology_basis()
sage: m = S.matrix_of_integral_values(B)
sage: parent(m)
Full MatrixSpace of 1 by 2 dense matrices over Complex Field with 53 bits of precision
sage: (m[0,0]/m[0,1]).algdep(3).degree() # curve is CM, so the period is...
\end{verbatim}
Note: If `differentials` is `self.cohomology_basis()`, the calculations of the integrals along the edges are written to `self._integral_dict`. This is as this data will be required when computing the Abel-Jacobi map, and so it is helpful to have is stored rather than recomputing.

**monodromy_group()**

Compute local monodromy generators of the Riemann surface.

For each branch point, the local monodromy is encoded by a permutation. The permutations returned correspond to positively oriented loops around each branch point, with a fixed base point. This means the generators are properly conjugated to ensure that together they generate the global monodromy. The list has an entry for every finite point stored in `self.branch_locus`, plus an entry for the ramification above infinity.

**OUTPUT:**

A list of permutations, encoding the local monodromy at each branch point.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ['z, w']; (z, w,) = R._first_ngens(2)
>>> f = z**Integer(3)*w + w**Integer(3) + z
>>> S = RiemannSurface(f)
>>> G = S.monodromy_group(); G
[(0,1,2), (0,1), (0,2), (1,2), (1,2), (1,2), (0,1), (0,2), (0,2)]
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ['z, w']; (z, w,) = R._first_ngens(2)
>>> f = z**Integer(3)*w + w**Integer(3) + z
>>> S = RiemannSurface(f)
>>> G = S.monodromy_group(); G
[(0,1,2), (0,1), (0,2), (1,2), (1,2), (1,2), (0,1), (0,2), (0,2)]
```

The permutations give the local monodromy generators for the branch points:

```python
sage: list(zip(S.branch_locus + [unsigned_infinity], G)) # abs tol 0.0000001
[(0.000000000000000, (0,1,2)),
 (-1.31362670141929, (0,1)),
 (-0.819032851784253 - 1.02703471138023*I, (0,2)),
 (continues on next page)
```
>>> from sage.all import *

```python
>>> list(zip(S.branch_locus + [unsigned_infinity], G))  # abs tol 0.000001
[(0.000000000000000, (0,1,2)),
 (-1.31362670141929, (0,1)),
 (-0.819032851784253 - 1.02703471138023*I, (0,2)),
 (-0.819032851784253 + 1.02703471138023*I, (1,2)),
 (0.292309440469772 - 1.28069133740100*I, (1,2)),
 (0.292309440469772 + 1.28069133740100*I, (1,2)),
 (1.18353676202412 - 0.569961265016465*I, (0,1)),
 (1.18353676202412 + 0.569961265016465*I, (0,2)),
 (Infinity, (0,2))]```

We can check the ramification by looking at the cycle lengths and verify it agrees with the Riemann-Hurwitz formula:

```
sage: 2*S.genus-2 == -2*S.degree + sum(e-1 for g in G for e in g.cycle_type())
True
```
One can check that the two methods give similar answers:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
sage: f = y^2 - x^3 + 1
sage: S = RiemannSurface(f, integration_method="rigorous")
sage: T = RiemannSurface(f, integration_method="heuristic")
sage: RM_S = S.riemann_matrix()
sage: RM_T = T.riemann_matrix()
sage: (RM_S-RM_T).norm() < 1e-10
True
```

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R = QQ[x, y]; (x, y,) = R._first_ngens(2)
sage: f = y**Integer(2) - x**Integer(3) + Integer(1)
sage: S = RiemannSurface(f, integration_method="rigorous")
sage: T = RiemannSurface(f, integration_method="heuristic")
sage: RM_S = S.riemann_matrix()
sage: RM_T = T.riemann_matrix()
sage: (RM_S-RM_T).norm() < RealNumber('1e-10')
True
```

places_at_branch_locus()

Return the places above the branch locus.

Return a list of the of places above the branch locus. This must be done over the base ring, and so the places are given in terms of the factors of the discriminant. Currently, this method only works when self._R.base_ring() == QQ as for other rings, the function field for Curve(self.f) is not implemented. To go from these divisors to a divisor list, see divisor_to_divisor_list().

OUTPUT:

List of places of the functions field Curve(self.f).function_field().

EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
sage: S = RiemannSurface(25*(x^4+y^4+1) - 34*(x^2*y^2+x^2+y^2))
```
Place \((x + 1/2, (x + 1/2)*y, y^2 - 17/20, y^3 - 17/20*y),\)
Place \((x^4 - 34/25*x^2 + 1, y, y^2, y^3),\)
Place \((x^4 - 34/25*x^2 + 1, (x^4 - 34/25*x^2 + 1)*y, y^2 - 34/25*x^2 - 34/25, \rightarrow y^3 + (-34/25*x^2 - 34/25)*y)\]

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> S = RiemannSurface(Integer(25)*(x**Integer(4)+y**Integer(4)+Integer(1)) -
\rightarrow Integer(34)*(x**Integer(2)*y**Integer(2)+x**Integer(2)+y**Integer(2)))
>>> S.places_at_branch_locus()
[Place (x - 2, (x - 2)*y, y^2 - 17/5, y^3 - 17/5*y),
Place (x + 2, (x + 2)*y, y^2 - 17/5, y^3 - 17/5*y),
Place (x - 1/2, (x - 1/2)*y, y^2 - 17/20, y^3 - 17/20*y),
Place (x + 1/2, (x + 1/2)*y, y^2 - 17/20, y^3 - 17/20*y),
Place (x^4 - 34/25*x^2 + 1, y, y^2, y^3),
Place (x^4 - 34/25*x^2 + 1, (x^4 - 34/25*x^2 + 1)*y, y^2 - 34/25*x^2 - 34/25, \rightarrow y^3 + (-34/25*x^2 - 34/25)*y)]
```

```
plot_paths()
```

Make a graphical representation of the integration paths.

This returns a two dimensional plot containing the branch points (in red) and the integration paths (obtained from the Voronoi cells of the branch points). The integration paths are plotted by plotting the points that have been computed for homotopy continuation, so the density gives an indication of where numerically sensitive features occur.

EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
sage: S = RiemannSurface(y^2 - x^3 - x)
sage: S.plot_paths()  # needs sage.plot
Graphics object consisting of 2 graphics primitives
```

```
plot_paths3d(thickness=0.01)
```

Return the homology basis as a graph in 3-space.

The homology basis of the surface is constructed by taking the Voronoi cells around the branch points and taking the inverse image of the edges on the Riemann surface. If the surface is given by the equation \(f(z, w)\), the returned object gives the image of this graph in 3-space with coordinates \((\text{Re}(z), \text{Im}(z), \text{Im}(w))\).

EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
sage: S = RiemannSurface(y^2 - x^3 - x)
```

(continues on next page)
reduce_over_period_lattice (vector, method='ip', b=None, r=None, normalised=False)
Reduce a vector over the period lattice.

Given a vector of length self.genus, this method returns a vector in the same orbit of the period lattice that is short. There are two possible methods, 'svp' which returns a certified shortest vector, but can be much slower for higher genus curves, and 'ip', which is faster but not guaranteed to return the shortest vector. In general the latter will perform well when the lattice basis vectors are of similar size.

INPUT:

- vector -- vector. A vector of length self.genus to reduce over the lattice.
- method -- string (default: 'ip'). String specifying the method to use to reduce the vector. The options are 'ip' and 'svp'.
- b -- integer (default provided): as for homomorphism_basis(), and used in its invocation if (re)calculating said basis.
- r -- integer (default: b/4). as for homomorphism_basis(), and used in its invocation if (re)calculating said basis.
- normalised -- logical (default: False). Whether to use the period matrix with the differentials normalised s.t. the $A$-matrix is the identity.

OUTPUT:
Complex vector of length self.genus in the same orbit as vector in the lattice.

EXAMPLES:
We can check that the lattice basis vectors themselves are reduced to zero:

reduce_over_period_lattice (vector, method='ip', b=None, r=None, normalised=False)
We can also check that the method 'svp' always gives a smaller norm than 'ip':

```python
sage: for vector in S.period_matrix().columns():
    n1 = S.reduce_over_period_lattice(vector).norm()
    n2 = S.reduce_over_period_lattice(vector, method="svp").norm()
    print(bool(n2<=n1))
```

We can also check that the method 'svp' always gives a smaller norm than 'ip':

```python
sage: for vector in S.period_matrix().columns():
    n1 = S.reduce_over_period_lattice(vector).norm()
    n2 = S.reduce_over_period_lattice(vector, method="svp").norm()
    print(bool(n2<=n1))
```

riemann_matrix()
Compute the Riemann matrix.
OUTPUT:
A matrix of complex values.
EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
```

The Klein quartic has a Riemann matrix with values in a quadratic field:

```python
sage: x = polygen(QQ)
```

```python
sage: K.<a> = NumberField(x**2 - x + 2)
```

```python
sage: all(len(m.algdep(6).roots(K)) > 0 for m in M.list())
```
from sage.all import *
x = polygen(QQ)
K = NumberField(x**Integer(2) - x + Integer(2), names=('a',)); (a,) = K._first_ngens(1)
all(len(m.algdep(Integer(6)).roots(K)) > Integer(0) for m in M.list())
True

rigorous_line_integral (upstairs_edge, differentials, bounding_data)

Perform vectorized integration along a straight path.

Using the error bounds for Gauss-Legendre integration found in [Neu2018] and a method for bounding an algebraic integrand on a circular domains using Cauchy’s form of the remainder in Taylor approximation coupled to Fujiwara’s bound on polynomial roots (see Bruin-Disney-Hogg-Gao, in preparation), this method calculates (semi-)rigorously the integral of a list of differentials along an edge of the upstairs graph.

INPUT:

• upstairs_edge – tuple. Either a pair of integer tuples corresponding to an edge of the upstairs graph, or a tuple ((z_start, sb), (z_end, )) as in the input of make_zw_interpolator.

• differentials – a list of polynomials; a polynomial $g$ represents the differential $g(z,w)/(df/dw)dz$ where $f(z,w) = 0$ is the equation defining the Riemann surface.

• bounding_data – tuple containing the data required for bounding the integrands. This should be in the form of the output from _bounding_data().

OUTPUT:

A complex number, the value of the line integral.

EXAMPLES:

sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
sage: f = w^2 - z^4 + 1
sage: S = RiemannSurface(f); S
Riemann surface defined by polynomial f = -z^4 + w^2 + 1 = 0, with 53 bits of...

Since we make use of data from homotopy continuation, we need to compute the necessary data:

sage: _ = S.homology_basis()
sage: differentials = S.cohomology_basis()
sage: bounding_data = S._bounding_data(differentials)
sage: S.rigorous_line_integral([(0,0), (1,0)], differentials, bounding_data)
# abs tol 1e-10
(1.80277751848459e-16 - 0.352971844594760*I)

4.1. Riemann matrices and endomorphism rings of algebraic Riemann surfaces 251
```python
>>> differentials = S.cohomology_basis()
>>> bounding_data = S._bounding_data(differentials)
>>> S.rigorous_line_integral(((Integer(0),Integer(0)), (Integer(1), Integer(0))), differentials, bounding_data)  # abs tol 1e-10
(1.80277751848459e-16 - 0.352971844594760*I)
```

**Note:** Uses data that `homology_basis` initializes, and may give incorrect values if `homology_basis()` has not initialized them.

Note also that the data of the differentials is contained within `bounding_data`. It is, however, still advantageous to have this be a separate argument, as it lets the user supply a fast-callable version of the differentials, to significantly speed up execution of the integrand calls, and not have to re-calculate these fast-callables for every run of the function. This is also the benefit of representing the differentials as a polynomial over a known common denominator.

**Todo:** Note that `bounding_data` contains the information of the integrands, so one may want to check for consistency between `bounding_data` and `differentials`. If so one would not want to do so at the expense of speed.

Moreover, the current implementation bounds along a line by splitting it up into segments, each of which can be covered entirely by a single circle, and then placing inside that the ellipse required to bound as per [Neu2018]. This is reliably more efficient than the heuristic method, especially in poorly-conditioned cases where discriminant points are close together around the edges, but in the case where the branch locus is well separated, it can require slightly more nodes than necessary. One may want to include a method here to transition in this regime to an algorithm that covers the entire line with one ellipse, then bounds along that ellipse with multiple circles.

### `rosati_involution(R)`

Compute the Rosati involution of an endomorphism.

The endomorphism in question should be given by its homology representation with respect to the symplectic basis of the Jacobian.

**INPUT:**

• R – integral matrix.

**OUTPUT:**

The result of applying the Rosati involution to R.

**EXAMPLES:**

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: A.<x,y> = QQ[]
```

```python
sage: S = RiemannSurface(y**2 - (x**6 + 2*x**4 + 4*x**2 + 8), prec = 100)
```

```python
sage: Rs = S.endomorphism_basis()
```

```python
sage: S.rosati_involution(S.rosati_involution(Rs[1])) == Rs[1]
True
```

\[
\text{simple_vector_line_integral} \ (\text{upstairs_edge}, \text{differentials})
\]

Perform vectorized integration along a straight path.

INPUT:

- \text{upstairs_edge} – tuple. Either a pair of integer tuples corresponding to an edge of the upstairs graph, or a tuple \((\text{z} _ \text{start}, \text{sb}), (\text{z} _ \text{end}, \text{ })\) as the input in \text{make_zw_interpolator}.

- \text{differentials} – a list of polynomials; a polynomial \(g\) represents the differential \(g(z, w)/(df/dw)dz\) where \(f(z, w) = 0\) is the equation defining the Riemann surface.

OUTPUT:

A complex number, the value of the line integral.

EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
... f = w^2 - z^4 + 1
sage: S = RiemannSurface(f); S
Riemann surface defined by polynomial f = -z^4 + w^2 + 1 = 0, with 53 bits of precision
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> R = QQ['z', 'w']; (z, w,) = R._first_ngens(2)
>>> f = w**Integer(2) - z**Integer(4) + Integer(1)
>>> S = RiemannSurface(f); S
Riemann surface defined by polynomial f = -z^4 + w^2 + 1 = 0, with 53 bits of precision
```

Since we make use of data from homotopy continuation, we need to compute the necessary data:

```python
sage: M = S.riemann_matrix()
sage: differentials = S.cohomology_basis()
sage: S.simple_vector_line_integral([(0, 0), (1, 0)], differentials) #abs tol 0.000000001
(1.14590610929717e-16 - 0.352971844594760*I)
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> M = S.riemann_matrix()
>>> differentials = S.cohomology_basis()
>>> S.simple_vector_line_integral([(Integer(0), Integer(0)), (Integer(1), Integer(0))], differentials) #abs tol 0.000000001
(1.14590610929717e-16 - 0.352971844594760*I)
```

Note: Uses data that \text{homology_basis()} initializes, and may give incorrect values if \text{homology_basis()} has not initialized them. In practice it is more efficient to set \text{differentials} to a fast-callable version of differentials to speed up execution.

4.1. Riemann matrices and endomorphism rings of algebraic Riemann surfaces
**strong_approximation**(*divisor, S*)

Apply the method of strong approximation to a divisor.

As described in [Neu2018], apply the method of strong approximation to *divisor* with list of places to avoid *S*. Currently, this method only works when `self._R.base_ring() == QQ` as for other rings, the function field for `Curve(self.f)` is not implemented.

**INPUT:**
- *divisor* - an element of `Curve(self.f).function_field().divisor_group()`  
- *S* – list of places to avoid

**OUTPUT:**
A tuple (*D*, *B*), where *D* is a new divisor, linearly equivalent to *divisor*, but not intersecting *S*, and *B* is a list of tuples (*v*, *b*) where *b* are the functions giving the linear equivalence, added with multiplicity *v*.

**EXAMPLES:**

```sage
def from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
sage: S = RiemannSurface(y^2-x^3+1)
sage: avoid = Curve(S.f).places_at_infinity()
sage: D = 1*avoid[0]
sage: S.strong_approximation(D, avoid)
(- Place (x - 2, (x - 2)*y)
 + Place (x - 1, y)
 + Place (x^2 + x + 1, y),
 [(1, (1/(x - 2))*y)])
```

**symplectic_automorphism_group**(*endo_basis=None, b=None, r=None*)

Numerically compute the symplectic automorphism group as a permutation group.

**INPUT:**
- *endo_basis* (default: None) – a *Z*-basis of the endomorphisms of *self*, as obtained from `endomorphism_basis()`.
  If you have already calculated this basis, it saves time to pass it via this keyword argument. Otherwise the method will calculate it.
- *b* – integer (default provided): as for `homomorphism_basis()`, and used in its invocation if (re)calculating said basis.
- *r* – integer (default: *b*/4). as for `homomorphism_basis()`, and used in its invocation if (re)calculating said basis.

**OUTPUT:**
The symplectic automorphism group of the Jacobian of the Riemann surface. The automorphism group of the Riemann surface itself can be recovered from this; if the curve is hyperelliptic, then it is identical, and if not, then one divides out by the central element corresponding to multiplication by -1.

**EXAMPLES:**

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: A.<x,y> = QQ[]
sage: S = RiemannSurface(y^2 - (x^6 + 2*x^4 + 4*x^2 + 8), prec = 100)
```

```python
sage: G = S.symplectic_automorphism_group()
sage: G.as_permutation_group().is_isomorphic(DihedralGroup(4))
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
>>> A = QQ['x, y']; (x, y,) = A._first_ngens(2)
>>> S = RiemannSurface(y**2 - (x**6 + x**4 + x**2 + 1), prec = 100)
>>> G = S.symplectic_automorphism_group()
>>> G.as_permutation_group().is_isomorphic(DihedralGroup(4))
```

The symplectic_isomorphisms method provides tools for numerically computing symplectic isomorphisms.

**INPUT:**

- `other` (default: `self`) – the codomain, another Riemann surface.
- `hom_basis` (default: `None`) – a \( \mathbb{Z} \)-basis of the homomorphisms from `self` to `other`, as obtained from `homomorphism_basis()`. If you have already calculated this basis, it saves time to pass it via this keyword argument. Otherwise the method will calculate it.
- `b` – integer (default provided): as for `homomorphism_basis()`, and used in its invocation if (re)calculating said basis.
- `r` – integer (default: `b/4`). as for `homomorphism_basis()`, and used in its invocation if (re)calculating said basis.

**OUTPUT:**

This returns the combinations of the elements of `homomorphism_basis()` that correspond to symplectic isomorphisms between the Jacobians of `self` and `other`.

**EXAMPLES:**

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<x,y> = QQ[]
```

```python
sage: f = y^2 - (x^6 + 2*x^4 + 4*x^2 + 8)
```
tangent_representation_algebraic(Rs, other=None, epscomp=None)

Compute the algebraic tangent representations corresponding to the homology representations in Rs.

The representations on homology Rs have to be given with respect to the symplectic homology basis of the Jacobian of self and other. Such matrices can for example be obtained via endomorphism_basis().

Let P and Q be the period matrices of self and other. Then for a homology representation R, the corresponding tangential representation T satisfies TP = QR.

INPUT:

• Rs – a set of matrices on homology to be converted to their tangent representations.
  
• other (default: self) – the codomain, another Riemann surface.

• epscomp – real number (default: 2^(-prec + 30)). Used to determine whether a complex number is close enough to a root of a polynomial.

OUTPUT:

The algebraic tangent representations of the matrices in Rs.

EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: A.<x,y> = QQ[]

sage: S = RiemannSurface(y^2 - (x^6 + 2*x^4 + 4*x^2 + 8), prec = 100)

sage: Rs = S.endomorphism_basis()

sage: Ts = S.tangent_representation_algebraic(Rs)

sage: Ts[0].base_ring().maximal_order().discriminant() == 8
True
```

Plane and Space Curves, Release 10.4

(continued from previous page)

```python
>>> Integer(2)*x**Integer(4) + Integer(4)*x**Integer(2) + Integer(8)), prec =
>>> Integer(100))
>>> Rs = S.endomorphism_basis()
>>> Ts = S.tangent_representation_algebraic(Rs)
>>> Ts[Int(0)].base_ring().maximal_order().discriminant() == Integer(8)
True
```

tangent_representation_numerical(Rs, other=None)

Compute the numerical tangent representations corresponding to the homology representations in Rs.

The representations on homology Rs have to be given with respect to the symplectic homology basis of the Jacobian of self and other. Such matrices can for example be obtained via endomorphism_basis().

Let $P$ and $Q$ be the period matrices of self and other. Then for a homology representation $R$, the corresponding tangential representation $T$ satisfies $TP = QR$.

**INPUT:**

- Rs – a set of matrices on homology to be converted to their tangent representations.
- other (default: self) – the codomain, another Riemann surface.

**OUTPUT:**

The numerical tangent representations of the matrices in Rs.

**EXAMPLES:**

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: A.<x,y> = QQ[]
sage: S = RiemannSurface(y^2 - (x^6 + 2*x^4 + 4*x^2 + 8), prec = 100)
```

```python
>>> P = S.period_matrix()
```

```python
>>> Rs = S.endomorphism_basis()
>>> Ts = S.tangent_representation_numerical(Rs)
>>> all(((T*P - P*R).norm() < 2^(-80)) for [T, R] in zip(Ts, Rs))
True
```

upstairs_edges()

Compute the edgeset of the lift of the downstairs graph onto the Riemann surface.

**OUTPUT:**

An edgeset between vertices (i, j), where i corresponds to the i-th point in the Voronoi diagram vertices, and j is the j-th w-value associated with that point.

**EXAMPLES:**
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
sage: f = w^2 + z^3 - z^2
sage: S = RiemannSurface(f)
sage: edgeset = S.upstairs_edges()
sage: len(edgeset) == S.degree*len(S.downstairs_edges())
True
sage: ((v[0],w[0]) for v,w in edgeset) == set(S.downstairs_edges())
True

upstairs_graph()

Return the graph of the upstairs edges.

This method can be useful for generating paths in the surface between points labelled by upstairs vertices, and verifying that a homology basis is likely computed correctly. See also downstairs_graph().

OUTPUT:

The homotopy-continued Voronoi decomposition as a graph, with appropriate 3D embedding.

EXAMPLES:

sage: R.<z,w> = QQ[]
sage: S = Curve(w^2-z^4+1).riemann_surface()
sage: G = S.upstairs_graph(); G
Graph on 22 vertices
sage: G.genus()
1
sage: G.is_connected()
True

w_values(z0)

Return the points lying on the surface above z0.

INPUT:

• z0 – (complex) a point in the complex z-plane.
OUTPUT:

A set of complex numbers corresponding to solutions of $f(z_0, w) = 0$.

EXAMPLES:

```
sage: from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface
sage: R.<z,w> = QQ[]
sage: f = w^2 - z^4 + 1
sage: S = RiemannSurface(f)
```

Find the $w$-values above the origin, i.e. the solutions of $w^2 + 1 = 0$:

```
sage: S.w_values(0)  # abs tol 1e-14
[-1.00000000000000*I, 1.00000000000000*I]
```

Note that typically the method returns a list of length `self.degree`, but that at ramification points, this may no longer be true:

```
sage: S.w_values(1)  # abs tol 1e-14
[0.000000000000000]
```

class `sage.schemes.riemann_surfaces.riemann_surface.RiemannSurfaceSum(L)`

Bases: `RiemannSurface`

Represent the disjoint union of finitely many Riemann surfaces.

Rudimentary class to represent disjoint unions of Riemann surfaces. Exists mainly (and this is the only functionality actually implemented) to represents direct products of the complex tori that arise as analytic Jacobians of Riemann surfaces.

INPUT:

- $L$ -- list of RiemannSurface objects

EXAMPLES:

```
sage: _.<x> = QQ[]
sage: SC = HyperellipticCurve(x^6-2*x^4+3*x^2-7).riemann_surface(prec=60)
sage: S1 = HyperellipticCurve(x^3-2*x^2+3*x-7).riemann_surface(prec=60)
sage: S2 = HyperellipticCurve(1-2*x+3*x^2-7*x^3).riemann_surface(prec=60)
sage: len(SC.homomorphism_basis(S1+S2))
2
```
from sage.all import *
...
len(SC.homomorphism_basis(S1+S2))
2

period_matrix()

Return the period matrix of the surface.

This is just the diagonal block matrix constructed from the period matrices of the constituents.

EXAMPLES:
sage: from sage.schemes.riemann_surfaces.riemann_surface import ...

sage: S1S2 = S1.period_matrix().block_sum(S2.period_matrix())
sage: S.period_matrix() == S1S2
True

riemann_matrix()

Return the normalized period matrix of the surface.

This is just the diagonal block matrix constructed from the Riemann matrices of the constituents.

EXAMPLES:
sage: from sage.schemes.riemann_surfaces.riemann_surface import ...

sage: S1S2 = S1.riemann_matrix().block_sum(S2.riemann_matrix())
sage: S.riemann_matrix() == S1S2
True
sage.schemes.riemann_surfaces.riemann_surface.bisect \((L, t)\)

Find position in a sorted list using bisection.

Given a list \(L = [(t_0, \ldots), (t_1, \ldots), \ldots (t_n, \ldots)]\) with increasing \(t_i\), find the index \(i\) such that \(t_i \leq t < t_{i+1}\) using bisection. The rest of the tuple is available for whatever use required.

**INPUT:**

- \(L\) – A list of tuples such that the first term of each tuple is a real number between 0 and 1. These real numbers must be increasing.
- \(t\) – A real number between \(t_0\) and \(t_n\).

**OUTPUT:**

An integer \(i\), giving the position in \(L\) where \(t\) would be in

**EXAMPLES:**

Form a list of the desired form, and pick a real number between 0 and 1:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import bisect
sage: L = [(0.0, 'a'), (0.3, 'b'), (0.7, 'c'), (0.8, 'd'), (0.9, 'e'), (1.0, 'f')]
sage: t = 0.5
sage: bisect(L, t)
1
```

Another example which demonstrates that if \(t\) is equal to one of the \(t_i\), it returns that index:

```python
sage: L = [(0.0, 'a'), (0.1, 'b'), (0.45, 'c'), (0.5, 'd'), (0.65, 'e'), (1.0, 'f')]
sage: t = 0.5
sage: bisect(L, t)
3
```

(continues on next page)
sage.schemes.riemann_surfaces.riemann_surface.differential_basis_baker(f)

Compute a differential basis for a curve that is nonsingular outside (1:0),(0:1),(0:0:1)

Baker’s theorem tells us that if a curve has its singularities at the coordinate vertices and meets some further easily tested genericity criteria, then we can read off a basis for the regular differentials from the interior of the Newton polygon spanned by the monomials. While this theorem only applies to special plane curves it is worth implementing because the analysis is relatively cheap and it applies to a lot of commonly encountered curves (e.g., curves given by a hyperelliptic model). Other advantages include that we can do the computation over any exact base ring (the alternative Singular based method for computing the adjoint ideal requires the rationals), and that we can avoid being affected by subtle bugs in the Singular code.

None is returned when $f$ does not describe a curve of the relevant type. If $f$ is of the relevant type, but is of genus 0 then $[]$ is returned (which are both False values, but they are not equal).

INPUT:

- $f$ – a bivariate polynomial

EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import differential_basis_baker
sage: R.<x,y> = QQ[]
sage: f = x^3 + y^3 + x^5*y^5
sage: differential_basis_baker(f)
[y^2, x*y, x*y^2, x^2*y^2, x^2*y^3, x^3*y^2, x^3*y^3]
sage: f = y^2 - (x-3)^2*x
sage: differential_basis_baker(f) is None
True
sage: differential_basis_baker(x^2+y^2-1)
[]
```

sage.schemes.riemann_surfaces.riemann_surface.find_closest_element(item, lst)

Return the index of the closest element of a list.

Given List and item, return the index of the element $l$ of List which minimises $|item-l|$. If there are multiple such elements, the first is returned.

INPUT:

- item – value to minimize the distance to over the list
- lst – list to look for closest element in

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import differential_basis_baker
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> f = x**Integer(3) + y**Integer(3) + x**Integer(5)*y**Integer(5)
>>> differential_basis_baker(f)
[y^2, x*y, x*y^2, x^2*y^2, x^2*y^3, x^3*y^2, x^3*y^3]
>>> f = y**Integer(2) - (x-Integer(3))**Integer(2)*x
>>> differential_basis_baker(f) is None
True
>>> differential_basis_baker(x**Integer(2)+y**Integer(2)-Integer(1))
[]
```
EXAMPLES:

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import find_closest_element
sage: i = 5
sage: l = list(range(10))
sage: i == find_closest_element(i, l)
True
```

```python
>>> from sage.all import *
>>> from sage.schemes.riemann_surfaces.riemann_surface import find_closest_element
>>> i = Integer(5)
>>> l = list(range(Integer(10)))
>>> i == find_closest_element(i, l)
True
```

Note that this method does no checks on the input, but will fail for inputs where the absolute value or subtraction do not make sense.

```python
sage.schemes.riemann_surfaces.riemann_surface.integer_matrix_relations(M1, M2, b=None, r=None)
```

Determine integer relations between complex matrices.

Given two square matrices with complex entries of size $g$, $h$ respectively, numerically determine an (approximate) $\mathbb{Z}$-basis for the $2g \times 2h$ matrices with integer entries of the shape $(D, B; C, A)$ such that $B + M_1 \ast A = (D + M_1 \ast C) \ast M_2$. By considering real and imaginary parts separately we obtain $2gh$ equations with real coefficients in $4gh$ variables. We scale the coefficients by a constant $2^b$ and round them to integers, in order to obtain an integer system of equations. Standard application of LLL allows us to determine near solutions.

The user can specify the parameter $b$, but by default the system will choose a $b$ based on the size of the coefficients and the precision with which they are given.

**INPUT:**

- $M_1$ – square complex valued matrix
- $M_2$ – square complex valued matrix of same size as $M_1$
- $b$ – integer (default provided). The equation coefficients are scaled by $2^b$ before rounding to integers.
- $r$ – integer (default: $b/4$). The vectors found by LLL that satisfy the scaled equations to within $2^r$ are reported as solutions.

**OUTPUT:**

A list of $2g \times 2h$ integer matrices that, for large enough $r$, $b - r$, generate the $\mathbb{Z}$-module of relevant transformations.

**EXAMPLES:**

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import integer_matrix_relations
sage: M1 = M2 = matrix(CC, 2, 2, [CC(d).sqrt() for d in [2,-3,-3,-6]])
```

```python
sage: T = integer_matrix_relations(M1, M2)
```

```python
sage: id = parent(M1)(1)
sage: M1t = [id.augment(M1) * t for t in T]
sage: [((m[:,:2]^(-1)*m)[:,2:]-M2).norm() < 1e-13 for m in M1t]
[True, True]
```
sage.schemes.riemann_surfaces.riemann_surface.numerical_inverse(C)

Compute numerical inverse of a matrix via LU decomposition

INPUT:

• C – A real or complex invertible square matrix

EXAMPLES:

```python
sage: C = matrix(CC, 3, 3, [-4.5606e-31 + 1.2326e-31*I,
                         ....: -0.21313 + 0.24166*I,
                         ....: -3.4513e-31 + 0.16111*I,
                         ....: -1.0175 + 9.8608e-32*I,
                         ....: 0.30912 + 0.19962*I,
                         ....: -4.9304e-32 + 0.39923*I,
                         ....: 0.96793 - 3.4513e-31*I,
                         ....: -0.091587 + 0.19276*I,
                         ....: 3.9443e-31 + 0.38552*I])
```

```python
sage: from sage.schemes.riemann_surfaces.riemann_surface import numerical_inverse
```

```python
sage: RealNumber(3e-16) < (C**-1*C-C^0).norm() < RealNumber(1e-15)
True
sage: (numerical_inverse(C)*C-C^0).norm() < RealNumber(3e-16)
True
```

sage.schemes.riemann_surfaces.riemann_surface.reparameterize_differential_minpoly(minpoly, z0)

Rewrites a minimal polynomial to write is around \( z_0 \).
Given a minimal polynomial \( m(z, g) \), where \( g \) corresponds to a differential on the surface (that is, it is represented as a rational function, and implicitly carries a factor \( dz \)), we rewrite the minpoly in terms of variables \( \bar{z}, \bar{g} \) s.t now \( \bar{z} = 0 \Leftrightarrow z = z_0 \).

**INPUT:**

- **minpoly** – a polynomial in two variables, where the first variable corresponds to the base coordinate on the Riemann surface
- **z0** – complex number or infinity; the point about which to reparameterize

**OUTPUT:**

A polynomial in two variables giving the reparameterize minimal polynomial.

**EXAMPLES:**

On the curve given by \( w^2 - z^3 + 1 = 0 \), we have differential \( \frac{dz}{2w} = \frac{dz}{2\sqrt{z^3 - 1}} \) with minimal polynomial \( g^2(z^3 - 1) - 1/4 = 0 \). We can make the substitution \( \bar{z} = z^{-1} \) to parameterise the differential about \( z = \infty \) as

\[
\frac{-\bar{z}^{-2}d\bar{z}}{2\sqrt{\bar{z}^3 - 1}} = \frac{-d\bar{z}}{2\sqrt{\bar{z}(1 - \bar{z}^3)}}.
\]

Hence the transformed differential should have minimal polynomial \( \bar{g}^2\bar{z}(1 - \bar{z}^3) - 1/4 = 0 \), and we can check this:

```sage
from sage.schemes.riemann_surfaces.riemann_surface import RiemannSurface,
˓→reparameterize_differential_minpoly
sage: R.<z,w> = QQ[]
sage: S = RiemannSurface(w^2-z^3+1)
sage: minpoly = S._cohomology_basis_bounding_data[1][0][2]
sage: z0 = Infinity
sage: reparameterize_differential_minpoly(minpoly, z0)
-zbar^4*gbar^2 + zbar*gbar^2 - 1/4
```

We can further check that reparameterising about 0 is the identity operation:

```sage
reparameterize_differential_minpoly(minpoly, 0)(*minpoly.parent().gens()) == minpoly
True
```

**Note:** As part of the routine, when reparameterising about infinity, a rational function is reduced and then the
numerator is taken. Over an inexact ring this is numerically unstable, and so it is advisable to only reparameterize about infinity over an exact ring.

.. code-block::

    sage.schemes.riemann_surfaces.riemann_surface.voronoighost(cpoints, n=6, CC=Complex Double Field)

Convert a set of complex points to a list of real tuples \((x, y)\), and appends \(n\) points in a big circle around them.

The effect is that, with \(n \geq 3\), a Voronoi decomposition will have only finite cells around the original points. Furthermore, because the extra points are placed on a circle centered on the average of the given points, with a radius \(3/2\) times the largest distance between the center and the given points, these finite cells form a simply connected region.

**INPUT:**
- \(\textbf{cpoints} - \) a list of complex numbers

**OUTPUT:**
A list of real tuples \((x, y)\) consisting of the original points and a set of points which surround them.

**EXAMPLES:**

.. code-block::

    sage: from sage.schemes.riemann_surfaces.riemann_surface import voronoi_ghost
    sage: L = [1 + 1*I, 1 - 1*I, -1 + 1*I, -1 - 1*I]

5.1 Jacobians of curves

This module defines the base class of Jacobians as an abstract scheme.

AUTHORS:

• William Stein (2005)

sage.schemes.jacobians.abstract_jacobian.Jacobian(C)

EXAMPLES:

```python
sage: from sage.schemes.jacobians.abstract_jacobian import Jacobian
sage: P2.<x, y, z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x^3 + y^3 + z^3)
sage: Jacobian(C)
Jacobian of Projective Plane Curve over Rational Field defined by x^3 + y^3 + z^3
```

```python
>>> from sage.all import *
>>> from sage.schemes.jacobians.abstract_jacobian import Jacobian
>>> P2 = ProjectiveSpace(QQ, Integer(2), names=(x, y, z,)); (x, y, z,) = P2._first_ngens(3)
>>> C = Curve(x**Integer(3) + y**Integer(3) + z**Integer(3))
>>> Jacobian(C)
Jacobian of Projective Plane Curve over Rational Field defined by x^3 + y^3 + z^3
```

class sage.schemes.jacobians.abstract_jacobian.Jacobian_generic(C, category=None)

Bases: Scheme

Base class for Jacobians of projective curves.

The input must be a projective curve over a field.

EXAMPLES:

```python
sage: from sage.schemes.jacobians.abstract_jacobian import Jacobian
sage: P2.<x, y, z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x^3 + y^3 + z^3)
sage: J = Jacobian(C); J
Jacobian of Projective Plane Curve over Rational Field defined by x^3 + y^3 + z^3
```

```python
>>> from sage.all import *
>>> from sage.schemes.jacobians.abstract_jacobian import Jacobian
>>> P2 = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P2._first_ngens(3)
>>> C = Curve(x**Integer(3) + y**Integer(3) + z**Integer(3))
>>> Jacobian(C)
Jacobian of Projective Plane Curve over Rational Field defined by x^3 + y^3 + z^3
```

(continues on next page)
Plane and Space Curves, Release 10.4

\[ \text{__first_ngens(3)} \]

\[
\begin{align*}
\text{C} & = \text{Curve}(x**\text{Integer}(3) + y**\text{Integer}(3) + z**\text{Integer}(3)) \\
\text{J} & = \text{Jacobian}(C); \ J
\end{align*}
\]

Jacobian of Projective Plane Curve over Rational Field defined by \(x^3 + y^3 + z^3\)

**base_curve()**

Return the curve of which \textit{self} is the Jacobian.

**EXAMPLES:**

```
sage: from sage.schemes.jacobians.abstract_jacobian import Jacobian
sage: P2.<x, y, z> = ProjectiveSpace(QQ, 2)
sage: J = Jacobian(Curve(x^3 + y^3 + z^3))
sage: J.curve()
Projective Plane Curve over Rational Field defined by x^3 + y^3 + z^3
```

**base_extend(\(R\))**

Return the natural extension of \textit{self} over \(R\).

**INPUT:**

- \(R\) – a field. The new base field.

**OUTPUT:** The Jacobian over the ring \(R\).

**EXAMPLES:**

```
sage: R.<x> = QQ['x']
sage: H = HyperellipticCurve(x^3 - 10*x + 9)
sage: Jac = H.jacobian(); Jac
Jacobian of Hyperelliptic Curve over Rational Field defined by y^2 = x^3 - 10*x + 9
```

(continues on next page)
Jac.base_extend(F)

Jacobian of Hyperelliptic Curve over Number Field in a with defining polynomial x^2 + 1 defined by y^2 = x^3 - 10*x + 9

change_ring(R)

Return the Jacobian over the ring $R$.

INPUT:

- $R$ – a field. The new base ring.

OUTPUT: The Jacobian over the ring $R$.

EXAMPLES:

```python
sage: R.<x> = QQ['x']
sage: H = HyperellipticCurve(x^3 - 10*x + 9)
sage: Jac = H.jacobian(); Jac
Jacobian of Hyperelliptic Curve over Rational Field defined by y^2 = x^3 - 10*x + 9
sage: Jac.change_ring(RDF)
Jacobian of Hyperelliptic Curve over Real Double Field defined by y^2 = x^3 - 10.0*x + 9.0
```

curve()

Return the curve of which `self` is the Jacobian.

EXAMPLES:

```python
sage: from sage.schemes.jacobians.abstract_jacobian import Jacobian
sage: P2.<x, y, z> = ProjectiveSpace(QQ, 2)
sage: J = Jacobian(Curve(x^3 + y^3 + z^3))
sage: J.curve()
Projective Plane Curve over Rational Field defined by x^3 + y^3 + z^3
```

sage.schemes.jacobians.abstract_jacobian.is_Jacobian(J)

Return True if $J$ is of type Jacobian_generic.

EXAMPLES:
```python
sage: from sage.schemes.jacobians.abstract_jacobian import Jacobian, is_Jacobian
sage: P2.<x, y, z> = ProjectiveSpace(QQ, 2)
sage: C = Curve(x^3 + y^3 + z^3)
sage: J = Jacobian(C)
sage: is_Jacobian(J)
... DeprecationWarning: Use Jacobian_generic directly
See https://github.com/sagemath/sage/issues/35467 for details.
True
```

```python
>>> from sage.all import *
>>> from sage.schemes.jacobians.abstract_jacobian import Jacobian, is_Jacobian
>>> P2 = ProjectiveSpace(QQ, Integer(2), names=('x', 'y', 'z',)); (x, y, z,) = P2._first_ngens(3)
>>> C = Curve(x**Integer(3) + y**Integer(3) + z**Integer(3))
>>> J = Jacobian(C)
>>> is_Jacobian(J)
... DeprecationWarning: Use Jacobian_generic directly
See https://github.com/sagemath/sage/issues/35467 for details.
True
```

```python
sage: E = EllipticCurve('37a1')
sage: is_Jacobian(E)
False
```

```python
>>> from sage.all import *
>>> E = EllipticCurve('37a1')
>>> is_Jacobian(E)
False
```
