HYPERBOLIC POINTS

This module implements points in hyperbolic space of arbitrary dimension. It also contains the implementations for specific models of hyperbolic geometry.

This module also implements ideal points in hyperbolic space of arbitrary dimension. It also contains the implementations for specific models of hyperbolic geometry.

Note that not all models of hyperbolic space are bounded, meaning that the ideal boundary is not the topological boundary of the set underlying the model. For example, the unit disk model is bounded with boundary given by the unit sphere. The hyperboloid model is not bounded.

AUTHORS:

- Greg Laun (2013): initial version

EXAMPLES:

We can construct points in the upper half plane model, abbreviated UHP for convenience:

\begin{verbatim}
sage: UHP = HyperbolicPlane().UHP()
sage: UHP.get_point(2 + I)
Point in UHP I + 2
sage: g = UHP.get_point(3 + I)
sage: g.dist(UHP.get_point(I))
arccosh(11/2)
\end{verbatim}

We can also construct boundary points in the upper half plane model:

\begin{verbatim}
sage: UHP.get_point(3)
Boundary point in UHP 3
\end{verbatim}

Some more examples:

\begin{verbatim}
sage: HyperbolicPlane().UHP().get_point(0)
Boundary point in UHP 0
sage: HyperbolicPlane().PD().get_point(I/2)
Point in PD 1/2*I
sage: HyperbolicPlane().KM().get_point((0,1))
Boundary point in KM (0, 1)
sage: HyperbolicPlane().HM().get_point((0,0,1))
Point in HM (0, 0, 1)
\end{verbatim}
class sage.geometry.hyperbolic_space.hyperbolic_point.HyperbolicPoint(model, coordinates, is_boundary, check=True, **graphics_options)

Bases: Element

Abstract base class for hyperbolic points. This class should never be instantiated.

INPUT:

- model – the model of the hyperbolic space
- coordinates – the coordinates of a hyperbolic point in the appropriate model
- is_boundary – whether the point is a boundary point
- check – (default: True) if True, then check to make sure the coordinates give a valid point in the model

EXAMPLES:

Comparison between different models is performed via coercion:

```sage
UHP = HyperbolicPlane().UHP()
p = UHP.get_point(0.2 + .3*I); p
Point in UHP 0.200000000000000 + 0.300000000000000*I

PD = HyperbolicPlane().PD()
q = PD.get_point(0.2 + 0.3*I); q
Point in PD 0.200000000000000 + 0.300000000000000*I

p == q
False

PD(p)
Point in PD 0.231213872832370 - 0.502890173410405*I

bool(p.coordinates() == q.coordinates())
True
```

Similarly for boundary points:

```sage
p = UHP.get_point(-1); p
Boundary point in UHP -1

q = PD.get_point(-1); q
Boundary point in PD -1

p == q
True

PD(p)
Boundary point in PD -1
```

It is an error to specify a point that does not lie in the appropriate model:

```sage
HyperbolicPlane().UHP().get_point(0.2 - 0.3*I)
Traceback (most recent call last):
...
ValueError: 0.200000000000000 - 0.300000000000000*I is not a valid point in the...
```
sage: HyperbolicPlane().PD().get_point(1.2)
Traceback (most recent call last):
...
ValueError: 1.20000000000000 is not a valid point in the PD model

sage: HyperbolicPlane().KM().get_point((1,1))
Traceback (most recent call last):
...
ValueError: (1, 1) is not a valid point in the KM model

sage: HyperbolicPlane().HM().get_point((1, 1, 1))
Traceback (most recent call last):
...
ValueError: (1, 1, 1) is not a valid point in the HM model

It is an error to specify an interior point of hyperbolic space as a boundary point:

sage: HyperbolicPlane().UHP().get_point(0.2 + 0.3*I, is_boundary=True)
Traceback (most recent call last):

This module implements the abstract base class for isometries of hyperbolic space of arbitrary dimension. It also contains the implementations for specific models of hyperbolic geometry.

The isometry groups of all implemented models are either matrix Lie groups or are doubly covered by matrix Lie groups. As such, the isometry constructor takes a matrix as input. However, since the isometries themselves may not be matrices, quantities like the trace and determinant are not directly accessible from this class.

**AUTHORS:**

- Greg Laun (2013): initial version

**EXAMPLES:**

We can construct isometries in the upper half plane model, abbreviated UHP for convenience:

```sage
sage: UHP = HyperbolicPlane().UHP()
sage: UHP.get_isometry(matrix(2, [1, 2, 3, 4]))
Isometry in UHP
[1 2]
[3 4]
sage: A = UHP.get_isometry(matrix(2, [0, 1, 1, 0]))
sage: A.inverse()
Isometry in UHP
[0 1]
[1 0]
```

**class** `sage.geometry.hyperbolic_space.hyperbolic_isometry.HyperbolicIsometry(model, A, check=True)`

**Bases:** `Morphism`

Abstract base class for hyperbolic isometries. This class should never be instantiated.

**INPUT:**

**EXAMPLES:**

```sage

[1 0 0]
[0 1 0]
[0 0 1]
```
attracting_fixed_point()
For a hyperbolic isometry, return the attracting fixed point; otherwise raise a ValueError.

OUTPUT:
• a hyperbolic point

```

It is an error to call this function on an isometry that is not hyperbolic:
```
sage: P = UHP.get_isometry(matrix(2,[1,4,0,1]))
sage: P.axis()
Traceback (most recent call last):
  ... ValueError: the isometry is not hyperbolic: axis is undefined
```

```
```
sage: P = UHP.get_isometry(matrix(2,[1,1,0,1]))

sage: UHP.get_isometry(identity_matrix(2)).is_identity()

```

**matrix()**
Return the matrix of the isometry.

**Note:** We do not allow the matrix constructor to work as these may be elements of a projective group (ex. \(PSL(n, \mathbb{R})\)), so these isometries aren’t true matrices.

-2/109*I + 43/109
sage: y = var('y')
sage: moebius_transform(matrix(2,[1,0,0,1]),x + I*y)

The matrix must be square and 2 × 2:

sage: moebius_transform(matrix(2,[0,0,0,0]),I)
Traceback (most recent call last):
  ...TypeError: A must be an invertible 2x2 matrix over the complex numbers or a symbolic ring

Graphics object consisting of 2 graphics primitives
```

Geodesics of both types in UHP are supported:

```
sage: g = HyperbolicPlane().UHP().get_geodesic(I, 3*I)
sage: g
Geodesic in UHP from I to 3*I
sage: g.plot()  # needs sage.plot
Graphics object consisting of 2 graphics primitives
```

Geodesics are oriented, which means that two geodesics with the same graph will only be equal if their starting and ending points are the same:

```
sage: g1 = HyperbolicPlane().UHP().get_geodesic(1,2)
sage: g2 = HyperbolicPlane().UHP().get_geodesic(2,1)
sage: g1 == g2
False
```
Todo: Implement a parent for all geodesics of the hyperbolic plane? Or implement geodesics as a parent in the subobjects category?

```python
class sage.geometry.hyperbolic_space.hyperbolic_geodesic.HyperbolicGeodesic(model, start, end, **graphics_options)

Bases: SageObject

Abstract base class for oriented geodesics that are not necessarily complete.

INPUT:

- start – a HyperbolicPoint or coordinates of a point in hyperbolic space representing the start of the geodesic
- end – a HyperbolicPoint or coordinates of a point in hyperbolic space representing the end of the geodesic

EXAMPLES:

We can construct a hyperbolic geodesic in any model:

```python
sage: HyperbolicPlane().UHP().get_geodesic(1, 0)
Geodesic in UHP from 1 to 0
sage: HyperbolicPlane().PD().get_geodesic(1, 0)
Geodesic in PD from 1 to 0
sage: HyperbolicPlane().KM().get_geodesic((0,1/2), (1/2, 0))

sage: g = PD.get_geodesic(3/5*I + 4/5, 15/17*I + 8/17)
sage: h = PD.get_geodesic(4/5*I + 3/5, I)
sage: g.angle(h)
1/2*pi
```

sage: g.common_perpendicular(h)
Geodesic in UHP from 1/2*sqrt(3) + 7/2 to -1/2*sqrt(3) + 7/2
```

It is an error to ask for the common perpendicular of two intersecting geodesics:

```
sage: g = HyperbolicPlane().UHP().get_geodesic(2,4)
sage: h = HyperbolicPlane().UHP().get_geodesic(3, infinity)
sage: g.common_perpendicular(h)

In this module, a hyperbolic model is a collection of data that allow the user to implement new models of hyperbolic space with minimal effort. The data include facts about the underlying set (such as whether the model is bounded), facts about the metric (such as whether the model is conformal), facts about the isometry group (such as whether it is a linear or projective group), and more. Generally speaking, any data or method that pertains to the model itself – rather than the points, geodesics, or isometries of the model – is implemented in this module.

Abstractly, a model of hyperbolic space is a connected, simply connected manifold equipped with a complete Riemannian metric of constant curvature $-1$. This module records information sufficient to enable computations in hyperbolic space without explicitly specifying the underlying set or its Riemannian metric. Although, see the SageManifolds project if you would like to take this approach.

This module implements the abstract base class for a model of hyperbolic space of arbitrary dimension. It also contains the implementations of specific models of hyperbolic geometry.

AUTHORS:

EXAMPLES:

We illustrate how the classes in this module encode data by comparing the upper half plane (UHP), Poincaré disk (PD) and hyperboloid (HM) models. First we create:

```
sage: U = HyperbolicPlane().UHP()
sage: P = HyperbolicPlane().PD()
sage: H = HyperbolicPlane().HM()
```

We note that the UHP and PD models are bounded while the HM model is not:

```
sage: U.is_bounded() and P.is_bounded()
True
sage: H.is_bounded()
False
```

The isometry groups of UHP and PD are projective, while that of HM is linear:

```
sage: U.is_isometry_group_projective()
True
sage: H.is_isometry_group_projective()
False
```

The models are responsible for determining if the coordinates of points and the matrix of linear maps are appropriate for constructing points and isometries in hyperbolic space:
```python
sage: U.point_in_model(2 + I)
True
sage: U.point_in_model(2 - I)
False
sage: U.point_in_model(2)
False
sage: U.boundary_point_in_model(2)
True
```

sage: p1 = KM.get_point((0, 0))
sage: p2 = KM.get_point((1/2, 1/2))
sage: numerical_approx(KM.dist(p1, p2))
0.881373587019543

sage: HM = HyperbolicPlane().HM()
sage: p1 = HM.get_point((0, 0, 1))
sage: p2 = HM.get_point((1, 0, sqrt(2)))

This module provides a convenient interface for interacting with models of hyperbolic space as well as their points, geodesics, and isometries.

The primary point of this module is to allow the code that implements hyperbolic space to be sufficiently decoupled while still providing a convenient user experience.

The interfaces are by default given abbreviated names. For example, UHP (upper half plane model), PD (Poincaré disk model), KM (Klein disk model), and HM (hyperboloid model).

Note: All of the current models of 2 dimensional hyperbolic space use the upper half plane model for their computations. This can lead to some problems, such as long coordinate strings for symbolic points. For example, the vector \((1, 0, \sqrt{2})\) defines a point in the hyperboloid model. Performing mapping this point to the upper half plane and performing computations there may return with vector whose components are unsimplified strings have several \(\sqrt{2}\)'s. Presently, this drawback is outweighed by the rapidity with which new models can be implemented.
