46 The Tachyon Ray Tracer
47 Interface to TIDES
48 Interface to the Sage cleaner
49 Quitting interfaces
50 An interface to read data files
51 Indices and Tables
Python Module Index
Sage provides a unified interface to the best computational software. This is accomplished using both C-libraries (see C/C++ Library Interfaces) and interpreter interfaces, which are implemented using pseudo-tty’s, system files, etc. This chapter is about these interpreter interfaces.

Note: Each interface requires that the corresponding software is installed on your computer. Sage includes GAP, PARI, Singular, and Maxima, but does not include Octave (very easy to install), MAGMA (non-free), Maple (non-free), or Mathematica (non-free).

There is overhead associated with each call to one of these systems. For example, computing \(2 + 2\) thousands of times using the GAP interface will be slower than doing it directly in Sage. In contrast, the C-library interfaces of C/C++ Library Interfaces incur less overhead.

In addition to the commands described for each of the interfaces below, you can also type e.g., \%gap, \%magma, etc., to directly interact with a given interface in its state. Alternatively, if \(X\) is an interface object, typing \(X\text{.interact()}\) allows you to interact with it. This is completely different than \(X\text{.console()}\) which starts a complete new copy of whatever program \(X\) interacts with. Note that the input for \(X\text{.interact()}\) is handled by Sage, so the history buffer is the same as for Sage, tab completion is as for Sage (unfortunately!), and input that spans multiple lines must be indicated using a backslash at the end of each line. You can pull data into an interactive session with \(X\) using \texttt{sage(expression)}.

The console and interact methods of an interface do very different things. For example, using gap as an example:

1. \texttt{gap.console():} You are completely using another program, e.g., gap/magma/gp Here Sage is serving as nothing more than a convenient program launcher, similar to bash.

2. \texttt{gap.interact():} This is a convenient way to interact with a running gap instance that may be “full of” Sage objects. You can import Sage objects into this gap (even from the interactive interface), etc.

The console function is very useful on occasion, since you get the exact actual program available (especially useful for tab completion and testing to make sure nothing funny is going on).
COMMON INTERFACE FUNCTIONALITY

See the examples in the other sections for how to use specific interfaces. The interface classes all derive from the generic interface that is described in this section.

AUTHORS:

- William Stein (2005): initial version
- William Stein (2006-03-01): got rid of infinite loop on startup if client system missing
- Felix Lawrence (2009-08-21): edited _sage__() to support lists and float exponents in foreign notation.
- Simon King (2010-09-25): Expect._local_tmpfile() depends on Expect.pid() and is cached; Expect.quit() clears that cache, which is important for forking.
- Simon King (2015): Improve pickling for InterfaceElement

```python
class sage.interfaces.interface.AsciiArtString
    Bases: str

class sage.interfaces.interface.Interface(name)
    Bases: WithEqualityById, ParentWithBase

    Interface interface object.

    Note: Two interfaces compare equal if and only if they are identical objects (this is a critical constraint so that caching of representations of objects in interfaces works correctly). Otherwise they are never equal.
```

call (function_name, *args, **kwds)

clear (var)
    Clear the variable named var.

console ()

cputime ()
    CPU time since this process started running.

eval (code, **kwds)
    Evaluate code in an interface.
    This method needs to be implemented in sub-classes.

    Note that it is not always to be expected that it returns a non-empty string. In contrast, get () is supposed to return the result of applying a print command to the object so that the output is easier to parse.
Likewise, the method \_eval\_line() for evaluation of a single line, often makes sense to be overridden.

\texttt{execute(*args, **kwds)}

\texttt{function\_call(function, args=None, kwds=None)}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: maxima.quad_qags(x, x, 0, 1, epsrel=1e-4)
[0.5, 5.5511151231257...e-15, 21, 0]
sage: maxima.function_call('quad_qags', [x, x, 0, 1], {'epsrel': '1e-4'})
[0.5, 5.5511151231257...e-15, 21, 0]

>>> from sage.all import *

>>> s = Singular()

>>> s.set_seed(107)
107

>>> s.get_seed()
107

>>> s = Singular()

>>> s.set_seed(Integer(107))
107

>>> s.get_seed()
107
\end{verbatim}

\texttt{get(var)}

Get the value of the variable var.

Note that this needs to be overridden in some interfaces, namely when getting the string representation of an object requires an explicit print command.

\texttt{get\_seed()}

Return the seed used to set the random number generator in this interface.

The seed is initialized as None but should be set when the interface starts.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: s = Singular()
sage: s.set_seed(107)
107
sage: s.get_seed()
107

>>> from sage.all import *

>>> s = Singular()

>>> s.set_seed(Integer(107))
107

>>> s.get_seed()
107
\end{verbatim}

\texttt{get\_using\_file(var)}

Return the string representation of the variable var in self, possibly using a file. Use this if var has a huge string representation, since it may be way faster.

\textbf{Warning:} In fact unless a special derived class implements this, it will not be any faster. This is the case for this class if you're reading it through introspection and seeing this.

\texttt{help(s)}
**interact()**

This allows you to interactively interact with the child interpreter.

Press Ctrl + D or type ‘quit’ or ‘exit’ to exit and return to Sage.

**Note:** This is completely different than the console() member function. The console function opens a new copy of the child interpreter, whereas the interact function gives you interactive access to the interpreter that is being used by Sage. Use sage(xxx) or interpretername(xxx) to pull objects in from sage to the interpreter.

**name (new_name=None)**

**new (code)**

**rand_seed()**

Return a random seed that can be put into set_seed function for any interpreter.

This should be overridden if the particular interface needs something other than a small positive integer.

**EXAMPLES:**

```python
sage: from sage.interfaces.interface import Interface
sage: i = Interface(""
```

```python
sage: i.rand_seed() # random
```

```python
318491487
```

```python
sage: s = Singular()
```

```python
sage: s.rand_seed() # random
```

```python
365260051
```

```python
>>> from sage.all import *
```

```python
>>> filename = tmp_filename()
```

```python
>>> f = open(filename, w)
```

```python
>>> _ = f.write(x = 2
```

```python
>>> octave.read(filename) # optional - octave
```

```python
>>> octave.get('x') # optional - octave
```

```python
2
```

```python
sage: import os
```

```python
sage: os.unlink(filename)
```

```python
>>> from sage.all import *
```

```python
>>> filename = tmp_filename()
```

```python
>>> f = open(filename, w)
```

```python
>>> _ = f.write('x = 2
```

(continues on next page)
set (var, value)

Set the variable var to the given value.

set_seed (seed=None)

Set the random seed for the interpreter and return the new value of the seed.

This is dependent on which interpreter so must be implemented in each separately. For examples see gap.py or singular.py.

If seed is None then should generate a random seed.

EXAMPLES:

```python
sage: s = Singular()
sage: s.set_seed(1)
1
sage: [s.random(1,10) for i in range(5)]
[8, 10, 4, 9, 1]

sage: from sage.interfaces.interface import Interface
class InterfaceElement (parent, value, is_name=False, name=None)
Bases: Element

Interface element.

attribute (attrname)

If this wraps the object x in the system, this returns the object x.attrname. This is useful for some systems that have object oriented attribute access notation.

EXAMPLES:

```
```python
sage: g = gap('SO(1,4,7)')
sage: k = g.InvariantQuadraticForm()
sage: k.attribute('matrix')
[ [ 0*Z(7), Z(7)^0, 0*Z(7), 0*Z(7) ],
  [ 0*Z(7), 0*Z(7), 0*Z(7), 0*Z(7) ],
  [ 0*Z(7), 0*Z(7), Z(7), 0*Z(7) ],
  [ 0*Z(7), 0*Z(7), 0*Z(7), Z(7)^0 ] ]
```

```python
>>> from sage.all import *

>>> g = gap('SO(1,4,7)')

>>> k = g.InvariantQuadraticForm()

>>> k.attribute('matrix')
[ [ 0*Z(7), Z(7)^0, 0*Z(7), 0*Z(7) ],
  [ 0*Z(7), 0*Z(7), 0*Z(7), 0*Z(7) ],
  [ 0*Z(7), 0*Z(7), Z(7), 0*Z(7) ],
  [ 0*Z(7), 0*Z(7), 0*Z(7), Z(7)^0 ] ]
```

```python
sage: e = gp('ellinit([0,-1,1,-10,-20]))
sage: e.attribute('j')
-122023936/161051
```

```python
>>> from sage.all import *

>>> e = gp('ellinit([0,-1,1,-10,-20]))

>>> e.attribute('j')
-122023936/161051
```

## bool()

Convert this element to a boolean.

**EXAMPLES:**

```python
sage: singular(0).bool()
False

sage: singular(1).bool()
True
```

```python
>>> from sage.all import *

>>> singular(Integer(0)).bool()
False

>>> singular(Integer(1)).bool()
True
```

## gen(n)

**get_using_file()**

Return this element's string representation using a file. Use this if self has a huge string representation. It'll be way faster.

**EXAMPLES:**

```python
sage: a = maxima(str(2^1000))
sage: a.get_using_file()
˓→'10715086071862673209484250490600018105614048117055336074437503883703510511249361224931983...

˓→'
```

```python
>>> from sage.all import *

>>> a = maxima(str(Integer(2)**Integer(1000)))

>>> a.get_using_file()
(continues on next page)```
hasattr(attrname)

Returns whether the given attribute is already defined by this object, and in particular is not dynamically generated.

EXAMPLES:

```python
sage: m = maxima('2')
sage: m.hasattr('integral')
True
sage: m.hasattr('gcd')
False
```

is_string()

Tell whether this element is a string.

By default, the answer is negative.

name(new_name=None)

Returns the name of self. If new_name is passed in, then this function returns a new object identical to self whose name is new_name.

Note that this can overwrite existing variables in the system.

EXAMPLES:

```python
sage: # optional - rpy2
sage: x = r([1,2,3]); x
[1] 1 2 3
sage: x.name()
'sage...

sage: x = r([1,2,3]).name('x'); x
[1] 1 2 3
sage: x.name()
'x'
```
sage: s5 = gap.SymmetricGroup(5).name('s5')
sage: s5
SymmetricGroup( [ 1 .. 5 ] )
sage: s5.name()
's5'

>>> from sage.all import *

>>> s5 = gap.SymmetricGroup(Integer(5)).name('s5')

>>> s5
SymmetricGroup( [ 1 .. 5 ] )

>>> s5.name()
's5'

sage(*args, **kwds)

Attempt to return a Sage version of this object.

This method does nothing more than calling _sage_(), simply forwarding any additional arguments.

EXAMPLES:

sage: gp(1/2).sage()
1/2

sage: _.parent()
Rational Field

sage: singular.lib("matrix")
sage: R = singular.ring(0, '(x,y,z)', 'dp')
sage: singular.matrix(2,2).sage()

[0 0]
[0 0]

>>> from sage.all import *

>>> gp(Integer(1)/Integer(2)).sage()
1/2

>>> _.parent()
Rational Field

>>> singular.lib("matrix")

>>> R = singular.ring(Integer(0), '(x,y,z)', 'dp')

>>> singular.matrix(Integer(2),Integer(2)).sage()

[0 0]
[0 0]

class sage.interfaces.interface.InterfaceFunction (parent, name)

Bases: SageObject

Interface function.

class sage.interfaces.interface.InterfaceFunctionElement (obj, name)

Bases: SageObject

Interface function element.

help()

sage.interfaces.interface.is_InterfaceElement (x)

Return True if x is of type InterfaceElement.

EXAMPLES:
sage: from sage.interfaces.interface import is_InterfaceElement
sage: is_InterfaceElement(2)
doctest:....: DeprecationWarning: the function is_InterfaceElement is deprecated;
→    use isinstance(x, sage.interfaces.abc.InterfaceElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
False

>>> from sage.all import *
>>> from sage.interfaces.interface import is_InterfaceElement
>>> is_InterfaceElement(Integer(2))
doctest:....: DeprecationWarning: the function is_InterfaceElement is deprecated;
→    use isinstance(x, sage.interfaces.abc.InterfaceElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
False
COMMON INTERFACE FUNCTIONALITY THROUGH PEXPECT

See the examples in the other sections for how to use specific interfaces. The interface classes all derive from the generic interface that is described in this section.

AUTHORS:

- William Stein (2005): initial version
- William Stein (2006-03-01): got rid of infinite loop on startup if client system missing
- Felix Lawrence (2009-08-21): edited __sage__() to support lists and float exponents in foreign notation.
- Simon King (2010-09-25): Expect.__local_tmpfile() depends on Expect.pid() and is cached; Expect.quit() clears that cache, which is important for forking.
- Simon King (2010-11-23): Ensure that the interface is started again after a crash, when a command is executed in __eval_line. Allow synchronisation of the GAP interface.
- François Bissey, Bill Page, Jeroen Demeyer (2015-12-09): Upgrade to pexpect 4.0.1 + patches, see Issue #10295.

```python
class sage.interfaces.expect.Expect
    name, prompt, command=None
    env={}, server=None
    server_tmpdir=None, ulimit=None, maxread=None,
    script_subdirectory=None, restart_on_ctrlc=False,
    verbose_start=False, init_code=[],
    max_startup_time=None,
    logfile=None, eval_using_file_cutoff=0,
    do_cleaner=True, remote_cleaner=False, path=None, terminal_echo=True)

Bases: Interface

Expect interface object.

clear_prompts()

command()

Return the command used in this interface as a string.

EXAMPLES:

```
sage: magma.set_server_and_command(command='magma-2.19')
sage: magma.command()  # indirect doctest
'magma-2.19'
```

```
>>> from sage.all import *
>>> magma.set_server_and_command(command='magma-2.19')
>>> magma.command()  # indirect doctest
'magma-2.19'
```
**detach()**

Forget the running subprocess: keep it running but pretend that it's no longer running.

**EXAMPLES:**

```
sage: a = maxima('y')
sage: saved_expect = maxima._expect  # Save this to close later
sage: maxima.detach()
sage: a._check_valid()
Traceback (most recent call last):
...  
ValueError: The maxima session in which this object was defined is no longer running.
sage: saved_expect.close()  # Close child process
```

Calling `detach()` a second time does nothing:

```
sage: maxima.detach()
```

**eval** (*code*, *strip=True*, *synchronize=False*, *locals=None*, *allow_use_file=True*, *split_lines='nofile'*, **kwds)**

**INPUT:**

- **code** – text to evaluate
- **strip** – bool; whether to strip output prompts, etc. (ignored in the base class).
- **locals** – None (ignored); this is used for compatibility with the Sage notebook's generic system interface.
- **allow_use_file** – bool (default: True); if True and code exceeds an interface-specific threshold then code will be communicated via a temporary file rather than the character-based interface. If False then the code will be communicated via the character interface.
- **split_lines** – Tri-state (default: “nofile”); if “nofile” then code is sent line by line unless it gets communicated via a temporary file. If True then code is sent line by line, but some lines individually might be sent via temporary file. Depending on the interface, this may transform grammatical code into ungrammatical input. If False, then the whole block of code is evaluated all at once.
- **kwds** – All other arguments are passed onto the _eval_line method. An often useful example is reformat=False.

**expect()**
\textbf{interrupt} \((\text{tries}=5, \text{timeout}=2.0, \text{quit}_\text{on}_\text{fail}=\text{True})\)

\textbf{is\_local}()

\textbf{is\_remote}()

\textbf{is\_running}()
\quad Return \text{True} if self is currently running.

\textbf{path}()

\textbf{pid}()
\quad Return the PID of the underlying sub-process.

**REMARK:**
If the interface terminates unexpectedly, the original PID will still be used. But if it was terminated using \text{quit()}, a new sub-process with a new PID is automatically started.

**EXAMPLES:**
\begin{center}
\begin{verbatim}
sage: pid = gap.pid()
sage: gap.eval('quit;')
''
sage: pid == gap.pid()
True
sage: gap.quit()
sage: pid == gap.pid()
False
\end{verbatim}
\end{center}

\textbf{quit} \((\text{verbose}=\text{False})\)
\quad Quit the running subprocess.

**INPUT:**
\quad • \text{verbose} – (boolean, default \text{False}) print a message when quitting this process?

**EXAMPLES:**
\begin{center}
\begin{verbatim}
>>> from sage.all import *

>>> pid = gap.pid()
>>> gap.eval('quit;')
''
>>> pid == gap.pid()
True
>>> gap.quit()
>>> pid == gap.pid()
False
\end{verbatim}
\end{center}
Interpreter Interfaces, Release 10.4

>>> from sage.all import *
>>> a = maxima('y')
>>> maxima.quit(verbos= True)
Exiting Maxima with PID ... running ...maxima...
>>> a._check_valid()
Traceback (most recent call last):
  ...
ValueError: The maxima session in which this object was defined is no longer...
->running.

Calling quit() a second time does nothing:

sage: maxima.quit(verbos= True)

>>> from sage.all import *
>>> maxima.quit(verbos= True)

server()
Return the server used in this interface.

EXAMPLES:

sage: magma.set_server_and_command(server= 'remote')
No remote temporary directory (option server_tmpdir) specified, using /tmp/
->on remote
sage: magma.server() # indirect doctest
'remote'

>>> from sage.all import *
>>> magma.set_server_and_command(server= 'remote')
No remote temporary directory (option server_tmpdir) specified, using /tmp/
->on remote
>>> magma.server() # indirect doctest
'remote'

set_server_and_command (server=None, command=None, server_tmpdir=None, ulimit=None)
Changes the server and the command to use for this interface.

This raises a RuntimeError if the interface is already started.

INPUT:

• server – string or None (default); name of a remote host to connect to using ssh.
• command – one of:
  – a string; command line passed to the shell
  – a sequence of an Executable and strings, arguments to pass to the executable.

EXAMPLES:

sage: magma.set_server_and_command(server= 'remote', command= 'mymagma') #...
->indirect doctest
No remote temporary directory (option server_tmpdir) specified, using /tmp/
->on remote
sage: magma.server()
'remote'

(continues on next page)
>>> from sage.all import *
>>> magma.set_server_and_command(server='remote', command='mymagma')  # _
˓→indirect doctest
No remote temporary directory (option server_tmpdir) specified, using /tmp/␣
˓→on remote
>>> magma.server()
'remote'
>>> magma.command()
'ssh -t remote mymagma'

user_dir()

class sage.interfaces.expect.ExpectElement (parent, value, is_name=False, name=None)
   Bases: InterfaceElement, ExpectElement

Expect element.

class sage.interfaces.expect.ExpectFunction (parent, name)
   Bases: InterfaceFunction

Expect function.

class sage.interfaces.expect.FunctionElement (obj, name)
   Bases: InterfaceFunctionElement

Expect function element.

class sage.interfaces.expect.StdOutContext (interface, silent=False, stdout=None)
   Bases: object

A context in which all communication between Sage and a subprocess interfaced via pexpect is printed to stdout.

class sage.interfaces.expect.gc_disabled
   Bases: object

This is a "with" statement context manager. Garbage collection is disabled within its scope. Nested usage is properly handled.

EXAMPLES:

sage: import gc
sage: from sage.interfaces.expect import gc_disabled
sage: gc.isenabled()
True
sage: with gc_disabled():
    ...
        print(gc.isenabled())
    ...
        with gc_disabled():
        ...
            print(gc.isenabled())
        ...
            print(gc.isenabled())
False
False
False
sage: gc.isenabled()
True
>>> from sage.all import *
>>> import gc
>>> from sage.interfaces.expect import gc_disabled

>>> gc.isenabled()
True
>>> with gc_disabled():
...    print(gc.isenabled())
... with gc_disabled():
...    print(gc.isenabled())
... print(gc.isenabled())
False
False
False
>>> gc.isenabled()
True

sage.interfaces.expect.\texttt{is\_ExpectElement}(x)

Return True if $x$ is of type \texttt{ExpectElement}

This function is deprecated; use \texttt{isinstance()} (of \texttt{sage.interfaces.abc.ExpectElement}) instead.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.interfaces.expect import is_ExpectElement
sage: is_ExpectElement(2)

Warning: the function is_ExpectElement is deprecated; use...
\end{verbatim}
See https://github.com/sagemath/sage/issues/34804 for details.
False

\begin{verbatim}
>>> from sage.all import *
>>> from sage.interfaces.expect import is_ExpectElement
>>> is_ExpectElement(Integer(2))

Warning: the function is_ExpectElement is deprecated; use...
\end{verbatim}
See https://github.com/sagemath/sage/issues/34804 for details.
False
the ptyprocess’s PtyProcess class.

AUTHOR:

- Jeroen Demeyer (2015-02-01): initial version, see Issue #17686.
- Jeroen Demeyer (2015-12-04): add support for pexpect 4 + ptyprocess, see Issue #10295.

```python
class sage.interfaces.sagespawn.SagePtyProcess(pid, fd)
Bases: PtyProcess

close(force=None)
Quit the child process: send the quit string, close the pseudo-tty and kill the process.
This function returns immediately, it doesn’t wait for the child process to die.

EXAMPLES:

```sage
from sage.interfaces.sagespawn import SageSpawn
s = SageSpawn("sleep 1000")
s.close()
while s.isalive():  # long time (5 seconds)
    sleep(float(0.1))
```

```sage
from sage.all import *
from sage.interfaces.sagespawn import SageSpawn
s = SageSpawn("sleep 1000")
s.close()
while s.isalive():  # long time (5 seconds)
    sleep(float(RealNumber(0.1)))
```

terminate_async(interval=5.0)

Terminate the child process group asynchronously.

This function returns immediately, while the child is slowly being killed in the background.

INPUT:

- interval – (default: 5) how much seconds to wait between sending two signals.

EXAMPLES:

Run an infinite loop in the shell:

```sage
from sage.interfaces.sagespawn import SageSpawn
s = SageSpawn("sh", ["-c", "while true; do sleep 1; done"])
```
>>> from sage.all import *
>>> from sage.interfaces.sagespawn import SageSpawn
>>> s = SageSpawn("sh", ["-c", "while true; do sleep 1; done"])  

Check that the process eventually dies after calling terminate_async:

```python
sage: s.ptyproc.terminate_async(interval=float(0.2))
```

```python
sage: while True:
    try:
        os.kill(s.pid, 0)
    except OSError:
        sleep(float(0.1))
    else:
        break  # process got killed
```

```python
>>> from sage.all import *
>>> s.ptyproc.terminate_async(interval=float(RealNumber('0.2')))
>>> while True:
    try:
        os.kill(s.pid, Integer(0))
    except OSError:
        sleep(RealNumber('0.1'))
    else:
        break  # process got killed
```

class sage.interfaces.sagespawn.SageSpawn(*args, **kwds)

Bases: spawn

Spawn a subprocess in a pseudo-pty.

- *args, **kwds: see pexpect.spawn.
- name – human-readable name for this process, used for display purposes only.
- quit_string – (default: None) if not None, send this string to the child process before killing it.

EXAMPLES:

```python
sage: from sage.interfaces.sagespawn import SageSpawn
sage: SageSpawn("sleep 1", name="Sleeping Beauty")
Sleeping Beauty with PID ... running ...
```

```python
>>> from sage.all import *
>>> SageSpawn("sleep 1", name="Sleeping Beauty")
Sleeping Beauty with PID ... running ...
```

expect_peek (*args, **kwds)

Like expect() but restore the read buffer such that it looks like nothing was actually read. The next reading will continue at the current position.

EXAMPLES:

```python
sage: from sage.interfaces.sagespawn import SageSpawn
sage: E = SageSpawn("sh", ["-c", "echo hello world"])  
sage: _ = E.expect_peek("w")
```

```python
sage: E.read().decode('ascii')
'hello world\r\n'
```
>>> from sage.all import *
>>> from sage.interfaces.sagespawn import SageSpawn
>>> E = SageSpawn("sh", ['-c', "echo hello world"])
>>> _ = E.expect_peek("w")
>>> E.read().decode('ascii')
'hello world\r\n'

\texttt{expect_upto}(*\texttt{args}, **\texttt{kwds})

Like \texttt{expect()} but restore the read buffer starting from the matched string. The next reading will continue starting with the matched string.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.interfaces.sagespawn import SageSpawn
sage: E = SageSpawn("sh", ['-c', "echo hello world"])
sage: _ = E.expect_upto("w")
sage: E.read().decode('ascii')
'world\r\n'
\end{verbatim}
Chapter 3. Sage wrapper around pexpect's spawn class and
ABSTRACT BASE CLASSES FOR INTERFACE ELEMENTS

class sage.interfaces.abc.AxiomElement
   Bases: object

   Abstract base class for AxiomElement.
   This class is defined for the purpose of isinstance tests. It should not be instantiated.

   EXAMPLES:
   By design, there is a unique direct subclass:

   >>> from sage.all import *
   >>> len(sage.interfaces.abc.AxiomElement.__subclasses__()) <= 1
   True

class sage.interfaces.abc.ExpectElement
   Bases: object

   Abstract base class for ExpectElement.
   This class is defined for the purpose of isinstance tests. It should not be instantiated.

   EXAMPLES:
   By design, there is a unique direct subclass:

   >>> from sage.all import *
   >>> len(sage.interfaces.abc.ExpectElement.__subclasses__()) <= Integer(1)
   True

class sage.interfaces.abc.FriCASElement
   Bases: object

   Abstract base class for FriCASElement.
   This class is defined for the purpose of isinstance tests. It should not be instantiated.

   EXAMPLES:
   By design, there is a unique direct subclass:
class sage.interfaces.abc.GapElement

    Bases: object

    Abstract base class for \texttt{GapElement}.

    This class is defined for the purpose of \texttt{isinstance} tests. It should not be instantiated.

    EXAMPLES:

    By design, there is a unique direct subclass:

    sage: len(sage.interfaces.abc.GapElement.__subclasses__()) <= 1
    True

    >>> from sage.all import *
    >>> len(sage.interfaces.abc.GapElement.__subclasses__()) <= Integer(1)
    True

class sage.interfaces.abc.GpElement

    Bases: object

    Abstract base class for \texttt{GpElement}.

    This class is defined for the purpose of \texttt{isinstance} tests. It should not be instantiated.

    EXAMPLES:

    By design, there is a unique direct subclass:

    sage: len(sage.interfaces.abc.GpElement.__subclasses__()) <= 1
    True

    >>> from sage.all import *
    >>> len(sage.interfaces.abc.GpElement.__subclasses__()) <= Integer(1)
    True

class sage.interfaces.abc.Macaulay2Element

    Bases: object

    Abstract base class for \texttt{Macaulay2Element}.

    This class is defined for the purpose of \texttt{isinstance} tests. It should not be instantiated.

    EXAMPLES:

    By design, there is a unique direct subclass:

    sage: len(sage.interfaces.abc.Macaulay2Element.__subclasses__()) <= 1
    True

    >>> from sage.all import *
    >>> len(sage.interfaces.abc.Macaulay2Element.__subclasses__()) <= Integer(1)
    True
class sage.interfaces.abc.MagmaElement
Bases: object

Abstract base class for MagmaElement.
This class is defined for the purpose of isinstance tests. It should not be instantiated.

EXAMPLES:
By design, there is a unique direct subclass:

```
sage: len(sage.interfaces.abc.MagmaElement.__subclasses__()) <= 1
True
```
```
>>> from sage.all import *
>>> len(sage.interfaces.abc.MagmaElement.__subclasses__()) <= Integer(1)
True
```

class sage.interfaces.abc.SingularElement
Bases: object

Abstract base class for SingularElement.
This class is defined for the purpose of isinstance tests. It should not be instantiated.

EXAMPLES:
By design, there is a unique direct subclass:

```
sage: len(sage.interfaces.abc.SingularElement.__subclasses__()) <= 1
True
```
```
>>> from sage.all import *
>>> len(sage.interfaces.abc.SingularElement.__subclasses__()) <= Integer(1)
True
```
CHAPTER
FIVE

INTERFACE TO AXIOM

Todo:

• Evaluation using a file is not done. Any input line with more than a few thousand characters would hang the system, so currently it automatically raises an exception.

• All completions of a given command.

• Interactive help.

Axiom is a free GPL-compatible (modified BSD license) general purpose computer algebra system whose development started in 1973 at IBM. It contains symbolic manipulation algorithms, as well as implementations of special functions, including elliptic functions and generalized hypergeometric functions. Moreover, Axiom has implementations of many functions relating to the invariant theory of the symmetric group \(S_n\). For many links to Axiom documentation see http://wiki.axiom-developer.org.

AUTHORS:

• Bill Page (2006-10): Created this (based on Maxima interface)

  Note: Bill Page put a huge amount of effort into the Sage Axiom interface over several days during the Sage Days 2 coding sprint. This is contribution is greatly appreciated.

• Bill Page (2007-08): Minor modifications to support axiom4sage-0.3

  Note: The axiom4sage-0.3.spkg is based on an experimental version of the FriCAS fork of the Axiom project by Waldek Hebisch that uses pre-compiled cached Lisp code to build Axiom very quickly with clisp.

If the string “error” (case insensitive) occurs in the output of anything from axiom, a RuntimeError exception is raised.

EXAMPLES: We evaluate a very simple expression in axiom.

```
sage: axiom('3 * 5')                         #optional - axiom
15
sage: a = axiom(3) * axiom(5); a              #optional - axiom
15
```
The type of \( a \) is \texttt{AxiomElement}, i.e., an element of the axiom interpreter.

```python
sage: type(a) #optional - axiom
<class 'sage.interfaces.axiom.AxiomElement'>
sage: parent(a) #optional - axiom
Axiom
```

The underlying Axiom type of \( a \) is also available, via the type method:

```python
sage: a.type() #optional - axiom
PositiveInteger
```

We factor \( x^5 - y^5 \) in Axiom in several different ways. The first way yields a Axiom object.

```python
sage: F = axiom.factor('x^5 - y^5'); F #optional - axiom
- (y - x)(y + x y + x y + x y + x y + x)

sage: type(F) #optional - axiom
<class 'sage.interfaces.axiom.AxiomElement'>
```

Note that Axiom objects are normally displayed using “ASCII art”.

```python
sage: a = axiom(2/3); a #optional - axiom
2
-
3
```

```python
sage: a = axiom('x^2 + 3/7'); a #optional - axiom
2
-
3
x
```
The `axiom.eval` command evaluates an expression in Axiom and returns the result as a string. This is exact as if we typed in the given line of code to Axiom; the return value is what Axiom would print out.

```
sage: print(axiom.eval('factor(x^5 - y^5)'))  # optional - axiom
    - (y - x)(y + x y + x y + x y + x )
Type: Factored Polynomial Integer
```

We can create the polynomial \( f \) as a Axiom polynomial, then call the factor method on it. Notice that the notation \( f.factor() \) is consistent with how the rest of Sage works.

```
sage: f = axiom('x^5 - y^5')  #optional - axiom
sage: f^2  #optional - axiom
    10 5 5 10
    y - 2x y + x
sage: f.factor()  #optional - axiom
    4 3 2 2 3 4
    - (y - x)(y + x y + x y + x y + x )
```

Control-C interruption works well with the axiom interface, because of the excellent implementation of axiom. For example, try the following sum but with a much bigger range, and hit control-C.

```
sage: f = axiom('(x^5 - y^5)^10000')  # not tested
Interrupting Axiom...
...
<class 'exceptions.TypeError'>: Ctrl-c pressed while running Axiom
```

(continues on next page)
Interpreter Interfaces, Release 10.4

...<class 'exceptions.TypeError'>: Ctrl-c pressed while running Axiom

```
sage: axiom('1/100 + 1/101')  #optional - axiom
201
-----
10100
sage: a = axiom('(1 + sqrt(2))^5'); a  #optional - axiom
++
29\|2 + 41
```

```
>>> from sage.all import *

>>> axiom('1/100 + 1/101')  #optional - axiom
201
-----
10100
>>> a = axiom('(1 + sqrt(2))^5'); a  #optional - axiom
++
29\|2 + 41
```

class sage.interfaces.axiom.Axiom

Bases: PanAxiom

```
console()

Spawn a new Axiom command-line session.

EXAMPLES:
```
```
sage: axiom.console() #not tested
AXIOM Computer Algebra System

sage.interfaces.axiom.AxiomElement

alias of PanAxiomElement

sage.interfaces.axiom.AxiomExpectFunction

alias of PanAxiomExpectFunction

28 Chapter 5. Interface to Axiom
sage.interfaces.axiom.AxiomFunctionElement

alias of PanAxiomFunctionElement

class sage.interfaces.axiom.PanAxiom

(name='axiom', command='axiom -nox -noclef',
script_subdirectory=None, logfile=None, server=None,
server_tmpdir=None, init_code=['')lisp (si::readline-off')] )

Bases: ExtraTabCompletion, Expect

Interface to a PanAxiom interpreter.

def get(var)

Get the string value of the Axiom variable var.

EXAMPLES:

```python
sage: # optional - axiom
sage: axiom.set('xx', '2')
sage: axiom.get('xx')
'2'
sage: a = axiom('(1 + sqrt(2))^5')
sage: axiom.get(a.name())
' +---\r\r\n 29\|2 + 41
```

```python
>>> from sage.all import *

>>> # optional - axiom

>>> axiom.set('xx', '2')

>>> axiom.get('xx')

>>> a = axiom('(1 + sqrt(2))^5')

>>> axiom.get(a.name())
' +---\r\r\n 29\|2 + 41'
```

def set(var, value)

Set the variable var to the given value.

EXAMPLES:

```python
sage: axiom.set('xx', '2')
#optional - axiom
sage: axiom.get('xx')
'2'

>>> from sage.all import *

>>> # optional - axiom

>>> axiom.set('xx', '2')
#optional - axiom

>>> axiom.get('xx')
#optional - axiom

>>> 2
```

class sage.interfaces.axiom.PanAxiomElement

(parent, value, is_name=False, name=None)

Bases: ExpectElement, AxiomElement

as_type(type)

Returns self as type.

EXAMPLES:

```python
sage: a = axiom(1.2); a
#optional - axiom
1.2
sage: a.as_type(axiom.DoubleFloat)
#optional - axiom
```
(continues on next page)
1.2
sage: _.type()   #optional - axiom
DoubleFloat

>>> from sage.all import *

>>> a = axiom(RealNumber('1.2')); a   #optional - axiom
1.2
>>> a.as_type(axiom.DoubleFloat)   #optional - axiom
1.2
>>> _.type()   #optional - axiom
DoubleFloat

coma (**args)

Returns a Axiom tuple from self and args.

EXAMPLES:

sage:  # optional - axiom
sage: two = axiom(2)
sage: two.comma(3)
[2,3]
sage: two.comma(3,4)
[2,3,4]
sage: _.type()
Tuple PositiveInteger

>>> from sage.all import *

>>> # optional - axiom

>>> two = axiom(Integer(2))

>>> two.comma(Integer(3))
[2,3]

>>> two.comma(Integer(3),Integer(4))
[2,3,4]

>>> _.type()
Tuple PositiveInteger

type()  

Returns the type of an AxiomElement.

EXAMPLES:

sage: axiom(x+2).type()   #optional - axiom
 Polynomial Integer

>>> from sage.all import *

>>> axiom(x+Integer(2)).type()   #optional - axiom
 Polynomial Integer

unparsed_input_form()  

Get the linear string representation of this object, if possible (often it isn’t).

EXAMPLES:

sage: a = axiom(x^2+1); a   #optional - axiom
2
x + 1
sage: a.unparsed_input_form() #optional - axiom
'x'*x+1'

```python
>>> from sage.all import *
>>>
>>> a = axiom(x**Integer(2)+Integer(1)); a  #optional - axiom
   2
  x + 1
>>> a.unparsed_input_form() #optional - axiom
'x'*x+1'
```

class sage.interfaces.axiom.PanAxiomExpectFunction (parent, name)
Bases: ExpectFunction
class sage.interfaces.axiom.PanAxiomFunctionElement (object, name)
Bases: FunctionElement

sage.interfaces.axiom.axiom_console()
 Spawn a new Axiom command-line session.

EXAMPLES:

```python
sage: axiom_console() #not tested
    AXIOM Computer Algebra System
    Version: Axiom (January 2009)
    Timestamp: Sunday January 25, 2009 at 07:08:54
_____________________________________________________________________
Issue )copyright to view copyright notices.
Issue )summary for a summary of useful system commands.
Issue )quit to leave AXIOM and return to shell.
```

```python
>>> from sage.all import *
>>>
>>> axiom_console() #not tested
    AXIOM Computer Algebra System
    Version: Axiom (January 2009)
    Timestamp: Sunday January 25, 2009 at 07:08:54
_____________________________________________________________________
Issue )copyright to view copyright notices.
Issue )summary for a summary of useful system commands.
Issue )quit to leave AXIOM and return to shell.
```

sage.interfaces.axiom.is_AxiomElement (x)
 Return True if x is of type AxiomElement.

EXAMPLES:

```python
sage: from sage.interfaces.axiom import is_AxiomElement
sage: is_AxiomElement(2)
doctest::: DeprecationWarning: the function is_AxiomElement is deprecated; use...
   False
sage: is_AxiomElement(axiom(2))  # optional - axiom
    True
```
```python
>>> from sage.all import *
>>> from sage.interfaces.axiom import is_AxiomElement

>>> is_AxiomElement(Integer(2))
doctest:...: DeprecationWarning: the function is_AxiomElement is deprecated; use
→isinstance(x, sage.interfaces.abc.AxiomElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
False
>>> is_AxiomElement(axiom(Integer(2)))  # optional - axiom
True
```

```
 sage.interfaces.axiom.reduce_load_Axiom()

Returns the Axiom interface object defined in sage.interfaces.axiom.

EXAMPLES:
```
```
CHAPTER SIX

THE ELLIPTIC CURVE FACTORIZATION METHOD

The elliptic curve factorization method (ECM) is the fastest way to factor a known composite integer if one of the factors is relatively small (up to approximately 80 bits / 25 decimal digits). To factor an arbitrary integer it must be combined with a primality test. The $ECM.factor()$ method is an example for how to combine ECM with a primality test to compute the prime factorization of integers.

Sage includes GMP-ECM, which is a highly optimized implementation of Lenstra's elliptic curve factorization method. See https://gitlab.inria.fr/zimmerma/ecm for more about GMP-ECM.

AUTHORS:

These people wrote GMP-ECM: Pierrick Gaudry, Jim Fougeron, Laurent Fousse, Alexander Kruppa, Dave Newman, Paul Zimmermann

BUGS:

Output from $ecm$ is non-deterministic. Doctests should set the random seed, but currently there is no facility to do so.

```python
class sage.interfaces.ecm.ECM(B1=10, B2=None, **kwds)
    Bases: SageObject
    Create an interface to the GMP-ECM elliptic curve method factorization program.
    See https://gitlab.inria.fr/zimmerma/ecm

INPUT:

• B1 – integer. Stage 1 bound
• B2 – integer. Stage 2 bound (or interval B2min-B2max)

In addition the following keyword arguments can be used:

• x0 – integer $x$. use $x$ as initial point
• sigma – integer $s$. Use $s$ as curve generator [ecm]
• A – integer $a$. Use $a$ as curve parameter [ecm]
• k – integer $n$. Perform $> = n$ steps in stage 2
• power – integer $n$. Use $x^n$ for Brent-Suyama's extension
• dickson – integer $n$. Use $n$-th Dickson's polynomial for Brent-Suyama's extension
• c – integer $n$. Perform $n$ runs for each input
• pm1 – boolean. perform P-1 instead of ECM
• pp1 – boolean. perform P+1 instead of ECM
• q – boolean. quiet mode
```
• v – boolean. verbose mode
• timestamp – boolean. print a time stamp with each number
• mpzmod – boolean. use GMP’s mpz_mod for mod reduction
• modmuln – boolean. use Montgomery’s MODMULN for mod reduction
• redc – boolean. use Montgomery’s REDC for mod reduction
• nobase2 – boolean. Disable special base-2 code
• base2 – integer n. Force base 2 mode with 2^n+1 (n>0) or 2^n-1 (n<0)
• save – string filename. Save residues at end of stage 1 to file
• savea – string filename. Like -save, appends to existing files
• resume – string filename. Resume residues from file, reads from stdin if file is “-”
• primetest – boolean. Perform a primality test on input
• treefile – string. Store product tree of F in files f.0 f.1 …
• i – integer. increment B1 by this constant on each run
• I – integer f. auto-calculated increment for B1 multiplied by f scale factor.
• inp – string. Use file as input (instead of redirecting stdin)
• b – boolean. Use breadth-first mode of file processing
• d – boolean. Use depth-first mode of file processing (default)
• one – boolean. Stop processing a candidate if a factor is found (looping mode )
• n – boolean. Run ecm in ‘nice’ mode (below normal priority)
• nn – boolean. Run ecm in ‘very nice’ mode (idle priority)
• t – integer n. Trial divide candidates before P-1, P+1 or ECM up to n.
• ve – integer n. Verbosely show short (< n character) expressions on each loop
• B2scale – integer. Multiplies the default B2 value
• go – integer. Preload with group order val, which can be a simple expression, or can use N as a placeholder for the number being factored.
• prp – string. use shell command cmd to do large primality tests
• prplen – integer. only candidates longer than this number of digits are ‘large’
• prpval – integer. value>=0 which indicates the prp command found number to be PRP.
• prptmp – file. outputs n value to temp file prior to running (NB. gets deleted)
• prplog – file. otherwise get PRP results from this file (NB. gets deleted)
• prpyes – string. Literal string found in prplog file when number is PRP
• prpno – string. Literal string found in prplog file when number is composite

factor(n, factor_digits=None, B1=2000, proof=False, **kwds)
Return a probable prime factorization of n.

Combines GMP-ECM with a primality test, see is_prime(). The primality test is provable or probabilistic depending on the proof flag.

Moreover, for small n PARI is used directly.
Warning: There is no mathematical guarantee that the factors returned are actually prime if proof=False (default). It is extremely likely, though. Currently, there are no known examples where this fails.

INPUT:

- \( n \) – a positive integer
- \( \text{factor_digits} \) – integer or None (default). Optional guess at how many digits are in the smallest factor.
- \( B1 \) – initial lower bound, defaults to 2000 (15 digit factors). Used if \( \text{factor_digits} \) is not specified.
- \( \text{proof} \) – boolean (default: False). Whether to prove that the factors are prime.
- \( \text{kwds} \) – keyword arguments to pass to ecm-gmp. See help for ECM for more details.

OUTPUT:

A list of integers whose product is \( n \).

Note: Trial division should typically be performed, but this is not implemented (yet) in this method.

If you suspect that \( n \) is the product of two similarly-sized primes, other methods (such as a quadratic sieve – use the qsieve command) will usually be faster.

The best known algorithm for factoring in the case where all factors are large is the general number field sieve. This is not implemented in Sage; You probably want to use a cluster for problems of this size.

EXAMPLES:

```
sage: ecm.factor(60240069161242215451628278947806249229526581)
[45949729863572179, 1310999419499930367061460439]
sage: ecm.factor((2^197 + 1)/3)  # long time
[197002597249, 1348959352853811313, 251951573867253012259144010843]
sage: ecm.factor((179427217)^13) == [179427217] * 13
True
```

```
>>> from sage.all import *
>>> ecm.factor(Integer(60240069161242215451628278947806249229526581))
[45949729863572179, 1310999419499930367061460439]
>>> ecm.factor((Integer(2)**Integer(197) + Integer(1))/Integer(3))  # long time
[197002597249, 1348959352853811313, 251951573867253012259144010843]
>>> ecm.factor(Integer(179427217)**Integer(13)) == [Integer(179427217)] * Integer(13)
True
```

\texttt{find\_factor} \( (n, \text{factor\_digits}=\text{None}, B1=2000, **\text{kwds}) \)

Return a factor of \( n \).

See also \texttt{factor()} if you want a prime factorization of \( n \).

INPUT:

- \( n \) – a positive integer,
- \( \text{factor\_digits} \) – integer or None (default). Decimal digits estimate of the wanted factor.
- \( B1 \) – integer. Stage 1 bound (default 2000). This is used as bound if \( \text{factor\_digits} \) is not specified.
• kwds – optional keyword parameters.

OUTPUT:

List of integers whose product is n. For certain lengths of the factor, this is the best algorithm to find a factor.

Note: ECM is not a good primality test. Not finding a factorization is only weak evidence for \( n \) being prime. You should run a good primality test before calling this function.

EXAMPLES:

```python
sage: f = ECM()
sage: n = 508021860739623467191080372196682785441177798407961
sage: f.find_factor(n)
[7979226297612017, 6366805760909027985741435139224233]
```

Note that the input number cannot have more than 4095 digits:

```python
sage: f = 2^2^14+1
sage: ecm.find_factor(f)
Traceback (most recent call last):
  ... ValueError: n must have at most 4095 digits
```

```python
>>> from sage.all import *
>>> f = ECM()
>>> n = Integer(508021860739623467191080372196682785441177798407961)
>>> f.find_factor(n)
[7979226297612017, 6366805760909027985741435139224233]
```

get_last_params()

Return the parameters (including the curve) of the last ecm run.

In the case that the number was factored successfully, this will return the parameters that yielded the factorization.

OUTPUT:

A dictionary containing the parameters for the most recent factorization.

EXAMPLES:

```python
sage: ecm.factor((2^197 + 1)/3)  # long time
[197002597249, 134895935285181313, 251951573867253012259144010843]
sage: ecm.get_last_params()  # random output
{'poly': 'x^1', 'sigma': '1785694449', 'B1': '8885', 'B2': '1002846'}
```

```python
>>> from sage.all import *
>>> ecm.factor((Integer(2)**Integer(197) + Integer(1))/Integer(3))  # long time
```

(continues on next page)
Interpreter Interfaces, Release 10.4

(continued from previous page)

```python
>>> ecm.get_last_params()  # random output
{'poly': 'x^1', 'sigma': '1785694449', 'B1': '8885', 'B2': '1002846'}
```

`interact()`

Interactively interact with the ECM program.

**EXAMPLES:**

```python
sage: ecm.interact()  # not tested

>>> from sage.all import *

>>> ecm.interact()  # not tested
```

`one_curve(n, factor_digits=None, B1=2000, algorithm='ECM', **kwds)`

Run one single ECM (or P-1/P+1) curve on input n.

Note that trying a single curve is not particularly useful by itself. One typically needs to run over thousands of trial curves to factor n.

**INPUT:**

- n – a positive integer
- factor_digits – integer. Decimal digits estimate of the wanted factor.
- B1 – integer. Stage 1 bound (default 2000)
- algorithm – either “ECM” (default), “P-1” or “P+1"

**OUTPUT:**

a list [p, q] where p and q are integers and n = p * q. If no factor was found, then p = 1 and q = n.

**Warning:** Neither p nor q in the output is guaranteed to be prime.

**EXAMPLES:**

```python
sage: f = ECM()
sage: n = 508021860739623467191080372196682785441177798407961
sage: f.one_curve(n, B1=10000, sigma=11)
[1, 508021860739623467191080372196682785441177798407961]
```

(continues on next page)
recommended_B1

Return recommended B1 setting.

INPUT:

- factor_digits – integer. Number of digits.

OUTPUT:

EXAMPLES:

```
sage: ecm.recommended_B1(33)
1000000
```

time

Print a runtime estimate.

BUGS:

This method should really return something and not just print stuff on the screen.

INPUT:

- n – a positive integer
- factor_digits – the (estimated) number of digits of the smallest factor

OUTPUT:

An approximation for the amount of time it will take to find a factor of size factor_digits in a single process on the current computer. This estimate is provided by GMP-ECM's verbose option on a single run of a curve.

EXAMPLES:

```
sage: n = next_prime(11^23)*next_prime(11^37)
sage: ecm.time(n, 35) # random output
Expected curves: 910, Expected time: 23.95m
```

```
sage: ecm.time(n, 30, verbose=True) # random output

https://4ti2.github.io/

You must have the 4ti2 Sage package installed on your computer for this interface to work.

Use `sage -i 4ti2` to install the package.

AUTHORS:

- Bjarke Hammersholt Roune (2009-06-26): Added Groebner, made code usable as part of the Sage library and added documentation and some doctests.

```python
class sage.interfaces.four_ti_2.FourTi2(directory=None)
    Bases: object
    An interface to the program 4ti2.
    Each 4ti2 command is exposed as a method of this class.

call(command, project, verbose, options=True)
    Run the 4ti2 program `command` on the project named `project` in the directory `directory()`.

    INPUT:
    - command – The 4ti2 program to run.
    - project – The file name of the project to run on.
    - verbose – Display the output of 4ti2 if True.
    - options – A list of strings to pass to the program.

    EXAMPLES:

    sage: from sage.interfaces.four_ti_2 import four_ti_2
    sage: four_ti_2.write_matrix([[6,10,15]], "test_file")
    sage: four_ti_2.call("groebner", "test_file", False)  # optional - 4ti2
    sage: four_ti_2.read_matrix("test_file.gro")  # optional - 4ti2
    [-5  0  2]
    [-5  3  0]
```

```python
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.write_matrix([Integer(6),Integer(10),Integer(15)], "test_file")
>>> four_ti_2.call("groebner", "test_file", False)  # optional - 4ti2
(continues on next page)
```
circuit\(s\) \((\mat = \text{None}, \project = \text{None})\)

Run the 4ti2 program `circuits` on the parameters.

See [4ti2 website](#) for details.

**EXAMPLES:**

```python
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.circuits([1, 2, 3])  # optional - 4ti2
[ 0 3 -2]
[ 2 -1 0]
[ 3 0 -1]
```

```python
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2

>>> four_ti_2.circuits([Integer(1), Integer(2), Integer(3)])  # optional - 4ti2
[ 0 3 -2]
[ 2 -1 0]
[ 3 0 -1]
```

directory()

Return the directory where the input files for 4ti2 are written by Sage and where 4ti2 is run.

**EXAMPLES:**

```python
sage: from sage.interfaces.four_ti_2 import FourTi2
sage: f = FourTi2("/tmp/")
```

```python
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import FourTi2

>>> f.directory()  # optional - 4ti2
'/tmp/'
```

graver \((\mat = \text{None}, \lat = \text{None}, \project = \text{None})\)

Run the 4ti2 program `graver` on the parameters.

See [4ti2 website](#) for details.

**EXAMPLES:**

```python
sage: four_ti_2.graver([1, 2, 3])  # optional - 4ti2
[ 2 -1 0]
[ 3 0 -1]
[ 1 1 -1]
[ 1 -2 1]
[ 0 3 -2]

sage: four_ti_2.graver(lat=[[1, 2, 3], [1, 1, 1]])  # optional - 4ti2
[ 1 0 -1]
```

(continues on next page)
Interpreter Interfaces, Release 10.4

(continued from previous page)

>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.graver([Integer(1), Integer(2), Integer(3)])  # optional - 4ti2
[ 2 -1 0]
[ 3 0 -1]
[ 1 1 -1]
[1 -2 1]
[ 0 3 -2]

>>> four_ti_2.graver(lat=[[Integer(1), Integer(2), Integer(3)],[Integer(1),
˓→Integer(1), Integer(1)]])  # optional - 4ti2
[ 1 0 -1]
[ 0 1 2]
[1 1 1]
[2 1 0]

\[ \text{groebner} \ (\text{mat=None, lat=None, project=None}) \]

Run the 4ti2 program \texttt{groebner} on the parameters.

This computes a toric Groebner basis of a matrix.

See 4ti2 website for details.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: A = [6,10,15]
sage: four_ti_2.groebner(A)  # optional - 4ti2
[-5 0 2]
[-5 3 0]
sage: four_ti_2.groebner(lat=[[1,2,3],[1,1,1]])  # optional - 4ti2
[-1 0 1]
[ 2 1 0]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> A = [Integer(6), Integer(10), Integer(15)]
>>> four_ti_2.groebner(A)  # optional - 4ti2
[-5 0 2]
[-5 3 0]

>>> four_ti_2.groebner(lat=[[Integer(1), Integer(2), Integer(3)],[Integer(1),
˓→Integer(1), Integer(1)]])  # optional - 4ti2
[-1 0 1]
[2 1 0]
\end{verbatim}

\[ \text{hilbert} \ (\text{mat=None, lat=None, project=None}) \]

Run the 4ti2 program \texttt{hilbert} on the parameters.

See 4ti2 website for details.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.hilbert(four_ti_2._magic3x3())  # optional - 4ti2
\end{verbatim}

(continues on next page)
Interpreter Interfaces, Release 10.4

(continued from previous page)

sage: four_ti_2.hilbert(lat=[[1,2,3],[1,1,1]])  # optional - 4ti2
[2 1 0]
[0 1 2]
[1 1 1]

>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.hilbert(four_ti_2._magic3x3())  # optional - 4ti2
[2 0 1 0 1 2 1 2 0]
[1 0 2 1 0 0 2 1]
[0 2 1 2 1 0 1 0 2]
[1 2 0 0 1 2 2 0 1]
[1 1 1 1 1 1 1 1 1]

sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.minimize()  # optional - 4ti2
Traceback (most recent call last):
... Not Implemented Error: 4ti2 command 'minimize' not implemented in Sage.

>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.minimize()  # optional - 4ti2
Traceback (most recent call last):
... Not Implemented Error: 4ti2 command 'minimize' not implemented in Sage.

minimize(mat=None, lat=None)

Run the 4ti2 program minimize on the parameters.
See 4ti2 website for details.

EXAMPLES:

sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.minimize()  # optional - 4ti2
Traceback (most recent call last):
... Not Implemented Error: 4ti2 command 'minimize' not implemented in Sage.

ppi(n)

Run the 4ti2 program ppi on the parameters.
See 4ti2 website for details.

EXAMPLES:

sage: from sageinterfaces.four_ti_2 import four_ti_2
sage: four_ti_2.ppi(3)  # optional - 4ti2
[-2 1 0]
[ 0 -3 2]
[-1 -1 1]

(continues on next page)
qsolve (mat=None, rel=None, sign=None, project=None)

Run the 4ti2 program qsolve on the parameters.

See 4ti2 website for details.

EXAMPLES:

```python
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: A = [[1,1,1],[1,2,3]]
sage: four_ti_2.qsolve(A) # optional - 4ti2
[[], [1 -2 1]]
```

rays (mat=None, project=None)

Run the 4ti2 program rays on the parameters.

See 4ti2 website for details.

EXAMPLES:

```python
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.rays(four_ti_2._magic3x3()) # optional - 4ti2
[0 2 1 2 1 0 1 0 2]
[1 0 2 2 1 0 0 2 1]
[1 2 0 0 1 2 2 0 1]
[2 0 1 0 1 2 1 2 0]
```

read_matrix (filename)

Read a matrix in 4ti2 format from the file filename in directory directory().

INPUT:
• **filename** – The name of the file to read from.

**OUTPUT:**

The data from the file as a matrix over \(\mathbb{Z}\).

**EXAMPLES:**

```python
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.write_matrix([[1,2,3],[3,4,6]], "test_file")
sage: four_ti_2.read_matrix("test_file")
[1 2 3]
[3 4 6]
```

```python
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.write_matrix([[Integer(1),Integer(2),Integer(3)],[Integer(3),
→Integer(4),Integer(6)]], "test_file")
>>> four_ti_2.read_matrix("test_file")
[1 2 3]
[3 4 6]
```

**temp_project()**

Return an input project file name that has not been used yet.

**EXAMPLES:**

```python
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.temp_project()
project_...
```

```python
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.temp_project()
project_...
```

**write_array(array, nrows, ncols, filename)**

Write the integer matrix `array` to the file `filename` in directory `directory()` in 4ti2 format.

The matrix must have `nrows` rows and `ncols` columns. It can be provided as a list of lists.

**INPUT:**

- **array** – A matrix of integers. Can be represented as a list of lists.
- **nrows** – The number of rows in `array`.
- **ncols** – The number of columns in `array`.
- **file** – A file name not including a path.

**EXAMPLES:**

```python
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.write_array([[1,2,3],[3,4,5]], 2, 3, "test_file")
```

```python
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.write_array([[Integer(1),Integer(2),Integer(3)],[Integer(3),
→Integer(4),Integer(5)]], Integer(2), Integer(3), "test_file")
```
write_matrix(mat, filename)
Write the matrix mat to the file filename in 4ti2 format.

INPUT:
- mat – A matrix of integers or something that can be converted to that.
- filename – A file name not including a path.

EXAMPLES:
```
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.write_matrix([[1,2],[3,4]], "test_file")
```
```
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.write_matrix([[Integer(1),Integer(2)],[Integer(3),Integer(4)]], "test_file")
```
write_single_row(row, filename)
Write the list row to the file filename in 4ti2 format as a matrix with one row.

INPUT:
- row – A list of integers.
- filename – A file name not including a path.

EXAMPLES:
```
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: four_ti_2.write_single_row([1,2,3,4], "test_file")
```
```
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> four_ti_2.write_single_row([Integer(1),Integer(2),Integer(3),Integer(4)], "test_file")
```
zsolve(mat=None, rel=None, rhs=None, sign=None, lat=None, project=None)
Run the 4ti2 program zsolve on the parameters.

See 4ti2 website for details.

EXAMPLES:
```
sage: from sage.interfaces.four_ti_2 import four_ti_2
sage: A = [[1,1,1],[1,2,3]]
sage: rel = ['<', '<']
sage: rhs = [2, 3]
sage: sign = [1,0,1]
sage: four_ti_2.zsolve(A, rel, rhs, sign) # optional - 4ti2
[ [1 -1 0]
  [0 -1 0]
[0 0 1] [0 -3 2]
[1 1 0] [1 -2 1]
[0 1 0], [0 -2 1], []
]
sage: four_ti_2.zsolve(lat=[[1,2,3],[1,1,1]]) # optional - 4ti2
[...
```
(continues on next page)
>>> from sage.all import *
>>> from sage.interfaces.four_ti_2 import four_ti_2
>>> A = [[Integer(1),Integer(1),Integer(1)], [Integer(1),Integer(2), Integer(3)]
>>> rel = ['<', '<']
>>> rhs = [Integer(2), Integer(3)]
>>> sign = [Integer(1),Integer(0),Integer(1)]

```python
>>> four_ti_2.zsolve(A, rel, rhs, sign)  # optional - 4ti2
[[1 -1 0],
 [0 -1 0],
 [1 1 0], [0 0 1], [1 2 3]]
```

```python
>>> four_ti_2.zsolve(lat=[[Integer(1),Integer(2),Integer(3)], [Integer(1), Integer(1), Integer(1)]])  # optional - 4ti2
[[1 2 3],
 [0 0 0], [1 1 1]]
```
Todo:

- some conversions in `sage.functions` are still missing and all should be checked and tested

FriCAS is a free GPL-compatible (modified BSD license) general purpose computer algebra system based on Axiom. The FriCAS website can be found at http://fricas.sourceforge.net/.

AUTHORS:

- Mike Hansen (2009-02): Split off the FriCAS interface from the Axiom interface.
- Martin Rubey, Bill Page (2016-08): Completely separate from Axiom, implement more complete translation from FriCAS to SageMath types.

EXAMPLES:

```python
sage: fricas('3 * 5')
15
sage: a = fricas(3) * fricas(5); a
15
```

```python
>>> from sage.all import *

>>> fricas('3 * 5')
15
>>> a = fricas(Integer(3)) * fricas(Integer(5)); a
15
```

The type of `a` is `FriCASElement`, i.e., an element of the FriCAS interpreter:

```python
sage: type(a)
<class 'sage.interfaces.fricas.FriCASElement'>
sage: a.parent()
FriCAS
```

```python
>>> from sage.all import *

>>> type(a)
<class 'sage.interfaces.fricas.FriCASElement'>
>>> a.parent()
FriCAS
```

The underlying FriCAS type of `a` is also available, via the type method:
FriCAS objects are normally displayed using “ASCII art”:

```sage
sage: fricas(2/3)
 2
-3
sage: fricas('x^2 + 3/7')
x + -7
```

Functions defined in FriCAS are available as methods of the `fricas` object:

```sage
sage: F = fricas.factor('x^5 - y^5'); F
4 3 2 2 3 4
- (y - x)(y + x y + x y + x y + x)
sage: type(F)
<class 'sage.interfaces.fricas.FriCASElement'>
sage: F.typeOf()
Factored(Polynomial(Integer))
```

We can also create a FriCAS polynomial and apply the function `factor` from FriCAS. The notation `f.factor()` is consistent with how the rest of SageMath works:

```sage
sage: f = fricas('x^5 - y^5')
sage: f^2
10 5 5 10
y - 2 x y + x
sage: f.factor()
```

(continues on next page)
>>> from sage.all import *
>>> f = fricas('x^5 - y^5')
>>> f**Integer(2)
10 5 5 10
y - 2 x y + x
>>> f.factor()
4 3 2 2 3 4
- (y - x)(y + x y + x y + x y + x y + x )

For many FriCAS types, translation to an appropriate SageMath type is available:

```python
sage: f.factor().sage()
(y - x) * (y^4 + y^3*x + y^2*x^2 + y*x^3 + x^4)
```

Control-C interruption works well with the FriCAS interface. For example, try the following sum but with a much bigger range, and hit control-C:

```python
sage: f = fricas((x^5 - y^5)^10000)
# not tested
Interrupting FriCAS...
...
KeyboardInterrupt: Ctrl-c pressed while running FriCAS
```

Let us demonstrate some features of FriCAS. FriCAS can guess a differential equation for the generating function for integer partitions:

```
sage: fricas("guessADE([partition n for n in 0..40], homogeneous==4)"")
[  
  [x ]f(x):
    2 3 (iv) 2 2 , 3 ,,,
    x f(x) f (x) + (20 x f(x) f (x) + 5 x f(x) )f (x)
  
  +
  2 2 ,, 2
  - 39 x f(x) f (x)

  +
  2 ,, 2
  2 , 3 ,,, 2 , 4
  (12 x f(x)f (x) - 15 x f(x) f (x) + 4 f(x) )f (x) + 6 x f (x)
```

(continues on next page)
FriCAS can solve linear ordinary differential equations:

```python
sage: fricas.set("y", "operator y")
sage: fricas.set("deq", "x^3*D(y x, x, 3) + x^2*D(y x, x, 2) - 2*x*D(y x, x) + 2*y x - 2*x^4")
sage: fricas.set("sol", "solve(deq, y, x)"); fricas("sol")
```

```plaintext
[particular = ------------------,
  15 x
  3 2
  2 x - 3 x + 1 x - 1 x - 3 x - 1]
```

```plaintext
basis = [------------------, ------, ----------]
  x x x
```

```python
sage: fricas("sol.particular").sage()
1/15*(x^5 - 10*x^3 + 20*x^2 + 41)/x
```

(continues on next page)
FriCAS can expand expressions into series:

```python
given as
```
```
from sage.all import *

x = var('x'); ex = sqrt(cos(x)); a = fricas(ex).series(x=Integer(0)); a

1 2 1 4 6
- - - - - x + O(x )

a.coefficients()[Integer(38)].sage() # Fractions are not simplified

-294720263353372271504236594908326406468979/
2742144820663293682430667508979749984665600000000

ex = sqrt(atan(x)); a = fricas(ex).series(x=Integer(0)); a

1 5 9
- - -
2 1 2 31 2 6
x - - x + --- x + O(x )
6 360

a.coefficient(Integer(9)/Integer(2)).sage() # Fractions are simplified

31/360

x = fricas("x::TaylorSeries Fraction Integer")
y = fricas("y::TaylorSeries Fraction Integer")

Integer(2)* (Integer(1)+Integer(2)*x+sqrt(Integer(1)-Integer(4)*x)-Integer(2)*x*y).

FriCAS does some limits right:

sage: x = var('x'); ex = x^2*exp(-x)*Ei(x) - x; fricas(ex).limit(x=oo)

1

>>> from sage.all import *

x = var('x'); ex = x^2*exp(-x)*Ei(x) - x; fricas(ex).limit(x=oo)

1
class sage.interfaces.fricas.FriCAS(name='fricas', command=None, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None)

Bases: ExtraTabCompletion, Expect

Interface to a FriCAS interpreter.

console()

Spawn a new FriCAS command-line session.

EXAMPLES:

>>> from sage.all import *

```python
>>> fricas.set("x", "1783"); fricas("x")
1783
```

```python
>>> fricas.eval(")cl val x");
```

```
>>> from sage.all import *

```python
>>> fricas.set("x", "1783"); fricas("x")
1783
```

```python
>>> fricas.eval(")cl val x");
```

(continues on next page)
get (var)

Get the string representation of the value (more precisely, the OutputForm) of a variable or expression in FriCAS.

If FriCAS cannot evaluate var an error is raised.

EXAMPLES:

```python
sage: fricas.set('xx', '2')
sage: fricas.get('xx')
'2'
sage: a = fricas('(1 + sqrt(2))^5')
a
sage: fricas.get(a.name())
'+-+
29 \|2 + 41
sage: fricas.get('(1 + sqrt(2))^5')
'+-+
29 \|2 + 41
sage: fricas.new('(1 + sqrt(2))^5')
++
29 \|2 + 41
```

get_InputForm (var)

Return the InputForm as a string.

get_boolean (var)

Return the value of a FriCAS boolean as a boolean, without checking that it is a boolean.

get_integer (var)

Return the value of a FriCAS integer as an integer, without checking that it is an integer.

get_string (var)

Return the value of a FriCAS string as a string, without checking that it is a string.

get_unparsed_InputForm (var)

Return the unparsed InputForm as a string.

Todo:

- catch errors, especially when InputForm is not available:
  - for example when integration returns "failed"
UnivariatePolynomial

* should we provide workarounds, too?

**set** *(var, value)*

Set a variable to a value in FriCAS.

**INPUT:**

* var, value: strings, the first representing a valid FriCAS variable identifier, the second a FriCAS expression.

**OUTPUT:** None

**EXAMPLES:**

```python
sage: fricas.set('xx', 2)
sage: fricas.get('xx')
2
```

```python
>>> from sage.all import *
>>> fricas.set('xx', '2')
>>> fricas.get('xx')
'2'
```

**class** `sage.interfaces.fricas.FriCASElement` *(parent, value=False, name=None)*

**Bases:** `ExpectElement`, `FriCASElement`

Instances of this class represent objects in FriCAS.

Using the method `sage()` we can translate some of them to SageMath objects:

**_sage_()**

Convert `self` to a Sage object.

**EXAMPLES:**

**Floats:**

```python
sage: fricas(2.1234).sage()
2.12340000000000
sage: _.parent()
Real Field with 53 bits of precision
sage: a = RealField(100)(pi)
sage: fricas(a).sage()
3.1415926535897932384626433833
sage: _.parent()
Real Field with 100 bits of precision
sage: fricas(2.0).sage()
2.00000000000000
sage: _.parent()
Real Field with 53 bits of precision
```

```python
>>> from sage.all import *
>>> fricas(RealNumber('2.1234')).sage()
2.12340000000000
>>> _.parent()
```
Real Field with 53 bits of precision

```python
>>> a = RealField(Integer(100))(pi)
>>> fricas(a).sage()
3.1415926535897932384626433833
>>> _.parent()
Real Field with 100 bits of precision
>>> fricas(a).sage() == a
True
>>> fricas(RealNumber('2.0')).sage()
2.00000000000000
>>> _.parent()
Real Field with 53 bits of precision
```

Algebraic numbers:

```python
sage: a = fricas('(1 + sqrt(2))^5'); a
\(29 \sqrt{2} + 41\)
sage: b = a.sage(); b
82.0121933088198?
sage: b.radical_expression()
29\sqrt{2} + 41
```

Integers modulo n:

```python
sage: fricas("((42^17)^1783)::IntegerMod(5^(5^5))").sage() == Integers(5^(5^(5^5)))((42^17)^1783)
True
```

Matrices over a prime field:

```python
sage: fricas("matrix [[1::PF 3, 2],[2, 0]]").sage().parent()
Full MatrixSpace of 2 by 2 dense matrices over Finite Field of size 3
```

We can also convert FriCAS’s polynomials to Sage polynomials:
sage: a = fricas("x^2 + 1"); a.typeOf()
Polynomial(Integer)
sage: a.sage()
x^2 + 1
sage: _.parent()
Univariate Polynomial Ring in x over Integer Ring
sage: fricas('x^2 + y^2 + 1/2').sage()
y^2 + x^2 + 1/2
sage: _.parent()
Multivariate Polynomial Ring in y, x over Rational Field

sage: fricas("1$Polynomial Integer").sage()
1

sage: fricas("x^2/2").sage()
1/2*x^2

sage: x = polygen(QQ, 'x')
sage: fricas(x+3).sage()
x + 3
sage: fricas(x+3).domainOf()
Polynomial(Integer...)

sage: fricas(matrix([[2,3],[4,x+5]])).diagonal().sage()
(2, x + 5)

sage: f = fricas("(y^2+3)::UP(y, INT)").sage(); f
y^2 + 3
sage: f.parent()
Univariate Polynomial Ring in y over Integer Ring

sage: fricas("(y^2+sqrt 3)::UP(y, AN)"").sage()
y^2 + 1.732050807568878?

>>> from sage.all import *
>>> a = fricas("x^2 + 1"); a.typeOf()
Polynomial(Integer)
>>> a.sage()
x^2 + 1
>>> _.parent()
Univariate Polynomial Ring in x over Integer Ring
>>> fricas('x^2 + y^2 + 1/2').sage()
y^2 + x^2 + 1/2
>>> _.parent()
Multivariate Polynomial Ring in y, x over Rational Field

>>> fricas("1$Polynomial Integer").sage()
1

>>> fricas("x^2/2").sage()
1/2*x^2

>>> x = polygen(QQ, 'x')
>>> fricas(x+Integer(3)).sage()
x + 3
>>> fricas(x+Integer(3)).domainOf()
Polynomial(Integer...)

(continues on next page)
Interpreter Interfaces, Release 10.4

Rational functions:

```python
>>> from sage.all import *
>>> fricas("x^2 + 1/z")
sage()  
x^2 + 1/z
```

Expressions:

```python
>>> fricas(pi).sage()
sage()  
pi

>>> fricas("sin(x+y)/exp(z)*log(1+8e")
sage()  
e^(-z)*log(e + 1)*sin(x + y)

>>> fricas("factorial(n")
sage()  
factorial(n)

>>> fricas("integrate(sin(x+y), x=0..1")
sage()  
-integrate(sin((x^2+1)/x), x)
```

(continues on next page)
'failed'

```python
>>> fricas("integrate(sin((x^2+1)/x),x)").sage()
integral(sin((x^2 + 1)/x), x)
```

**Todo:**
- Converting matrices and lists takes much too long.

**Matrices:**

```python
sage: fricas("matrix [[x^n/2^m for n in 0..5] for m in 0..3]").sage()  # long time
[ [ 1/4 1/4*x 1/4*x^2 1/4*x^3 1/4*x^4 1/4*x^5 ]
 [ 1/8 1/8*x 1/8*x^2 1/8*x^3 1/8*x^4 1/8*x^5 ]
 [ 1/16 1/16*x 1/16*x^2 1/16*x^3 1/16*x^4 1/16*x^5 ]
```

```python
>>> from sage.all import *
```

```python
>>> fricas("matrix [[x^n/2^m for n in 0..5] for m in 0..3]").sage()  # long time
```

**Lists:**

```python
sage: fricas("[2^n/x^n for n in 0..5]").sage()  # long time
[ 1, 2/x, 4/x^2, 8/x^3, 16/x^4, 32/x^5 ]
```

```python
sage: fricas("[matrix [[i for i in 1..n]] for n in 0..5]").sage()  # long time
[[[]], [[1]], [[1, 2]], [[1, 2, 3]], [[1, 2, 3, 4]], [[1, 2, 3, 4, 5]]]
```

```python
>>> from sage.all import *
```

```python
>>> fricas("[2^n/x^n for n in 0..5]").sage()  # long time
[ 1, 2/x, 4/x^2, 8/x^3, 16/x^4, 32/x^5 ]
```

```python
>>> fricas("[matrix [[i for i in 1..n]] for n in 0..5]").sage()  # long time
[[[]], [[1]], [[1, 2]], [[1, 2, 3]], [[1, 2, 3, 4]], [[1, 2, 3, 4, 5]]]
```

**Error handling:**

```python
sage: s = fricas.guessPade("[fibonacci i for i in 0..10]"); s
n  x
[[[x ]- ----------]]
  2
  x + x - 1
```

```python
sage: s.sage()
Traceback (most recent call last):
...
NotImplementedError: the translation of the FriCAS Expression 'FEseries' to...
```
Interpreter Interfaces, Release 10.4

(continued from previous page)

→sage is not yet implemented

sage: s = fricas("series(sqrt(1+x), x=0)"); s

    65536 262144

>> s.sage()
Traceback (most recent call last):
...
NotImplementedError: the translation of the FriCAS object
<BLANKLINE>
**bool()**

Coerce the expression into a boolean.

**EXAMPLES:**

```python
sage: fricas("1=1").bool()
True
sage: fricas("1~=1").bool()
False
```

```python
>>> from sage.all import *
>>> fricas("1=1").bool()
True
>>> fricas("1~=1").bool()
False
```

**gen(n)**

Return an error, since the n-th generator in FriCAS is not well defined.

```python
class sage.interfaces.fricas.FriCASExpectFunction (parent, name)

Bases: ExpectFunction

Translate the pythonized function identifier back to a FriCAS operation name.

class sage.interfaces.fricas.FriCASFunctionElement (object, name)

Bases: FunctionElement

Make FriCAS operation names valid python function identifiers.
```

```python
sage.interfaces.fricas.fricas_console()
```

Spawn a new FriCAS command-line session.

**EXAMPLES:**

```python
sage: fricas_console()  # not tested
FriCAS (AXIOM fork) Computer Algebra System
Version: FriCAS 1.0.5
Timestamp: Thursday February 19, 2009 at 06:57:33
```

```python
---

Issue )copyright to view copyright notices.
Issue )summary for a summary of useful system commands.
Issue )quit to leave AXIOM and return to shell.
---
```
sage.interfaces.fricas.is_FriCASElement(x)
Return True if x is of type FriCASElement.

EXAMPLES:

```python
sage: from sage.interfaces.fricas import is_FriCASElement
sage: is_FriCASElement(2)
False
sage: is_FriCASElement(fricas(2))
True
```

sage.interfaces.fricas.reduce_load_fricas()
Return the FriCAS interface object defined in sage.interfaces.fricas.

EXAMPLES:

```python
sage: from sage.interfaces.fricas import reduce_load_fricas
sage: reduce_load_fricas()
FriCAS
```

```python
globals()`) # not tested
FriCAS (AXIOM fork) Computer Algebra System
Version: FriCAS 1.0.5

Issue )copyright to view copyright notices.
Issue )summary for a summary of useful system commands.
Issue )quit to leave AXIOM and return to shell.

sage.interfaces.fricas.is_FriCASElement(x)
Return True if x is of type FriCASElement.

EXAMPLES:

```python
sage: from sage.interfaces.fricas import is_FriCASElement
sage: is_FriCASElement(2)
False
sage: is_FriCASElement(fricas(2))
True
```

sage.interfaces.fricas.reduce_load_fricas()
Return the FriCAS interface object defined in sage.interfaces.fricas.

EXAMPLES:

```python
sage: from sage.interfaces.fricas import reduce_load_fricas
sage: reduce_load_fricas()
FriCAS
```

```python
globals()`) # not tested

The software package Frobby provides a number of computations on monomial ideals. The current main feature is the socle of a monomial ideal, which is largely equivalent to computing the maximal standard monomials, the Alexander dual or the irreducible decomposition.

Operations on monomial ideals are much faster than algorithms designed for ideals in general, which is what makes a specialized library for these operations on monomial ideals useful.

AUTHORS:

• Bjarke Hammersholt Roune (2008-04-25): Wrote the Frobby C++ program and the initial version of the Python interface.

Note: The official source for Frobby is <https://www.broune.com/frobby>, which also has documentation and papers describing the algorithms used.

```python
class sage.interfaces.frobby.Frobby
    Bases: object

    alexander_dual(monomial_ideal)

    This function computes the Alexander dual of the passed-in monomial ideal. This ideal is the one corresponding to the simplicial complex whose faces are the complements of the nonfaces of the simplicial complex corresponding to the input ideal.

    INPUT:

    • monomial_ideal – The monomial ideal to decompose.

    OUTPUT:

    The monomial corresponding to the Alexander dual.

    EXAMPLES:

    This is a simple example of computing irreducible decomposition.

    sage: # optional - frobby
    sage: (a, b, c, d) = QQ['a,b,c,d'].gens()
    sage: id = ideal(a * b, b * c, c * d, d * a)
    sage: alexander_dual = frobby.alexander_dual(id)
    sage: true_alexander_dual = ideal(b * d, a * c)
    sage: alexander_dual == true_alexander_dual  # use sets to ignore order
    True
```
We see how it is much faster to compute this with frobby than the built-in procedure for simplicial complexes:

```
sage: # optional - frobby
t=simplicial_complexes.PoincareHomologyThreeSphere()
sage: R=PolynomialRing(QQ,Integer(16),'x')
sage: I=R.ideal([prod([R.gen(i-Integer(1)) for i in a]) for a in t.facets()])
sage: len(frobby.alexander_dual(I).gens())
643
```

```python
>>> from sage.all import *
>>> # optional - frobby
t=simplicial_complexes.PoincareHomologyThreeSphere()
>>> R=PolynomialRing(QQ,Integer(16),'x')
>>> I=R.ideal([prod([R.gen(i-Integer(1)) for i in a]) for a in t.facets()])
>>> len(frobby.alexander_dual(I).gens())
643
```
**INPUT:**
- `monomial_ideal` – The monomial ideal to decompose.

**OUTPUT:**

The dimension of the zero set of the ideal.

**EXAMPLES:**

```sage
code

sage: R.<d,b,c>=QQ[] # optional - frobby
sage: I=[d*b*c,b^2*c,b^10,d^10]*R # optional - frobby
sage: frobby.dimension(I)   # optional - frobby
1
```

```sage
>>> from sage.all import *
>>> R = QQ['d, b, c']; (d, b, c,) = R._first_ngens(3)# optional - frobby 
>>> I=[d*b*c,b**Integer(2)*c,b**Integer(10),d**Integer(10)]*R # optional - 
                →frobby
>>> frobby.dimension(I) # optional - frobby
1
```

**hilbert** (`monomial_ideal`)  
Comes from the multigraded Hilbert-Poincaré series of the input ideal. Use the -univariate option to get the univariate series.

The Hilbert-Poincaré series of a monomial ideal is the sum of all monomials not in the ideal. This sum can be written as a (finite) rational function with \((x_1-1)(x_2-1)\ldots(x_n-1)\) in the denominator, assuming the variables of the ring are \(x_1, x_2, \ldots, x_n\). This action computes the polynomial in the numerator of this fraction.

**INPUT:**
- `monomial_ideal` – A monomial ideal.

**OUTPUT:**

A polynomial in the same ring as the ideal.

**EXAMPLES:**

```sage
code

sage: R.<d,b,c>=QQ[] # optional - frobby
sage: I=[d*b*c,b^2*c,b^10,d^10]*R # optional - frobby
sage: frobby.hilbert(I) # optional - frobby
```

```sage
>>> from sage.all import *
>>> R = QQ['d, b, c']; (d, b, c,) = R._first_ngens(3)# optional - frobby 
>>> I=[d*b*c,b**Integer(2)*c,b**Integer(10),d**Integer(10)]*R # optional - 
                →frobby
>>> frobby.hilbert(I) # optional - frobby
```

**irreducible_decomposition** (`monomial_ideal`)  
This function computes the irreducible decomposition of the passed-in monomial ideal. I.e. it computes the unique minimal list of irreducible monomial ideals whose intersection equals `monomial_ideal`.

**INPUT:**
- `monomial_ideal` – The monomial ideal to decompose.

```sage
>>> from sage.all import *
>>> R = QQ['d, b, c']; (d, b, c,) = R._first_ngens(3)# optional - frobby 
>>> I=[d*b*c,b**Integer(2)*c,b**Integer(10),d**Integer(10)]*R # optional - 
                →frobby
>>> frobby.hilbert(I) # optional - frobby
```
OUTPUT:
A list of the unique irredundant irreducible components of monomial_ideal. These ideals are constructed in the same ring as monomial_ideal is.

EXAMPLES:
This is a simple example of computing irreducible decomposition.

```python
sage: # optional - frobby
sage: (x, y, z) = QQ['x,y,z'].gens()
sage: id = ideal(x ** 2, y ** 2, x * z, y * z)
sage: decom = frobby.irreducible_decomposition(id)
sage: true_decom = [ideal(x, y), ideal(x ** 2, y ** 2, z)]
sage: set(decom) == set(true_decom) # use sets to ignore order
True
```

We now try the special case of the zero ideal in different rings.

We should also try PolynomialRing(QQ, names=[]), but it has a bug which makes that impossible (see Issue #3028).

```python
sage: # optional - frobby
sage: rings = [ZZ['x'], CC['x,y']]

sage: allOK = True
sage: for ring in rings:
...:

id1 = ring.ideal(1)
decom1 = frobby.irreducible_decomposition(id1)
allOK = allOK and decom1 == [id1]
sage: allOK
True

>>> from sage.all import *
>>> # optional - frobby
>>> rings = [ZZ['x'], CC['x,y']]
>>> allOK = True
>>> for ring in rings:
...    id1 = ring.ideal(Integer(1))
...    decom1 = frobby.irreducible_decomposition(id1)
...    allOK = allOK and decom1 == [id1]
>>> allOK
True
Chapter 9. Interface to Frobbby for fast computations on monomial ideals.
Sage provides an interface to the GAP system. This system provides extensive group theory, combinatorics, etc.

The GAP interface will only work if GAP is installed on your computer; this should be the case, since GAP is included with Sage. The interface offers three pieces of functionality:

1. gap_console() – A function that dumps you into an interactive command-line GAP session.
2. gap(expr) – Evaluation of arbitrary GAP expressions, with the result returned as a string.
3. gap.new(expr) – Creation of a Sage object that wraps a GAP object. This provides a Pythonic interface to GAP. For example, if \( f = \text{gap.new}(10) \), then \( f.\text{Factors()} \) returns the prime factorization of 10 computed using GAP.

### 10.1 First Examples

We factor an integer using GAP:

```python
sage: n = gap(20062006); n
20062006
sage: n.parent()
Gap
sage: fac = n.Factors(); fac
[ 2, 17, 59, 73, 137 ]
```

```python
sage: fac.parent()  # same as in Python
Gap
sage: fac[1]        # same as in Python
2
```

```python
>>> from sage.all import *
>>> n = gap(Integer(20062006)); n
20062006
>>> n.parent()
Gap
>>> fac = n.Factors(); fac
[ 2, 17, 59, 73, 137 ]
>>> fac.parent()  # same as in Python
Gap
>>> fac[Integer(1)]  # same as in Python
2
```
10.2 GAP and Singular

This example illustrates conversion between Singular and GAP via Sage as an intermediate step. First we create and factor a Singular polynomial.

```sage
sage: singular(389)
389
sage: R1 = singular.ring(0, 'x,y', 'dp')
sage: f = singular(9*x^16-18*x^13*y^2-9*x^12*y^3+9*x^10*y^4-18*x^11*y^2+36*x^8*y^4+18*x^7*y^5-18*x^5*y^6+9*x^6*y^4-18*x^3*y^6-9*x^2*y^7+9*y^8')
sage: F = f.factorize()
sage: print(F)
[1]:
  _[1]=9
  _[2]=x^6-2*x^3*y^2-x^2*y^3+y^4
  _[3]=-x^5+y^2
[2]:
  1,1,2
```

Next we convert the factor $-x^5 + y^2$ to a Sage multivariate polynomial. Note that it is important to let $x$ and $y$ be the generators of a polynomial ring, so the `eval` command works.

```sage
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: s = F[1][3].sage_polystring(); s
'-x**5+y**2'
sage: g = eval(s); g
-x^5 + y^2
```

Next we create a polynomial ring in GAP and obtain its indeterminates:

```sage
>>> from sage.all import *
>>> R = gap.PolynomialRing(Rationals, 2); (x, y) = R._first_ngens(2)
>>> s = F[Integer(1)][Integer(3)].sage_polystring(); s
'-x**5+y**2'
>>> g = eval(s); g
-x^5 + y^2
```

Next we create a polynomial ring in GAP and obtain its indeterminates:
In order to eval \( g \) in GAP, we need to tell GAP to view the variables \( x_0 \) and \( x_1 \) as the two generators of \( R \). This is the one tricky part. In the GAP interpreter the object \( I \) has its own name (which isn’t \( I \)). We can access its name using \( I.name() \).

```python
sage: _ = gap.eval("x := $s[1];; y := $s[2];;"%(I.name(), I.name()))
```

Now \( x_0 \) and \( x_1 \) are defined, so we can construct the GAP polynomial \( f \) corresponding to \( g \):

```python
sage: R.<x,y> = PolynomialRing(QQ,2)
sage: f = gap(str(g)); f
-x_1^5+x_2^2
```

We can call GAP functions on \( f \). For example, we evaluate the GAP `Value` function, which evaluates \( f \) at the point \((1,2)\).

```python
sage: f.Value(I, [1,2])
3
sage: g(1,2)  # agrees
3
```

## 10.3 Saving and loading objects

Saving and loading GAP objects (using the dumps method, etc.) is not supported, since the output string representation of Gap objects is sometimes not valid input to GAP. Creating classes that wrap GAP objects is supported, via simply defining the a `_gap_init_` member function that returns a string that when evaluated in GAP constructs the object. See `groups/perm_gps/permgroup.py` for a nontrivial example of this.
10.4 Long Input

The GAP interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

**Note:** Using `gap.eval` for long input is much less robust, and is not recommended.

```plaintext
sage: t = "%s"%10^10000 # ten thousand character string.
sage: a = gap(t)
```

10.5 Changing which GAP is used, and how

Set the environment variable `SAGE_GAP_COMMAND` to specify how GAP executable is called. E.g.

```plaintext
$ SAGE_GAP_COMMAND = "/usr/local/bin/gap -s 4G" ./sage
```

will use GAP installed in `/usr/local/bin`, with 4Gb RAM.

Set the environment variable `SAGE_GAP_MEMORY` to specify the amount of RAM allocated to `libgap` and to the GAP executable. If `SAGE_GAP_COMMAND` is set, as well, then `SAGE_GAP_MEMORY` is only used for `libgap`.

```plaintext
sage: gap.eval(GAPInfo.CommandLineOptions.s) # not tested
"42m"
```

After the GAP interface initialisation, setting `SAGE_GAP_MEMORY` has no effect:

```plaintext
sage: os.environ['SAGE_GAP_MEMORY'] = '24M'
sage: gap.eval(GAPInfo.CommandLineOptions.s) # not tested
"4g"
```

AUTHORS:

- David Joyner and William Stein: initial version(s)
- William Stein (2006-02-01): modified `gap_console` command so it uses exactly the same startup command as `Gap.__init__`
- William Stein (2006-03-02): added tab completions: `gap.[tab]`, `x = gap(...)`, `x.[tab]`, and docs, e.g., `gap.function?` and `x.function?`
class sage.interfaces.gap.Gap(max_workspace_size=None, maxread=None, script_subdirectory=None, use_workspace_cache=True, server=None, server_tmpdir=None, logfile=None, seed=None, env={})

Bases: Gap_generic

Interface to the GAP interpreter.

AUTHORS:

• William Stein and David Joyner

console()

Spawn a new GAP command-line session.

EXAMPLES:

sage: gap.console()  # not tested
********* GAP, Version 4.5.7 of 14-Dec-2012 (free software, GPL)
* GAP * https://www.gap-system.org
********* Architecture: x86_64-unknown-linux-gnu-gcc-default64
Libs used: gmp, readline
Loading the library and packages ...
Packages: GAPDoc 1.5.1
Try '?help' for help. See also '?copyright' and '?authors'
gap>

>>> from sage.all import *

>>> gap.console()  # not tested
********* GAP, Version 4.5.7 of 14-Dec-2012 (free software, GPL)
* GAP * https://www.gap-system.org
********* Architecture: x86_64-unknown-linux-gnu-gcc-default64
Libs used: gmp, readline
Loading the library and packages ...
Packages: GAPDoc 1.5.1
Try '?help' for help. See also '?copyright' and '?authors'
gap>

cputime(t=None)

Returns the amount of CPU time that the GAP session has used. If t is not None, then it returns the difference between the current CPU time and t.

EXAMPLES:

sage: t = gap.cputime()
sage: t  #random
0.13600000000000001
sage: gap.Order(gap.SymmetricGroup(5))
120
sage: gap.cputime(t)  #random
0.05999999999999998

>>> from sage.all import *

>>> t = gap.cputime()

>>> t  #random
0.13600000000000001

>>> gap.Order(gap.SymmetricGroup(Integer(5)))
120

>>> gap.cputime(t)  #random
0.05999999999999998
**get** *(var, use_file=False)*

Get the string representation of the variable var.

**EXAMPLES:**

```python
sage: gap.set('x', '2')
sage: gap.get('x')
'2'
```

**help** *(s, pager=True)*

Print help on a given topic.

**EXAMPLES:**

Note: In order to ensure consistent unicode handling from GAP we start a GAP instance with a forced UTF-8 locale:

```python
sage: gap = Gap(env={'LC_CTYPE': 'en_US.UTF-8'})
sage: print(gap.help('SymmetricGroup', pager=False))

50.1-... SymmetricGroup
  • SymmetricGroup( [filt, ]deg ) ─────────────────────────────────── function ...
```

**save_workspace()**

Save the GAP workspace.

**set** *(var, value)*

Set the variable var to the given value.

**EXAMPLES:**

```python
sage: gap.set('x', '2')
sage: gap.get('x')
'2'
```
set_seed (seed=None)
Set the seed for gap interpreter.
The seed should be an integer.

EXAMPLES:

```
sage: g = Gap()
sage: g.set_seed(0)
0
sage: [g.Random(1,10) for i in range(5)]
[2, 3, 3, 4, 2]
```

```none
>>> from sage.all import *
>>> g = Gap()
>>> g.set_seed(Integer(0))
0
>>> [g.Random(Integer(1),Integer(10)) for i in range(Integer(5))]
[2, 3, 3, 4, 2]
```

class sage.interfaces.gap.GapElement (parent, value, is_name=False, name=None)
Bases: GapElement_generic, GapElement

str (use_file=False)

EXAMPLES:

```
sage: print(gap(2))
2
```

```none
>>> from sage.all import *
>>> print(gap(Integer(2)))
2
```

class sage.interfaces.gap.GapElement_generic (parent, value, is_name=False, name=None)
Bases: ModuleElement, ExtraTabCompletion, ExpectElement

Generic interface to the GAP3/GAP4 interpreters.

AUTHORS:
• William Stein and David Joyner (interface for GAP4)
• Franco Saliola (Feb 2010): refactored to separate out the generic code

is_string ()
Tell whether this element is a string.

EXAMPLES:

```
sage: gap("abc").is_string()
True
sage: gap('[1,2,3]').is_string()
False
```

```none
>>> from sage.all import *
>>> gap("abc").is_string()
True
>>> gap('[1,2,3]').is_string()
False
```
Generic interface to the GAP3/GAP4 interpreters.

AUTHORS:

• William Stein and David Joyner (interface for GAP4)
• Franco Saliola (Feb 2010): refactored to separate out the generic code

eval \((x, \text{newlines=False}, \text{strip=True}, \text{split_lines=True}, **\text{kwds})\)

Send the code in the string \(s\) to the GAP interpreter and return the output as a string.

INPUT:

• \(s\) – string containing GAP code.
• \(\text{newlines}\) – bool (default: True); if False, remove all backslash-newlines inserted by the GAP output formatter.
• \(\text{strip}\) – ignored
• \(\text{split_lines}\) – bool (default: True); if True then each line is evaluated separately. If False, then the whole block of code is evaluated all at once.

EXAMPLES:

```
sage: gap.eval('2+2')
'4'
sage: gap.eval('Print(4); #test\nPrint(6);')
'46'
sage: gap.eval('Print("#"); Print(6);')
'#6'
sage: gap.eval('4; \n 6;')
'4
6'
sage: gap.eval('if 3>2 then\nPrint("hi");\nfi;')
'hi'
sage: gap.eval('## this is a test\nPrint("OK");')
'OK'
sage: gap.eval('Print("This is a test. Oh no, a #");# but this is a comment\n--\nPrint("OK");')
'This is a test. Oh no, a #OK'
sage: gap.eval('if 4>3 then')
'...'
sage: gap.eval('Print("Hi how are you?")')
'Hi how are you?'
sage: gap.eval('fi')
```
>>> from sage.all import *
>>> gap.eval('2+2')
'4'
>>> gap.eval('Print(4); #test\n Print(6);')
'46'
>>> gap.eval('Print("#"); Print(6);')
'#6'
>>> gap.eval('4; \n 6;')
'4\n6'
>>> gap.eval('if 3>2 then\n Print("hi");\n fi;')
'hi'
>>> gap.eval('## this is a test\n Print("OK")')
'OK'
>>> gap.eval('Print("This is a test. Oh no, a #");# but this is a comment\n \n Print("OK")')
'This is a test. Oh no, a #OK'
>>> gap.eval('if 4>3 then')

>>> gap.eval('Print("Hi how are you?")')
'Hi how are you?'
>>> gap.eval('fi')

function_call (function, args=None, kwds=None)
Calls the GAP function with args and kwds.

EXAMPLES:

sage: gap.function_call(SymmetricGroup, [5])
SymmetricGroup([1..5])

sage: s = gap.function_call(Display, [gap.SymmetricGroup(5).CharacterTable()])

If the GAP function does not return a value, but prints something to the screen, then a string of the printed output is returned.

sage: s = gap.function_call(Display, [gap.SymmetricGroup(Integer(5)).CharacterTable()])
sage: type(s)
<class 'sage.interfaces.interface.AsciiArtString'>
sage: s.startswith('CT')
True

get_record_element (record, name)
Return the element of a GAP record identified by name.

INPUT:
• record – a GAP record
• name – str

OUTPUT:
• GapElement

EXAMPLES:

```
sage: rec = gap('rec a := 1, b := "2" ')
sage: gap.get_record_element(rec, 'a')
1
sage: gap.get_record_element(rec, 'b')
2
```

```
>>> from sage.all import *
>>> rec = gap('rec a := 1, b := "2" ')
>>> gap.get_record_element(rec, 'a')
1
>>> gap.get_record_element(rec, 'b')
2
```

interrupt (tries=None, timeout=1, quit_on_fail=True)
Interrupt the GAP process

Gap installs a SIGINT handler, we call it directly instead of trying to sent Ctrl-C. Unlike interrupt(), we only try once since we are knowing what we are doing.

Sometimes GAP dies while interrupting.

EXAMPLES:

```
sage: gap._eval_line('while(1=1) do i:=1;; od;', wait_for_prompt=False) ''
  sage: rc = gap.interrupt(timeout=1)
  sage: [ gap(i) for i in range(10) ]  # check that it is still working
  [0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
>>> from sage.all import *
>>> gap._eval_line('while(1=1) do i:=1;; od;', wait_for_prompt=False) ''
  >>> rc = gap.interrupt(timeout=Integer(1))
  >>> [ gap(i) for i in range(Integer(10)) ]  # check that it is still working
  [0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

load_package (pkg, verbose=False)
Load the Gap package with the given name.

If loading fails, raise a RuntimeError exception.

unbind (var)
Clear the variable named var.

EXAMPLES:

```
sage: gap.set('x', '2')
sage: gap.get('x')
'2'
sage: gap.unbind('x')
```

(continues on next page)
sage: gap.get('x')
Traceback (most recent call last):
 ...
RuntimeError: Gap produced error output
Error, Variable: 'x' must have a value
 ...

>>> from sage.all import *

>>> gap.set('x', '2')

>>> gap.get('x')
'2'

>>> gap.unbind('x')

>>> gap.get('x')
Traceback (most recent call last):
 ...
RuntimeError: Gap produced error output
Error, Variable: 'x' must have a value
 ...

version()

Returns the version of GAP being used.

EXAMPLES:

sage: print(gap.version())
4...

sage.interfaces.gap.gap_command(use_workspace_cache=True, local=True)
sage.interfaces.gap.gap_console()

Spawn a new GAP command-line session.

Note that in gap-4.5.7 you cannot use a workspace cache that had no commandline to restore a gap session with commandline.

EXAMPLES:

sage: gap_console()  # not tested

********* GAP, Version 4.5.7 of 14-Dec-2012 (free software, GPL)
* GAP * https://www.gap-system.org
********* Architecture: x86_64-unknown-linux-gnu-gcc-default64
Libs used: gmp, readline
Loading the library and packages ...
Packages: GAPDoc 1.5.1
Try '?help' for help. See also '?copyright' and '?authors'
gap>

>>> from sage.all import *

>>> gap_console()  # not tested

********* GAP, Version 4.5.7 of 14-Dec-2012 (free software, GPL)
* GAP * https://www.gap-system.org
********* Architecture: x86_64-unknown-linux-gnu-gcc-default64
sage.interfaces.gap.gap_reset_workspace(max_workspace_size=None, verbose=False)

Call this to completely reset the GAP workspace, which is used by default when Sage first starts GAP.

The first time you start GAP from Sage, it saves the startup state of GAP in a file $HOME/.sage/gap/workspace-gap-HASH, where HASH is a hash of the directory where Sage is installed. This is useful because the subsequent startup of GAP is at least ten times as fast. But if you update GAP or any of its packages, those changes won’t take effect until the workspace is reset.

sage.interfaces.gap.gfq_gap_to_sage(x, F)

INPUT:

- x – GAP finite field element
- F – Sage finite field

OUTPUT: element of F

EXAMPLES:

```python
sage: x = gap(Z(13))
sage: F = GF(13, 'a')
sage: F(x)
2
sage: F(gap(0*Z(13)))
0
sage: F = GF(13^2, 'a')
sage: x = gap(Z(13))
sage: F(x)
2
sage: x = gap(Z(13^2)^3)
sage: F(x)
12*a + 11
sage: F.multiplicative_generator()^3
12*a + 11
```

```python
>>> from sage.all import *
>>> x = gap('Z(13)')
>>> F = GF(Integer(13), 'a')
>>> F(x)
2
>>> F(gap('0*Z(13)'))
0
>>> F = GF(Integer(13)**Integer(2), 'a')
>>> x = gap('Z(13)')
>>> F(x)
2
>>> x = gap('Z(13^2)^3')
>>> F(x)
12*a + 11
>>> F.multiplicative_generator()**Integer(3)
12*a + 11
```
AUTHOR:

- David Joyner and William Stein

`sage.interfaces.gap.intmod_gap_to_sage(x)`

**INPUT:**

- `x` – Gap integer mod ring element

**EXAMPLES:**

```python
def main():
    a = gap(Mod(3, 18)); a
    b = sage.interfaces.gap.intmod_gap_to_sage(a); b
    print(b.parent())

    a = gap(Mod(3, 17)); a
    b = sage.interfaces.gap.intmod_gap_to_sage(a); b
    print(b.parent())

    a = gap(Mod(0, 17)); a
    b = sage.interfaces.gap.intmod_gap_to_sage(a); b
    print(b.parent())

    a = gap(Mod(3, 65537)); a
    b = sage.interfaces.gap.intmod_gap_to_sage(a); b
    print(b.parent())

if __name__ == '__main__':
    main()
```

```bash
>>> from sage.all import *
>>> a = gap(Mod(Integer(3), Integer(18))); a
ZmodnZObj( 3, 18 )
>>> b = sage.interfaces.gap.intmod_gap_to_sage(a); b
3
>>> b.parent()
Ring of integers modulo 18

>>> a = gap(Mod(Integer(3), Integer(17))); a
Z(17)
>>> b = sage.interfaces.gap.intmod_gap_to_sage(a); b
3
>>> b.parent()
Finite Field of size 17

>>> a = gap(Mod(Integer(0), Integer(17))); a
0*Z(17)
>>> b = sage.interfaces.gap.intmod_gap_to_sage(a); b
0
>>> b.parent()
Finite Field of size 17

>>> a = gap(Mod(Integer(3), Integer(65537))); a
ZmodpZObj( 3, 65537 )
>>> b = sage.interfaces.gap.intmod_gap_to_sage(a); b
3
>>> b.parent()
Ring of integers modulo 65537
```

(continues on next page)
Finite Field of size 17

```python
>>> a = gap(Mod(Integer(3), Integer(65537))); a
ZmodpZObj( 3, 65537 )
```
```python
>>> b = sage.interfaces.gap.intmod_gap_to_sage(a); b
3
```
```python
>>> b.parent()
Ring of integers modulo 65537
```

`sage.interfaces.gap.is_GapElement(x)`

Return True if `x` is a `GapElement`

This function is deprecated; use `isinstance()` (of `sage.interfaces.abc.GapElement`) instead.

**EXAMPLES:**

```python
sage: from sage.interfaces.gap import is_GapElement
sage: is_GapElement(gap(2))
```
```
doctest:...: DeprecationWarning: the function is_GapElement is deprecated; use...
  →isinstance(x, sage/interfaces/abc/GapElement) instead
See https://github.com/sagemath/sage/issues/34823 for details.
```
```python
True
```
```python
sage: is_GapElement(2)
```
```
False
```

```python
>>> from sage.all import *
>>> from sage.interfaces.gap import is_GapElement
```
```python
>>> is_GapElement(gap(Integer(2)))
```
```
doctest:...: DeprecationWarning: the function is_GapElement is deprecated; use...
  →isinstance(x, sage/interfaces/abc/GapElement) instead
See https://github.com/sagemath/sage/issues/34823 for details.
```
```python
True
```
```python
>>> is_GapElement(Integer(2))
```
```
False
```

`sage.interfaces.gap.reduce_load_GAP()`

Returns the GAP interface object defined in `sage.interfaces.gap`.

**EXAMPLES:**

```python
sage: from sage.interfaces.gap import reduce_load_GAP
sage: reduce_load_GAP()
```
```
```
```python
>>> from sage.all import *
>>> from sage.interfaces.gap import reduce_load_GAP
```
```python
>>> reduce_load_GAP()
```
```
```python
```
```python
```
This module implements an interface to GAP3.

AUTHORS:
- Franco Saliola (February 2010)
- Christian Stump (March 2016)

**Warning:** The experimental package for GAP3 is Jean Michel's pre-packaged GAP3, which is a minimal GAP3 distribution containing packages that have no equivalent in GAP4, see Issue #20107 and also

https://webusers.imj-prg.fr/~jean.michel/gap3/

### 11.1 Obtaining GAP3

Instead of installing the experimental GAP3 package, one can as well install by hand either of the following two versions of GAP3:

- Frank Luebeck maintains a GAP3 Linux executable, optimized for i686 and statically linked for jobs of 2 GByte or more:
  
  http://www.math.rwth-aachen.de/~Frank.Luebeck/gap/GAP3

- or you can download GAP3 from the GAP website below. Since GAP3 is no longer supported, it may not be easy to install this version.

### 11.2 Changing which GAP3 is used

**Warning:** There is a bug in the pexpect module (see Issue #8471) that prevents the following from working correctly. For now, just make sure that `gap3` is in your `PATH`.

Sage assumes that GAP3 can be launched with the command `gap3`; that is, Sage assumes that the command `gap3` is in your `PATH`. If this is not the case, then you can start GAP3 using the following command:

```
sage: gap3 = Gap3(command=’/usr/local/bin/gap3’)       # not tested
```
11.3 Functionality and Examples

The interface to GAP3 offers the following functionality.

1. `gap3(expr)` – Evaluation of arbitrary GAP3 expressions, with the result returned as a Sage object wrapping the corresponding GAP3 element:

```plaintext
sage: # optional - gap3
sage: a = gap3('3+2')
sage: a
5
sage: type(a)
<class 'sage.interfaces.gap3.GAP3Element'>
```

This provides a Pythonic interface to GAP3. If `gap_function` is the name of a GAP3 function, then the syntax `gap_element.gap_function()` returns the `gap_element` obtained by evaluating the command `gap_function(gap_element)` in GAP3:

```plaintext
sage: # optional - gap3
sage: S5 = gap3('SymmetricGroup(5)')
sage: S5
Group( (1,5), (2,5), (3,5), (4,5) )
sage: type(S5)
<class 'sage.interfaces.gap3.GAP3Record'>
```
Alternatively, you can instead use the syntax `gap3.gap_function(gap_element):`

```sage
sage: gap3.DerivedSeries(S5) #optional - gap3
[ Group( (1,5), (2,5), (3,5), (4,5) ),
  Subgroup( Group( (1,5), (2,5), (3,5), (4,5) ),
            [ (1,2,5), (1,3,5), (1,4,5) ] ) ]
```

If `gap_element` corresponds to a GAP3 record, then `gap_element.recfield` provides a means to access the record element corresponding to the field `recfield`:

```sage
sage: # optional - gap3
sage: S5.IsRec()
true
sage: S5.recfields()
['isDomain', 'isGroup', 'identity', 'generators', 'operations',
 'isPermGroup', 'isFinite', '1', '2', '3', '4', 'degree']

sage: S5.identity
()

sage: S5.degree
5

sage: S5.1
(1,5)

sage: S5.2
(2,5)
```

2. By typing `%gap3` or `gap3.interact()` at the command-line, you can interact directly with the underlying GAP3 session.

```sage
sage: gap3.interact() # not tested
```

(continues on next page)
-- Switching to Gap3 --

```
>>> from sage.all import *
>>> gap3.interact()
```

-- Switching to Gap3 --

```
sage: gap3.console()
```

3. You can start a new GAP3 session as follows:

```
# not tested
Lehrstuhl D fuer Mathematik
RWTH Aachen

# # Alice Niemeyer, Werner Nickel, Martin Schoenert
# # Johannes Meier, Alex Wegner, Thomas Bischops
# # Frank Celler, Juergen Mnich, Udo Polis
# # Thomas Breuer, Goetz Pfeiffer, Hans U. Besche
# # Volkmar Felsch, Heiko Theissen, Alexander Hulpke
# # Ansgar Kaup, Akos Seress, Erzsebet Horvath
# # Bettina Eick
# For help enter: ?<return>

gap>
```

```
# not tested
Lehrstuhl D fuer Mathematik
RWTH Aachen

# # Alice Niemeyer, Werner Nickel, Martin Schoenert
# # Johannes Meier, Alex Wegner, Thomas Bischops
# # Frank Celler, Juergen Mnich, Udo Polis
# # Thomas Breuer, Goetz Pfeiffer, Hans U. Besche
# # Volkmar Felsch, Heiko Theissen, Alexander Hulpke
# # Ansgar Kaup, Akos Seress, Erzsebet Horvath
# # Bettina Eick
# For help enter: ?<return>

gap>
```

(continues on next page)
4. The interface also has access to the GAP3 help system:

```plaintext
sage: gap3.help('help', pager=False)  # not tested
Help _______________________________________________________...
This section describes together with the following sections the GAP help system. The help system lets you read the manual interactively...
```

```plaintext
>>> from sage.all import *
>>> gap3.help('help', pager=False)  # not tested
Help _______________________________________________________...
This section describes together with the following sections the GAP help system. The help system lets you read the manual interactively...
```

### 11.4 Common Pitfalls

1. If you want to pass a string to GAP3, then you need to wrap it in single quotes as follows:

```plaintext
sage: gap3("This is a GAP3 string")  #optional - gap3
"This is a GAP3 string"
```

```plaintext
>>> from sage.all import *
>>> gap3("This is a GAP3 string")  #optional - gap3
"This is a GAP3 string"
```

This is particularly important when a GAP3 package is loaded via the `RequirePackage` method (note that one can instead use the `load_package` method):

```plaintext
sage: gap3.RequirePackage("chevie")  #optional - gap3
```

```plaintext
>>> from sage.all import *
>>> gap3.RequirePackage("chevie")  #optional - gap3
```
11.5 Examples

Load a GAP3 package:

```python
sage: # optional - gap3
gap3.load_package("chevie")
sage: gap3.version() # random # not tested
'lib: v3r4p4 1997/04/18, src: v3r4p0 1994/07/10, sys: usg gcc ansi'
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> gap3.load_package("chevie")
>>> gap3.version() # random # not tested
'lib: v3r4p4 1997/04/18, src: v3r4p0 1994/07/10, sys: usg gcc ansi'
```

Working with GAP3 lists. Note that GAP3 lists are 1-indexed:

```python
sage: # optional - gap3
sage: L = gap3([1,2,3])
sage: L[1]
1
sage: L[2]
2
sage: 3 in L
True
sage: 4 in L
False
sage: m = gap3([[1,2],[3,4]])
sage: m[2,1]
3
sage: [1,2] in m
True
sage: [3,2] in m
False
sage: gap3([1,2]) in m
True
```

```python
>>> from sage.all import *
>>> # optional - gap3
>>> L = gap3([Integer(1),Integer(2),Integer(3)])
>>> L[1]
1
>>> L[Integer(2)]
2
>>> Integer(3) in L
True
>>> Integer(4) in L
False
>>> m = gap3([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]))
>>> m[Integer(2),Integer(1)]
3
>>> [Integer(1),Integer(2)] in m
True
>>> [Integer(3),Integer(2)] in m
False
>>> gap3([Integer(1),Integer(2)]) in m
True
```
Controlling variable names used by GAP3:

```
sage: # optional - gap3
gap3('2', name='x')
2
sage: gap3('x')
2
sage: gap3.unbind('x')
sage: gap3('x')
Traceback (most recent call last):
  ...  
TypeError: Gap3 produced error output
Error, Variable: 'x' must have a value
...
```

```python
>>> from sage.all import *
>>> # optional - gap3
>>> gap3('2', name='x')
2
>>> gap3('x')
2
>>> gap3.unbind('x')
>>> gap3('x')
Traceback (most recent call last):
  ...  
TypeError: Gap3 produced error output
Error, Variable: 'x' must have a value
...
```

class `sage.interfaces.gap3.GAP3Element` (`parent`, `value`, `is_name=False`, `name=None`)

```
A GAP3 element

Note: If the corresponding GAP3 element is a GAP3 record, then the class is changed to a GAP3Record.

INPUT:

- `parent` – the GAP3 session
- `value` – the GAP3 command as a string
- `is_name` – bool (default: False); if True, then value is the variable name for the object
- `name` – str (default: None); the variable name to use for the object. If None, then a variable name is generated.

Note: If you pass E, X or Z for name, then an error is raised because these are sacred variable names in GAP3 that should never be redefined. Sage raises an error because GAP3 does not!

EXAMPLES:

```
sage: # optional - gap3
from sage.interfaces.gap3 import GAP3Element
sage: gap3 = Gap3()
sage: GAP3Element(gap3, value='3+2')
(continues on next page)
```

11.5. Examples 91
AUTHORS:

- Franco Saliola (Feb 2010)

```python
class sage.interfaces.gap3.GAP3Record (parent, value, is_name=False, name=None)
```

A GAP3 record

**Note:** This class should not be called directly, use GAP3Element instead. If the corresponding GAP3 element is a GAP3 record, then the class is changed to a GAP3Record.

AUTHORS:

- Franco Saliola (Feb 2010)

```python
operations ()
```

Return a list of the GAP3 operations for the record.

**OUTPUT:**

- list of strings – operations of the record

**EXAMPLES:**

```python
sage: S5 = gap3.SymmetricGroup(5) #optional - gap3
sage: S5.operations() #optional - gap3
[...,'NormalClosure','NormalIntersection','Normalizer',
 'NumberConjugacyClasses','PCore','Radical','SylowSubgroup',
 'TrivialSubgroup','FusionConjugacyClasses','DerivedSeries',...]
```

```python
sage: S5.DerivedSeries() #optional - gap3
[ Group( (1,5), (2,5), (3,5), (4,5) ),
  Subgroup( Group( (1,5), (2,5), (3,5), (4,5) ),
  [ (1,2,5), (1,3,5), (1,4,5) ] ) ]
```

(continues on next page)
recfields()

Return a list of the fields for the record. (Record fields are akin to object attributes in Sage.)

OUTPUT:

• list of strings – the field records

EXAMPLES:

```
sage: S5 = gap3.SymmetricGroup(5)                      #optional - gap3
sage: S5.recfields()                                   #optional - gap3
['isDomain', 'isGroup', 'identity', 'generators',
 'operations', 'isPermGroup', 'isFinite', '1', '2',
 '3', '4', 'degree']
sage: S5.degree                                        #optional - gap3
5
```

## Lehrstuhl D fuer Mathematik
### RWTH Aachen
## 

```python
>>> from sage.all import *
>>> from sage.interfaces.gap3 import Gap3
>>> gap3 = Gap3(command='gap3')
```

AUTHORS:

• Franco Saliola (Feb 2010)

console()

Spawn a new GAP3 command-line session.

EXAMPLES:

```
sage: gap3.console()  # not tested
```

(continues on next page)
cputime (t=None)

Return the amount of CPU time that the GAP session has used in seconds.

If t is not None, then it returns the difference between the current CPU time and t.

EXAMPLES:

```python
sage: # optional - gap3
sage: t = gap3.cputime()
sage: t  # random
```

(continued on next page)
sage: gap3.SymmetricGroup(5).Size()
120
sage: gap3.cputime()  # random
0.14999999999999999
sage: gap3.cputime(t)  # random
0.13

>>> from sage.all import *
>>> # optional - gap3
>>> t = gap3.cputime()
>>> t  # random
0.02
>>> gap3.SymmetricGroup(Integer(5)).Size()
120
>>> gap3.cputime()  # random
0.14999999999999999
>>> gap3.cputime(t)  # random
0.13

help (topic, pager=True)
Print help on the given topic.

INPUT:
- topic - string

EXAMPLES:

sage: gap3.help('help', pager=False)  # optional - gap3
Help __________________________________________________...
This section describes together with the following section...
help system. The help system lets you read the manual inter...

>>> from sage.all import *
>>> # optional - gap3
>>> gap3.help('help', pager=False)  # optional - gap3
Help __________________________________________________...
<BLANKLINE>
This section describes together with the following section...
help system. The help system lets you read the manual inter...

sage: gap3.help('SymmetricGroup', pager=False)  # optional - gap3
no section with this name was found

>>> from sage.all import *
>>> # optional - gap3
>>> gap3.help('SymmetricGroup', pager=False)  # optional - gap3
no section with this name was found

sage.interfaces.gap3.gap3_console()
Spawn a new GAP3 command-line session.

EXAMPLES:

sage: gap3.console()  # not tested

(continues on next page)
sage.interfaces.gap3.gap3_version()

Return the version of GAP3 that you have in your PATH on your computer.

EXAMPLES:
sage: gap3_version()  # random, optional
˓→ gap3
'lib: v3r4p4 1997/04/18, src: v3r4p0 1994/07/10, sys: usg gcc ansi'

>>> from sage.all import *

>>> gap3_version()  # random, optional ...
˓→ gap3
'lib: v3r4p4 1997/04/18, src: v3r4p0 1994/07/10, sys: usg gcc ansi'

11.5. Examples
INTERFACE TO GROEBNER FAN

AUTHOR:

- Anders Nedergaard Jensen: Write gfan C++ program, which implements algorithms many of which were invented by Jensen, Komei Fukuda, and Rekha Thomas.
- William Stein (2006-03-18): wrote gfan interface (first version)
- Marshall Hampton (2008-03-17): modified to use gfan-0.3, subprocess instead of os.popen2

TODO – much functionality of gfan-0.3 is still not exposed:

```
* at most 52 variables:
  - use gfan_substitute to make easier (?)
    MH: I think this is now irrelevant since gfan can accept the original ring
  --variables

* --symmetry is really useful
  - permutations are 0-based *not* cycle notation; a <---> 0
    output is broken up much more nicely.

* -- can work in Z/pZ for p <= 32749

* -- can compute individual GB's for lex and revlex (via buchberger)
```

```python
class sage.interfaces.gfan.Gfan
  Bases: object

  Interface to Anders Jensen’s Groebner Fan program.
```
(You should prefer the cython interface: giacpy_sage and its libgiac command)
(adapted by F. Han from William Stein and Gregg Musiker maple’s interface)

You must have the Giac interpreter installed and available as the command giac in your PATH in order to use this interface. You need a giac version supporting “giac –sage” (roughly after 0.9.1). In this case you do not have to install any optional Sage packages. If giac is not already installed, you can download binaries or sources or spkg (follow the sources link) from the homepage:

Homepage <https://www-fourier.ujf-grenoble.fr/~parisse/giac.html>

Type giac.[tab] for a list of all the functions available from your Giac install. Type giac.[tab]? for Giac’s help about a given function. Type giac(...) to create a new Giac object, and giac.eval(...) to run a string using Giac (and get the result back as a string).

If the giac spkg is installed, you should find the full html documentation there:

$SAGE_LOCAL/share/giac/doc/en/cascmd_local/index.html

EXAMPLES:

```
sage: giac('3 * 5')
15
sage: giac.eval('ifactor(2005)')
'5*401'
sage: giac.ifactor(2005)
2005
sage: l=giac.ifactors(2005); l; l[2]
[5,1,401,1]
401
sage: giac.fsolve('x^2=cos(x)+4', 'x','0..5')
[1.9140206190...
```

```
sage: giac.factor(x^4 - y^4)
(x-y)*(x+y)*(x^2+y^2)
sage: R.<x,y>=QQ[];f=(x+y)^5;f2=giac(f);(f-f2).normal()
0
sage: x,y=giac('x,y'); giac.int(y/(cos(2*x)+cos(x)),x)  # random
y*2*((-(tan(x/2)))/6+(-2*1/6/sqrt(3))*ln(abs(6*tan(x/2)-2*sqrt(3))/abs(6*tan(x/
˓→2)+2*sqrt(3))))
```

>>> from sage.all import *
>>> giac('3 * 5')
15
>>> giac.eval('ifactor(2005)')
'5*401'

(continues on next page)
If the string “error” (case insensitive) occurs in the output of anything from Giac, a RuntimeError exception is raised.

## 13.1 Tutorial

**AUTHORS:**

- Frederic Han: adapted to giac.

This tutorial is based on the Maple Tutorial for number theory from [http://www.math.mun.ca/~drideout/m3370/numtheory.html](http://www.math.mun.ca/~drideout/m3370/numtheory.html).

### 13.1.1 Syntax

There are several ways to use the Giac Interface in Sage. We will discuss two of those ways in this tutorial.

1. If you have a giac expression such as

   ```python
   factor( (x^4-1));
   ```

   We can write that in sage as

   ```python
   sage: giac('factor(x^4-1)')
   (x-1) *(x+1) *(x^2+1)
   ```

2. Since Sage is written in Python, we can also import giac commands and write our scripts in a pythonic way. For example, `factor()` is a giac command, so we can also factor in Sage using

   ```python
   sage: giac('(x^4-1)').factor()
   (x-1) *(x+1) *(x^2+1)
   ```

Notice, there is no need to use a semicolon.
where `expression.command()` means the same thing as `command(expression)` in Giac. We will use this second type of syntax whenever possible, resorting to the first when needed.

```python
>>> from sage.all import *
>>> giac('(x^4-1)').factor()
(x-1)*(x+1)*(x^2+1)
```

### 13.1.2 Some typical input

The `normal` command will reduce a rational function to the lowest terms. In giac, `simplify` is slower than `normal` because it tries more sophisticated simplifications (ex algebraic extensions). The `factor` command will factor a polynomial with rational coefficients into irreducible factors over the ring of integers (if your default configuration of giac (cf. `xcasrc`) has not allowed square roots). So for example,

```python
sage: giac('(x^12-1)/(x-1)').normal()
x^11+x^10+x^9+x^8+x^7+x^6+x^5+x^4+x^3+x^2+x+1
```

13.1.3 Giac console

Another important feature of giac is its online help. We can access this through `sage` as well. After reading the description of the command, you can press `q` to immediately get back to your original prompt.

Incidentally you can always get into a giac console by the command

```python
sage: giac.console()  # not tested
sage: !giac       # not tested
```

```python
>>> from sage.all import *
>>> giac.console()  # not tested
>>> !giac         # not tested
```
Note that the above two commands are slightly different, and the first is preferred.

For example, for help on the giac command factors, we type:

```sage
sage: giac.help('factors') # not tested
```

```sage
>>> from sage.all import *

>>> giac.help('factors') # not tested
```

```sage
sage: alpha = giac((1+sqrt(5))/2)
sage: beta = giac(1-sqrt(5))/2
sage: f19 = alpha^19 - beta^19/sqrt(5)
sage: f19
(sqrt(5)/2+1/2)^19-((-sqrt(5)+1)/2)^19/sqrt(5)
sage: (f19-(5778*sqrt(5)+33825)/5).normal()
0
```

```sage
>>> from sage.all import *

>>> alpha = giac((Integer(1)+sqrt(Integer(5)))/Integer(2))

>>> beta = giac(Integer(1)-sqrt(Integer(5)))/Integer(2)

>>> f19 = alpha**Integer(19) - beta**Integer(19)/sqrt(Integer(5))

>>> f19
(sqrt(5)/2+1/2)^19-((-sqrt(5)+1)/2)^19/sqrt(5)

>>> (f19-(Integer(5778)*sqrt(Integer(5))+Integer(33825))/Integer(5)).normal()
0
```

### 13.1.4 Function definitions

Let’s say we want to write a giac program now that squares a number if it is positive and cubes it if it is negative. In giac, that would look like:

```plaintext
cmysqcu := proc(x)
  if x > 0 then x^2;
  else x^3; fi;
end;
```

In Sage, we write:

```sage
sage: mysqcu = giac('proc(x) if x > 0 then x^2 else x^3 fi end')

sage: mysqcu(5)
25
sage: mysqcu(-5)
-125
```

```sage
>>> from sage.all import *

>>> mysqcu = giac('proc(x) if x > 0 then x^2 else x^3 fi end')

>>> mysqcu(Integer(5))
25

>>> mysqcu(-Integer(5))
-125
```

More complicated programs should be put in a separate file and loaded.
### 13.1.5 Conversions

The `GiacElement.sage()` method tries to convert a Giac object to a Sage object. In many cases, it will just work. In particular, it should be able to convert expressions entirely consisting of:

- numbers, i.e. integers, floats, complex numbers;
- functions and named constants also present in Sage, where Sage knows how to translate the function or constant’s name from Giac’s;
- symbolic variables whose names don’t pathologically overlap with objects already defined in Sage.

This method will not work when Giac’s output includes functions unknown to Sage.

If you want to convert more complicated Giac expressions, you can instead call `GiacElement._sage_()` and supply a translation dictionary:

```python
sage: g = giac('NewFn(x)')
sage: g._sage_(locals={('NewFn', 1): sin})
```

Moreover, new conversions can be permanently added using Pynac’s `register_symbol`, and this is the recommended approach for library code. For more details, see the documentation for `.sage()`.

```python
class sage.interfaces.giac.Giac(maxread=None, script_subdirectory=None, server=None, server_tmpdir=None, logfile=None)

Bases: Expect

Interface to the Giac interpreter.

You must have the optional Giac interpreter installed and available as the command `giac` in your PATH in order to use this interface. Try the command: `print(giac._install_hints())` for more informations on giac installation.

Type `giac.[tab]` for a list of all the functions available from your Giac install. Type `giac.[tab]?` for Giac’s help about a given function. Type `giac(...)` to create a new Giac object.

Full html documentation for giac is available from your giac installation at `$PREFIX/share/giac/doc/en/cascmd_en/index.html`

**EXAMPLES:**

Any Giac instruction can be evaluated as a string by the `giac` command. You can access the giac functions by adding the `giac.` prefix to the usual Giac name.

```python
sage: l=giac('normal((y+sqrt(2))^4)'); l
```

```python
>>> l=giac('normal((y+sqrt(2))^4)'); l
```

```python
>>> l=giac('normal((y+sqrt(2))^4)'); l
```

```python
>>> f=giac('(u,v)->{ if (u<v){ [u,v] } else { [v,u] }}');f(1,2),f(3,1)
```

```python
>>> f=giac('(u,v)->{ if (u<v){ [u,v] } else { [v,u] }}');f(Integer(1),Integer(2)), f(Integer(3),Integer(1))
```
The output of the giac command is a Giac object, and it can be used for another giac command.

```python
sage: 1.factors()
[y+sqrt(2), 4]
sage: giac('x^12-1').factor()
(x-1)*(x+1)*(x^2+1)*(x^2-x+1)*(x^2+x+1)*(x^4-x^2+1)
sage: giac('assume(y>0)'); giac('y^2=3').solve('y')
y...
[sqrt(3)]
```

```python
>>> from sage.all import *

>>> 1.factors()
[y+sqrt(2), 4]
>>> giac('x^12-1').factor()
(x-1)*(x+1)*(x^2+1)*(x^2-x+1)*(x^2+x+1)*(x^4-x^2+1)
>>> giac('assume(y>0)'); giac('y^2=3').solve('y')
y...
[sqrt(3)]
```

You can create some Giac elements and avoid many quotes like this:

```python
sage: x, y, z = giac('x, y, z'); type(y)
<class 'sage.interfaces.giac.GiacElement'>
sage: I1 = Integral(1/(cos(2*y)+cos(y))).integral(y, 0, pi/4).simplify()
sage: I1 = ((1/(3*3)*tan(1/8*pi))/(sqrt(3)+3*3*tan(1/8*pi)))*sqrt(3)-
       3*3*tan(1/8*pi))/9).normal()
0
sage: ((y+z*sqrt(5))*(y-sqrt(5)*z)).normal()
y^2-5*z^2

>>> from sage.all import *

>>> x, y, z = giac('x, y, z'); type(y)
<class 'sage.interfaces.giac.GiacElement'>
>>> I1 = (Integer(1)/(cos(Integer(2)*y)+cos(y))).integral(y, Integer(0), Integer(4)).simplify()
>>> I1 = ((-2*ln((sqrt(Integer(3))-3*3*tan(Integer(1)/Integer(8)*pi))/(sqrt(Integer(3))+3*3*tan(Integer(1)/Integer(8)*pi))))*sqrt(3)-
       3*3*tan(1/8*pi))/9).normal()
0
>>> ((y+z*sqrt(5))*(y-sqrt(5)*z)).normal()
y^2-5*z^2
```

Polynomials or elements of SR can be evaluated directly by the giac interface.

```python
sage: R.<a,b> = QQ[]; f = (2+a+b)
sage: p = giac.gcd(f^3+5*f^5,f^2+f^5); p; R(p.sage())
sageVARa^2+2*sageVARa*sageVARb+4*sageVARa+sageVARb^2+4*sageVARb+4
a^2 + 2*a*b + b^2 + 4*a + 4*b + 4
```

```python
>>> from sage.all import *

>>> R = QQ['a, b']; (a, b,) = R._first_ngens(2); f = (Integer(2)+a+b)
>>> p = giac.gcd(f**Integer(3)+Integer(5)*f**Integer(5),
       -f**Integer(2)+f**Integer(5)); p; R(p.sage())
sageVARa^2+2*sageVARa*sageVARb+4*sageVARa+sageVARb^2+4*sageVARb+4
a^2 + 2*a*b + b^2 + 4*a + 4*b + 4
```

Variable names in python and giac are independent:
sage: a=sqrt(2); giac('Digits:=30;a:=5'); a, giac(a), giac(a), giac(a).evalf()
30
(sqrt(2), 5, sqrt(2), 1.41421356237309504880168872421)

>>> from sage.all import *
>>>
a=sqrt(Integer(2)); giac('Digits:=30;a:=5'); a, giac(a), giac(a), giac(a).evalf()
30
(sqrt(2), 5, sqrt(2), 1.41421356237309504880168872421)

clear(var)
Clear the variable named var.

EXAMPLES:

sage: giac('xx', '2')
sage: giac.get('xx')
'2'
sage: giac.clear('xx')
sage: giac.get('xx')
'xx'

completions(s)
Return all commands that complete the command starting with the string s.

EXAMPLES:

sage: c = giac.completions('cas')
sage: 'cas_setup' in c
True

console()
Spawn a new Giac command-line session.

EXAMPLES:

sage: giac_console()  # not tested - giac
...
cputime (t=None)

Return the amount of CPU time that the Giac session has used.

If t is not None, then it returns the difference between the current CPU time and t.

EXAMPLES:

```python
sage: t = giac.cputime()
sage: t
0.02
sage: x = giac('x')
sage: giac.diff(x^2, x)
2*x
sage: giac.cputime(t)
0.0
```

eval (code, strip=True, **kwds)

Send the code x to the Giac interpreter. Remark: To enable multi-lines codes in the notebook magic mode: %giac, the \n are removed before sending the code to giac.

INPUT:

- code – str
- strip – Default is True and removes \n
EXAMPLES:

```python
sage: giac.eval("2+2;\n3")
4,3
sage: giac.eval("2+2;\n3",False)
'4\n3'
sage: s='g(x):={nx+1;\nx+2;\n}'
sage: giac(s)
...x+1...x+2...
sage: giac.g(5)
7
```
>>> from sage.all import *
>>> giac.eval("2+2;\n3")
'4,3'
>>> giac.eval("2+2;\n3", False)
'4\n3'
>>> s='g(x):=\{nx+1;nx+2;\n}''
>>>
>>> giac(s)
...x+1...x+2...
>>> giac.g(Integer(5))
7

**expect()**

Return the pexpect object for this Giac session.

**EXAMPLES:**

```python
sage: m = Giac()
sage: m.expect() is None
True
sage: m._start()
sage: m.expect()
Giac with PID ... running .../giac --sage
sage: m.quit()
```

**get(var)**

Get the value of the variable var.

**EXAMPLES:**

```python
sage: giac.set('xx', '2')
sage: giac.get('xx')
'2''
```

**help(string)**

Display Giac help about string.

This is the same as typing “?-string” in the Giac console.

**INPUT:**

- string – a string to search for in the giac help system

**EXAMPLES:**
Interpreter Interfaces, Release 10.4

```python
sage: giac.help('Psi')  # not tested - depends of giac and $LANG
Psi(a,n)=nth-derivative of the function DiGamma (=ln@Gamma) at point a (Psi(a, \rightarrow 0)=Psi(a))...
```

```python
>>> from sage.all import *
>>> giac.help('Psi')  # not tested - depends of giac and $LANG
Psi(a,n)=nth-derivative of the function DiGamma (=ln@Gamma) at point a (Psi(a, \rightarrow 0)=Psi(a))...
```

**set** *(var, value)*

Set the variable var to the given value.

**EXAMPLES:**

```python
sage: giac.set('xx', '2')
sage: giac.get('xx')
'2'
```

```python
>>> from sage.all import *
>>> giac.set('xx', '2')
>>> giac.get('xx')
'2'
```

**version()**

Wrapper for giac’s version().

**EXAMPLES:**

```python
sage: giac.version()
"giac...
```

```python
>>> from sage.all import *
>>> giac.version()
"giac...
```

**class** `sage.interfaces.giac.GiacElement` *(parent, value, is_name=False, name=None)*

**Bases:** `ExpectElement`

**integral** *(var='x', min=None, max=None)*

Return the integral of self with respect to the variable x.

**INPUT:**

- var – variable
- min – default: None
- max – default: None

This returns the definite integral if xmin is not None, otherwise an indefinite integral.

**EXAMPLES:**

```python
sage: y=giac('y'); f=(sin(2*y)/y).integral(y).simplify(); f
Si(2*y)
sage: f.diff(y).simplify()
\sin(2*y)/y
```
>>> from sage.all import *
>>> y=giac('y'); f=(sin(Integer(2)*y)/y).integral(y).simplify(); f
Si(2*y)

sage: f = giac('exp(x^2)').integral('x',0,1); f
1.46265174...

sage: x,y=giac('x'),giac('y'); integrate(cos(x+y),x=0..pi).simplify()
-2*sin(y)

>>> from sage.all import *
>>> y=giac('y'); f=(sin(Integer(2)*y)/y).integral(y).simplify(); f
Si(2*y)

>>> f.diff(y).simplify()
sin(2*y)/y

sage: f = giac('exp(x^2)').integral('x',Integer(0),Integer(1)); f
1.46265174...

sage: x,y=giac('x'),giac('y'); integrate(cos(x+y),x=0..pi).simplify()
-2*sin(y)

integrate (var='x', min=None, max=None)
Return the integral of self with respect to the variable x.

INPUT:
- var – variable
- min – default: None
- max – default: None

This returns the definite integral if xmin is not None, otherwise an indefinite integral.

EXAMPLES:

sage: y=giac('y'); f=(sin(2*y)/y).integral(y).simplify(); f
Si(2*y)

sage: f.diff(y).simplify()
sin(2*y)/y

>>> from sage.all import *
>>> y=giac('y'); f=(sin(Integer(2)*y)/y).integral(y).simplify(); f
Si(2*y)

>>> f.diff(y).simplify()
sin(2*y)/y

sage: f = giac('exp(x^2)').integral('x',0,1); f
1.46265174...

sage: x,y=giac('x'),giac('y'); integrate(cos(x+y),x=0..pi).simplify()
-2*sin(y)

>>> from sage.all import *
>>> f = giac('exp(x^2)').integral('x',Integer(0),Integer(1)) ; f
1.46265174...

>>> x,y=giac('x'),giac('y');integrate(cos(x+y),x=0..pi).simplify()
-2*sin(y)

sum (var='x', min=None, max=None)
Return the sum of self with respect to the variable x.

INPUT:
• var – variable
• min – default: None
• max – default: None

This returns the definite integral if xmin is not None, otherwise an indefinite integral.

EXAMPLES:

```
sage: giac('1/(1+k^2)').sum(k,-oo,+infinity).simplify()
(pi*exp(pi)^2+pi)/(exp(pi)^2-1)
```

```
>>> from sage.all import *
>>> giac('1/(1+k^2)').sum(k,-oo,+infinity).simplify()
(pi*exp(pi)^2+pi)/(exp(pi)^2-1)
```

unapply (var)

Creates a Giac function in the given arguments from a Giac symbol.

EXAMPLES:

```
sage: f=giac('y^3+1+t')
sage: g=(f.unapply('y,t'))
sage: g
(y,t)->y^3+1+t
sage: g(1,2)
4
```

```
>>> from sage.all import *
>>> f=giac('y^3+1+t')
>>> g=(f.unapply('y,t'))
>>> g
(y,t)->y^3+1+t
>>> g(Integer(1),Integer(2))
4
```

class sage.interfaces.giac.GiacFunction (parent, name)

Bases: ExpectFunction
class sage.interfaces.giac.GiacFunctionElement (obj, name)

Bases: FunctionElement

sage.interfaces.giac.giac_console()

Spawn a new Giac command-line session.

EXAMPLES:

```
sage: giac.console()  # not tested - giac
```

Homepage http://www-fourier.ujf-grenoble.fr/~parisse/giac.html
Released under the GPL license 3.0 or above
See http://www.gnu.org for license details
Press CTRL and D simultaneously to finish session
Type [commandname] for help
>>> from sage.all import *
>>> giac.console()  # not tested - giac
...
Homepage http://www-fourier.ujf-grenoble.fr/~parisse/giac.html
Released under the GPL license 3.0 or above
See http://www.gnu.org for license details
Press CTRL and D simultaneously to finish session

Type `commandname for help`

sage.interfaces.giac.reduce_load_Giac()

Return the giac object created in sage.interfaces.giac.

EXAMPLES:

```python
sage: from sage.interfaces.giac import reduce_load_Giac
sage: reduce_load_Giac()
Giac
```

```python
>>> from sage.all import *
>>> from sage.interfaces.giac import reduce_load_Giac
>>> reduce_load_Giac()
Giac
```
CHAPTER
FOURTEEN

INTERFACE TO THE GNUPLOT INTERPRETER

class sage.interfaces.gnuplot.Gnuplot
    Bases: SageObject

    Interface to the Gnuplot interpreter.

    console()

    gnuplot()

    interact(cmd)

    plot(cmd, file=None, verbose=True, reset=True)

    Draw the plot described by cmd, and possibly also save to an eps or png file.

    INPUT:
    • cmd – string
    • file – string (default: None), if specified save plot to given file, which may be either an eps (default) or png file.
    • verbose – print some info
    • reset – True: reset gnuplot before making graph

    OUTPUT: displays graph

    Note: Note that ^ s are replaced by ** s before being passed to gnuplot.

    plot3d(f, xmin=-1, xmax=1, ymin=-1, ymax=1, zmin=-1, zmax=1, title=None, samples=25, isosamples=20, xlabel='x', ylabel='y', interact=True)

    plot3d_parametric(f='cos(u)*(3 + v*cos(u/2)), sin(u)*(3 + v*cos(u/2)), v*sin(u/2)', range1='[u=-pi:pi]', range2='[v=-0.2:0.2]', samples=50, title=None, interact=True)

    Draw a parametric 3d surface and rotate it interactively.

    INPUT:
    • f – (string) a function of two variables, e.g., 'cos(u)*(3 + v*cos(u/2)), sin(u)*(3 + v*cos(u/2)), v*sin(u/2)'
    • range1 – (string) range of values for one variable, e.g., '[u=-pi:pi]'
    • range2 – (string) range of values for another variable, e.g., '[v=-0.2:0.2]'
    • samples – (int) number of sample points to use
    • title – (string) title of the graph.
EXAMPLES:

```python
sage: gnuplot.plot3d_parametric('v^2*sin(u), v*cos(u), v*(1-v)')  # optional-
                           # gnuplot, not tested (since something pops up)
```

```python
>>> from sage.all import *
>>> gnuplot.plot3d_parametric('v^2*sin(u), v*cos(u), v*(1-v)')  # optional -
                           # gnuplot, not tested (since something pops up)
```

`sage.interfaces.gnuplot.gnuplot_console()`
CHAPTER
FIFTEEN

INTERFACE TO THE GP CALCULATOR OF PARI/GP

Type gp.[tab] for a list of all the functions available from your Gp install. Type gp.[tab]? for Gp’s help about a given function. Type gp(...) to create a new Gp object, and gp.eval(...) to evaluate a string using Gp (and get the result back as a string).

EXAMPLES: We illustrate objects that wrap GP objects (gp is the PARI interpreter):

```
sage: M = gp('[1,2;3,4]')
sage: M
[1, 2; 3, 4]
sage: M * M
[7, 10; 15, 22]
sage: M + M
[2, 4; 6, 8]
sage: M.matdet()
-2

>>> from sage.all import *
>>> M = gp('[1,2;3,4]')
>>> M
[1, 2; 3, 4]
>>> M * M
[7, 10; 15, 22]
>>> M + M
[2, 4; 6, 8]
>>> M.matdet()
-2

sage: E = gp.ellinit([1,2,3,4,5])
sage: E.ellglobalred()
[10351, [1, -1, 0, -1], 1, [11, 1; 941, 1], [[1, 5, 0, 1], [1, 5, 0, 1]]]
sage: E.ellan(20)
[1, 1, 0, -1, -3, 0, -1, -3, -3, -3, -1, 0, 1, -1, 0, -1, 5, -3, 4, 3]

>>> from sage.all import *
>>> E = gp.ellinit([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)])
>>> E.ellglobalred()
[10351, [1, -1, 0, -1], 1, [11, 1; 941, 1], [[1, 5, 0, 1], [1, 5, 0, 1]]]
>>> E.ellan(Integer(20))
[1, 1, 0, -1, -3, 0, -1, -3, -3, -3, -1, 0, 1, -1, 0, -1, 5, -3, 4, 3]

sage: primitive_root(7)
3
sage: x = gp("znlog( Mod(2,7), Mod(3,7))")

(continues on next page)
sage: \(3^x \mod 7\)
2

```python
>>> from sage.all import *
>>> primitive_root(Integer(7))
3
>>> x = gp("znlog( Mod(2,7), Mod(3,7))")
>>> Integer(3)**x % Integer(7)
2
```

```
sage: print(gp("taylor(sin(x),x)"))
x - 1/6*x^3 + 1/120*x^5 - 1/5040*x^7 + 1/362880*x^9 - 1/39916800*x^11 + 1/
→ 6227020800*x^13 - 1/1307674368000*x^15 + O(x^16)
```

```
GP has a powerful very efficient algorithm for numerical computation of integrals.
```

```python
sage: gp("a = intnum(x=0,6,sin(x))")
0.03982971334963397945434770208 # 32-bit
0.039829713349633979454347702077075594548 # 64-bit
```

```
>>> from sage.all import *
>>> gp("a")
0.03982971334963397945434770208 # 32-bit
0.039829713349633979454347702077075594548 # 64-bit
```

```
>>> gp.kill("a")
```

```
>>> from sage.all import *
>>> gp("a = intnum(x=0,6,sin(x))")
0.03982971334963397945434770208 # 32-bit
0.039829713349633979454347702077075594548 # 64-bit
```

```
Note that gp ASCII plots do work in Sage, as follows:
```

```python
sage: print(gp.eval("plot(x=0,6,sin(x))"))
```

(continues on next page)
The GP interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

```python
sage: t = '%s' % 10**10000  # ten thousand character string.
sage: a = gp.eval(t)
sage: a = gp(t)
```

In Sage, the PARI large Galois groups datafiles should be installed by default:

```python
>>> from sage.all import *
>>> print(gp.eval("plot(x=0,6,sin(x))"))
<BLANKLINE>
>>> from sage.all import *
>>> t = '%s' % Integer(10)**Integer(10000)  # ten thousand character string.
>>> a = gp.eval(t)
>>> a = gp(t)
```
sage: f = gp('x^9 - x - 2')
sage: f.polgalois()
[362880, -1, 34, "S9"]

>>> from sage.all import *
>>> f = gp('x^9 - x - 2')
>>> f.polgalois()
[362880, -1, 34, "S9"]

AUTHORS:

• William Stein
• David Joyner: some examples
• William Stein (2006-03-01): added tab completion for methods: gp.[tab] and x = gp(blah); x.[tab]
• William Stein (2006-03-01): updated to work with PARI 2.2.12-beta
• William Stein (2006-05-17): updated to work with PARI 2.2.13-beta

class sage.interfaces.gp.Gp(stacksize=10000000, maxread=None, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, init_list_length=1024, seed=None)

Bases: ExtraTabCompletion, Expect

Interfaceto the PARI gp interpreter.

Type gp.[tab] for a list of all the functions available from your Gp install. Type gp.[tab]? for Gp's help about a given function. Type gp(...) to create a new Gp object, and gp.eval(...) to evaluate a string using Gp (and get the result back as a string).

INPUT:

• stacksize (int, default 10000000) – the initial PARI stacksize in bytes (default 10MB)
• script_subdirectory (string, default None) – name of the subdirectory of SAGE_EXTCODE/pari from which to read scripts
• logfile (string, default None) – log file for the pexpect interface
• server – name of remote server
• server_tmpdir – name of temporary directory on remote server
• init_list_length (int, default 1024) – length of initial list of local variables.
• seed (int, default random) – random number generator seed for pari

EXAMPLES:

```python
sage: Gp()
PARI/GP interpreter

>>> from sage.all import *
>>> Gp()
PARI/GP interpreter
```

console()

Spawn a new GP command-line session.

EXAMPLES:
Interpreter Interfaces, Release 10.4

```python
sage: gp.console()  # not tested
GP/PARI CALCULATOR Version 2.4.3 (development svn-12577)
amd64 running linux (x86-64/GMP-4.2.1 kernel) 64-bit version
compiled: Jul 21 2010, gcc-4.6.0 20100705 (experimental) (GCC)
(readline v6.0 enabled, extended help enabled)
```

```python
>>> from sage.all import *
```

```python
>>> gp.console()  # not tested
GP/PARI CALCULATOR Version 2.4.3 (development svn-12577)
amd64 running linux (x86-64/GMP-4.2.1 kernel) 64-bit version
compiled: Jul 21 2010, gcc-4.6.0 20100705 (experimental) (GCC)
(readline v6.0 enabled, extended help enabled)
```

cputime (t=\texttt{None})
cputime for pari - cputime since the pari process was started.

INPUT:

- \( t \) – (default: None); if not None, then returns time since \( t \)

**Warning:** If you call \texttt{gettime} explicitly, e.g., \texttt{gp.eval('gettime')}, you will throw off this clock.

```
sage: gp.cputime()  # random output
0.0080000000000000002
sage: gp.factor(2^157-1)
[852133201, 1; 60726444167, 1; 1654058017289, 1; 2134387368610417, 1]
sage: gp.cputime()  # random output
0.26900000000000002
```

```python
>>> from sage.all import *
```

```python
>>> gp.set(x, 2)
```

```python
>>> gp.get(x)
2
```

get (\texttt{var})
Get the value of the GP variable \texttt{var}.

INPUT:

- \texttt{var} (string) – a valid GP variable identifier

**Examples:**

```
sage: gp.set('x', '2')
sage: gp.get('x')
'2'
```

```python
>>> from sage.all import *
```

```python
>>> gp.set('x', '2')
>>> gp.get('x')
'2'
```
get_default (var)

Return the current value of a PARI gp configuration variable.

INPUT:

- var (string) – the name of a PARI gp configuration variable. (See gp.default() for a list.)

OUTPUT:

(string) the value of the variable.

EXAMPLES:

```
sage: gp.get_default('log')
0
sage: gp.get_default('datadir')
'../share/pari'
sage: gp.get_default('seriesprecision')
16
sage: gp.get_default('realprecision')
28 # 32-bit
38 # 64-bit
```

get_precision()

Return the current PARI precision for real number computations.

EXAMPLES:

```
sage: gp.get_precision()
28 # 32-bit
38 # 64-bit
```

get_real_precision()

Return the current PARI precision for real number computations.

EXAMPLES:

```
sage: gp.get_real_precision()
28 # 32-bit
38 # 64-bit
```
```python
>>> from sage.all import *
>>> gp.get_precision()
28  # 32-bit
38  # 64-bit
```

**get_series_precision()**

Return the current PARI power series precision.

EXAMPLES:

```
sage: gp.get_series_precision()
16
```

**help**(command)

Returns GP's help for command.

EXAMPLES:

```
sage: gp.help('gcd')
gcd(x,(y)): greatest common divisor of x and y.
```

**kill**(var)

Kill the value of the GP variable var.

INPUT:

- var (string) – a valid GP variable identifier

EXAMPLES:

```
sage: gp.set('xx', '22')
sage: gp.get('xx')
'22'
sage: gp.kill('xx')
sage: gp.get('xx')
'xx'
```

**new_with_bits_prec**(s, precision=0)

Creates a GP object from s with precision bits of precision. GP actually automatically increases this precision to the nearest word (i.e. the next multiple of 32 on a 32-bit machine, or the next multiple of 64 on a 64-bit machine).
EXAMPLES:

```python
sage: # needs sage.symbolic
sage: pi_def = gp(pi); pi_def
3.141592653589793238462643383 # 32-bit
3.1415926535897932384626433832795028842 # 64-bit
sage: pi_def.precision()
28 # 32-bit
38 # 64-bit
sage: pi_150 = gp.new_with_bits_prec(pi, 150)
sage: new_prec = pi_150.precision(); new_prec
48 # 32-bit
57 # 64-bit
sage: old_prec = gp.set_precision(new_prec); old_prec
28 # 32-bit
38 # 64-bit
sage: pi_150
3.14159265358979323846264338327950288419716939938 # 32-bit
3.14159265358979323846264338327950288419716939937510582098 # 64-bit
sage: gp.set_precision(old_prec)
48 # 32-bit
57 # 64-bit
sage: gp.get_precision()
28 # 32-bit
38 # 64-bit
```

```python
>>> from sage.all import *
>>> # needs sage.symbolic
>>> pi_def = gp(pi); pi_def
3.141592653589793238462643383 # 32-bit
3.1415926535897932384626433832795028842 # 64-bit
>>> pi_def.precision()
28 # 32-bit
38 # 64-bit
>>> pi_150 = gp.new_with_bits_prec(pi, Integer(150))
>>> new_prec = pi_150.precision(); new_prec
48 # 32-bit
57 # 64-bit
>>> old_prec = gp.set_precision(new_prec); old_prec
28 # 32-bit
38 # 64-bit
>>> pi_150
3.14159265358979323846264338327950288419716939938 # 32-bit
3.14159265358979323846264338327950288419716939937510582098 # 64-bit
>>> gp.set_precision(old_prec)
48 # 32-bit
57 # 64-bit
>>> gp.get_precision()
28 # 32-bit
38 # 64-bit
```

**set** *(var, value)*

Set the GP variable var to the given value.

**INPUT:**

- var (string) – a valid GP variable identifier
- value – a value for the variable
**set_default** *(var, value)*  
Set a PARI gp configuration variable, and return the old value.  

**INPUT:**  
- **var** (string) – the name of a PARI gp configuration variable. (See `gp.default()` for a list.)  
- **value** – the value to set the variable to.  

**EXAMPLES:**

```
sage: old_prec = gp.set_default('realprecision', 110)  
sage: gp.get_default('realprecision')  
115  
sage: gp.set_default('realprecision', old_prec)  
115  
sage: gp.get_default('realprecision')  
28  # 32-bit  
38  # 64-bit
```

```
>>> from sage.all import *  
>>> old_prec = gp.set_default('realprecision', Integer(110))  
>>> gp.get_default('realprecision')  
115  
>>> gp.set_default('realprecision', old_prec)  
115  
>>> gp.get_default('realprecision')  
28  # 32-bit  
38  # 64-bit
```

**set_precision** *(prec)*  
Sets the PARI precision (in decimal digits) for real computations, and returns the old value.  

**Note:** PARI/GP rounds up precisions to the nearest machine word, so the result of `get_precision()` is not always the same as the last value inputted to `set_precision()`.

**EXAMPLES:**

```
sage: old_prec = gp.set_precision(53); old_prec  
28  # 32-bit  
38  # 64-bit  
sage: gp.get_precision()  
57  
sage: gp.set_precision(old_prec)  
57
```

(continues on next page)
set_real_precision(prec)

Sets the PARI precision (in decimal digits) for real computations, and returns the old value.

**Note:** PARI/GP rounds up precisions to the nearest machine word, so the result of `get_precision()` is not always the same as the last value inputted to `set_precision()`.

**EXAMPLES:**

```python
sage: old_prec = gp.set_precision(Integer(53)); old_prec
28 # 32-bit
38 # 64-bit
sage: gp.get_precision()
57
sage: gp.set_precision(old_prec)
57
sage: gp.get_precision()
28 # 32-bit
38 # 64-bit

>>> from sage.all import *
>>> old_prec = gp.set_precision(Integer(53)); old_prec
28 # 32-bit
38 # 64-bit
>>> gp.get_precision()
57
>>> gp.set_precision(old_prec)
57
>>> gp.get_precision()
28 # 32-bit
38 # 64-bit
```

set_seed (seed=None)

Set the seed for gp interpreter.

The seed should be an integer.

**EXAMPLES:**
```python
sage: g = Gp()
sage: g.set_seed(1)
1
sage: [g.random() for i in range(5)]
[1546275796, 879788114, 1745191708, 771966234, 1247963869]
>>> from sage.all import *
>>>
g = Gp()
>>> g.set_seed(Integer(1))
1
>>> [g.random() for i in range(Integer(5))]
[1546275796, 879788114, 1745191708, 771966234, 1247963869]
```

**set_series_precision** *(prec=*)

Sets the PARI power series precision, and returns the old precision.

**EXAMPLES:**

```python
sage: old_prec = gp.set_series_precision(50); old_prec
16
sage: gp.get_series_precision()
50
sage: gp.set_series_precision(old_prec)
50
sage: gp.get_series_precision()
16
>>> from sage.all import *
>>>
old_prec = gp.set_series_precision(Integer(50)); old_prec
16
>>> gp.get_series_precision()
50
>>> gp.set_series_precision(old_prec)
50
>>> gp.get_series_precision()
16
```

**version()**

Returns the version of GP being used.

**EXAMPLES:**

```python
sage: gp.version()  # not tested
((2, 4, 3), 'GP/PARI CALCULATOR Version 2.4.3 (development svn-12577)')
>>> from sage.all import *
>>>
gp.version()  # not tested
((2, 4, 3), 'GP/PARI CALCULATOR Version 2.4.3 (development svn-12577)')
```

**class sage.interfaces.gp.GpElement (parent, value, is_name=False, name=None)**

**Bases:** ExpectElement, GpElement

**EXAMPLES:** This example illustrates dumping and loading GP elements to compressed strings.

```python
sage: a = gp(39393)
sage: loads(a.dumps()) == a
True
```
Since dumping and loading uses the string representation of the object, it need not result in an identical object from the point of view of PARI:

```
>>> from sage.all import *
>>> a = gp(Integer(39393))
>>> loads(a.dumps()) == a
True
``` 

```
sage: E = gp('ellinit([1,2,3,4,5])')
sage: loads(dumps(E)) == E
True
sage: x = gp.Pi()/3
sage: loads(dumps(x)) == x
False
sage: x
1.047197551196597746154214461 # 32-bit
1.0471975511965977461542144610931676281 # 64-bit
sage: loads(dumps(x))
1.0471975511965977461542144610931676281 # 32-bit
1.0471975511965977461542144610931676281 # 64-bit
``` 

The two elliptic curves look the same, but internally the floating point numbers are slightly different.

```
>>> from sage.all import *
>>> E = gp('ellinit([1,2,3,4,5])')
>>> loads(dumps(E)) == E
True
>>> x = gp.Pi()/Integer(3)
>>> loads(dumps(x)) == x
False
>>> x
1.047197551196597746154214461 # 32-bit
1.0471975511965977461542144610931676281 # 64-bit
>>> loads(dumps(x))
1.0471975511965977461542144610931676281 # 32-bit
1.0471975511965977461542144610931676281 # 64-bit
``` 

**is_string()**

Tell whether this element is a string.

**EXAMPLES:**

```
sage: gp("abc").is_string()
True
sage: gp('[1,2,3]').is_string()
False
``` 

```
>>> from sage.all import *
>>> gp("abc").is_string()
True
>>> gp('[1,2,3]').is_string()
False
``` 

**sage.interfaces.gp.gp_console()**

Spawn a new GP command-line session.

**EXAMPLES:**
sage: gp.console()  # not tested
GP/PARI CALCULATOR Version 2.4.3 (development svn-12577)
amd64 running linux (x86-64/GMP-4.2.1 kernel) 64-bit version
compiled: Jul 21 2010, gcc-4.6.0 20100705 (experimental) (GCC)
(readline v6.0 enabled, extended help enabled)

>>> from sage.all import *

>>> gp.console()  # not tested
GP/PARI CALCULATOR Version 2.4.3 (development svn-12577)
amd64 running linux (x86-64/GMP-4.2.1 kernel) 64-bit version
compiled: Jul 21 2010, gcc-4.6.0 20100705 (experimental) (GCC)
(readline v6.0 enabled, extended help enabled)

sage.interfaces.gp gp_version()

EXAMPLES:
sage: gp.version()  # not tested
((2, 4, 3), 'GP/PARI CALCULATOR Version 2.4.3 (development svn-12577)')

>>> from sage.all import *

>>> gp.version()  # not tested
((2, 4, 3), 'GP/PARI CALCULATOR Version 2.4.3 (development svn-12577)')

sage.interfaces.gp is_GpElement(x)

Return True if x is of type GpElement

This function is deprecated; use isinstance() (of sage.interfaces.abc.GpElement) instead.

EXAMPLES:
sage: from sage.interfaces.gp import is_GpElement
sage: is_GpElement(gp(2))

DeprecationWarning: the function is_GpElement is deprecated; use...
See https://github.com/sagemath/sage/issues/34804 for details.
True

sage: is_GpElement(Integer(2))
False

>>> from sage.all import *

>>> from sage.interfaces.gp import is_GpElement

>>> is_GpElement(gp(Integer(2)))

DeprecationWarning: the function is_GpElement is deprecated; use...
See https://github.com/sagemath/sage/issues/34804 for details.
True

>>> is_GpElement(Integer(2))
False

sage.interfaces.gp reduce_load_GP()

Returns the GP interface object defined in sage.interfaces.gp.

EXAMPLES:
sage: from sage.interfaces.gp import reduce_load_GP
sage: reduce_load_GP()
PARI/GP interpreter
>>> from sage.all import *
>>> from sage.interfaces.gp import reduce_load_GP
>>> reduce_load_GP()
PARI/GP interpreter
INTERFACE FOR EXTRACTING DATA AND GENERATING IMAGES FROM JMOL READABLE FILES.

JmolData is a no GUI version of Jmol useful for extracting data from files Jmol reads and for generating image files.

AUTHORS:
- Jonathan Gutow (2012-06-14): complete doctest coverage
- Jonathan Gutow (2012-03-21): initial version

```python
class sage.interfaces.jmoldata.JmolData
    Bases: SageObject
```

TODO: Create an animated image file (GIF) if spin is on and put data extracted from a file into a variable/string/structure to return

```python
export_image(targetfile, datafile, datafile_cmd='script', image_type='PNG', figsize=5, **kwds)
```

This executes JmolData.jar to make an image file.

INPUT:
- targetfile – the full path to the file where the image should be written.
- datafile – full path to the data file Jmol can read or text of a script telling Jmol what to read or load.
- datafile_cmd – (default 'script') 'load' or 'script' should be "load" for a data file.
- image_type – (default "PNG") 'PNG' 'JPG' or 'GIF'
- figsize – number (default 5) equal to (pixels/side)/100

OUTPUT:
Image file, .png, .gif or .jpg (default .png)

**Note:** Examples will generate an error message if a functional Java Virtual Machine (JVM) is not installed on the machine the Sage instance is running on.

**Warning:** Programmers using this module should check that the JVM is available before making calls to avoid the user getting error messages. Check for the JVM using the function `is_jvm_available()`, which returns True if a JVM is available.

**EXAMPLES:**
Use Jmol to load a pdb file containing some DNA from a web database and make an image of the DNA. If you execute this in the notebook, the image will appear in the output cell:

```python
sage: from sage.interfaces.jmoldata import JmolData
sage: JData = JmolData()
sage: script = "load =1lcd;display DNA;moveto 0.0 { -473 -713 -518 59.94} 100.0
0.0 0.0 (21.17 26.72 27.295) 27.544636 {0.0 0.0 0.0} -25.287832 64.8414 0.0;
"
sage: testfile = tmp_filename(ext="DNA.png")
sage: JData.export_image(targetfile=testfile,datafile=script,image_type="PNG")
# optional -- java internet
sage: print(os.path.exists(testfile)) # optional -- java internet
True
```

Use Jmol to save an image of a 3-D object created in Sage. This method is used internally by plot3d to generate static images. This example doesn’t have correct scaling:

```python
sage: from sage.interfaces.jmoldata import JmolData
sage: JData = JmolData()

<<< sage: D = dodecahedron() 
# needs sage.plot
<<< sage: from tempfile import NamedTemporaryFile
<<< sage: archive = NamedTemporaryFile(suffix=".zip")
<<< sage: D.export_jmol(archive.name) 
# needs sage.plot
<<< sage: archive_native = archive.name
<<< sage: script = f"set defaultdirectory "f{archive_native}"\\n"
<<< sage: script += script SCRIPT
<<< sage: with NamedTemporaryFile(suffix=".png") as testfile: 
# optional -- java, 
# needs sage.plot
....: JData.export_image(targetfile=testfile.name, 
....: datafile=script, 
....: image_type="PNG")
....: os.path.exists(testfile.name)
True
<<< sage: archive.close()
```

(continues on next page)
needs sage.plot

archive_native = archive.name

script = f'set defaultdirectory "f\{archive_native}\"

script += 'script SCRIPT

with NamedTemporaryFile(suffix=".png") as testfile:  # optional - java,

... JData.export_image(targetfile=testfile.name,
... datafile=script,
... image_type="PNG")

... os.path.exists(testfile.name)

True

archive.close()

is_jmol_available()

Returns True if jmol is available and False if not.

EXAMPLES:

Check that it returns a boolean:

sage: from sage.interfaces.jmoldata import JmolData
sage: JData = JmolData()

sage: type(JData.is_jmol_available())
<... 'bool'>

is_jvm_available()

Returns True if the Java Virtual Machine is available and False if not.

EXAMPLES:

Check that it returns a boolean:

sage: from sage.interfaces.jmoldata import JmolData
sage: JData = JmolData()

sage: type(JData.is_jvm_available())
<... 'bool'>

jmolpath()

Return the path to the jar file.

EXAMPLES:
sage: JData.jmolpath()  # needs jmol
'.../JmolData.jar'

```python
from sage.all import *
from sage.interfaces.jmoldata import JmolData
JData = JmolData()
JData.jmolpath()  # needs jmol
'.../JmolData.jar'
```
Sage provides an interface to the KASH computer algebra system, which is a *free* (as in beer!) but *closed source* program for algebraic number theory that shares much common code with Magma. To use KASH, you must first install it. Visit its web page: http://page.math.tu-berlin.de/~kant/kash.html

**Todo:** Update the following sentence.

It is not enough to just have KASH installed on your computer.

The KASH interface offers three pieces of functionality:

1. `kash_console()` - A function that dumps you into an interactive command-line KASH session. Alternatively, type `!kash` from the Sage prompt.
2. `kash(expr)` - Creation of a Sage object that wraps a KASH object. This provides a Pythonic interface to KASH. For example, if `f=kash.new(10)`, then `f.Factors()` returns the prime factorization of 10 computed using KASH.
3. `kash.function_name(args ...)` - Call the indicated KASH function with the given arguments are return the result as a KASH object.
4. `kash.eval(expr)` - Evaluation of arbitrary KASH expressions, with the result returned as a string.

### 17.1 Issues

For some reason hitting Control + C to interrupt a calculation does not work correctly. (TODO)

### 17.2 Tutorial

The examples in this tutorial require that kash be installed.
17.2.1 Basics

Basic arithmetic is straightforward. First, we obtain the result as a string.

```sage
kash.eval('(9 - 7) * (5 + 6)') # optional -- kash
'22'
```

Next we obtain the result as a new KASH object.

```sage
a = kash('(9 - 7) * (5 + 6)'); a # optional -- kash
22
```

We can do arithmetic and call functions on KASH objects:

```sage
a*a # optional -- kash
484
```

17.2.2 Integrated Help

Use the `kash.help(name)` command to get help about a given command. This returns a list of help for each of the definitions of name. Use `print kash.help(name)` to nicely print out all signatures.

17.2.3 Arithmetic

Using the `kash.new` command we create KASH objects on which one can do arithmetic.

```sage
# optional -- kash
sage: a = kash(12345)
sage: b = kash(25)
sage: a/b
2469/5
sage: a**b
1937659030411463935651167391656422626577614411586152317674869233464019922771432158872187137603759765625
```
>> from sage.all import *
>>> # optional -- kash
>>> a = kash(Integer(12345))
>>> b = kash(Integer(25))
>>> a/b
2469/5
>>> a**b
1937659030411463565116739165642262657761441158615231767486923346401992777143215887226711376037559765625
17.2.4 Variable assignment

Variable assignment using kash is takes place in Sage.

```
sage: a = kash('32233')  # optional -- kash
sage: a
32233
```

In particular, `a` is not defined as part of the KASH session itself.

```
sage: kash.eval('a')  # optional -- kash
"Error, the variable 'a' must have a value"
```

Use `a.name()` to get the name of the KASH variable:

```
sage: a.name()  # somewhat random; optional -- kash
'sage0'
sage: kash(a.name())  # optional -- kash
32233
```
17.2.5 Integers and Rationals

We illustrate arithmetic with integers and rationals in KASH.

```
sage: # optional - kash
sage: F = kash.Factorization(4352)
sage: F[1]
<2, 8>
sage: F[2]
<17, 1>
sage: F
[ <2, 8>, <17, 1> ], extended by:
  ext1 := 1,
  ext2 := Unassign
```

```
>>> from sage.all import *
>>> # optional - kash
>>> F = kash.Factorization(Integer(4352))
>>> F[Integer(1)]
<2, 8>
>>> F[Integer(2)]
<17, 1>
>>> F
[ <2, 8>, <17, 1> ], extended by:
  ext1 := 1,
  ext2 := Unassign
```

Note: For some very large numbers KASH's integer factorization seems much faster than PARI's (which is the default in Sage).

```
sage: # optional - kash
sage: kash.GCD(15,25)
5
sage: kash.LCM(15,25)
75
sage: kash.Div(25,15)
1
sage: kash(17) % kash(5)
2
sage: kash.IsPrime(10007)
TRUE
FALSE
sage: kash.NextPrime(10007)
# optional -- kash
10009
```

```
>>> from sage.all import *
>>> # optional - kash
>>> kash.GCD(Integer(15),Integer(25))
5
>>> kash.LCM(Integer(15),Integer(25))
75
>>> kash.Div(Integer(25),Integer(15))
1
```

(continues on next page)
17.2.6 Real and Complex Numbers

```python
sage: # optional -- kash
sage: kash.Precision()
30
sage: kash('R')
Real field of precision 30
sage: kash.Precision(40)
40
sage: kash('R')
Real field of precision 40
sage: z = kash('1 + 2*I')
sage: z
1.00000000000000000000000000000000 + 2.00000000000000000000000000000000*I
sage: z*z
-3.00000000000000000000000000000000 + 4.00000000000000000000000000000000*I
sage: kash.Cos('1.24') # optional -- kash
0.3247962844387762365776934156973803996992
sage: kash('1.24').Cos() # optional -- kash
0.3247962844387762365776934156973803996992
sage: kash.Exp(1.24) # optional -- kash
3.45561346476267598057615494121998175400
sage: kash.Precision(30) # optional -- kash
30
sage: kash.Log('3+4*I') # optional -- kash
1.60943791243410037460075933323 + 0.92729521800161232428512462922*I
sage: kash.Log('I') # optional -- kash
1.570796326794896619231261964*I
sage: kash.Sqrt(4) # optional -- kash
2.00000000000000000000000000000000
sage: kash.Sqrt(2) # optional -- kash
1.41421356237309504880168872421
sage: kash.Floor('3/5') # optional -- kash
1
sage: kash.Floor('3/5') # optional -- kash
0
sage: x_c = kash('3+I') # optional -- kash
```

### Interpreter Interfaces, Release 10.4

#### from sage.all import *

```
>>> from sage.all import *
>>> # optional -- kash
>>> kash.Precision()
30
>>> kash('R')
Real field of precision 30
>>> kash.Precision(Integer(40))
40
>>> kash('R')
Real field of precision 40
>>> z = kash('1 + 2*I')
>>> z
1.000000000000000000000000000000000000000 + 2.000000000000000000000000000000000000000*I
>>> z*z
-3.000000000000000000000000000000000000000 + 4.000000000000000000000000000000000000000*I
```

1.000000000000000000000000000000000000000
```

140 Chapter 17. Interface to KASH
17.2.7 Lists

Note that list appends are completely different in KASH than in Python. Use underscore after the function name for the mutation version.

```
sage: # optional - kash
sage: v = kash([1,2,3]); v
[ 1, 2, 3 ]
sage: v[1]
1
sage: v[3]
3
sage: v.Append([5])
[ 1, 2, 3, 5 ]
sage: v
[ 1, 2, 3 ]
sage: v.Append_([5, 6])
SUCCESS
sage: v
[ 1, 2, 3, 5, 6 ]
sage: v.Add(5)
[ 1, 2, 3, 5, 6, 5 ]
sage: v
[ 1, 2, 3, 5, 6 ]
sage: v.Add_(5)
SUCCESS
sage: v
[ 1, 2, 3, 5, 6, 5 ]
```

```
>>> from sage.all import *

>>> # optional - kash
>>> v = kash([Integer(1),Integer(2),Integer(3)]); v
[ 1, 2, 3 ]
>>> v[Integer(1)]
1
>>> v[Integer(3)]
3
>>> v.Append([Integer(5)])
[ 1, 2, 3, 5 ]
>>> v
[ 1, 2, 3 ]
>>> v.Append_([Integer(5), Integer(6)])
SUCCESS
>>> v
[ 1, 2, 3, 5, 6 ]
>>> v.Add(Integer(5))
[ 1, 2, 3, 5, 6, 5 ]
>>> v
[ 1, 2, 3, 5, 6 ]
>>> v.Add_(Integer(5))
SUCCESS
>>> v
[ 1, 2, 3, 5, 6, 5 ]
```

The `Apply` command applies a function to each element of a list:

```
sage: # optional - kash
```
The following are examples of ranges.

The following are examples of ranges.

17.2.9 Sequences

17.2.10 Tuples

17.2.11 Polynomials

sage: f = kash('(X^3 + X + 1)')
17.2.12 Number Fields

We create an equation order.

```python
sage: f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192') # optional -- kash
sage: OK = f.EquationOrder() # optional -- kash
sage: OK
Equation Order with defining polynomial X^5 + 4*X^4 - 56*X^2 - 16*X + 192 over Z
```

```python
>>> from sage.all import *

>>> f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192') # optional -- kash

>>> OK = f.EquationOrder() # optional -- kash

>>> OK
Equation Order with defining polynomial X^5 + 4*X^4 - 56*X^2 - 16*X + 192 over Z
```

```python
sage: # optional -- kash
sage: f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192')

sage: O = f.EquationOrder()

sage: a = O.gen(2)

sage: a
[0, 1, 0, 0, 0]

sage: O.Basis()
_[NG.1, NG.2, NG.3, NG.4, NG.5_]

sage: O.Discriminant()
1364202618880
```

(continues on next page)
```python
sage: O.MaximalOrder()
Maximal Order of sage2

sage: O = kash.MaximalOrder('X^3 - 77') # optional -- kash
sage: I = O.Ideal(5,[2, 1, 0]) # optional -- kash
sage: I
# name sage14 below random; optional -- kash
Ideal of sage14
Two element generators:
[5, 0, 0]
[2, 1, 0]

sage: F = I.Factorisation() # optional -- kash
sage: F
# name sage14 random; optional -- kash
[<Prime Ideal of sage14
Two element generators:
[5, 0, 0]
[2, 1, 0], 1>]

>>> from sage.all import *
>>> # optional - kash
>>> f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192')
>>> O = f.EquationOrder()
>>> a = O.gen(Integer(2))
>>> a
[0, 1, 0, 0, 0]
>>> O.Basis()
[ _NG.1,
  _NG.2,
  _NG.3,
  _NG.4,
  _NG.5
]
>>> O.Discriminant()
1364202618880
>>> O.MaximalOrder()
Maximal Order of sage2

>>> O = kash.MaximalOrder('X^3 - 77') # optional -- kash
>>> I = O.Ideal(Integer(5),[Integer(2), Integer(1), Integer(0)]) # optional -- kash
>>> I
# name sage14 below random; optional -- kash
Ideal of sage14
Two element generators:
[5, 0, 0]
[2, 1, 0]

>>> F = I.Factorisation() # optional -- kash
>>> F
# name sage14 random; optional -- kash
[<Prime Ideal of sage14
Two element generators:
[5, 0, 0]
[2, 1, 0], 1>]
```
Determining whether an ideal is principal.

```python
sage: I.IsPrincipal() # optional -- kash
FALSE, extended by:
ext1 := Unassign
```

```python
>>> from sage.all import *
>>> I.IsPrincipal() # optional -- kash
FALSE, extended by:
ext1 := Unassign
```

Computation of class groups and unit groups:

```python
sage: # optional - kash
sage: f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192')
```

```python
sage: O = kash.EquationOrder(f)
```

```python
sage: OK = O.MaximalOrder()
```

```python
sage: OK.ClassGroup()
Abelian Group isomorphic to Z/6
  Defined on 1 generator
  Relations:
  6*sage32.1 = 0, extended by:
  ext1 := Mapping from: grp^abl: sage32 to ids/ord^num: _AA
```

```python
>>> from sage.all import *
>>> # optional - kash
>>> f = kash('X^5 + 4*X^4 - 56*X^2 -16*X + 192')
```

```python
>>> O = kash.EquationOrder(f)
```

```python
>>> OK = O.MaximalOrder()
```

```python
>>> OK.ClassGroup()
Abelian Group isomorphic to Z/6
  Defined on 1 generator
  Relations:
  6*sage32.1 = 0, extended by:
  ext1 := Mapping from: grp^abl: sage32 to ids/ord^num: _AA
```

```python
sage: U = OK.UnitGroup() # optional -- kash
```

```python
sage: # name sage34 below random; optional -- kash
```

```python
sage: U = OK.UnitGroup() # optional -- kash
```

```python
sage: # name sage34 below random; optional -- kash
```

```python
sage: kash.Apply('x->%s.ext1(x)'%U.name(), U.Generators().List()) # optional -- kash
[ [1, -1, 0, 0, 0], [1, 1, 0, 0, 0], [-1, 0, 0, 0, 0] ]
```

```python
>>> from sage.all import *
```

```python
>>> U = OK.UnitGroup() # optional -- kash
```

```python
>>> # name sage34 below random; optional -- kash
```

```python
>>> U = OK.UnitGroup() # optional -- kash
```

```python
>>> # name sage34 below random; optional -- kash
```

```
(continues on next page)
17.2.13 Function Fields

```python
sage: # optional - kash
sage: k = kash.FiniteField(25)
sage: kT = k.RationalFunctionField()
sage: kTy = kT.PolynomialAlgebra()
sage: T = kT.gen(1)
sage: y = kTy.gen(1)
sage: f = y**3 + T**4 + 1
```

```python
>>> from sage.all import *
```

```python
>>> k = kash.FiniteField(Integer(25))
>>> kT = k.RationalFunctionField()
>>> kTy = kT.PolynomialAlgebra()
>>> T = kT.gen(Integer(1))
>>> y = kTy.gen(Integer(1))
>>> f = y**Integer(3) + T**Integer(4) + Integer(1)
```

17.3 Long Input

The KASH interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

**Note:** Using `kash.eval` for long input is much less robust, and is not recommended.

```python
sage: a = kash(range(10000)) # optional -- kash
```

```python
>>> from sage.all import *
```

```python
>>> a = kash(range(Integer(10000))) # optional -- kash
```

Note that KASH seems to not support string or integer literals with more than 1024 digits, which is why the above example uses a list unlike for the other interfaces.

```python
class sage.interfaces.kash.Kash(max_workspace_size=None, maxread=None, script_subdirectory=None, restart_on_ctrlc=True, logfile=None, server=None, server_tmpdir=None):
```

**Bases:** `Expect`

Interface to the Kash interpreter.

**AUTHORS:**

- William Stein and David Joyner
clear\( (\text{var}) \)
Clear the variable named \text{var}.

Kash variables have a record structure, so if \text{sage1} is a polynomial ring, \text{sage1.1} will be its indeterminate. This prevents us from easily reusing variables, since \text{sage1.1} might still have references even if \text{sage1} does not.

For now, we don’t implement variable clearing to avoid these problems, and instead implement this method with a noop.

c\text{onsole}()

eval\( (x, \text{newlines=False, strip=True, **kwds}) \)
Send the code in the string \text{s} to the Kash interpreter and return the output as a string.

INPUT:

\begin{itemize}
\item \text{s} – string containing Kash code.
\item \text{newlines} – bool (default: True); if False, remove all backslash-newlines inserted by the Kash output formatter.
\item \text{strip} – ignored
\end{itemize}

function\_call\( (\text{function, args=None, kwds=None}) \)
EXAMPLES:

\begin{verbatim}
sage: kash.function_call('ComplexToPolar', [1+I], {'Results' : 1}) # optional -- kash
1.41421356237309504880168872421

>>> from sage.all import *

>>> kash.function_call('ComplexToPolar', [Integer(1)+I], {'Results' :
Integer(1)}) # optional -- kash
1.41421356237309504880168872421
\end{verbatim}

get\( (\text{var}) \)
Get the value of the variable \text{var}.

help\( (\text{name=\text{None}}) \)
Return help on KASH commands.

This returns help on all commands with a given name. If \text{name} is \text{None}, return the location of the installed Kash HTML documentation.

EXAMPLES:

\begin{verbatim}
sage: X = kash.help('IntegerRing') # random; optional -- kash
1439: IntegerRing() -> \langle \text{ord}^\text{rat}\rangle
1440: IntegerRing(<\text{elt-ord}^\text{rat}\rangle m) -> \langle \text{res}^\text{rat}\rangle
1441: IntegerRing(<\text{seq}() Q) -> \langle \text{res}^\text{rat}\rangle
1442: IntegerRing(<\text{fld}^\text{rat}\rangle K) -> \langle \text{ord}^\text{rat}\rangle
1443: IntegerRing(<\text{fld}^\text{fra}\rangle K) -> \langle \text{ord}^\text{num}\rangle
1444: IntegerRing(<\text{rng} K) -> \langle \text{rng}\rangle
1445: IntegerRing(<\text{fld}^\text{pad}\rangle L) -> \langle \text{ord}^\text{pad}\rangle

>>> from sage.all import *

>>> X = kash.help('IntegerRing') # random; optional -- kash
1439: IntegerRing() -> <\text{ord}^\text{rat}>
1440: IntegerRing(<\text{elt-ord}^\text{rat}\rangle m) -> <\text{res}^\text{rat}>
\end{verbatim}

(continues on next page)
There is one entry in X for each item found in the documentation for this function: If you type `print(X[0])` you will get help on about the first one, printed nicely to the screen.

AUTHORS:

- Sebastion Pauli (2006-02-04): during Sage coding sprint

```
help_search(name)
```

```
set(var, value)
```

Set the variable var to the given value.

```
version()
```

```
class sage.interfaces.kash.KashDocumentation(iterable=(), /)
```

Bases: list

```
class sage.interfaces.kash.KashElement(parent, value, is_name=False, name=None)
```

Bases: ExpectElement

```
sage.interfaces.kash.is_KashElement(x)
```

Returns True if x is of type `KashElement`.

EXAMPLES:

```
sage: from sage.interfaces.kash import is_KashElement
sage: is_KashElement(2)
...: DeprecationWarning: the function is_KashElement is deprecated; use...
 →isinstance(x, sage.interfaces.abc.KashElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
False
sage: is_KashElement(kash(2))  # optional - kash
True
```

```
>>> from sage.all import *
>>> from sage.interfaces.kash import is_KashElement
>>> is_KashElement(Integer(2))
...: DeprecationWarning: the function is_KashElement is deprecated; use...

Chapter 17. Interface to KASH
Kenzo is a set of lisp functions to compute homology and homotopy groups of topological spaces.

AUTHORS:
- Miguel Marco, Ana Romero (2019-01): Initial version

For this interface, Kenzo is loaded into ECL which is itself loaded as a C library in Sage. Kenzo objects in this interface are nothing but wrappers around ECL objects.

`sage.interfaces.kenzo.BicomplexSpectralSequence(l)`

Construct the spectral sequence associated to the bicomplex given by a list of morphisms.

**INPUT:**
- `l` - A list of morphisms of chain complexes

**OUTPUT:**
- A `KenzoSpectralSequence`

**EXAMPLES:**

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import BicomplexSpectralSequence
sage: C1 = ChainComplex({1: matrix(ZZ, 0, 2, [])}, degree_of_differential=-1)
sage: C2 = ChainComplex({1: matrix(ZZ, 1, 2, [1, 0]), degree_of_differential=-1})
sage: C3 = ChainComplex({0: matrix(ZZ, 0, 2, []), degree_of_differential=-1})
sage: M1 = Hom(C2, C1)({1: matrix(ZZ, 2, 2, [2, 0, 0, 2])})
sage: M2 = Hom(C3, C2)({0: matrix(ZZ, 1, 2, [2, 0])})
sage: l = [M1, M2]
sage: E = BicomplexSpectralSequence(l)
sage: E.group(2, 0, 1)
Additive abelian group isomorphic to Z/2 + Z
sage: E.table(3, 0, 2, 0, 2)
0 0 0
Z/2 + Z/4 0 0
0 0 Z
sage: E.matrix(2, 2, 0)
[ 0 0]
[-4 0]
```

```bash
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import BicomplexSpectralSequence
>>> C1 = ChainComplex({Integer(1): matrix(ZZ, Integer(0), Integer(2), [])}, ...
                   degree_of_differential=-Integer(1))
```
C2 = ChainComplex({Integer(1): matrix(ZZ, Integer(1), Integer(2), [Integer(1), → Integer(0)]), degree_of_differential=Integer(1))}
C3 = ChainComplex({Integer(0): matrix(ZZ, Integer(0), Integer(2), []), degree_ →of_differential=Integer(1))}
M1 = Hom(C2,C1)({Integer(1): matrix(ZZ, Integer(2), Integer(2), [Integer(2), → Integer(0), Integer(0), Integer(2)])})
M2 = Hom(C3,C2)({Integer(0): matrix(ZZ, Integer(1), Integer(2), [Integer(2), → Integer(0)])})
l = [M1, M2]
E = BicomplexSpectralSequence(l)
E.group(Integer(2),Integer(0),Integer(1))
Additive abelian group isomorphic to Z/2 + Z
E.table(Integer(3),Integer(0),Integer(2),Integer(0),Integer(2))
0 0 0
Z/2 + Z/4 0 0
0 0 Z
E.matrix(Integer(2),Integer(2),Integer(0))
[ 0 0]
[-4 0]

```

sage.interfaces.kenzo.EilenbergMacLaneSpace(G, n)
Return the Eilenberg-MacLane space K(G, n) as a Kenzo simplicial group.

The Eilenberg-MacLane space K(G, n) is the space whose has n’th homotopy group isomorphic to G, and the rest of the homotopy groups are trivial.

INPUT:

• G – group. Currently only ZZ and the additive group of two elements are supported.

• n – the dimension in which the homotopy is not trivial

OUTPUT:

• A KenzoSimplicialGroup

EXAMPLES:

```sage:
# optional - kenzo
from sage.interfaces.kenzo import EilenbergMacLaneSpace
e3 = EilenbergMacLaneSpace(ZZ, 3)
[e3.homology(i) for i in range(8)]
[2, 0, 0, 0, 0, 0, 0, 0]
e3 = EilenbergMacLaneSpace(AdditiveAbelianGroup([2]), 3)
[f3.homology(i) for i in range(8)]
[2, 0, 0, 2, 0, 2, 2, 2]
```

sage.interfaces.kenzo.KAbstractSimplex(simplex)
Convert an AbstractSimplex in Sage to an abstract simplex of Kenzo.
INPUT:

- **simplex** – An AbstractSimplex.

OUTPUT:

- An abstract simplex of Kenzo.

EXAMPLES:

```sage
# optional - kenzo
from sage.topology.simplicial_set import AbstractSimplex
from sage.interfaces.kenzo import (...
KAbstractSimplex, SAbstractSimplex)
SAbSm = AbstractSimplex(1, (2,0,3,2,1), name = 'SAbSm')
KAbSm = KAbstractSimplex(SAbSm)
SAbSm2 = SAbstractSimplex(KAbSm, 1)
SAbSm.degeneracies() == SAbSm2.degeneracies()
True
SAbSm.dimension() == SAbSm2.dimension()
True
```

```sage
>>> from sage.all import *
>>> from sage.topology.simplicial_set import AbstractSimplex
>>> from sage.interfaces.kenzo import (...
SAbSm = AbstractSimplex(Integer(1), (Integer(2),Integer(0),Integer(3),...
KAbSm = KAbstractSimplex(SAbSm)
SAbSm2 = SAbstractSimplex(KAbSm, Integer(1))
SAbSm.degeneracies() == SAbSm2.degeneracies()
True
SAbSm.dimension() == SAbSm2.dimension()
True
```

`sage.interfaces.kenzo.KChainComplex(chain_complex)`

Construct a KenzoChainComplex from a ChainComplex of degree = -1 in Sage.

INPUT:

- **chain_complex** – A ChainComplex of degree = -1

OUTPUT:

- A KenzoChainComplex

EXAMPLES:

```sage
# optional - kenzo
from sage.interfaces.kenzo import KChainComplex
m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])
sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1)
sage: kenzo_chcm = KChainComplex(sage_chcm)
kchain complexes [K...
Chain-Complex]
sage: kenzo_chcm.homology(5)
Z x Z
```
sage.interfaces.kenzo.\texttt{KChainComplexMorphism}(\textit{morphism})

Construct a Kenzo\texttt{ChainComplexMorphism} from a \texttt{ChainComplexMorphism} in Sage.

INPUT:

- \texttt{morphism} – A morphism of chain complexes

OUTPUT:

- A \texttt{KenzoChainComplexMorphism}

EXAMPLES:

```python
sage: # optional - kenzo
d from sage.interfaces.kenzo import KChainComplexMorphism
d C = ChainComplex({0: identity_matrix(ZZ, 1)})
d D = ChainComplex({0: zero_matrix(ZZ, 1), 1: zero_matrix(ZZ, 1)})
d f = Hom(C,D)({0: identity_matrix(ZZ, 1), 1: zero_matrix(ZZ, 1)})
d g = KChainComplexMorphism(f); g
[K... Morphism (degree 0): K... -> K...]
sage: g.source_complex()
[K... Chain-Complex]
sage: g.target_complex()
[K... Chain-Complex]
```

sage.interfaces.kenzo.\texttt{KFiniteSimplicialSet}(\textit{sset})

Convert a finite \texttt{SimplicialSet} in Sage to a finite simplicial set of Kenzo.
INPUT:

- \texttt{sset} – A finite SimplicialSet.

OUTPUT:

- A finite simplicial set of Kenzo.

EXAMPLES:

```python
sage: from sage.topology.simplicial_set import AbstractSimplex, SimplicialSet
sage: from sage.interfaces.kenzo import KFiniteSimplicialSet
sage: Triangle = SimplicialSet({s01: (s1, s0), s02: (s2, s0), s12: (s2, s1)}, base_point = s0)
```

```python
class sage.interfaces.kenzo.KenzoChainComplex(kenzo_object)
Bases: KenzoObject
```
Wrapper to Kenzo chain complexes. Kenzo simplicial sets are a particular case of Kenzo chain complexes.

**basis** *(dim)*

Return the list of generators of the chain complex associated to the kenzo object `self` in dimension `dim`.

**INPUT:**

- `dim` – An integer number

**OUTPUT:**

- A list of the form `['G"dim"G0', 'G"dim"G1', 'G"dim"G2', ...].`

**EXAMPLES:**

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import KChainComplex
sage: m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
sage: m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
sage: m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])
sage: sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1)
sage: kenzo_chcm = KChainComplex(sage_chcm)

sage: kenzo_chcm
[K... Chain-Complex]

sage: for i in range(6):
....:     print("Basis in dimension %i: %s" % (i, kenzo_chcm.basis(i)))
Basis in dimension 0: ['G0G0', 'G0G1', 'G0G2']
Basis in dimension 1: ['G1G0', 'G1G1']
Basis in dimension 2: None
Basis in dimension 3: ['G3G0', 'G3G1']
Basis in dimension 4: ['G4G0', 'G4G1']
Basis in dimension 5: ['G5G0', 'G5G1', 'G5G2']
```

```python
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import KChainComplex

>>> m1 = matrix(ZZ, Integer(3), Integer(2), [-Integer(1), Integer(1), Integer(3), -Integer(4), Integer(5), Integer(6)])
>>> m4 = matrix(ZZ, Integer(2), Integer(2), [Integer(1), Integer(2), Integer(3), Integer(6)])
>>> m5 = matrix(ZZ, Integer(2), Integer(3), [Integer(2), Integer(2), Integer(3), Integer(2), -Integer(1), -Integer(1), -Integer(1)])

>>> sage_chcm = ChainComplex({Integer(1): m1, Integer(4): m4, Integer(5): m5}, degree = -Integer(1))

>>> kenzo_chcm = KChainComplex(sage_chcm)

>>> kenzo_chcm
[K... Chain-Complex]

>>> for i in range(Integer(6)):
....:     print("Basis in dimension %i: %s" % (i, kenzo_chcm.basis(i)))
Basis in dimension 0: ['G0G0', 'G0G1', 'G0G2']
Basis in dimension 1: ['G1G0', 'G1G1']
Basis in dimension 2: None
Basis in dimension 3: ['G3G0', 'G3G1']
Basis in dimension 4: ['G4G0', 'G4G1']
Basis in dimension 5: ['G5G0', 'G5G1', 'G5G2']
```

**differential** *(dim=None, comb=None)*

Return the differential of a combination.

**INPUT:**

- `dim` – An integer number
- `comb` – A combination
- **dim** – An integer number or None (default)
- **comb** – A list representing a formal sum of generators in the module of dimension **dim** or None (default). For example, to represent $G7G12 + 3*G7G0 - 5*G7G3$ we use the list $[3, 'G7G0', -5, 'G7G3', 1, 'G7G12']$. Note that the generators must be in ascending order with respect to the number after the second G in their representation; the parameter $\text{comb} = [1, 'G7G12', 3, 'G7G0', -5, 'G7G3']$ will produce an error in Kenzo.

**OUTPUT:**

- If **dim** and **comb** are not None, it returns a Kenzo combination representing the differential of the formal combination represented by **comb** in the chain complex **self** in dimension **dim**. On the other hand, if **dim** or **comb** (or both) take None value, the differential **KenzoMorphismChainComplex** of **self** is returned.

**EXAMPLES:**

```python
from sage.interfaces.kenzo import KChainComplex

m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])
sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1)
sage: kenzo_chcm = KChainComplex(sage_chcm)
sage: kenzo_chcm
[K... Chain-Complex]

sage: kenzo_chcm.basis(4)
['G4G0', 'G4G1']

sage: kenzo_chcm.differential(4, [1, 'G4G0'])
1 * G3G0
3 * G3G1

sage: kenzo_chcm.basis(5)
['G5G0', 'G5G1', 'G5G2']

sage: kenzo_chcm.differential(5, [1, 'G5G0', 2, 'G5G2'])
6 * G4G0
-3 * G4G1
```

```python
>>> from sage.all import *
>>> from sage.interfaces.kenzo import KChainComplex
>>> m1 = matrix(ZZ, Integer(3), Integer(2), [-Integer(1), Integer(1),...
˓→ Integer(2), Integer(3), -Integer(4), Integer(5), Integer(6)])
>>> m4 = matrix(ZZ, Integer(2), Integer(2), [Integer(1), Integer(2),...
˓→ Integer(3), Integer(6)])
>>> m5 = matrix(ZZ, Integer(2), Integer(3), [Integer(2), Integer(2),...
˓→ Integer(2), -Integer(1), -Integer(1), -Integer(1)])
>>> sage_chcm = ChainComplex({Integer(1): m1, Integer(4): m4, Integer(5): m5},...
˓→ degree = -Integer(1)})
>>> kenzo_chcm = KChainComplex(sage_chcm)
>>> kenzo_chcm
[K... Chain-Complex]
```

(continues on next page)
homology \((n)\)

Return the \(n\)'th homology group of the chain complex associated to this kenzo object.

**INPUT:**

- \(n\) – the dimension in which compute the homology

**OUTPUT:**

- A homology group.

**EXAMPLES:**

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: s2 = Sphere(2)
sage: s2
[K1 Simplicial-Set]
sage: s2.homology(2)
Z
```

```python
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> s2 = Sphere(Integer(2))
>>> s2
[K1 Simplicial-Set]
>>> s2.homology(Integer(2))
Z
```

identity_morphism()

Return the identity morphism (degree 0) between self and itself.

**OUTPUT:**

- A `KenzoChainComplexMorphism`

**EXAMPLES:**
null_morphism (target=None, degree=None)

Return the null morphism between the chain complexes self and target of degree degree.

INPUT:

• target – A KenzoChainComplex or None (default).

• degree – An integer number or None (default).

OUTPUT:

• A KenzoChainComplexMorphism representing the null morphism between self and target of degree degree. If target takes None value, self is assumed as the target chain complex; if degree takes None value, 0 is assumed as the degree of the null morphism.

EXAMPLES:
Interpreter Interfaces, Release 10.4

from sage.interfaces.kenzo import Sphere
s2 = Sphere(2)
sage: s2
Loop-space of S^2

sage: s2 = Sphere(2)

sage: A = s2.cartesian_product(s2)

sage: A.orgn()
(CRTS-PRDC [K... Simplicial-Group] [K... Simplicial-Set])

>>> from sage.all import *

>>> from sage.interfaces.kenzo import Sphere

>>> s2 = Sphere(Integer(2))

>>> A = s2.cartesian_product(s2)

>>> A.orgn()
(CRTS-PRDC [K... Simplicial-Group] [K... Simplicial-Set])

orgn()  
Return the :orgn: slot of Kenzo, which stores as a list the origin of the object

EXAMPLES:

sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere

sage: s2 = Sphere(2)

sage: s3 = Sphere(3)

sage: s2 = Sphere(2)

sage: s2 = Sphere(2)

sage: p = s2.tensor_product(s3)

sage: type(p)
<class 'sage.interfaces.kenzo.KenzoChainComplex'>

EXAMPLES:

Tensor product (other)

Return the tensor product of self and other.

INPUT:

• other – The Kenzo object with which to compute the tensor product

OUTPUT:

• A :KenzoChainComplex:

EXAMPLES:

orgn()  
Return the :orgn: slot of Kenzo, which stores as a list the origin of the object

EXAMPLES:

sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere

sage: s2 = Sphere(2)

sage: s2 = Sphere(2)

sage: A = s2.cartesian_product(s2)

sage: A.orgn()
(CRTS-PRDC [K... Simplicial-Group] [K... Simplicial-Set])

tensor_product (other)

Return the tensor product of self and other.

INPUT:

• other – The Kenzo object with which to compute the tensor product

OUTPUT:

• A :KenzoChainComplex:

EXAMPLES:

sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere

sage: s2 = Sphere(2)

sage: s3 = Sphere(3)

sage: s2 = Sphere(2)

sage: p = s2.tensor_product(s3)

sage: type(p)
<class 'sage.interfaces.kenzo.KenzoChainComplex'>

(continues on next page)
sage: [p.homology(i) for i in range(8)]
[\text{Z}, 0, \text{Z}, 0, \text{Z}, 0, 0, 0]

```python
>>> from sage.all import *

# optional - kenzo
>>> from sage.interfaces.kenzo import Sphere

s2 = Sphere(Integer(2))
s3 = Sphere(Integer(3))
p = s2.tensor_product(s3)
type(p)

<class 'sage.interfaces.kenzo.KenzoChainComplex'>

>>> [p.homology(i) for i in range(Integer(8))]
[\text{Z}, 0, \text{Z}, 0, \text{Z}, 0, 0, 0]
```

class sage.interfaces.kenzo.KenzoChainComplexMorphism(kenzo_object)

Bases: KenzoObject

Wrapper to Kenzo morphisms between chain complexes.

**change_source_target_complex** *(source=None, target=None)*

Build, from the morphism `self`, a new morphism with `source` and `target` as source and target Kenzo chain complexes, respectively.

**INPUT:**

- `source` – A `KenzoChainComplex` instance or None (default).
- `target` – A `KenzoChainComplex` instance or None (default).

**OUTPUT:**

- A `KenzoChainComplexMorphism` inheriting from `self` the degree (`degr` slot in Kenzo), the algorithm (`intr` slot in Kenzo) and the strategy (`strt` slot in Kenzo). The source and target slots of this new morphism are given by the parameters `source` and `target` respectively; if any parameter is omitted, the corresponding slot is inherited from `self`.

**EXAMPLES:**

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere, KenzoChainComplex
sage: from sage.libs.ecl import ecl_eval

sage: ZCC = KenzoChainComplex(ecl_eval("(z-chcm)"))
sage: ZCC
[\text{K... Chain-Complex}]

sage: s2 = Sphere(2)
sage: s3 = Sphere(3)
sage: tp = s2.tensor_product(s3)
sage: tp
[\text{K... Filtered-Chain-Complex}]

sage: null = ZCC.null_morphism(tp)
sage: null
[\text{K... Morphism (degree 0): K... \rightarrow K...}]

sage: null.source_complex()
[\text{K... Chain-Complex}]

sage: null2 = null.change_source_target_complex(source = tp)
sage: null2
[\text{K... Morphism (degree 0): K... \rightarrow K...}]

sage: null2.source_complex()
[\text{K... Filtered-Chain-Complex}]
```
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere, KenzoChainComplex
>>> from sage.libs.ecl import ecl_eval
>>> ZCC = KenzoChainComplex(ecl_eval("(z-chcm)"))
>>> ZCC
[K... Chain-Complex]
>>> s2 = Sphere(Integer(2))
>>> s3 = Sphere(Integer(3))
>>> tp = s2.tensor_product(s3)
>>> tp
[K... Filtered-Chain-Complex]
>>> null = ZCC.null_morphism(tp)
>>> null
[K... Morphism (degree 0): K... -> K...]
>>> null.source_complex()
[K... Chain-Complex]
>>> null2 = null.change_source_target_complex(source = tp)
>>> null2
[K... Morphism (degree 0): K... -> K...]
>>> null2.source_complex()
[K... Filtered-Chain-Complex]

composite (object=None)

Return the composite of self and the morphism(s) given by the parameter object.

INPUT:

• object – A KenzoChainComplexMorphism instance, a KenzoChainComplex instance, a tuple of KenzoChainComplexMorphism and KenzoChainComplex instances, or None (default).

OUTPUT:

• A KenzoChainComplexMorphism: if object is a KenzoChainComplexMorphism, the composite of self and object is returned; if object is a KenzoChainComplex, the composite of self and the differential morphism of object is returned; if object is a tuple, the composite of self and the morphisms or the differential morphisms of the given chain complexes in object is returned (if object is None, self morphism is returned).

EXAMPLES:

sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: s2 = Sphere(2)
sage: s3 = Sphere(3)
sage: tp22 = s2.tensor_product(s2)
sage: tp23 = s2.tensor_product(s3)
sage: idnt = tp22.identity_morphism()
sage: idnt
[K... Morphism (degree 0): K... -> K...]
sage: null = tp23.null_morphism(target = tp22, degree = 4)
sage: null
[K... Morphism (degree 4): K... -> K...]
sage: idnt composite((tp22, null))
[K... Morphism (degree 3): K... -> K...]

(continues on next page)
...from sage.interfaces.kenzo import Sphere
>>> s2 = Sphere(Integer(2))
>>> s3 = Sphere(Integer(3))
>>> tp22 = s2.tensor_product(s2)
>>> tp23 = s2.tensor_product(s3)
>>> idnt = tp22.identity_morphism()
>>> idnt
[... Morphism (degree 0): ... -> ...]
>>> null = tp23.null_morphism(target = tp22, degree = Integer(4))
>>> null
[... Morphism (degree 4): ... -> ...]
>>> idnt.composite((tp22, null))
[... Morphism (degree 3): ... -> ...]

**degree()**

Return the degree of the morphism.

**OUTPUT:**

- An integer number, the degree of the morphism.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.interfaces.kenzo import * KChainComplex
>>> m1 = matrix(ZZ, Integer(3), Integer(2), [-Integer(1), Integer(1), ...
˓→ Integer(3), -Integer(4), Integer(5), Integer(6)])
>>> m4 = matrix(ZZ, Integer(2), Integer(2), [Integer(1), Integer(2), ...
˓→ Integer(3), Integer(6)])
>>> m5 = matrix(ZZ, Integer(2), Integer(3), [Integer(2), Integer(2), ...
˓→ Integer(2), -Integer(1), -Integer(1), -Integer(1)])
>>> sage_chcm = ChainComplex({Integer(1): m1, Integer(4): m4, Integer(5): m5}, degree=Integer(-1))
>>> kenzo_chcm = KChainComplex(sage_chcm)
>>> kenzo_chcm
[... Chain-Complex]
>>> differential_morphism = kenzo_chcm.differential()
>>> differential_morphism
[... Morphism]
>>> differential_morphism.degree() -1
>>> differential_morphism.composite(differential_morphism).degree() -2
>>> kenzo_chcm.null_morphism().degree() 0
```

(continues on next page)
differential_morphism

*K... Morphism (degree -1): K... -> K...*

*differential_morphism.degree()*

-1

*differential_morphism.composite(differential_morphism).degree()*

-2

*kenzo_chcm.null_morphism().degree()*

0

**destructive_change_source_target_complex** (*source=None, target=None*)

Modify destructively the morphism *self* taking *source* and *target* as source and target Kenzo chain complexes of *self*, respectively.

**INPUT:**

- *source* – A KenzoChainComplex instance or None (default).
- *target* – A KenzoChainComplex instance or None (default).

**OUTPUT:**

- A KenzoChainComplexMorphism. The source and target slots of *self* are replaced respectively by the parameters *source* and *target*; if any parameter is omitted, the corresponding slot is inherited from *self*.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.interfaces.kenzo import Sphere, KenzoChainComplex
>>> ZCC = KenzoChainComplex(ecl_eval("(z-chcm)"))
```

```python
>>> s2 = Sphere(Integer(2))
>>> s3 = Sphere(Integer(3))
>>> tp = s2.tensor_product(s3)
```

```python
>>> null = ZCC.null_morphism(tp)
```

```python
>>> null.destructive_change_source_target_complex(target = ZCC)
```

```python
sage: from sage.interfaces.kenzo import Sphere, KenzoChainComplex
sage: from sage.libs.ecl import ecl_eval
sage: ZCC = KenzoChainComplex(ecl_eval("(z-chcm)"))
```

```python
sage: s2 = Sphere(Integer(2))
```

```python
sage: s3 = Sphere(Integer(3))
```

```python
sage: tp = s2.tensor_product(s3)
```

evaluation \((\text{dim}, \text{comb})\)

Apply the morphism on a combination \(\text{comb}\) of dimension \(\text{dim}\).

**INPUT:**

- \(\text{dim}\) – An integer number
- \(\text{comb}\) – A list representing a formal sum of generators in the module of dimension \(\text{dim}\). For example, to represent \(G7G12 + 3*G7G0 - 5*G7G3\) we use the list \([3, 'G7G0', -5, 'G7G3', 1, 'G7G12']\). Note that the generators must be in ascending order respect to the number after the second G in their representation; the parameter \(\text{comb} = [1, 'G7G12', 3, 'G7G0', -5, 'G7G3']\) will produce an error in Kenzo.

**OUTPUT:**

- A Kenzo combination representing the result of applying the morphism on the formal combination represented by \(\text{comb}\) in the chain complex \(\text{self}\) in dimension \(\text{dim}\).

**EXAMPLES:**

```
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import KChainComplex
sage: m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
sage: m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
sage: m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])

sage: sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1)

sage: kenzo_chcm = KChainComplex(sage_chcm)

sage: kenzo_chcm

sage: differential_morphism = kenzo_chcm.differential()

sage: differential_morphism

sage: dif_squared = differential_morphism . composite(differential_morphism)

sage: kenzo_chcm.basis(5)

sage: kenzo_chcm.differential(5, [1, 'G5G0', 2, 'G5G2'])
```

\(<6 * G4G0>\)
\(<-3 * G4G1>\)

```
sage: differential_morphism.evaluation(5, [1, 'G5G0', 2, 'G5G2'])
```

(continues on next page)
Interpreter Interfaces, Release 10.4

>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import KChainComplex
>>> m1 = matrix(ZZ, Integer(3), Integer(2), [-Integer(1), Integer(1),
   Integer(3), -Integer(4), Integer(5), Integer(6)])
>>> m4 = matrix(ZZ, Integer(2), Integer(2), [Integer(1), Integer(2),
   Integer(3), Integer(6)])
>>> m5 = matrix(ZZ, Integer(2), Integer(3), [Integer(2), Integer(2),
   Integer(2), -Integer(1), -Integer(1), -Integer(1)])

>>> kenzo_chcm.differential(Integer(5), [Integer(1), 'G5G0', Integer(2), 'G5G2'])

(continued from previous page)
opposite()

Return the opposite morphism of self, i.e., -1 x self.

OUTPUT:

- A KenzoChainComplexMorphism

EXAMPLES:

```sage
# optional - kenzo
sage: from sage.interfaces.kenzo import KChainComplex
sage: m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
sage: m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
sage: m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])
```

```sage
sage: sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1)
sage: kenzo_chcm = KChainComplex(sage_chcm)
```

```sage
sage: idnt = kenzo_chcm.identity_morphism()
sage: idnt
```

```sage
sage: opps_id = idnt.opposite()
sage: opps_id
```

```sage
sage: idnt.evaluation(4, [2, 'G4G0', -5, 'G4G1'])
```

(continues on next page)
source_complex()  
Return the source chain complex of the morphism.

OUTPUT:

• A KenzoChainComplex

EXAMPLES:
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import KChainComplex
sage: m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
sage: m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
sage: m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])

sage: sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1)

sage: kenzo_chcm = KChainComplex(sage_chcm)

sage: kenzo_chcm
[K... Chain-Complex]

sage: differential_morphism = kenzo_chcm.differential()

sage: differential_morphism
[K... Morphism (degree -1): K... -> K...]

sage: differential_morphism.source_complex()
[K... Chain-Complex]

>>> from sage.all import *

>>> # optional - kenzo

>>> from sage.interfaces.kenzo import KChainComplex

>>> m1 = matrix(ZZ, Integer(3), Integer(2), [-Integer(1), Integer(1),
˓→Integer(3), -Integer(4), Integer(5), Integer(6)])

>>> m4 = matrix(ZZ, Integer(2), Integer(2), [Integer(1), Integer(2),
˓→Integer(3), Integer(4)])

>>> m5 = matrix(ZZ, Integer(2), Integer(3), [Integer(2), Integer(2),
˓→Integer(2), -Integer(1), -Integer(1), -Integer(1)])

>>> sage_chcm = ChainComplex({Integer(1): m1, Integer(4): m4, Integer(5): m5},
˓→degree = -Integer(1))

>>> differential_morphism
[K... Morphism (degree -1): K... -> K...]

>>> differential_morphism.source_complex()
[K... Chain-Complex]

\textbf{substract}(\texttt{object=None})

Return a morphism, difference of the morphism \texttt{self} and the morphism(s) given by the parameter \texttt{object}. 

\textbf{INPUT:}

- \texttt{object} – A Kenzo\texttt{ChainComplexMorphism} instance, a tuple of Kenzo\texttt{ChainComplexMorphism} instances or None (default).

\textbf{OUTPUT:}

- A Kenzo\texttt{ChainComplexMorphism}, difference of the morphism \texttt{self} and the morphism(s) given by \texttt{object} (if \texttt{object} is None, \texttt{self} morphism is returned). For example, if \texttt{object = (mrph1, mrph2, mrph3)} the result is \texttt{self - mrph1 - mrph2 - mrph3}.

\textbf{EXAMPLES:}
sage: kenzo_chcm
[K... Chain-Complex]
sage: idnt = kenzo_chcm.identity_morphism()
sage: idnt
[K... Morphism (degree 0): K... -> K...]
sage: opps_id = idnt.opposite()

<table>
<thead>
<tr>
<th>sum</th>
<th>(object=None)</th>
</tr>
</thead>
</table>

Return a morphism, sum of the morphism self and the morphism(s) given by the parameter object.

**INPUT:**

- object – A KenzoChainComplexMorphism instance, a tuple of KenzoChainComplexMorphism instances or None (default).

**OUTPUT:**

- A KenzoChainComplexMorphism, sum of the morphism self and the morphism(s) given by object (if object is None, self morphism is returned).

**EXAMPLES:**

```python
sage: from sage.interfaces.kenzo import KChainComplex
sage: m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
sage: m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
sage: m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])
sage: sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1)
sage: kenzo_chcm = KChainComplex(sage_chcm)
sage: idnt = kenzo_chcm.identity_morphism()
sage: idnt
[K... Morphism (degree 0): K... -> K...]
sage: opps_id = idnt.opposite()
sage: opps_id
[K... Morphism (degree 0): K... -> K...]
sage: null = kenzo_chcm.null_morphism()
sage: null
[K... Morphism (degree 0): K... -> K...]
sage: idx2 = idnt.sum(idnt)
sage: idx5 = idx2.sum(
    ...: (opps_id, idnt, null, idx2.sum(idnt), opps_id))
sage: kenzo_chcm.basis(4)
['G4G0', 'G4G1']
sage: idx2.evaluation(4, [2, 'G4G0', -5, 'G4G1'])
```

(continues on next page)
target_complex()

Return the target chain complex of the morphism.
OUTPUT:

• A KenzoChainComplex

EXAMPLES:

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import KChainComplex
sage: m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
sage: m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
sage: m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])

sage: sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1)

sage: kenzo_chcm = KChainComplex(sage_chcm)

sage: kenzo_chcm
[K... Chain-Complex]

sage: differential_morphism = kenzo_chcm.differential()

sage: differential_morphism
[K... Morphism (degree -1): K... -> K...]

sage: differential_morphism.target_complex()
[K... Chain-Complex]
```

```python
>>> from sage.all import *

>>> # optional - kenzo
>>> from sage.interfaces.kenzo import KChainComplex

>>> m1 = matrix(ZZ, Integer(3), Integer(2), [-Integer(1), Integer(1), Integer(3), -Integer(3), -Integer(4), Integer(5), Integer(6)])

>>> m4 = matrix(ZZ, Integer(2), Integer(2), [Integer(1), Integer(2), -Integer(1), -Integer(1), -Integer(1), -Integer(1), -Integer(6)])

>>> m5 = matrix(ZZ, Integer(2), Integer(3), [Integer(2), Integer(2), -Integer(2), -Integer(1), -Integer(1), -Integer(1)])

>>> sage_chcm = ChainComplex({Integer(1): m1, Integer(4): m4, Integer(5): m5}, degree = -Integer(1))

>>> kenzo_chcm = KChainComplex(sage_chcm)

>>> kenzo_chcm
[K... Chain-Complex]

>>> differential_morphism = kenzo_chcm.differential()

>>> differential_morphism
[K... Morphism (degree -1): K... -> K...]

>>> differential_morphism.target_complex()
[K... Chain-Complex]
```

```
class sage.interfaces.kenzo.KenzoObject(kenzo_object)

    Bases: SageObject

    Wrapper to Kenzo objects

    INPUT:

    • kenzo_object – a wrapper around a Kenzo object (which is an ecl object).

class sage.interfaces.kenzo.KenzoSimplicialGroup(kenzo_object)

    Bases: KenzoSimplicialSet

    Wrapper around Kenzo simplicial groups.

classifying_space()

    Return the classifying space.

    OUTPUT:

    • A KenzoSimplicialGroup
```
EXAMPLES:

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import MooreSpace
sage: m2 = MooreSpace(2,4)
sage: l2 = m2.loop_space()
sage: c = l2.classifying_space()
sage: type(c)
<class 'sage.interfaces.kenzo.KenzoSimplicialGroup'>
sage: [c.homology(i) for i in range(8)]
[0, 0, 0, 0, 0, 0, 0, 0]
```

```python
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import MooreSpace
>>> m2 = MooreSpace(Integer(2),Integer(4))
>>> l2 = m2.loop_space()
>>> c = l2.classifying_space()
>>> type(c)
<class 'sage.interfaces.kenzo.KenzoSimplicialGroup'>
>>> [c.homology(i) for i in range(Integer(8))]
[0, 0, 0, 0, 0, 0, 0, 0]
```

class sage.interfaces.kenzo.KenzoSimplicialSet(kenzo_object)

Bases: KenzoChainComplex

Wrapper to Kenzo simplicial sets.

In Kenzo, the homology of a simplicial set is computed from its associated chain complex. Hence, this class inherits from KenzoChainComplex.

cartesian_product(other)

Return the cartesian product of self and other.

INPUT:

- other – the Kenzo simplicial set with which the product is made

OUTPUT:

- A KenzoSimplicialSet

EXAMPLES:

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: s2 = Sphere(2)
sage: s3 = Sphere(3)
sage: p = s2.cartesian_product(s3)
sage: type(p)
<class 'sage.interfaces.kenzo.KenzoSimplicialSet'>
sage: [p.homology(i) for i in range(6)]
[0, 0, 0, 0, 0, 0]
```
\begin{verbatim}
>>> p = s2.cartesian_product(s3)
>>> type(p)
<class 'sage.interfaces.kenzo.KenzoSimplicialSet'>
>>> [p.homology(i) for i in range(Integer(6))]
[2, 0, 2, 0, 0, 2]
em_spectral_sequence()
Return the Eilenberg-Moore spectral sequence of self.

OUTPUT:
\begin{itemize}
\item A KenzoSpectralSequence
\end{itemize}

EXAMPLES:
\begin{verbatim}
sage: from sage.interfaces.kenzo import Sphere
sage: S2 = Sphere(2)
sage: EMS = S2.em_spectral_sequence()
sage: EMS.table(0, -2, 2, -2, 2)
0 Z 0 0 0
0 0 0 0 0
0 0 Z 0 0
0 0 0 0 0
0 0 0 0 0
\end{verbatim}
\begin{verbatim}
>>> from sage.all import *

>>> from sage.interfaces.kenzo import Sphere
>>> S2 = Sphere(Integer(2))
>>> EMS = S2.em_spectral_sequence()
>>> EMS.table(Integer(0), -Integer(2), Integer(2), -Integer(2), Integer(2))
0 Z 0 0 0
0 0 0 0 0
0 0 Z 0 0
0 0 0 0 0
0 0 0 0 0
\end{verbatim}
\end{verbatim}

**Warning:** This method assumes that the underlying space is simply connected. You might get wrong answers if it is not.

\begin{verbatim}
homotopy_group(n)
Return the n’th homotopy group of self

INPUT:
\begin{itemize}
\item n – the dimension of the homotopy group to be computed
\end{itemize}

EXAMPLES:
\begin{verbatim}
sage: from sage.interfaces.kenzo import Sphere
sage: S2 = Sphere(2)
sage: p = S2.cartesian_product(s2)
sage: p.homotopy_group(3)  # optional - kenzo
Multiplicative Abelian group isomorphic to Z x Z
\end{verbatim}
\end{verbatim}
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> s2 = Sphere(Integer(2))
>>> p = s2.cartesian_product(s2)
>>> p.homotopy_group(Integer(3))

Multiplicative Abelian group isomorphic to \( \mathbb{Z} \times \mathbb{Z} \)

**Warning:** This method assumes that the underlying space is simply connected. You might get wrong answers if it is not.

### join \((\text{other})\)

Return the join of \(\text{self}\) and \(\text{other}\).

**INPUT:**
- \(\text{other}\) – the Kenzo simplicial set with which the join is made

**OUTPUT:**
- A \texttt{KenzoSimplicialSet}

**EXAMPLES:**

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: s2 = Sphere(2)
sage: s3 = Sphere(3)
sage: j = s2.join(s3)
sage: type(j)
<class 'sage.interfaces.kenzo.KenzoSimplicialSet'>
sage: [j.homology(i) for i in range(Integer(6))]
[2, 0, 0, 0, 0, 0]
```

```python
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> s2 = Sphere(Integer(2))
>>> s3 = Sphere(Integer(3))
>>> j = s2.join(s3)
>>> type(j)
<class 'sage.interfaces.kenzo.KenzoSimplicialSet'>
>>> [j.homology(i) for i in range(Integer(6))]
[2, 0, 0, 0, 0, 0]
```

### loop_space \((n=1)\)

Return the \(n\) th iterated loop space.

**INPUT:**
- \(n\) – (default: 1) the number of times to iterate the loop space construction

**OUTPUT:**
- A \texttt{KenzoSimplicialGroup}

**EXAMPLES:**
```
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: s2 = Sphere(2)
sage: l2 = s2.loop_space()
sage: type(l2)
<class 'sage.interfaces.kenzo.KenzoSimplicialGroup'>
sage: l2 = s2.loop_space()

```

```
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> s2 = Sphere(Integer(2))
>>> l2 = s2.loop_space()
>>> type(l2)
<class 'sage.interfaces.kenzo.KenzoSimplicialGroup'>
>>> l2 = s2.loop_space()

```

```
serre_spectral_sequence()

Return the spectral sequence of self.

The object self must be created as a cartesian product (twisted or not).

OUTPUT:

• A KenzoSpectralSequence

EXAMPLES:
```
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: S2 = Sphere(2)
sage: S3 = Sphere(3)
sage: P = S2.cartesian_product(S3)
sage: E = P.serre_spectral_sequence()
sage: E.table(0, 0, 2, 0, 3)

```

```
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> S2 = Sphere(Integer(2))
>>> S3 = Sphere(Integer(3))
>>> P = S2.cartesian_product(S3)
>>> E = P.serre_spectral_sequence()

```
```
**smash_product** (other)

Return the smash product of self and other.

**INPUT:**

- other – the Kenzo simplicial set with which the smash product is made

**OUTPUT:**

- A *KenzoSimplicialSet*

**EXAMPLES:**

```python
sage: from sage.interfaces.kenzo import Sphere
sage: s2 = Sphere(2)
sage: s3 = Sphere(3)
sage: s = s2.smash_product(s3)
sage: type(s)
<class 'sage.interfaces.kenzo.KenzoSimplicialSet'>
sage: [s.homology(i) for i in range(6)]
[Z, 0, 0, 0, 0, Z]
```

**suspension** ()

Return the suspension of the simplicial set.

**OUTPUT:**

- A *KenzoSimplicialSet*

**EXAMPLES:**

```python
sage: from sage.interfaces.kenzo import EilenbergMacLaneSpace
sage: e3 = EilenbergMacLaneSpace(ZZ, 3)
sage: s = e3.suspension()
sage: type(s)
<class 'sage.interfaces.kenzo.KenzoSimplicialSet'>
sage: [s.homology(i) for i in range(6)]
[Z, 0, 0, 0, Z, 0]
```

(continues on next page)
Interpreter Interfaces, Release 10.4

>>> e3 = EilenbergMacLaneSpace(ZZ, Integer(3))
>>> s = e3.suspension()
>>> type(s)
<class 'sage.interfaces.kenzo.KenzoSimplicialSet'>

>>> [s.homology(i) for i in range(Integer(6))]
[2, 0, 0, 0, 2, 0]

sw_spectral_sequence()
Return the Serre sequence of the first step of the Whitehead tower.

OUTPUT:
- A KenzoSpectralSequence

EXAMPLES:

```sage
# optional - kenzo
from sage.interfaces.kenzo import Sphere
S3 = Sphere(3)
E = S3.sw_spectral_sequence()
T = E.table(0, 0, 4, 0, 4)
T
```

```
Z 0 0 Z 0
0 0 0 0 0
Z 0 0 Z 0
0 0 0 0 0
Z 0 0 Z 0
```

wedge(other)
Return the wedge of self and other.

INPUT:
- other – the Kenzo simplicial set with which the wedge is made

OUTPUT:
- A KenzoSimplicialSet

EXAMPLES:

```sage
from sage.all import *
# optional - kenzo
from sage.interfaces.kenzo import Sphere
S3 = Sphere(Integer(3))
E = S3.sw_spectral_sequence()
T = E.table(Integer(0), Integer(0), Integer(4), Integer(0), Integer(4))
T
```

```
Z 0 0 Z 0
0 0 0 0 0
Z 0 0 Z 0
0 0 0 0 0
Z 0 0 Z 0
```
class sage.interfaces.kenzo.KenzoSpectralSequence(kenzo_object)

Bases: KenzoObject

Wrapper around Kenzo spectral sequences

differential \((p, i, j)\)

Return the \((p, i, j)\) differential morphism of the spectral sequence.

INPUT:

- \(p\) – the page.
- \(i\) – the column of the differential domain.
- \(j\) – the row of the differential domain.

EXAMPLES:

```python
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: S3 = Sphere(3)
sage: L = S3.loop_space()
sage: EMS = L.em_spectral_sequence()
sage: EMS.table(1, -5, -2, 5, 8)
0 Z Z + Z + Z Z + Z + Z
0 0 0 0
0 0 Z Z + Z
0 0 0 0
sage: EMS.matrix(1, -3, 8)
[ 2 -2 2]
```

```python
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> S3 = Sphere(Integer(3))
>>> L = S3.loop_space()
>>> EMS = L.em_spectral_sequence()
>>> EMS.table(Integer(1), -Integer(3), 8)
[ 2 -2 2]
```
Interpreter Interfaces, Release 10.4

(continued from previous page)

```
0  Z  Z + Z + Z  Z + Z + Z
0  0  0          0
0  0  Z          Z + Z
0  0  0          0
>>> EMS.matrix(Integer(1), -Integer(3), Integer(8))
[ 2  -2  2]
>>> EMS.differential(Integer(1), -Integer(3), Integer(8))
Morphism from module over Integer Ring with invariants (0, 0, 0) to module...
˓→with invariants (0,) that sends the generators to [(2), (-2), (2)]
```

**group** *(p, i, j)*

Return the *i, j*’th group of the *p* page.

**INPUT:**

- *p* – the page to take the group from.
- *i* – the column where the group is taken from.
- *j* – the row where the group is taken from.

**EXAMPLES:**

```
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: S2 = Sphere(2)
sage: EMS = S2.em_spectral_sequence()
sage: EMS.group(0, -1, 2)
Additive abelian group isomorphic to Z
sage: EMS.group(0, -1, 3)
Trivial group
```

```
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> S3 = Sphere(Integer(3))
>>> EMS = S3.em_spectral_sequence()
>>> EMS.group(Integer(0), -Integer(1), Integer(2))
Additive abelian group isomorphic to Z
>>> EMS.group(Integer(0), -Integer(1), Integer(3))
Trivial group
```

**matrix** *(p, i, j)*

Return the matrix that determines the differential from the *i, j*’th group of the *p*’th page.

**INPUT:**

- *p* – the page.
- *i* – the column of the differential domain.
- *j* – the row of the differential domain.

**EXAMPLES:**

```
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: S3 = Sphere(3)
sage: L = S3.loop_space()
```

(continues on next page)
sage: EMS = L.em_spectral_sequence()
sage: EMS.table(1, -5, -2, 5, 8)

0 Z Z + Z + Z Z + Z + Z
0 0 0 0
0 0 Z Z + Z
0 0 0 0
sage: EMS.matrix(1, -2, 8)

[ 3  -2  0]
[ 3   0 -3]
[ 0   2 -3]

>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> S3 = Sphere(Integer(3))
>>> L = S3.loop_space()
>>> EMS = L.em_spectral_sequence()
>>> EMS.table(Integer(1), -Integer(5), -Integer(2), Integer(5), Integer(8))

0 Z Z + Z + Z Z + Z + Z
0 0 0 0
0 0 Z Z + Z
0 0 0 0

>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere

**table** *(p, i1, i2, j1, j2)*

Return a table printing the groups in the *p* page.

**INPUT:**

- *p* – the page to print.
- *i1* – the first column to print.
- *i2* – the last column to print.
- *j1* – the first row to print.
- *j2* – the last row to print.

**EXAMPLES:**

sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: S2 = Sphere(2)
sage: EMS = S2.em_spectral_sequence()
sage: EMS.table(0, -2, 2, -2, 2)

0 Z 0 0 0
0 0 0 0 0
0 0 Z 0 0
0 0 0 0 0
0 0 0 0 0

>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
Sage interfaces kenzo. **MooreSpace** \((m, n)\)

Return the Moore space \(M(m, n)\) as a Kenzo simplicial set.

The Moore space \(M(m, n)\) is the space whose \(n\)th homology group is isomorphic to the cyclic group of order \(m\), and the rest of the homology groups are trivial.

**INPUT:**
- \(m\) – A positive integer. The order of the nontrivial homology group.
- \(n\) – The dimension in which the homology is not trivial

**OUTPUT:**
- A KenzoSimplicialSet

**EXAMPLES:**

```python
sage: from sage.interfaces.kenzo import MooreSpace
sage: m24 = MooreSpace(2,4)
sage: m24
[K10 Simplicial-Set]
sage: [m24.homology(i) for i in range(8)]
[Z, 0, 0, 0, C2, 0, 0, 0]
```

Sage interfaces kenzo. **SAbstractSimplex** \((\text{simplex}, \text{dim})\)

Convert an abstract simplex of Kenzo to an AbstractSimplex.

**INPUT:**
- \(\text{simplex}\) – An abstract simplex of Kenzo.
- \(\text{dim}\) – The dimension of \(\text{simplex}\).

**OUTPUT:**
- An AbstractSimplex.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.interfaces.kenzo import MooreSpace
>>> m24 = MooreSpace(Integer(2),Integer(4))
>>> m24
[K10 Simplicial-Set]
```

```python
>>> [m24.homology(i) for i in range(Integer(8))]
[Z, 0, 0, 0, C2, 0, 0, 0]
```

```python
>>> from sage.interfaces.kenzo import SAbstractSimplex
>>> SAbstractSimplex(simplex, dim)
```
sage: # optional - kenzo
sage: from sage.libs.ecl import EclObject, ecl_eval
sage: from sage.interfaces.kenzo import (....: KenzoObject, SAbstractSimplex)
sage: KAbSm = KenzoObject(ecl_eval("(ABSM 15 'K')"))
sage: SAbSm1 = SAbstractSimplex(KAbSm, 2)
sage: SAbSm2 = SAbstractSimplex(KAbSm, 7)
sage: SAbSm1.degeneracies()
[3, 2, 1, 0]
sage: SAbSm1.dimension()
6
sage: SAbSm2.dimension()
11

sage.interfaces.kenzo.SChainComplex(kchaincomplex, start=0, end=15)
Convert the KenzoChainComplex kchcm (between dimensions start and end) to a ChainComplex.

INPUT:

• kchaincomplex – A KenzoChainComplex
• start – An integer number (default: 0)
• end – An integer number greater than or equal to start (default: 15)

OUTPUT:

• A ChainComplex

EXAMPLES:

sage: from sage.interfaces.kenzo import KChainComplex, SChainComplex # optional...
← kenzo
sage: m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
sage: m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
sage: m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])
sage: sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1) # optional...
← kenzo
sage: SChainComplex(KChainComplex(sage_chcm)) == sage_chcm # optional...
← kenzo
True

>>> from sage.all import *
>>> from sage.libs.ecl import EclObject, ecl_eval
>>> from sage.interfaces.kenzo import (...: KenzoObject, SAbstractSimplex)
>>> KAbSm = KenzoObject(ecl_eval("(ABSM 15 'K')"))
>>> SAbSm1 = SAbstractSimplex(KAbSm, Integer(2))
>>> SAbSm2 = SAbstractSimplex(KAbSm, Integer(7))
>>> SAbSm1.degeneracies()
[3, 2, 1, 0]
>>> SAbSm1.dimension()
6
>>> SAbSm2.dimension()
11

sage.interfaces.kenzo.SChainComplex(kchaincomplex, start=0, end=15)
Convert the KenzoChainComplex kchcm (between dimensions start and end) to a ChainComplex.

INPUT:

• kchaincomplex – A KenzoChainComplex
• start – An integer number (default: 0)
• end – An integer number greater than or equal to start (default: 15)

OUTPUT:

• A ChainComplex

EXAMPLES:

sage: from sage.interfaces.kenzo import KChainComplex, SChainComplex # optional...
← kenzo
sage: m1 = matrix(ZZ, 3, 2, [-1, 1, 3, -4, 5, 6])
sage: m4 = matrix(ZZ, 2, 2, [1, 2, 3, 6])
sage: m5 = matrix(ZZ, 2, 3, [2, 2, 2, -1, -1, -1])
sage: sage_chcm = ChainComplex({1: m1, 4: m4, 5: m5}, degree = -1) # optional...
← kenzo
sage: SChainComplex(KChainComplex(sage_chcm)) == sage_chcm # optional...
← kenzo
True

>>> from sage.all import *
>>> from sage.interfaces.kenzo import KChainComplex, SChainComplex # optional ...
(continues on next page)
\begin{verbatim}
\texttt{kenzo}
>>> m1 = matrix(ZZ, Integer(3), Integer(2), [-Integer(1), Integer(1), Integer(3),
   -Integer(4), Integer(5), Integer(6)])
>>> m4 = matrix(ZZ, Integer(2), Integer(2), [Integer(1), Integer(2), Integer(3),
   Integer(6)])
>>> m5 = matrix(ZZ, Integer(2), Integer(3), [Integer(2), Integer(2), Integer(2),
   -Integer(1), -Integer(1), -Integer(1)])
>>> sage_chcm = ChainComplex({Integer(1): m1, Integer(4): m4, Integer(5): m5},
   degree = -Integer(1))
# optional - kenzo
>>> SChainComplex(KChainComplex(sage_chcm)) == sage_chcm                      # optional - kenzo
True

sage: from sage.interfaces.kenzo import SChainComplex, Sphere
sage: S4 = Sphere(4)
sage: C = SChainComplex(S4)
sage: C
Chain complex with at most 3 nonzero terms over Integer Ring
sage: C._ascii_art_()
0 <-- C_4 <-- 0 ... 0 <-- C_0 <-- 0
sage: [C.homology(i) for i in range(6)]
[Z, 0, 0, 0, Z, 0]

\texttt{from sage.all import *}
\texttt{from sage.interfaces.kenzo import SChainComplex, Sphere}
\texttt{S4 = Sphere(Integer(4))}
\texttt{C = SChainComplex(S4)}
\texttt{C}
Chain complex with at most 3 nonzero terms over Integer Ring
\texttt{C._ascii_art_()}
0 <-- C_4 <-- 0 ... 0 <-- C_0 <-- 0
\texttt{[C.homology(i) for i in range(Integer(6))]}
[Z, 0, 0, 0, Z, 0]
\end{verbatim}

\texttt{sage.interfaces.kenzo.SFiniteSimplicialSet (ksimpset, limit)}

Convert the limit-skeleton of a finite simplicial set in Kenzo to a finite SimplicialSet in Sage.

INPUT:

- \texttt{ksimpset} – A finite simplicial set in Kenzo.
- \texttt{limit} – A natural number.

OUTPUT:

- A finite SimplicialSet.

EXAMPLES:

\begin{verbatim}
\texttt{sage: from sage.topology.simplicial_set import SimplicialSet}
\texttt{sage: from sage.interfaces.kenzo import (}
\texttt{....: AbstractSimplex, KFiniteSimplicialSet,
\texttt{....: SFiniteSimplicialSet, Sphere)}
\texttt{sage: s0 = AbstractSimplex(0, name='s0')}
\texttt{sage: s1 = AbstractSimplex(0, name='s1')}
\end{verbatim}
sage: s2 = AbstractSimplex(0, name='s2')
sage: s01 = AbstractSimplex(1, name='s01')
sage: s02 = AbstractSimplex(1, name='s02')
sage: s12 = AbstractSimplex(1, name='s12')
sage: s012 = AbstractSimplex(2, name='s012')
sage: Triangle = SimplicialSet({s01: (s1, s0),
...:             s02: (s2, s0),
...:             s12: (s2, s1)},
...:             base_point = s0)
sage: KTriangle = KFiniteSimplicialSet(Triangle)
sage: STriangle = SFiniteSimplicialSet(KTriangle, 1)
sage: STriangle.homology()
{0: 0, 1: Z}
sage: S1 = simplicial_sets.Sphere(1)
sage: S3 = simplicial_sets.Sphere(3)
sage: KS1vS3 = KFiniteSimplicialSet(S1.wedge(S3))
sage: SS1vS3 = SFiniteSimplicialSet(KS1vS3, 3)
sage: SS1vS3.homology()
{0: 0, 1: Z, 2: 0, 3: Z}

>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.topology.simplicial_set import SimplicialSet
>>> from sage.interfaces.kenzo import (...AbstractSimplex, KFiniteSimplicialSet,
...SFiniteSimplicialSet, Sphere)
>>> s0 = AbstractSimplex(Integer(0), name='s0')
>>> s1 = AbstractSimplex(Integer(0), name='s1')
>>> s2 = AbstractSimplex(Integer(0), name='s2')
>>> s01 = AbstractSimplex(Integer(1), name='s01')
>>> s02 = AbstractSimplex(Integer(1), name='s02')
>>> s12 = AbstractSimplex(Integer(1), name='s12')
>>> s012 = AbstractSimplex(Integer(2), name='s012')
>>> Triangle = SimplicialSet({s01: (s1, s0),
...:             s02: (s2, s0),
...:             s12: (s2, s1)},
...:             base_point = s0)
>>> KTriangle = KFiniteSimplicialSet(Triangle)
>>> STriangle = SFiniteSimplicialSet(KTriangle, Integer(1))
>>> STriangle.homology()
{0: 0, 1: Z}
>>> S1 = simplicial_sets.Sphere(Integer(1))
>>> S3 = simplicial_sets.Sphere(Integer(3))
>>> KS1vS3 = KFiniteSimplicialSet(S1.wedge(S3))
>>> SS1vS3 = SFiniteSimplicialSet(KS1vS3, Integer(3))
>>> SS1vS3.homology()
{0: 0, 1: Z, 2: 0, 3: Z}

sage.interfaces.kenzo.Sphere(n)

Return the n dimensional sphere as a Kenzo simplicial set.

INPUT:

- n - the dimension of the sphere

OUTPUT:

- A KenzoSimplicialSet
EXAMPLES:

```
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import Sphere
sage: s2 = Sphere(2)
sage: s2
[K1 Simplicial-Set]
sage: [s2.homology(i) for i in range(8)]
[Z, 0, Z, 0, 0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> # optional - kenzo
>>> from sage.interfaces.kenzo import Sphere
>>> s2 = Sphere(Integer(2))
>>> s2
[K1 Simplicial-Set]
>>> [s2.homology(i) for i in range(Integer(8))]
[Z, 0, Z, 0, 0, 0, 0, 0]
```

`sage.interfaces.kenzo.build_morphism(source_complex, target_complex, degree, algorithm, strategy, orgn)`

Build a morphism of chain complexes by means of the corresponding build-mrph Kenzo function.

**INPUT:**

- `source_complex` – The source object as a KenzoChainComplex instance
- `target_complex` – The target object as a KenzoChainComplex instance
- `degree` – An integer number representing the degree of the morphism
- `algorithm` – A Lisp function defining the mapping (intrinsic slot in Kenzo)
- `strategy` – The strategy (strt slot in Kenzo), which must be one of the two strings `gnrt` or `cmbn`, depending if the `algorithm` (a Lisp function) uses as arguments a degree and a generator or a combination, respectively.
- `orgn` – A list containing a description about the origin of the morphism

**OUTPUT:**

- A `KenzoChainComplexMorphism`

**EXAMPLES:**

```
sage: # optional - kenzo
sage: from sage.interfaces.kenzo import (KenzoChainComplex,
....:                                       build_morphism)
....:
sage: from sage.libs.ecl import ecl_eval
sage: ZCC = KenzoChainComplex(ecl_eval("(z-chcm)"))
....:
sage: A = build_morphism(
....:     ZCC, ZCC, -1,
....:     ecl_eval("#'(lambda (comb) (cmbn (- (degr comb))))"),
....:     "cmbn", "zero morphism on ZCC")
....:
sage: A.target_complex()
[K1 Chain-Complex]
sage: A.degree()
-1
sage: type(A)
<class 'sage.interfaces.kenzo.KenzoChainComplexMorphism'>
```
sage.interfaces.kenzo.k2s_matrix (kmatrix)

Convert an array of ECL to a matrix of Sage.

INPUT:

- kmatrix — An array in ECL

EXAMPLES:

```python
sage: from sage.interfaces.kenzo import k2s_matrix  # optional - kenzo
dsage: M = EclObject("#2A((1 2 3) (3 2 1) (1 1 1))")
dsage: k2s_matrix(M)  # optional - kenzo
[1 2 3]
[3 2 1]
[1 1 1]
```

sage.interfaces.kenzo.morphism_dictmat (morphism)

Computes a list of matrices in ECL associated to a morphism in Sage.

INPUT:

- morphism — A morphism of chain complexes

OUTPUT:

- A EclObject

EXAMPLES:

```python
sage: from sage.interfaces.kenzo import morphism_dictmat  # optional - kenzo
dsage: X = simplicial_complexes.Simplex(1)
dsage: Y = simplicial_complexes.Simplex(0)
```
sage: g = Hom(X,Y)({0:0, 1:0})
sage: f = g.associated_chain_complex_morphism()
sage: morphism_dictmat(f)   # optional - kenzo
<ECL: ((2 . #2A()) (1 . #2A()) (0 . #2A((1 1)))))>

>>> from sage.all import *
>>> from sage.interfaces.kenzo import morphism_dictmat   # optional - kenzo
>>> X = simplicial_complexes.Simplex(Integer(1))
>>> Y = simplicial_complexes.Simplex(Integer(0))
>>> g = Hom(X,Y)((Integer(0):Integer(0), Integer(1):Integer(0)))
>>> f = g.associated_chain_complex_morphism()
>>> morphism_dictmat(f)   # optional - kenzo
<ECL: ((2 . #2A()) (1 . #2A()) (0 . #2A((1 1)))))>

sage.interfaces.kenzo.pairing(slist)

Convert a list of Sage (which has an even length) to an assoc list in ECL.

INPUT:

* slist – A list in Sage

OUTPUT:

* A EclObject

EXAMPLES:

sage: from sage.interfaces.kenzo import pairing   # optional - kenzo
sage: l = [1,2,3]

sage: pairing(l)   # optional - kenzo
<ECL: ((2 . 3))>

sage: from sage.all import *
>>> from sage.interfaces.kenzo import pairing   # optional - kenzo
>>> l = [Integer(1),Integer(2),Integer(3)]

sage: pairing(l)   # optional - kenzo
<ECL: ((2 . 3))>

sage.interfaces.kenzo.s2k_dictmat(sdictmat)

Convert a dictionary in Sage, whose values are matrices, to an assoc list in ECL.

INPUT:

* sdictmat – A dictionary in Sage

OUTPUT:

* A EclObject

EXAMPLES:

sage: from sage.interfaces.kenzo import s2k_dictmat   # optional - kenzo
sage: A = Matrix([[1,2,3],[3,2,1],[1,1,1]])
sage: B = Matrix([[1,2],[2,1],[1,1]])
sage: d = {1 : A, 2 : B}

sage: s2k_dictmat(d)   # optional - kenzo
<ECL: ((2 . #2A((1 2) (2 1) (1 1))) (1 . #2A((1 2 3) (3 2 1) (1 1 1)))))>
```python
>>> from sage.all import *
>>> from sage.interfaces.kenzo import s2k_dictmat  # optional - kenzo
>>> A = Matrix([[Integer(1), Integer(2), Integer(3)],
              [Integer(3), Integer(2), Integer(1)],
              [Integer(1), Integer(1), Integer(1)]])
>>> B = Matrix([[Integer(1), Integer(2)], [Integer(2), Integer(1)],
              [Integer(1), Integer(1)]]))
>>> d = {Integer(1) : A, Integer(2) : B}
>>> s2k_dictmat(d)  # optional - kenzo
<ECL: ((2 . #2A((1 2) (2 1) (1 1))) (1 . #2A((1 2 3) (3 2 1) (1 1 1))))>
```

**sage.interfaces.kenzo.s2k_listofmorphisms(l)**

Computes a list of morphisms of chain complexes in Kenzo from a list of morphisms in Sage.

**INPUT:**
- `l` – A list of morphisms of chain complexes

**OUTPUT:**
- An `EclObject`

**EXAMPLES:**
```
sage: from sage.interfaces.kenzo import s2k_listofmorphisms  # optional - kenzo
sage: C1 = ChainComplex({1: matrix(ZZ, 0, 2, [])}, degree_of_differential=-1)
sage: C2 = ChainComplex({1: matrix(ZZ, 1, 2, [1, 0]), degree_of_differential=-1})
sage: C3 = ChainComplex({0: matrix(ZZ, 2, 2, [1, 0, 2, 0]), degree_of_differential=-1})
sage: M1 = Hom(C2,C1)({1: matrix(ZZ, 2, 2, [2, 0, 2, 2])})
sage: M2 = Hom(C3,C2)({0: matrix(ZZ, 1, 2, [2, 0])})
sage: l = [M1, M2]
sage: s2k_listofmorphisms(l)  # optional - kenzo
<ECL: ((K... Morphism (degree 0): K... -> K... [K... Morphism (degree 0): K... -> K...]))>
```

```python
>>> from sage.all import *
>>> from sage.interfaces.kenzo import s2k_listofmorphisms  # optional - kenzo
>>> C1 = ChainComplex({Integer(1): matrix(ZZ, Integer(0), Integer(2), [])},
                    degree_of_differential=-Integer(1))
>>> C2 = ChainComplex({Integer(1): matrix(ZZ, Integer(1), Integer(2), [Integer(1),
                    Integer(0)]), degree_of_differential=-Integer(1)})
>>> C3 = ChainComplex({Integer(0): matrix(ZZ, Integer(0), Integer(2), [0]), degree_-
                    of_differential=-Integer(1)})
>>> M1 = Hom(C2,C1)({Integer(1): matrix(ZZ, Integer(2), Integer(2), [Integer(2),
                    Integer(0), Integer(2), Integer(0)])}
>>> M2 = Hom(C3,C2)({Integer(0): matrix(ZZ, Integer(1), Integer(2), [Integer(2),
                    Integer(0), Integer(2), Integer(0)])}
>>> l = [M1, M2]
>>> s2k_listofmorphisms(l)  # optional - kenzo
<ECL: ([K... Morphism (degree 0): K... -> K...] [K... Morphism (degree 0): K... ->
        K...])>
```

**sage.interfaces.kenzo.s2k_matrix(smatrix)**

Convert a matrix of Sage to an array of ECL.

**INPUT:**
- `smatrix` – A matrix in Sage

**OUTPUT:**

```python
>>> from sage.all import *
>>> from sage.interfaces.kenzo import s2k_matrix  # optional - kenzo
>>> A = Matrix([[Integer(1), Integer(2), Integer(3)],
              [Integer(3), Integer(2), Integer(1)],
              [Integer(1), Integer(1), Integer(1)]])
>>> B = Matrix([[Integer(1), Integer(2)], [Integer(2), Integer(1)],
              [Integer(1), Integer(1)]]))
>>> s2k_matrix(A)  # optional - kenzo
<ECL: ((2 . #2A((1 2) (2 1) (1 1))) (1 . #2A((1 2 3) (3 2 1) (1 1 1))))>
```
• A **EclObject**

**EXAMPLES:**

```python
sage: from sage.interfaces.kenzo import s2k_matrix   # optional - kenzo
sage: A = Matrix([[1,2,3],[3,2,1],[1,1,1]])
sage: s2k_matrix(A) # optional - kenzo
<ECL: #2A((1 2 3) (3 2 1) (1 1 1))>
```

```python
>>> from sage.all import *
>>> from sage.interfaces.kenzo import s2k_matrix  # optional - kenzo
>>> A = Matrix([[Integer(1), Integer(2), Integer(3)],
              [Integer(3), Integer(2), Integer(1)],
              [Integer(1), Integer(1), Integer(1)]]
>>> s2k_matrix(A) # optional - kenzo
<ECL: #2A((1 2 3) (3 2 1) (1 1 1))>
```
sage.interfaces.latte.count (arg, ehrhart_polynomial=False, multivariate_generating_function=False, raw_output=False, verbose=False, **kwds)

Call to the program count from LattE integrale

INPUT:

• arg – a cdd or LattE description string
• ehrhart_polynomial, multivariate_generating_function – to compute Ehrhart polynomial or multivariate generating function instead of just counting points
• raw_output – if True then return directly the output string from LattE
• For all other options of the count program, consult the LattE manual

OUTPUT:

Either a string (if raw_output if set to True) or an integer (when counting points), or a polynomial (if ehrhart_polynomial is set to True) or a multivariate THING (if multivariate_generating_function is set to True)

EXAMPLES:

sage: from sage.interfaces.latte import count # optional - latte_int
sage: P = 2 * polytopes.cube()

Counting integer points from either the H or V representation:

sage: count(P.cdd_Hrepresentation(), cdd=True) # optional - latte_int
125
sage: count(P.cdd_Vrepresentation(), cdd=True) # optional - latte_int
125

Ehrhart polynomial:
Multivariate generating function currently only work with raw_output=True:

```
sage: opts = {'cdd': True,
            'multivariate_generating_function': True,
            'raw_output': True}

sage: cddin = P.cdd_Hrepresentation()

sage: print(count(cddin, **opts))
# optional - latte_int
x[0]^2*x[1]^(-2)*x[2]^(-2)/((1-x[1])* (1-x[2])* (1-x[0])^(-1))
+ x[0]^(-2)*x[1]^(-2)*x[2]^(-2)/((1-x[1])* (1-x[2])* (1-x[0]))
+ x[0]^2*x[1]^(-2)*x[2]^(-2)/((1-x[1])* (1-x[2])* (1-x[0])^(-1))
+ x[0]^(-2)*x[1]^(-2)*x[2]^(-2)/((1-x[1])* (1-x[0])* (1-x[2])^(-1))
+ x[0]^2*x[1]^(-2)*x[2]^(-2)/((1-x[2])* (1-x[1])* (1-x[0])^(-1))
+ x[0]^(-2)*x[1]^(-2)*x[2]^(-2)/((1-x[0])* (1-x[2])* (1-x[1])^(-1))
```

```
sage.interfaces.latte.integrate(arg, polynomial=None, algorithm='triangulate', raw_output=False, verbose=False, **kwds)
```

Call to the function integrate from LattE integrale.

**INPUT:**

- **arg** – a cdd or LattE description string.
- **polynomial** – multivariate polynomial or valid LattE polynomial description string. If given, the evaluation parameter of LattE is set to integrate, and is set to volume otherwise.
- **algorithm** – (default: 'triangulate') the integration method. Use 'triangulate' for polytope triangulation or 'cone-decompose' for tangent cone decomposition method.
- **raw_output** – if True then return directly the output string from LattE.
- **verbose** – if True then return directly verbose output from LattE.
- For all other options of the integrate program, consult the LattE manual.
OUTPUT:

Either a string (if raw_output if set to True) or a rational.

EXAMPLES:

```python
sage: from sage.interfaces.latte import integrate # optional - latte_int
sage: P = 2 * polytopes.cube()
sage: x, y, z = polygen(QQ, 'x, y, z')
```

Integrating over a polynomial over a polytope in either the H or V representation:

```python
sage: integrate(P.cdd_Hrepresentation(), x^2*y^2*z^2, cdd=True) # optional - latte_int
4096/27
sage: integrate(P.cdd_Vrepresentation(), x^2*y^2*z^2, cdd=True) # optional - latte_int
4096/27
```

Computing the volume of a polytope in either the H or V representation:

```python
sage: integrate(P.cdd_Hrepresentation(), cdd=True) # optional - latte_int
64
sage: integrate(P.cdd_Vrepresentation(), cdd=True) # optional - latte_int
64
```

Polynomials given as a string in LattE description are also accepted:

```python
sage: integrate(P.cdd_Hrepresentation(), '[[1,[2,2,2]]]', cdd=True) # optional - latte_int
4096/27
```

`sage.interfaces.latte.to_latte_polynomial (polynomial)`

Helper function to transform a polynomial to its LattE description.
INPUT:

• polynomial – a multivariate polynomial.

OUTPUT:

A string that describes the monomials list and exponent vectors.
LiE is a software package under development at CWI since January 1988. Its purpose is to enable mathematicians and physicists to obtain on-line information as well as to interactively perform computations of a Lie group theoretic nature. It focuses on the representation theory of complex semisimple (reductive) Lie groups and algebras, and on the structure of their Weyl groups and root systems.

Type `lie` for a list of all the functions available from your LiE install. Type `lie`? for LiE's help about a given function. Type `lie(...)` to create a new LiE object, and `lie.eval(...)` to run a string using LiE (and get the result back as a string).

To access the LiE interpreter directly, run `lie_console()`.

**EXAMPLES:**

```
sage: a4 = lie('A4')  # optional - lie
sage: lie.diagram('A4')  # optional - lie
O---O---O---O
1 2 3 4
A4

sage: lie.diagram(a4)  # optional - lie
O---O---O---O
1 2 3 4
A4

sage: a4.diagram()  # optional - lie
O---O---O---O
1 2 3 4
A4

sage: a4.Cartan()  # optional - lie
[[2, -1, 0, 0],
 [-1, 2, -1, 0],
 [0, -1, 2, -1],
 [0, 0, -1, 2]]

sage: lie.LR_tensor([3,1],[2,2])  # optional - lie
1X[5,3]
```

```python
>>> from sage.all import *
>>> a4 = lie('A4')  # optional - lie
>>> lie.diagram('A4')  # optional - lie
O---O---O---O
1 2 3 4
A4
```
20.1 Tutorial

The following examples are taken from Section 2.1 of the LiE manual.

You can perform basic arithmetic operations in LiE.

```python
sage: # optional - lie
sage: lie.eval('19+68')
'87'
sage: a = lie('1111111111*1111111111')
sage: a
1234567900987654321
sage: a/1111111111
1111111111
sage: a = lie('345')
sage: a^2+3*a-5
120055
sage: _ / 7*a
5916750
```

```python
>>> from sage.all import *
>>> # optional - lie
>>> lie.eval('19+68')
'87'
>>> a = lie('1111111111*1111111111')
>>> a
1234567900987654321
>>> a/Integer(1111111111)
1111111111
>>> a = lie('345')
>>> a**Integer(2)+Integer(3)*a-Integer(5)
120055
>>> _ / Integer(7)*a
5916750
```
Vectors in LiE are created using square brackets. Notice that the indexing in LiE is 1-based, unlike Python/Sage which is 0-based.

```sage
# optional - lie
v = lie('[[3,2,6873,-38]]')
v = [3,2,6873,-38]
v[3]
6873
v+v
[6,4,13746,-76]
v*v
47239586
v+234786
[3,2,6873,-38,234786]
v-3
[3,2,-38]
v*v
[3,2,6873,-38,3,2,6873,-38]
```

You can also work with matrices in LiE.

```sage
m = lie('[[[1,0,3,3],[12,4,-4,7],[-1,9,8,0],[3,-5,-2,9]]]') # optional - lie
m = [[ 1, 0, 3,3],
     [12, 4,-4,7],
     [-1, 9, 8,0],
     [ 3,-5,-2,9]]

print(lie.eval('**'+m._name)) # optional - lie
[[12, -1, 3],
 [0, 4, 9,-5],
 [3,-4, 8,-2],
 [3, 7, 0, 9]]
```

```sage
# optional - lie
m^3
[[ 220,  87, 81, 375],
 [168,-1089, 13,1013]]
```

You can also work with matrices in LiE.
sage: v*m
[-6960, 62055, 55061, -319]
sage: m*v
[20508, -27714, 54999, -14089]
sage: v*m*v
378549605
sage: m+v
[[ 1, 0, 3, 3],
 [12, 4, -4, 7],
 [-1, 9, 8, 0],
 [ 3,-5, -2, 9]]

>>> from sage.all import *
>>> m = lie('[[1,0,3,3],[12,4,-4,7],[-1,9,8,0],[3,-5,-2,9]]') # optional - lie
>>> m # optional - lie
[[ 1, 0, 3, 3],
 [12, 4, -4, 7],
 [-1, 9, 8, 0],
 [ 3,-5, -2, 9]]

>>> print(lie.eval('**+m._name)) # optional - lie
[[1,12,-1, 3],
 [0, 4, 9,-5],
 [3,-4, 8,-2],
 [3, 7, 0, 9]]

>>> m**Integer(3)
[[ 220, 87, 81, 375],
 [-168,-1089, 13,1013],
 [1550, -357,-55,1593],
 [-854, -652, 98,-170]]

>>> v*m
[-6960, 62055, 55061, -319]
>>> m*v
[20508, -27714, 54999, -14089]
>>> v*m*v
378549605
>>> m+v
[[ 1, 0, 3, 3],
 [12, 4, -4, 7],
 [-1, 9, 8, 0],
 [ 3,-5, -2, 9]]
LiE handles multivariate (Laurent) polynomials.

```python
sage: lie('X[1,2]')  
1X[1,2]

sage: -3*  
-3X[1,2]

sage: -3* _ + lie('4X[-1,4]')  
4X[-1,4] - 3X[1,2]

sage: _**2  
16X[-2,8] - 24X[0,6] + 9X[2,4]

sage: lie((4X[-1,4]-3X[1,2])*(X[2,0]-X[0,-4]))  
-4X[-1,0] + 3X[1,-2] + 4X[1,4] - 3X[3,2]
```

You can call LiE's built-in functions using `lie.functionname`.

```python
sage: lie.partitions(6)  
[[6,0,0,0,0,0], [5,1,0,0,0,0], [4,2,0,0,0,0], [4,1,1,0,0,0], [3,3,0,0,0,0], [3,2,1,0,0,0], [3,1,1,1,0,0], [2,2,2,0,0,0], [2,2,1,1,0,0], [2,1,1,1,1,0], [1,1,1,1,1,1]]

sage: lie.diagram('E8')  
```

(continues on next page)
You can define your own functions in LiE using lie.eval. Once you’ve defined a function (say f), you can call it using lie.f; however, user-defined functions do not show up when using tab-completion.

```python
sage: # optional - lie
sage: lie.eval('f(int x) = 2*x')

sage: lie.f(984)
1968
sage: lie.eval('f(int n) = a=3*n-7; if a < 0 then a = -a fi; 7^a+a^3-4*a-57')

sage: lie.f(2)
-53
sage: lie.f(5)
5765224
```

```python
>>> from sage.all import *

>>> lie.partitions(Integer(6)) # optional - lie
[[6, 0, 0, 0, 0, 0],
 [5, 1, 0, 0, 0, 0],
 [4, 2, 0, 0, 0, 0],
 [4, 1, 1, 0, 0, 0],
 [3, 3, 0, 0, 0, 0],
 [3, 2, 1, 0, 0, 0],
 [3, 1, 1, 1, 0, 0],
 [2, 2, 2, 0, 0, 0],
 [2, 2, 1, 1, 0, 0],
 [2, 1, 1, 1, 1, 0],
 [1, 1, 1, 1, 1, 1],
]

>>> lie.diagram('E8') # optional - lie

O 2
| |
O---O---O---O---O---O---O
1 3 4 5 6 7 8
E8
```

```python
>>> from sage.all import *

>>> lie.partitions(Integer(6)) # optional - lie
[[6, 0, 0, 0, 0, 0],
 [5, 1, 0, 0, 0, 0],
 [4, 2, 0, 0, 0, 0],
 [4, 1, 1, 0, 0, 0],
 [3, 3, 0, 0, 0, 0],
 [3, 2, 1, 0, 0, 0],
 [3, 1, 1, 1, 0, 0],
 [2, 2, 2, 0, 0, 0],
 [2, 2, 1, 1, 0, 0],
 [2, 1, 1, 1, 1, 0],
 [1, 1, 1, 1, 1, 1],
]

>>> lie.diagram('E8') # optional - lie

O 2
| |
O---O---O---O---O---O---O
1 3 4 5 6 7 8
E8
```

```python
>>> from sage.all import *

>>> lie.partitions(Integer(6)) # optional - lie
[[6, 0, 0, 0, 0, 0],
 [5, 1, 0, 0, 0, 0],
 [4, 2, 0, 0, 0, 0],
 [4, 1, 1, 0, 0, 0],
 [3, 3, 0, 0, 0, 0],
 [3, 2, 1, 0, 0, 0],
 [3, 1, 1, 1, 0, 0],
 [2, 2, 2, 0, 0, 0],
 [2, 2, 1, 1, 0, 0],
 [2, 1, 1, 1, 1, 0],
 [1, 1, 1, 1, 1, 1],
]

>>> lie.diagram('E8') # optional - lie

O 2
| |
O---O---O---O---O---O---O
1 3 4 5 6 7 8
E8
```
LiE's help can be accessed through `lie.help('functionname')` where functionname is the function you want to receive help for.

```python
sage: print(lie.help('diagram'))  # optional - lie
diagram(g). Prints the Dynkin diagram of g, also indicating
    the type of each simple component printed, and labeling the nodes as
done by Bourbaki (for the second and further simple components the
labels are given an offset so as to make them disjoint from earlier
labels). The labeling of the vertices of the Dynkin diagram prescribes
the order of the coordinates of root- and weight vectors used in LiE.
```

This can also be accessed with `lie.functionname?`.

With the exception of groups, all LiE data types can be converted into native Sage data types by calling the `.sage()` method.

Integers:

```python
sage: a = lie(1234)  # optional - lie
sage: b = a.sage(); b  # optional - lie
1234
sage: type(b)  # optional - lie
<class 'sage.rings.integer.Integer'>
```

Vectors:

```python
sage: a = lie([1,2,3])  # optional - lie
sage: b = a.sage(); b  # optional - lie
[1, 2, 3]
sage: type(b)  # optional - lie
<... 'list'>
```

Matrices:
**Interpreter Interfaces, Release 10.4**

```python
sage: a = lie('[[1,2],[3,4]]') # optional - lie
sage: b = a.sage(); b # optional - lie
[1 2]
[3 4]
sage: type(b) # optional - lie
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>
```

```python
>>> from sage.all import *
>>> a = lie('[[1,2],[3,4]]') # optional - lie
>>> b = a.sage(); b # optional - lie
[1 2]
[3 4]
>>> type(b) # optional - lie
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>
```

**Polynomials:**

```python
sage: a = lie('X[1,2] - 2*X[2,1]') # optional - lie
sage: b = a.sage(); b # optional - lie
-2*x0^2*x1 + x0*x1^2
sage: type(b) # optional - lie
<class 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>
```

```python
>>> from sage.all import *
>>> a = lie('X[1,2] - 2*X[2,1]') # optional - lie
>>> b = a.sage(); b # optional - lie
-2*x0^2*x1 + x0*x1^2
>>> type(b) # optional - lie
<class 'sage.rings.polynomial.multi_polynomial_libsingular.MPolynomial_libsingular'>
```

**Text:**

```python
sage: a = lie('"text"') # optional - lie
sage: b = a.sage(); b # optional - lie
'text'
sage: type(b) # optional - lie
<... 'str'>
```

```python
>>> from sage.all import *
>>> a = lie('"text"') # optional - lie
>>> b = a.sage(); b # optional - lie
'text'
>>> type(b) # optional - lie
<... 'str'>
```

LiE can be programmed using the Sage interface as well. Section 5.1.5 of the manual gives an example of a function written in LiE's language which evaluates a polynomial at a point. Below is a (roughly) direct translation of that program into Python / Sage.

```python
sage: # optional - lie
sage: def eval_pol(p, pt):
...     s = 0
...     for i in range(1,p.length().sage()+1):
...         m = 1
...         for j in range(1,pt.size().sage()+1):
...             m *= pt[j]^p.expon(i)[j]
...         s += m
...     return s
```

(continues on next page)
AUTHORS:

- Mike Hansen 2007-08-27
- William Stein (template)

```python
>>> from sage.all import *
>>> # optional - lie
>>> def eval_pol(p, pt):
...     s = Integer(0)
...     for i in range(Integer(1),p.length().sage()+Integer(1)):
...         m = Integer(1)
...         for j in range(Integer(1),pt.size().sage()+Integer(1)):
...             m *= pt[j]**p.expon(i)[j]
...         s += p.coef(i)*m
...     return s
>>> a = lie('X[1,2]')
>>> b1 = lie('X[1,2]')
>>> b2 = lie('X[2,3]')
>>> eval_pol(a, b1)
4
>>> eval_pol(a, b2)
18
```
eval \((\text{code, strip=}True, **\text{kwds})\)

**EXAMPLES:**

```python
sage: lie.eval('2+2')  # optional - lie
'4'

>>> from sage.all import *
>>> lie.eval('2+2')  # optional - lie
'4'
```

function_call \((\text{function, args=}None, \text{kwds=}None)\)

**EXAMPLES:**

```python
sage: lie.function_call("diagram", args=['A4'])  # optional - lie
O---O---O---O
1 2 3 4
A4

>>> from sage.all import *
>>> lie.function_call("diagram", args=['A4'])  # optional - lie
O---O---O---O
1 2 3 4
A4
```

get \((\text{var})\)

Get the value of the variable var.

**EXAMPLES:**

```python
sage: lie.set('x', '2')  # optional - lie
sage: lie.get('x')  # optional - lie
'2'

>>> from sage.all import *
>>> lie.set('x', '2')  # optional - lie
>>> lie.get('x')  # optional - lie
'2'
```

get_using_file \((\text{var})\)

**EXAMPLES:**

```python
sage: lie.get_using_file('x')
Traceback (most recent call last):
... Not Implemented Error

>>> from sage.all import *
>>> lie.get_using_file('x')
Traceback (most recent call last):
... Not Implemented Error
```
**help**(command)

Return a string of the LiE help for `command`.

**EXAMPLES:**

```python
sage: lie.help('diagram') # optional - lie
diagram(g)...
```

```python
>>> from sage.all import *
>>> lie.help('diagram') # optional - lie
diagram(g)...
```

**read**(filename)

**EXAMPLES:**

```python
sage: filename = tmp_filename()
sage: with open(filename, 'w') as f:
    _ = f.write('x = 2
')
sage: lie.read(filename) # optional - lie
sage: lie.get('x') # optional - lie
2
sage: import os
sage: os.unlink(filename)
```

```python
>>> from sage.all import *
>>> filename = tmp_filename()
>>> with open(filename, 'w') as f:
    ... = f.write('x = 2
')
>>> lie.read(filename) # optional - lie
>>> lie.get('x') # optional - lie
2
>>> import os
>>> os.unlink(filename)
```

**set**(var, value)

Set the variable `var` to the given value.

**EXAMPLES:**

```python
sage: lie.set('x', '2') # optional - lie
sage: lie.get('x') # optional - lie
'2'
```

```python
>>> from sage.all import *
>>> lie.set('x', '2') # optional - lie
>>> lie.get('x') # optional - lie
'2'
```

**version()**

**EXAMPLES:**

```python
sage: lie.version() # optional - lie
'2.2'
```
Interpreter Interfaces, Release 10.4

```
>>> from sage.all import *
>>> lie.version() # optional - lie
'2.2'
```

class sage.interfaces.lie.LiEEElement (parent, value, is_name=False, name=None)

Bases: ExtraTabCompletion, ExpectElement

\texttt{type()} \hspace{1cm} \textbf{EXAMPLES:}

```
sage: m = lie('[[1,0,3,3],[12,4,-4,7],[-1,9,8,0],[3,-5,-2,9]]') # optional - lie
sage: m.type() # optional - lie
'mat'
```

class sage.interfaces.lie.LiEFunct(\texttt{on}, \texttt{name})

Bases: ExpectFunction

class sage.interfaces.lie.LiEFunctE(\texttt{obj}, \texttt{name})

Bases: FunctionElement

```
sage.interfaces.lie.is_LiEEElement (x)

\textbf{EXAMPLES:}

```
sage: from sage.interfaces.lie import is_LiEEElement
sage: is_LiEEElement(2)
False
sage: l = lie(2)
# optional - lie
sage: is_LiEEElement(l)
# optional - lie
True
```

```
>>> from sage.all import *
>>> from sage.interfaces.lie import is_LiEEElement
>>> is_LiEEElement(Integer(2))
deprecation warning: the function is_LiEEElement is deprecated; use...
    isinstance(x, sage.interfaces.abc.LiEEElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
False
>>> l = lie(Integer(2))
# optional - lie
>>> is_LiEEElement(l)
# optional - lie
True
```

```
sage.interfaces.lie.lie_console()

Spawn a new LiE command-line session.

\textbf{EXAMPLES:}
```
sage: from sage.interfaces.lie import lie_console
sage: lie_console()
# not tested
LiE version 2.2.2 created on Sep 26 2007 at 18:13:19
Authors: Arjeh M. Cohen, Marc van Leeuwen, Bert Lisser.
Free source code distribution
...

>>> from sage.all import *
>>> from sage.interfaces.lie import lie_console
>>> lie_console()
# not tested
LiE version 2.2.2 created on Sep 26 2007 at 18:13:19
Authors: Arjeh M. Cohen, Marc van Leeuwen, Bert Lisser.
Free source code distribution
...

sage.interfaces.lie.lie_version()

EXAMPLES:

sage: from sage.interfaces.lie import lie_version
sage: lie_version() # optional - lie '2.2'

>>> from sage.all import *
>>> from sage.interfaces.lie import lie_version
>>> lie_version() # optional - lie '2.2'

sage.interfaces.lie.reduce_load_lie()

EXAMPLES:

sage: from sage.interfaces.lie import reduce_load_lie
sage: reduce_load_lie()
LiE Interpreter

>>> from sage.all import *
>>> from sage.interfaces.lie import reduce_load_lie
>>> reduce_load_lie()
LiE Interpreter
EXAMPLES:

```python
sage: lisp.eval('* 4 5')
'20'
sage: a = lisp(3); b = lisp(5)
sage: a + b
8
sage: a * b
15
sage: a / b
3/5
sage: a - b
-2
sage: a.sin()
0.14112
sage: b.cos()
0.2836622
sage: a.exp()
20.085537
sage: lisp.eval(('+' %s %s)%(a.name(), b.name()))
'8'
```

```python
>>> from sage.all import *
>>> lisp.eval('* 4 5')
'20'
>>> a = lisp(Integer(3)); b = lisp(Integer(5))
>>> a + b
8
>>> a * b
15
>>> a / b
3/5
>>> a - b
-2
>>> a.sin()
0.14112
>>> b.cos()
0.2836622
>>> a.exp()
20.085537
>>> lisp.eval(('+' %s %s)%(a.name(), b.name()))
'8'
```

One can define functions and the interface supports object-oriented notation for calling them:
Interpreter Interfaces, Release 10.4

```python
sage: lisp.eval('(defun factorial (n) (if (= n 1) 1 (* n (factorial (- n 1)))))')
'FACTORIAL'
sage: lisp('(factorial 10)')
3628800
sage: lisp(10).factorial()
3628800
sage: a = lisp(17)
sage: a.factorial()
355687428096000
```

AUTHORS:

class `sage.interfaces.lisp.Lisp`:

```python
sage: lisp == loads(dumps(lisp))
True
```

call method `console()`

Spawn a new Lisp command-line session.

```python
sage: lisp.console()  #not tested

(continues on next page)
eval \((\text{code, strip=} \text{True, **kwds})\)

EXAMPLES:

```sage
lisp.eval('(+ 2 2)')
'4'
```

```sage
from sage.all import *
>>> lisp.eval('(+ 2 2)')
'4'
```

function_call \((\text{function, args=} \text{None, kwds=} \text{None})\)

Calls the Lisp function with given args and kwds. For Lisp functions, the kwds are ignored.

EXAMPLES:

```sage
lisp.function_call('sin', [2])
0.9092974
```

```sage
lisp.sin(2)
0.9092974
```

```sage
from sage.all import *

```

help \((\text{command})\)

EXAMPLES:

```sage
lisp.help('setq')
Traceback (most recent call last):
...
NotImplementedError
```
Interpreter Interfaces, Release 10.4

```python
>>> from sage.all import *
>>> lisp.help('setq')
Traceback (most recent call last):
  ...  
NotImplementedError
```

**kill** *(var)*

EXAMPLES:

```python
sage: lisp.kill('x')
Traceback (most recent call last):
  ...  
NotImplementedError
```

**set** *(var, value)*

Set the variable var to the given value.

EXAMPLES:

```python
sage: lisp.set('x', '2')
sage: lisp.get('x')
'2'
```

**version()**

Returns the version of Lisp being used.

EXAMPLES:

```python
sage: lisp.version()
'Version information is given by lisp.console().'
```

```text
class sage.interfaces.lisp.LispElement (parent, value, is_name=False, name=None)

CHAPTER TWENTYTWO

INTERFACE TO MACAULAY2

Note: You must have Macaulay2 installed on your computer for this interface to work. Macaulay2 is not included with Sage, but you can obtain it from https://macaulay2.com/. No additional optional Sage packages are required.

Sage provides an interface to the Macaulay2 computational algebra system. This system provides extensive functionality for commutative algebra. You do not have to install any optional packages.

The Macaulay2 interface offers three pieces of functionality:

- `macaulay2_console()` – A function that dumps you into an interactive command-line Macaulay2 session.
- `macaulay2.eval(expr)` – Evaluation of arbitrary Macaulay2 expressions, with the result returned as a string.
- `macaulay2(expr)` – Creation of a Sage object that wraps a Macaulay2 object. This provides a Pythonic interface to Macaulay2. For example, if \( f = \text{macaulay2}(10) \), then \( f.gcd(25) \) returns the GCD of 10 and 25 computed using Macaulay2.

EXAMPLES:

```
sage: # optional - macaulay2
sage: macaulay2('3/5 + 7/11')
68
--
55
sage: f = macaulay2('f = i -> i^3')
sage: f
f
sage: f(5)
125
```

```
sage: # optional - macaulay2
sage: R = macaulay2('ZZ/5[x,y,z]')
sage: R
ZZ
--[x...z] 5
sage: x = macaulay2('x')
sage: y = macaulay2('y')
sage: (x+y)^5
5
5
x + y
sage: parent((x+y)^5)
Macaulay2
```
The name of the variable to which a Macaulay2 element is assigned internally can be passed as an argument. This is useful for types like polynomial rings which acquire that name in Macaulay2:

```python
sage: R = macaulay2('QQ[x,y,z,w]', 'R')
sage: R

sage: f = macaulay2('x^4 + 2*x*y^3 + x*y*z*w + x*y*z*w^2' + 2*x*z*w^2 + y^4 + y^3*w + 2*y^2*z*w + z^4 + w^4')
sage: f

sage: g = f * macaulay2('x+y^5')
sage: print(g.factor())

(continues on next page)
```
Use `eval()` for explicit control over what is sent to the interpreter. The argument is evaluated in Macaulay2 as is:

```
>>> from sage.all import *
```

```
sage: # optional - macaulay2
sage: macaulay2.eval('compactMatrixForm')
true
>>> macaulay2.eval('compactMatrixForm = false;')
true
>>> macaulay2.eval('matrix {{1, x^2+y}}')
| 2 |
| 1 x + y |
1 2
Matrix R <--- R
```

AUTHORS:

- Kiran Kedlaya and David Roe (2006-02-05, during Sage coding sprint)
- Kiran Kedlaya (2006-02-12): added ring and ideal constructors, list delimiters, is_Macaulay2Element, `sage_polystring`, `__floordiv__`, `__mod__`, `__iter__`, `__len__`; stripped extra leading space and trailing newline from output.

Todo: Get rid of all numbers in output, e.g., in ideal function below.

```python
class sage.interfaces.macaulay2.Macaulay2(maxread=None, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, command=None):
    Bases: ExtraTabCompletion, Expect

    Interface to the Macaulay2 interpreter.
```
clear(\texttt{var})

Clear the variable named \texttt{var}.

The interface automatically clears Macaulay2 elements when they fall out of use, so calling this method is usually not necessary.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: # optional - macaulay2
sage: macaulay2.eval('R = QQ[x,y];')
PolynomialRing
sage: macaulay2.eval('net class R')
Symbol
sage: macaulay2.clear('R')
sage: macaulay2.eval('net class R')
Symbol
\end{verbatim}

\textbf{console()}

Spawn a new M2 command-line session.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: macaulay2.console()   # not tested
Macaulay 2, version 1.1
with packages: Classic, Core, Elimination, IntegralClosure, LLLBases, Parsing, PrimaryDecomposition, SchurRings, TangentCone...
...\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> # optional - macaulay2
>>> macaulay2.eval('R = QQ[x,y];')
PolynomialRing
>>> macaulay2.clear('R')
>>> macaulay2.eval('R')
Symbol
\end{verbatim}

\textbf{cputime}(\texttt{t=\textit{None}})

\textbf{EXAMPLES:}

\begin{verbatim}
sage: # optional - macaulay2
sage: R = macaulay2("QQ[x,y]")
sage: x,y = R.gens()
sage: a = (x+y+1)^20
sage: macaulay2.cputime()      # random
0.4839370000000001
>>> from sage.all import *
>>> # optional - macaulay2
>>> R = macaulay2("QQ[x,y]")
>>> x,y = R.gens()
\end{verbatim}
Interpreter Interfaces, Release 10.4

>>> a = (x+y+Integer(1))**Integer(20)
>>> macaulay2.cputime()  # random
0.4839370000000001

**eval** (*code*, *strip=True*, **kwds*)

Send the code `x` to the Macaulay2 interpreter and return the output as a string suitable for input back into Macaulay2, if possible.

**INPUT:**
- `code` – str
- `strip` – ignored

**EXAMPLES:**

```python
sage: macaulay2.eval("2+2")  # optional - macaulay2
4
```

```python
>>> from sage.all import *
>>> macaulay2.eval("2+2")  # optional - macaulay2
4
```

**get** (*var*)

Get the value of the variable `var`.

**INPUT:**
- `var` – string; the name of the variable in Macaulay2

**OUTPUT:** a string of the textual representation of the variable in Macaulay2

**EXAMPLES:**

```python
sage: macaulay2.set("a", "2")  # optional - macaulay2
sage: macaulay2.get("a")  # optional - macaulay2
2
```

```python
>>> from sage.all import *
>>> macaulay2.set("a", "2")  # optional - macaulay2
>>> macaulay2.get("a")  # optional - macaulay2
2
```

Note that the following syntax is used to obtain a `Macaulay2Element` instead:

```python
sage: a = macaulay2('2'); a  # optional - macaulay2
2
sage: type(a)  # optional - macaulay2
<class 'sage.interfaces.macaulay2.Macaulay2Element'>
```

```python
>>> from sage.all import *
>>> a = macaulay2('2'); a  # optional - macaulay2
>>> type(a)  # optional - macaulay2
<class 'sage.interfaces.macaulay2.Macaulay2Element'>
```

**help** (*s*)

**EXAMPLES:**
ideal (*gens*)

Return the ideal generated by gens.

INPUT:

- *gens* – list or tuple of Macaulay2 objects (or objects that can be made into Macaulay2 objects via evaluation)

OUTPUT:

the Macaulay2 ideal generated by the given list of gens

EXAMPLES:
new_from\样的

Return a new Macaulay2Element of type \texttt{type} constructed from \texttt{value}.

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: l = macaulay2.new_from("MutableList", [1,2,3])  # optional - macaulay2
  sage: l
  # optional - macaulay2
  MutableList{...3...}
  sage: list(l)  # optional - macaulay2
  [1, 2, 3]

  >>> from sage.all import *
  >>> l = macaulay2.new_from("MutableList", [Integer(1),Integer(2),Integer(3)])
  # optional - macaulay2
  >>> l
  # optional - macaulay2
  MutableList{...3...}
  >>> list(l)  # optional - macaulay2
  [1, 2, 3]
\end{verbatim}

\textbf{options = Current options for Macaulay2 - after_print: False}

\textbf{restart()}

Restart Macaulay2 interpreter.

\textbf{ring (base\_ring='ZZ', vars='[x]', order='Lex')}

Create a Macaulay2 polynomial ring.

\textbf{INPUT:}

- \texttt{base\_ring} – base ring (see examples below)
- \texttt{vars} – a tuple or string that defines the variable names
- \texttt{order} – string (default: ‘Lex’); the monomial order

\textbf{OUTPUT:} a Macaulay2 ring

\textbf{EXAMPLES:}

This is a ring in variables named \texttt{a} through \texttt{d} over the finite field of order 7, with graded reverse lex ordering:

\begin{verbatim}
  sage: R1 = macaulay2.ring(ZZ/7, [a..d], GRevLex)  # optional - macaulay2
  sage: R1.describe()  # optional - macaulay2
  ZZ
  --[a..d, Degrees => {4:1}, Heft => {1}, MonomialOrder => {MonomialSize => 16},
     7 {GRevLex => {4:1} } ]
     {Position => Up }
  --
  DegreeRank => 1]
  sage: R1.char()  # optional - macaulay2
  7
\end{verbatim}
Interpreter Interfaces, Release 10.4

```python
>>> from sage.all import *
>>> R1 = macaulay2.ring("ZZ/7", [a..d], 'GRevLex')  # optional - macaulay2
>>> R1.describe()  # optional - macaulay2
ZZ
--[a..d, Degrees => {4:1}, Heft => {1}, MonomialOrder => {MonomialSize => 16},
  {GRevLex => {4:1} }
  {Position => Up }]

# optional - macaulay2
>>> R1.char()  # optional - macaulay2
7
```

This is a polynomial ring over the rational numbers:

```python
sage: R2 = macaulay2.ring('QQ', [x, y])  # optional - macaulay2
sage: R2.describe()  # optional - macaulay2
QQ[x..y, Degrees => {2:1}, Heft => {1}, MonomialOrder => {MonomialSize => 16},
  {Lex => 2 }
  {Position => Up }]

# optional - macaulay2
>>> from sage.all import *
>>> R2 = macaulay2.ring('QQ', [x, y])  # optional - macaulay2
>>> R2.describe()  # optional - macaulay2
QQ[x..y, Degrees => {2:1}, Heft => {1}, MonomialOrder => {MonomialSize => 16},
  {Lex => 2 }
  {Position => Up }]
```

```
set (var, value)
```

Set the variable var to the given value.

**INPUT:**

- var – string; the name of the variable in Macaulay2
- value – a string to evaluate

**EXAMPLES:**

```python
sage: macaulay2.set("a", "1+1")  # optional - macaulay2
sage: macaulay2.get("a")  # optional - macaulay2
2
```

```python
>>> from sage.all import *
>>> macaulay2.set("a", "1+1")  # optional - macaulay2
>>> macaulay2.get("a")  # optional - macaulay2
2
```

```
set_seed (seed=None)
```

Set the seed for Macaulay2 interpreter.

**INPUT:**
• seed – number (default: None). If None, it is set to a random number.

OUTPUT: the new seed

EXAMPLES:

```python
sage: m = Macaulay2()           # optional - macaulay2
sage: m.set_seed(123456)        # optional - macaulay2
123456
sage: [m.random(100) for _ in range(11)]  # optional - macaulay2
[8, 29, 5, 22, 4, 32, 35, 57, 3, 95, 36]
```

```python
>>> from sage.all import *
>>> m = Macaulay2()           # optional - macaulay2
>>> m.set_seed(Integer(123456))  # optional - macaulay2
123456
>>> [m.random(Integer(100)) for _ in range(Integer(11))]  # optional - macaulay2
[8, 29, 5, 22, 4, 32, 35, 57, 3, 95, 36]
```

```python
use(R)
```

Use the Macaulay2 ring R.

EXAMPLES:

```python
sage: R = macaulay2("QQ[x,y]")
sage: P = macaulay2("ZZ/7[symbol x, symbol y]")
sage: macaulay2("x").cls()._operator(===, P)
true
sage: macaulay2.use(R)
sage: macaulay2("x").cls()._operator(===, R)
true
```

```python
>>> from sage.all import *
>>> R = macaulay2("QQ[x,y]")
>>> P = macaulay2("ZZ/7[symbol x, symbol y]")
>>> macaulay2("x").cls()._operator(===, P)
true
>>> macaulay2.use(R)
>>> macaulay2("x").cls()._operator(===, R)
true
```

```python
version()
```

Return the version of Macaulay2 as a tuple.

EXAMPLES:

```python
sage: macaulay2.version()  # optional - macaulay2
(1, ...)
```

```python
>>> from sage.all import *
>>> macaulay2.version()  # optional - macaulay2
(1, ...)
```

```python
class sage.interfaces.macaulay2.Macaulay2Element (parent, value, is_name=False, name=None)
Bases: ExtraTabCompletion, ExpectElement, Macaulay2Element
```
Instances of this class represent objects in Macaulay2.

Using the method `sage()` we can translate some of them to SageMath objects:

```python
__sage__(*)
```

**EXAMPLES:**

```python
sage: # optional - macaulay2
sage: macaulay2(ZZ).sage()  # indirect doctest
Integer Ring
sage: macaulay2(QQ).sage()
Rational Field

sage: # optional - macaulay2
sage: macaulay2(2).sage()
2
sage: macaulay2(1/2).sage()
1/2
sage: macaulay2(2/1).sage()
2
sage: _.parent()
Rational Field
sage: macaulay2([1, 2, 3]).sage()
[1, 2, 3]

sage: # optional - macaulay2
sage: m = matrix([[1, 2], [3, 4]])
sage: macaulay2(m).sage()
[[1 2]
 [3 4]]

sage: # optional - macaulay2
sage: D = macaulay2('hashTable (4 => 1, 2 => 3)')

[(1, 2), (2, 1), (3, 1)]
Chain complexes and maps of chain complexes can be converted:

```sage
R = ZZ['a,b,c']
C = macaulay2(ideal(R.gens())).resolution() # optional - macaulay2
ascii_art(C.sage()) # optional - macaulay2

[-b 0 -c] [ c]
[a -c 0] [ a]
[a b c] [ 0 b a] [-b]
0 <-- C_0 <-------- C_1 <---------- C_2 <----- C_3 <-- 0

ascii_art(C.sage()) # optional - macaulay2

F = C.dot('dd') # optional - macaulay2
G = F.sage() # optional - macaulay2
G.in_degree(2) # optional - macaulay2
[-b 0 -c]
[a -c 0]
[ 0 b a]
F.underscore(2).sage() == G.in_degree(2) # optional - macaulay2
True

(F^2).sage() # optional - macaulay2

Chain complex morphism:
   From: Chain complex with at most 4 nonzero terms over Multivariate...
   To: Chain complex with at most 4 nonzero terms over Multivariate...

Quotient rings in Macaulay2 inherit variable names from the ambient ring, so we mimic this behaviour in Sage:

```sage
from sage.all import *
R = ZZ['a,b,c']
C = macaulay2(ideal(R.gens())).resolution() # optional - macaulay2
ascii_art(C.sage()) # optional - macaulay2

[-b 0 -c] [ c]
[a -c 0] [ a]
[a b c] [ 0 b a] [-b]
0 <-- C_0 <-------- C_1 <---------- C_2 <----- C_3 <-- 0

F = C.dot('dd') # optional - macaulay2
G = F.sage() # optional - macaulay2
G.in_degree(Integer(2)) # optional - macaulay2
[-b 0 -c]
[a -c 0]
[ 0 b a]
F.underscore(Integer(2)).sage() == G.in_degree(Integer(2)) # optional - macaulay2
True

(F**Integer(2)).sage() # optional - macaulay2

Chain complex morphism:
   From: Chain complex with at most 4 nonzero terms over Multivariate...
   To: Chain complex with at most 4 nonzero terms over Multivariate...

Quotient rings in Macaulay2 inherit variable names from the ambient ring, so we mimic this behaviour in Sage:
```python
>>> from sage.all import *
>>> # optional - macaulay2
>>> R = macaulay2("ZZ/7[x,y]")
>>> I = macaulay2("ideal (x^3 - y^2)")
>>> (R/I).gens()
{x, y}
>>> (R/I).sage().gens()
(x, y)
Elementsofquotientrings:
sage: x, y = (R/I).gens()  # optional - macaulay2
sage: f = ((x^3 + 2*y^2*x)^7).sage(); f  # optional - macaulay2
2*x*y^18 + y^14
sage: f.parent()  # optional - macaulay2
Quotient of Multivariate Polynomial Ring in x, y over Finite Field of size 7 →
by the ideal (x^3 - y^2)

>>> from sage.all import *
>>> x, y = (R/I).gens()  # optional - macaulay2
>>> f = ((x**Integer(3) + Integer(2)*y**Integer(2)*x)**Integer(7)).sage(); f →
2*x*y^18 + y^14
>>> f.parent()  # optional - macaulay2
Quotient of Multivariate Polynomial Ring in x, y over Finite Field of size 7 →
by the ideal (x^3 - y^2)
```

**after_print_text()**

Obtain type information for this Macaulay2 element.

This is the text that is displayed using AfterPrint in a Macaulay2 interpreter.

Macaulay2 by default includes this information in the output. In Sage, this behavior can optionally be enabled by setting the option after_print in Macaulay2.options.

**EXAMPLES:**

```python
sage: B = macaulay2(matrix([[1, 2], [3, 6]])).kernel(); B  # optional - macaulay2
ZZ-module, submodule of ZZ
```

```python
sage: B = macaulay2(matrix([[Integer(1), Integer(2)], [Integer(3), Integer(6)]])).kernel(); B  # optional - macaulay2
ZZ-module, submodule of ZZ
```

**cls()**

Since class is a keyword in Python, we have to use cls to call Macaulay2\'s class. In Macaulay2, class corresponds to Sage\'s notion of parent.
EXAMPLES:

```python
sage: macaulay2(ZZ).cls() # optional - macaulay2
Ring

>>> from sage.all import *
>>> macaulay2(ZZ).cls() # optional - macaulay2
Ring
```

dot(x)

EXAMPLES:

```python
sage: # optional - macaulay2
sage: d = macaulay2.new("MutableHashTable")
sage: d['k'] = 4
sage: d.dot("k")
4

>>> from sage.all import *
>>> # optional - macaulay2
>>> d = macaulay2.new("MutableHashTable")
>>> d['k'] = Integer(4)
>>> d.dot("k")
4
```

external_string()

EXAMPLES:

```python
sage: R = macaulay2("QQ[symbol x, symbol y]") # optional - macaulay2
sage: R.external_string() # optional - macaulay2
'QQ(monoid[x..y, Degrees => {2:1}, Heft => {1}, MonomialOrder => VerticalList
→{MonomialSize => 32, GRevLex => {2:1}, Position => Up}, DegreeRank => 1]')

>>> from sage.all import *
>>> R = macaulay2("QQ[symbol x, symbol y]") # optional - macaulay2
>>> R.external_string() # optional - macaulay2
'QQ(monoid[x..y, Degrees => {2:1}, Heft => {1}, MonomialOrder => VerticalList
→{MonomialSize => 32, GRevLex => {2:1}, Position => Up}, DegreeRank => 1]')
```

name(new_name=None)

Get or change the name of this Macaulay2 element.

INPUT:

- new_name - string (default: None). If None, return the name of this element; else return a new object identical to self whose name is new_name.

Note that this can overwrite existing variables in the system.

EXAMPLES:

```python
sage: # optional - macaulay2
sage: S = macaulay2(QQ['x,y'])
sage: S.name()
'sage...'
sage: R = S.name("R")
sage: R.name()
(continues on next page)```
The name can also be given at definition:

```
sage: A = macaulay2(ZZ['x,y,z'], name='A') # optional - macaulay2
sage: A.name() # optional - macaulay2
'A'
sage: A^1 # optional - macaulay2
1
```

```
>>> from sage.all import *
>>> A = macaulay2(ZZ['x,y,z'], name='A') # optional - macaulay2
>>> A.name() # optional - macaulay2
'A'
```

`sage_polystring()`

If this Macaulay2 element is a polynomial, return a string representation of this polynomial that is suitable for evaluation in Python. Thus * is used for multiplication and ** for exponentiation. This function is primarily used internally.

**EXAMPLES:**

```
sage: # optional - macaulay2
sage: R = macaulay2.ring(QQ,'(x,y)')
```

```
>>> from sage.all import *
>>> R = macaulay2.ring(QQ,'(x,y)')
```

```
sage: f = macaulay2('x^3 + 3*y^11 + 5')
sage: print(f)
3 11
x + 3y + 5
sage: f.sage_polystring()
'x**3+3*y**(11)+5'
```
>>> from sage.all import *
>>> # optional - macaulay2
>>> R = macaulay2.ring('QQ','(x,y)')
>>> f = macaulay2('x^3 + 3*y^11 + 5')
>>> print(f)
    3   11
  x  + 3y + 5
>>> f.sage_polystring()
  'x**3+3*y**11+5'

**sharp** *(x)*

EXAMPLES:

```python
sage: a = macaulay2([1,2,3])  # optional - macaulay2
sage: a.sharp(0)  # optional - macaulay2
1
```

**starstar** *(x)*

The binary operator ** in Macaulay2 is usually used for tensor or Cartesian power.

EXAMPLES:

```python
sage: a = macaulay2([Integer(1),Integer(2),Integer(3)])  # optional - macaulay2
sage: a.starstar(Integer(0))  # optional - macaulay2
1
```

**structure_sheaf()**

EXAMPLES:

```python
sage: # optional - macaulay2
sage: S = macaulay2('QQ[a..d]')
sage: R = S / macaulay2('a^3 + b^3 + c^3 + d^3')
sage: X = R.Proj().name('X')
sage: X.structure_sheaf()
doctest:...: DeprecationWarning: The function `structure_sheaf` is deprecated. → Use `self.sheaf()` instead.
See https://github.com/sagemath/sage/issues/27848 for details.
OO
X
sage: X.sheaf()
OO
X
```
sage: # optional - macaulay2
sage: R = macaulay2("QQ[x]")
sage: P = macaulay2("ZZ/7[symbol x]")
sage: x, = R.gens()
sage: a = x^2 + 1
sage: a = a.substitute(P)
sage: a.sage().parent()
Univariate Polynomial Ring in x over Finite Field of size 7

EXAMPLES:

sage: # optional - macaulay2
sage: a = macaulay2([1,2,3])  # optional - macaulay2
sage: a.underscore(0)  # optional - macaulay2
1

EXAMPLES:

class sage.interfaces.macaulay2.Macaulay2Function (parent, name)
Bases: ExpectFunction
class sage.interfaces.macaulay2.Macaulay2FunctionElement(obj, name)

Bases: FunctionElement

sage.interfaces.macaulay2.is_Macaulay2Element(x)

Return True if x is a Macaulay2Element

This function is deprecated; use isinstance() (of sage.interfaces.abc.Macaulay2Element) instead.

EXAMPLES:

```python
sage: from sage.interfaces.macaulay2 import is_Macaulay2Element
sage: is_Macaulay2Element(2)  # optional - macaulay2
False
sage: is_Macaulay2Element(macaulay2(2))  # optional - macaulay2
True
```

sage.interfaces.macaulay2.macaulay2_console()

Spawn a new M2 command-line session.

EXAMPLES:

```python
sage: macaulay2_console()  # not tested
Macaulay 2, version 1.1
with packages: Classic, Core, Elimination, IntegralClosure, LLLBases, Parsing, ...
    PrimaryDecomposition, SchurRings, TangentCone ...
```

sage.interfaces.macaulay2.reduce_load_macaulay2()

Used for reconstructing a copy of the Macaulay2 interpreter from a pickle.

EXAMPLES:

```python
sage: from sage.interfaces.macaulay2 import reduce_load_macaulay2
sage: reduce_load_macaulay2()
Macaulay2234 Chapter 22. Interface to Macaulay2
sage.interfaces.macaulay2.remove_output_labels(s)
Remove output labels of Macaulay2 from a string.

- s: output of Macaulay2
- s: string

Returns: the input string with n symbols removed from the beginning of each line, where n is the minimal number of spaces or symbols of Macaulay2 output labels (looking like 'o39 = ') present on every non-empty line.

Return type: string

Note: If s consists of several outputs and their labels have different width, it is possible that some strings will have leading spaces (or maybe even pieces of output labels). However, this function will try not cut any messages.

EXAMPLES:

```
>>> from sage.all import *
>>> from sage.interfaces.macaulay2 import reduce_load_macaulay2
>>> reduce_load_macaulay2()
Macaulay2

sage: from sage.interfaces.macaulay2 import remove_output_labels
sage: output = o1 = QQ [x, y] \n
o1 : PolynomialRing

sage: remove_output_labels(output)
QQ [x, y] \n
PolynomialRing
```

```
>>> from sage.all import *
>>> from sage.interfaces.macaulay2 import remove_output_labels
>>> output = o1 = QQ [x, y] \n
o1 : PolynomialRing

>>> remove_output_labels(output)
QQ [x, y] \n
PolynomialRing
```
Sage provides an interface to the Magma computational algebra system. This system provides extensive functionality for number theory, group theory, combinatorics and algebra.

**Note:** You must have Magma installed on your computer for this interface to work. Magma is not free, so it is not included with Sage, but you can obtain it from http://magma.maths.usyd.edu.au/.

The Magma interface offers three pieces of functionality:

1. `magma_console()` – A function that dumps you into an interactive command-line Magma session.

2. `magma.new(obj)` and alternatively `magma(obj)` – Creation of a Magma object from a Sage object `obj`. This provides a Pythonic interface to Magma. For example, if `f=magma.new(10)`, then `f.Factors()` returns the prime factorization of 10 computed using Magma. If `obj` is a string containing an arbitrary Magma expression, then the expression is evaluated in Magma to create a Magma object. An example is `magma.new('10 div 3')`, which returns Magma integer 3.

3. `magma.eval(expr)` – Evaluation of the Magma expression `expr`, with the result returned as a string.

Type `magma.[tab]` for a list of all functions available from your Magma. Type `magma.Function?` for Magma’s help about the Magma `Function`.

### 23.1 Parameters

Some Magma functions have optional “parameters”, which are arguments that in Magma go after a colon. In Sage, you pass these using named function arguments. For example,

```python
sage: E = magma('EllipticCurve([0,1,1,-1,0])')  # optional - magma
sage: E.Rank(Bound = 5)                           # optional - magma
0
```

```python
>>> from sage.all import *
>>> E = magma('EllipticCurve([0,1,1,-1,0])')    # optional - magma
>>> E.Rank(Bound = Integer(5))                  # optional - magma
    → magma
0
```
23.2 Multiple Return Values

Some Magma functions return more than one value. You can control how many you get using the nvals named parameter to a function call:

```
sage: # optional - magma
sage: n = magma(100)
true
sage: n.IsSquare(nvals = 1)
true
sage: n.IsSquare(nvals = 2)
(true, 10)
sage: n = magma(-2006)
sage: n.Factorization()
[<2, 1>, <17, 1>, <59, 1>]
sage: n.Factorization(nvals=2)
([<2, 1>, <17, 1>, <59, 1>], -1)
```

We verify that an obviously principal ideal is principal:

```
sage: # optional - magma
_ = magma.eval(R<x> := PolynomialRing(RationalField()))
O = magma.NumberField(x^2+23).MaximalOrder()
I = magma('ideal<%s,x^2+23>'%(O.name(),O.name()))
sage: I.IsPrincipal(nvals=2)
(true, [1, 0])
```

```
23.3 Long Input

The Magma interface reads in even very long input (using files) in a robust manner.

```python
sage: t = '%s'*10^10000 # ten thousand character string. 
    # optional - magma
sage: a = magma.eval(t) # optional - magma
sage: a = magma(t) # optional - magma
```

```python
>>> from sage.all import *

>>> t = '%s'*Integer(10)**Integer(10000) # ten thousand character string. # optional - magma
>>> a = magma.eval(t) # optional - magma
>>> a = magma(t) # optional - magma
```

23.4 Garbage Collection

There is a subtle point with the Magma interface, which arises from how garbage collection works. Consider the following session:

First, create a matrix m in Sage:

```python
sage: m=matrix(ZZ,2,[1,2,3,4]) # optional - magma
```

```python
>>> from sage.all import *

>>> m=matrix(ZZ,Integer(2),[Integer(1),Integer(2),Integer(3),Integer(4)]) # optional - magma
```

Then I create a corresponding matrix A in Magma:

```python
sage: A = magma(m) # optional - magma
```

```python
>>> from sage.all import *

>>> A = magma(m) # optional - magma
```

It is called _sage_[…] in Magma:

```python
sage: s = A.name(); s 
    '_sage_[…]'
```

```python
>>> from sage.all import *

>>> s = A.name(); s 
    '_sage_[…]'
```

It's there:

```python
sage: magma.eval(s) 
    '['1 2]\\n[3 4]' 
```

```python
>>> from sage.all import *

>>> magma.eval(s) 
    '['1 2]\\n[3 4]' 
```

Now I delete the reference to that matrix:
Interpreter Interfaces, Release 10.4

```python
sage: del A  # optional - magma
```

```python
>>> from sage.all import *
```  
```python
>>> del A  # optional - magma
```

Now _sage_[…] is “zeroed out” in the Magma session:

```python
sage: magma.eval(s)
'0'
```  
```python
>>> from sage.all import *
```  
```python
>>> magma.eval(s)  # optional - magma
'0'
```

If Sage did not do this garbage collection, then every single time you ever create any magma object from a sage object, e.g., by doing magma(m), you would use up a lot of memory in that Magma session. This would lead to a horrible memory leak situation, which would make the Magma interface nearly useless for serious work.

### 23.5 Other Examples

We compute a space of modular forms with character.

```python
sage: N = 20
sage: D = 20
sage: eps_top = fundamental_discriminant(D)
sage: eps = magma.KroneckerCharacter(eps_top, RationalField())  # optional - magma
sage: M2 = magma.ModularForms(eps)  # optional - magma
sage: print(M2)
# optional - magma
Space of modular forms on Gamma_1(5) ...
sage: print(M2.Basis())  # optional - magma
# optional - magma
[1 + 10*q^2 + 20*q^3 + 20*q^5 + 60*q^7 + ...
q + q^2 + 2*q^3 + 3*q^4 + 5*q^5 + 2*q^6 + ...
]
```

```python
>>> from sage.all import *
```  
```python
>>> N = Integer(20)
```  
```python
>>> D = Integer(20)
```  
```python
>>> eps_top = fundamental_discriminant(D)
```  
```python
>>> eps = magma.KroneckerCharacter(eps_top, RationalField())  # optional - magma
```  
```python
>>> M2 = magma.ModularForms(eps)  # optional - magma
```  
```python
>>> print(M2)
# optional - magma
Space of modular forms on Gamma_1(5) ...
```  
```python
>>> print(M2.Basis())  # optional - magma
# optional - magma
[1 + 10*q^2 + 20*q^3 + 20*q^5 + 60*q^7 + ...
q + q^2 + 2*q^3 + 3*q^4 + 5*q^5 + 2*q^6 + ...
]
```

In Sage/Python (and sort of C++) coercion of an element x into a structure S is denoted by S(x). This also works for the Magma interface:
We coerce some polynomial rings into Magma:

```
sage: R.<y> = PolynomialRing(QQ)
sage: S = magma(R)   # optional - magma
                # → magma
sage: print(S)     # optional - magma
Univariate Polynomial Ring in y over Rational Field
sage: S.1           # optional - magma
    → magma
    y
```

```
>>> from sage.all import *
>>> # optional - magma
>>> R = PolynomialRing(QQ, names=('y',)); (y,) = R._first_ngens(1)
>>> S = magma(R)   # optional - magma
                # → magma
>>> print(S)       # optional - magma
Univariate Polynomial Ring in y over Rational Field
>>> S.gen(1)       # optional - magma
    → magma
    y
```

This example illustrates that Sage doesn’t magically extend how Magma implicit coercion (what there is, at least) works. The errors below are the result of Magma having a rather limited automatic coercion system compared to Sage’s:

```
sage: R.<x> = ZZ[]
sage: x * 5
    → magma
    5*x
sage: x * 1.0
    → magma
    x
sage: x * (2/3)
    → magma
    2/3*x
sage: y = magma(x)   # optional - magma
                # → magma
sage: y * 5          # optional - magma
```

AUTHORS:

- William Stein (2005): initial version
- William Stein (2006-03-09): added nvals argument for magma.functions...

```python```

class sage.interfaces.magma.Magma (script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, user_config=False, seed=None, command=None)

Bases: ExtraTabCompletion, Expect

Interface to the Magma interpreter.

Type magma.[tab] for a list of all the functions available from your Magma install. Type magma.Function? for Magma's help about a given Function Type magma(...) to create a new Magma object, and magma.eval(...) to run a string using Magma (and get the result back as a string).

Note: If you do not own a local copy of Magma, try using the magma_free command instead, which uses the free demo web interface to Magma.
If you have ssh access to a remote installation of Magma, you can also set the `server` parameter to use it.

**EXAMPLES:**

You must use `nvals = 0` to call a function that doesn’t return anything, otherwise you’ll get an error. (`nvals` is the number of return values.)

```
sage: magma.SetDefaultRealFieldPrecision(200, nvals=0) # magma >= v2.12;
   # optional - magma
sage: magma.eval('1.1') # optional - magma
   '1.
   1000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000

sage: magma.SetDefaultRealFieldPrecision(30, nvals=0) # optional - magma
```

```
>>> from sage.all import *
>>> magma.SetDefaultRealFieldPrecision(Integer(200), nvals=Integer(0)) # magma >= v2.12; optional - magma
   # magma
>>> magma.eval('1.1') # optional - magma
   '1.
   1000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000

>>> magma.SetDefaultRealFieldPrecision(Integer(30), nvals=Integer(0)) # optional - magma
```

**Attach** *(filename)*

Attach the given file to the running instance of Magma.

Attaching a file in Magma makes all intrinsics defined in the file available to the shell. Moreover, if the file doesn’t start with the `freeze;` command, then the file is reloaded whenever it is changed. Note that functions and procedures defined in the file are *not* available. For only those, use `magma.load(filename)`.

**INPUT:**

- `filename` - a string

**EXAMPLES:** Attaching a file that exists is fine:

```
sage: SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE'] # optional - magma
sage: magma.attach(r'%s/magma/sage/basic.m'%(SAGE_EXTCODE)) # optional - magma
```

```
>>> from sage.all import *
>>> magma.SetDefaultRealFieldPrecision(Integer(200), nvals=Integer(0)) # magma >= v2.12; optional - magma
   # magma
>>> magma.eval('1.1') # optional - magma
   '1.
   1000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000

>>> magma.SetDefaultRealFieldPrecision(Integer(30), nvals=Integer(0)) # optional - magma
```

Attaching a file that doesn’t exist raises an exception:

```
sage: SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE'] # optional - magma
sage: magma.attach(r'%s/magma/sage/basic2.m'%(SAGE_EXTCODE)) # optional - magma
```

```
Traceback (most recent call last):
...
RuntimeError: Error evaluating Magma code...
```

```
>>> from sage.all import *
>>> magma.SetDefaultRealFieldPrecision(Integer(200), nvals=Integer(0)) # magma >= v2.12; optional - magma
   # magma
>>> magma.attach(r'%s/magma/sage/basic2.m'%(SAGE_EXTCODE)) # optional - magma
```

(continues on next page)
Interpreter Interfaces, Release 10.4

>>> magma.attach('%s/magma/sage/basic2.m','%SAGE_EXTCODE')  # optional - magma
Traceback (most recent call last):
...
RuntimeError: Error evaluating Magma code...

AttachSpec (filename)

Attach the given spec file to the running instance of Magma.

This can attach numerous other files to the running Magma (see the Magma documentation for more details).

INPUT:

• filename – a string

EXAMPLES:

sage: SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE']  # optional - magma
sage: magma.attach_spec('%s/magma/spec'%SAGE_EXTCODE)  # optional - magma
sage: magma.attach_spec('%s/magma/spec2'%SAGE_EXTCODE)  # optional - magma
Traceback (most recent call last):
...
RuntimeError: Can't open package spec file .../magma/spec2 for reading (No...

>>> from sage.all import *

>>> magma.set_nthreads(Integer(2))  #optional - magma
>>> magma.set_nthreads()  #optional - magma
2

GetNthreads ()

Get the number of threads used in Magma.

EXAMPLES:

sage: magma.set_nthreads(2)  #optional - magma
sage: magma.get_nthreads()  #optional - magma
2

>>> from sage.all import *

>>> magma.set_nthreads(Integer(2))  #optional - magma
>>> magma.get_nthreads()  #optional - magma
2

GetVerbose (type)

Get the verbosity level of a given algorithm class etc. in Magma.

INPUT:

• type – string (e.g. 'Groebner'), see Magma documentation

EXAMPLES:
SetNthreads \((n)\)
Set the number of threads used for parallelized algorithms in Magma.

**INPUT:**
- \(n\) – number of threads

**EXAMPLES:**

```sage
magma.set_nthreads(2)  # optional - magma
magma.get_nthreads()  # optional - magma
```

SetVerbose \((\text{type}, \text{level})\)
Set the verbosity level for a given algorithm, class, etc. in Magma.

**INPUT:**
- \(\text{type}\) – string (e.g. 'Groebner')
- \(\text{level}\) – integer \(\geq 0\)

**EXAMPLES:**

```sage
magma.set_verbose("Groebner", 2)  # optional - magma
magma.get_verbose("Groebner")  # optional - magma
```

attach \((\text{filename})\)
Attach the given file to the running instance of Magma.

Attaching a file in Magma makes all intrinsics defined in the file available to the shell. Moreover, if the file doesn’t start with the `freeze;` command, then the file is reloaded whenever it is changed. Note that functions and procedures defined in the file are not available. For only those, use `magma.load(filename)`.

**INPUT:**
- \(\text{filename}\) – a string

**EXAMPLES:** Attaching a file that exists is fine:
Interpreter Interfaces, Release 10.4

```python
sage: SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE'] # optional - magma
sage: magma.attach('$$/magma/sage/basic.m$$SAGE_EXTCODE) # optional - magma
```

```python
>>> from sage.all import *
>>> SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE'] # optional - magma
data: magma.attach('$$/magma/sage/basic.m$$SAGE_EXTCODE) # optional - magma
```

Attaching a file that doesn’t exist raises an exception:

```python
sage: SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE']
# optional: magma
sage: magma.attach('$$/magma/sage/basic2.m$$SAGE_EXTCODE) # optional: magma
Traceback (most recent call last):
...
RuntimeError: Error evaluating Magma code...
```

```python
>>> from sage.all import *
>>> SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE']
# optional: magma
>>> magma.attach('$$/magma/sage/basic2.m$$SAGE_EXTCODE) # optional: magma
Traceback (most recent call last):
...
RuntimeError: Error evaluating Magma code...
```

**attach_spec (filename)**

Attach the given spec file to the running instance of Magma.

This can attach numerous other files to the running Magma (see the Magma documentation for more details).

**INPUT:**

- `filename` -- a string

**EXAMPLES:**

```python
sage: SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE']
# optional: magma
sage: magma.attach_spec('$$/magma/spec$$SAGE_EXTCODE) # optional: magma
sage: magma.attach_spec('$$/magma/spec2$$SAGE_EXTCODE) # optional: magma
Traceback (most recent call last):
...
RuntimeError: Can't open package spec file .../magma/spec2 for reading (No... such file or directory)
```

```python
>>> from sage.all import *
>>> SAGE_EXTCODE = SAGE_ENV['SAGE_EXTCODE']
# optional: magma
>>> magma.attach_spec('$$/magma/spec$$SAGE_EXTCODE) # optional: magma
>>> magma.attach_spec('$$/magma/spec2$$SAGE_EXTCODE) # optional: magma
Traceback (most recent call last):
...
RuntimeError: Can't open package spec file .../magma/spec2 for reading (No... such file or directory)
```

**bar_call (left, name, gens, nvals=1)**

This is a wrapper around the Magma constructor

name=left gens

returning nvals.
INPUT:

- `left` – something coercable to a magma object
- `name` – name of the constructor, e.g., sub, quo, ideal, etc.
- `gens` – if a list/tuple, each item is coerced to magma; otherwise gens itself is converted to magma
- `nvals` – positive integer; number of return values

OUTPUT: a single magma object if `nvals == 1`; otherwise a tuple of `nvals` magma objects.

EXAMPLES: The `bar_call` function is used by the sub, quo, and ideal methods of Magma elements. Here we illustrate directly using `bar_call` to create quotients:

```python
sage: # optional - magma
sage: V = magma.RModule(ZZ, 3)
sage: V
RModule(IntegerRing(), 3)
sage: magma.bar_call(V, 'quo', [[1, 2, 3]], nvals=1)
RModule(IntegerRing(), 2)
sage: magma.bar_call(V, 'quo', [[1, 2, 3]], nvals=2)
(RModule(IntegerRing(), 2),
 Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 2))
sage: magma.bar_call(V, 'quo', V, nvals=2)
(RModule(IntegerRing(), 0),
 Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 0))
```

```python
>>> from sage.all import *

>>> # optional - magma

>>> V = magma.RModule(ZZ, Integer(3))

>>> V
RModule(IntegerRing(), 3)

>>> magma.bar_call(V, 'quo', [[Integer(1), Integer(2), Integer(3)]], nvals=Integer(1))
RModule(IntegerRing(), 2)

>>> magma.bar_call(V, 'quo', [[Integer(1), Integer(2), Integer(3)]], nvals=Integer(2))
(RModule(IntegerRing(), 2),
 Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 2))

>>> magma.bar_call(V, 'quo', V, nvals=Integer(2))
(RModule(IntegerRing(), 0),
 Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 0))
```

`chdir(dir)`

Change the Magma interpreter's current working directory.

INPUT:

- `dir` – a string

EXAMPLES:

```python
sage: magma.chdir('/') # optional - magma
''

sage: magma.eval('System("pwd")') # optional - magma
''
```

```python
>>> from sage.all import *

>>> # optional - magma

>>> magma.chdir('/') # optional - magma
''

>>> magma.eval('System("pwd")') # optional - magma
''
```
clear(var)

Clear the variable named var and make it available to be used again.

INPUT:

• var — a string

EXAMPLES:

sage: magma = Magma()  # optional - magma
sage: magma.clear('foo')  # sets foo to 0 in magma; optional - magma
sage: magma.eval('foo')  # optional - magma
'0'

Because we cleared foo, it is set to be used as a variable name in the future:

sage: a = magma('10')  # optional - magma
sage: a.name()  # optional - magma
'foo'

The following tests that the whole variable clearing and freeing system is working correctly.

sage: # optional - magma
sage: magma = Magma()
sage: a = magma('100')
sage: a.name()  # _sage_[1]
'foo'

sage: del a
sage: b = magma('257')
sage: b.name()  # _sage_[1]
'foo'

sage: del b
sage: magma('_sage_[1]')
0

(continues on next page)
console()

Run a command line Magma session. This session is completely separate from this Magma interface.

EXAMPLES:

```python
sage: magma().console()  # not tested
Magma V2.14-9 Sat Oct 11 2008 06:36:41 on one
[Seed = 1157408761]
Type ? for help. Type <Ctrl>-D to quit.
> Total time: 2.820 seconds, Total memory usage: 3.95MB
```

```python
>>> magma().console()  # not tested
Magma V2.14-9 Sat Oct 11 2008 06:36:41 on one
[Seed = 1157408761]
Type ? for help. Type <Ctrl>-D to quit.
> Total time: 2.820 seconds, Total memory usage: 3.95MB
```

cputime (t=None)

Return the CPU time in seconds that has elapsed since this Magma session started. This is a floating point number, computed by Magma.

If t is given, then instead return the floating point time from when t seconds had elapsed. This is useful for computing elapsed times between two points in a running program.

INPUT:

- t – float (default: None); if not None, return cputime since t

OUTPUT:

- float – seconds

EXAMPLES:

```python
sage: # optional - magma
sage: type(magma.cputime())
<... 'float'>
sage: magma.cputime() 1.9399999999999999
sage: t = magma.cputime()
sage: magma.cputime(t)
0.02
```

```python
>>> from sage.all import *
>>> magma().console()  # not tested
Magma V2.14-9 Sat Oct 11 2008 06:36:41 on one
[Seed = 1157408761]
Type ? for help. Type <Ctrl>-D to quit.
> Total time: 2.820 seconds, Total memory usage: 3.95MB
```

```python
>>> from sage.all import *
>>> # optional - magma
>>> type(magma.cputime())
<... 'float'>
>>> magma.cputime() 1.9399999999999999
>>> t = magma.cputime()
>>> magma.cputime(t)
0.02
```
**eval** *(x, strip=True, **kwds)*

Evaluate the given block `x` of code in Magma and return the output as a string.

**INPUT:**

- `x` – string of code
- `strip` – ignored

**OUTPUT:** string

**EXAMPLES:**

We evaluate a string that involves assigning to a variable and printing.

```
>>> from sage.all import *

>>> magma.eval("a := 10;print 2+a;")  # optional - magma
'12'
```

We evaluate a large input line (note that no weird output appears and that this works quickly).

```
>>> from sage.all import *

>>> magma.eval("a := %s;(10^10000)");
# optional - magma
```

Verify that Issue #9705 is fixed:

```
>>> from sage.all import *

>>> nl=chr(10)  # newline character

>>> magma.eval("a:=3; b:=5;") == nl
# optional - magma
```

Verify that Issue #11401 is fixed:

```
```
True
sage: magma.eval("[a,b];") # optional - magma
' [ 3, 5 ]'

>>> from sage.all import *
>>> nl=chr(Integer(10)) # newline character
>>> magma.eval("a:=3;"+nl+"b:=5;") == nl # optional - magma
True
>>> magma.eval("[a,b];") # optional - magma
' [ 3, 5 ]'

function_call (function, args=[], params={}, nvals=1)

Return result of evaluating a Magma function with given input, parameters, and asking for nvals as output.

INPUT:

- function – string, a Magma function name
- args – list of objects coercible into this magma interface
- params – Magma parameters, passed in after a colon
- nvals – number of return values from the function to ask Magma for

OUTPUT: MagmaElement or tuple of nvals MagmaElement’s

EXAMPLES:

sage: magma.function_call('Factorization', 100) # optional - magma
[ <2, 2>, <5, 2> ]
sage: magma.function_call('NextPrime', 100, {'Proof':False}) # optional - magma
101
sage: magma.function_call('PolynomialRing', [QQ,2]) # optional - magma
Polynomial ring of rank 2 over Rational Field
Order: Lexicographical
Variables: $.1, $.2

>>> from sage.all import *
>>> magma.function_call('Factorization', Integer(100)) # optional - magma
[ <2, 2>, <5, 2> ]
>>> magma.function_call('NextPrime', Integer(100), {'Proof':False}) # optional - magma
101
>>> magma.function_call('PolynomialRing', [QQ,Integer(2)]) # optional - magma
Polynomial ring of rank 2 over Rational Field
Order: Lexicographical
Variables: $.1, $.2

Next, we illustrate multiple return values:

sage: magma.function_call('IsSquare', 100) # optional - magma
true
sage: magma.function_call('IsSquare', 100, nvals=2) # optional - magma
(true, 10)
sage: magma.function_call('IsSquare', 100, nvals=3) # optional - magma
Traceback (most recent call last):

... Runtime error in :=: Expected to assign 3 value(s) but only computed 2 value(s)

```python
>>> from sage.all import *
>>> magma.function_call('IsSquare', Integer(100)) # optional - magma
  true
>>> magma.function_call('IsSquare', Integer(100), nvals=Integer(2)) #
  optional - magma
  (true, 10)
>>> magma.function_call('IsSquare', Integer(100), nvals=Integer(3)) #
  optional - magma
Traceback (most recent call last):
...
Runtime error in :=: Expected to assign 3 value(s) but only computed 2 value(s)
```

get (var)

Get the value of the variable var.

**INPUT:**

- var – string; name of a variable defined in the Magma session

**OUTPUT:**

- string – string representation of the value of the variable.

**EXAMPLES:**

```python
sage: magma.set('abc', '2 + 3/5')  # optional - magma
sage: magma.get('abc')  # optional - magma
'13/5'
```

get_nthreads ()

Get the number of threads used in Magma.

**EXAMPLES:**

```python
sage: magma.set_nthreads(2)  #optional - magma
sage: magma.get_nthreads()  #optional - magma
2
```

get_verbose (type)

Get the verbosity level of a given algorithm class etc. in Magma.
INPUT:

- **type** – string (e.g. 'Groebner'), see Magma documentation

EXAMPLES:

```plaintext
sage: magma.set_verbose("Groebner", 2)  # optional - magma
sage: magma.get_verbose("Groebner")  # optional - magma
2
```

```plaintext
>>> from sage.all import *
>>> magma.set_verbose("Groebner", Integer(2))  # optional - magma
>>> magma.get_verbose("Groebner")  # optional - magma
2
```

**help** *(s)*

Return Magma help on string *s*.

This returns what typing '?'s would return in Magma.

INPUT:

- **s** – string

OUTPUT: string

EXAMPLES:

```plaintext
sage: magma.help("NextPrime")  # optional - magma
================================================================================
PATH: /magma/ring-field-algebra/integer/prime/next-previous/NextPrime
KIND: Intrinsic
================================================================================
NextPrime(n) : RngIntElt -> RngIntElt
NextPrime(n: parameter) : RngIntElt -> RngIntElt
...
```

```plaintext
>>> from sage.all import *
>>> magma.help("NextPrime")  # optional - magma
================================================================================
PATH: /magma/ring-field-algebra/integer/prime/next-previous/NextPrime
KIND: Intrinsic
================================================================================
NextPrime(n) : RngIntElt -> RngIntElt
NextPrime(n: parameter) : RngIntElt -> RngIntElt
...
```

**ideal** *(L)*

Return the Magma ideal defined by *L*.

INPUT:

- **L** – a list of elements of a Sage multivariate polynomial ring.

OUTPUT: The magma ideal generated by the elements of *L*.

EXAMPLES:

```plaintext
sage: R.<x,y> = QQ[]
sage: magma.ideal([x^2, y^3*x])  # optional - magma
```

(continues on next page)
Ideal of Polynomial ring of rank 2 over Rational Field
Order: Graded Reverse Lexicographical
Variables: x, y
Homogeneous
Basis:
[
  x^2,
  x*y^3
]

load (filename)

Load the file with given filename using the ‘load’ command in the Magma shell.

Loading a file in Magma makes all the functions and procedures in the file available. The file should not contain any intrinsics (or you’ll get errors). It also runs code in the file, which can produce output.

INPUT:

* filename – string

OUTPUT: output printed when loading the file

EXAMPLES:

sage: from tempfile import NamedTemporaryFile as NTF
sage: with NTF(mode="w+t", suffix=".m") as f: # optional - magma
...:   _ = f.write("function f(n) return n^2; end function;\nprint "hi";"")
...:   print(magma.load(f.name))
Loading ".*/a.m"
hi
sage: magma("f(12)") # optional - magma
144

objgens (value, gens)

Create a new object with given value and gens.
**Interpreter Interfaces, Release 10.4**

**INPUT:**

- **value** – something coercible to an element of this Magma interface
- **gens** – string; comma separated list of variable names

**OUTPUT:** new Magma element that is equal to value with given gens

**EXAMPLES:**

```python
sage: R = magma.objgens('PolynomialRing(Rationals(),2)', 'alpha,beta')  # optional - magma
sage: R.gens()  # optional - magma
[alpha, beta]
```

Because of how Magma works you can use this to change the variable names of the generators of an object:

```python
c sage: S = magma.objgens(R, 'X,Y')  # optional - magma
c sage: R.gens()  # optional - magma
Polynomial ring of rank 2 over Rational Field
Order: Lexicographical
Variables: X, Y
c sage: S  # optional - magma
Polynomial ring of rank 2 over Rational Field
Order: Lexicographical
Variables: X, Y
```

**set**(var, value)

Set the variable var to the given value in the Magma interpreter.

**INPUT:**

- **var** – string; a variable name
- **value** – string; what to set var equal to

**EXAMPLES:**

```python
c sage: magma.set('abc', '2 + 3/5')  # optional - magma
c sage: magma('abc')  # optional - magma
13/5
```
Interpreter Interfaces, Release 10.4

```python
>>> from sage.all import *
>>> magma.set('abc', '2 + 3/5') # optional - magma
>>> magma('abc') # optional - magma
13/5
```

**set_nthreads** *(n)*

Set the number of threads used for parallelized algorithms in Magma.

**INPUT:**

- *n* – number of threads

**EXAMPLES:**

```python
sage: magma.set_nthreads(2) #optional - magma
sage: magma.get_nthreads() #optional - magma
2
```

```python
>>> from sage.all import *
>>> magma.set_nthreads(Integer(2)) #optional - magma
>>> magma.get_nthreads() #optional - magma
2
```

**set_seed** *(seed=None)*

Set the seed for the Magma interpreter.

The seed should be an integer.

**EXAMPLES:**

```python
sage: m = Magma() # optional - magma
sage: m.set_seed(1) # optional - magma
1
sage: [m.Random(100) for i in range(5)] # optional - magma
[14, 81, 45, 75, 67]
```

```python
>>> from sage.all import *
>>> m = Magma() # optional - magma
>>> m.set_seed(Integer(1)) # optional - magma
1
>>> [m.Random(Integer(100)) for i in range(Integer(5))] # optional - magma
[14, 81, 45, 75, 67]
```

**set_verbose** *(type, level)*

Set the verbosity level for a given algorithm, class, etc. in Magma.

**INPUT:**

- *type* – string (e.g. 'Groebner')
- *level* – integer >= 0

**EXAMPLES:**

```python
sage: magma.set_verbose("Groebner", 2) # optional - magma
sage: magma.get_verbose("Groebner") # optional - magma
2
```
version()

Return the version of Magma that you have in your PATH on your computer.

OUTPUT:

• numbers – 3-tuple: major, minor, etc.
• string – version as a string

EXAMPLES:

```python
sage: magma.version()  # random, optional - magma
((2, 14, 9), 'V2.14-9')
```

class sage.interfaces.magma.MagmaElement (parent, value, is_name=False, name=None)

Bases: ExtraTabCompletion, ExpectElement, MagmaElement

AssignNames (names)

EXAMPLES:

```python
sage: # optional - magma
sage: S = magma.PolynomialRing(magma.Integers(), 2)
sage: S.AssignNames(['a', 'b'])
sage: S.1
a
sage: S.1^2 + S.2
a^2 + b
```

assign_names (names)

EXAMPLES:

```python
sage: # optional - magma
sage: S = magma.PolynomialRing(magma.Integers(), 2)
sage: S.AssignNames(['a', 'b'])
sage: S.1
a
sage: S.1^2 + S.2
a^2 + b
```
```python
>>> from sage.all import *
>>> # optional - magma
>>> S = magma.PolynomialRing(magma.Integers(), Integer(2))
>>> S.AssignNames(['a', 'b'])
>>> S.gen(1)
a
>>> S.gen(1)**Integer(2) + S.gen(2)
a^2 + b
```

eval (*args)
Evaluate self at the inputs.

INPUT:
- *args – import arguments

OUTPUT: self(*args)

EXAMPLES:

```python
sage: # optional - magma
sage: f = magma('Factorization')
sage: f.evaluate(Integer(15))
[ <3, 1>, <5, 1> ]
sage: f(Integer(15))
[ <3, 1>, <5, 1> ]
sage: f = magma('GCD')
sage: f.evaluate(Integer(15),Integer(20))
5
```

evaluate (*args)
Evaluate self at the inputs.

INPUT:
- *args – import arguments

OUTPUT: `self(*args)`

EXAMPLES:

```python
sage: # optional - magma
sage: f = magma('Factorization')
sage: f.evaluate(15)
[<3, 1>, <5, 1>]
sage: f(15)
[<3, 1>, <5, 1>]
sage: f = magma('GCD')
sage: f.evaluate(15, 20)
5
sage: m = matrix(QQ, 2, 2, [2, 3, 5, 7])  # optional - magma
sage: f = magma('ElementaryDivisors')  # optional - magma
sage: f.evaluate(m)  # optional - magma
[1, 1]
```

```python
>>> from sage.all import *

>>> # optional - magma
>>> f = magma('Factorization')
>>> f.evaluate(Integer(15))
[<3, 1>, <5, 1>]

>>> f(Integer(15))
[<3, 1>, <5, 1>]

>>> f = magma('GCD')
>>> f.evaluate(Integer(15), Integer(20))
5

>>> m = matrix(QQ, 2, 2, [Integer(2), Integer(3), Integer(5), Integer(7)])  # optional - magma

>>> f = magma('ElementaryDivisors')  # optional - magma

>>> f.evaluate(m)  # optional - magma
[1, 1]
```

```
gen(n)
```

Return the n-th generator of this Magma element. Note that generators are 1-based in Magma rather than 0 based!

INPUT:

- `n` — a `positive` integer

OUTPUT: `MagmaElement`

EXAMPLES:

```python
sage: k.<a> = GF(9)
sage: magma(k).gen(1)  # optional -- magma

a
```

```python
sage: R.<s,t,w> = k[]
sage: m = magma(R)  # optional -- magma

s
```

```python
sage: m.gen(2)  # optional -- magma

t
```

```python
sage: m.gen(3)  # optional -- magma

w
```

(continues on next page)
Interpreter Interfaces, Release 10.4

sage: m.gen(0) # optional -- magma
Traceback (most recent call last):
...
IndexError: index must be positive since Magma indexes are 1-based
sage: m.gen(4) # optional -- magma
Traceback (most recent call last):
...
IndexError: list index out of range

>>> from sage.all import *
>>> k = GF(Integer(9), names=('a',)); (a,) = k._first_ngens(1)
>>> magma(k).gen(Integer(1)) # optional -- magma
a
>>> R = k['s, t, w']; (s, t, w,) = R._first_ngens(3)
>>> m = magma(R) # optional -- magma
>>> m.gen(Integer(1)) # optional -- magma
s
>>> m.gen(Integer(2)) # optional -- magma
t
>>> m.gen(Integer(3)) # optional -- magma
w
>>> m.gen(Integer(0)) # optional -- magma
Traceback (most recent call last):
...
IndexError: index must be positive since Magma indexes are 1-based
>>> m.gen(Integer(4)) # optional -- magma
Traceback (most recent call last):
...
IndexError: list index out of range

```python
def gen_names()
    """Return list of Magma variable names of the generators of self."
    """
    Note: As illustrated below, these are not the print names of the generators of the Magma object, but special variable names in the Magma session that reference the generators.

    EXAMPLES:
    >>> from sage.all import *
    >>> k = GF(Integer(9), names=('a',)); (a,) = k._first_ngens(1)
    >>> magma(k).gen(Integer(1)) # optional -- magma
    a
    >>> R = k['s, t, w']; (s, t, w,) = R._first_ngens(3)
    >>> m = magma(R) # optional -- magma
    >>> m.gen(Integer(1)) # optional -- magma
    s
    >>> m.gen(Integer(2)) # optional -- magma
t
    >>> m.gen(Integer(3)) # optional -- magma
    w
    >>> m.gen(Integer(0)) # optional -- magma
    Traceback (most recent call last):
      ... IndexError: index must be positive since Magma indexes are 1-based
    >>> m.gen(Integer(4)) # optional -- magma
    Traceback (most recent call last):
      ... IndexError: list index out of range
```

gens()
    Return generators for self.
If self is named X in Magma, this function evaluates X.1, X.2, etc., in Magma until an error occurs. It then returns a Sage tuple of the resulting X.i. Note - I don't think there is a Magma command that returns the list of valid X.i. There are numerous ad hoc functions for various classes but nothing systematic. This function gets around that problem. Again, this is something that should probably be reported to the Magma group and fixed there.

AUTHORS:

• William Stein (2006-07-02)

EXAMPLES:

```sage
sage: magma("VectorSpace(RationalField(),3)").gens()  # optional -- magma
((1 0 0), (0 1 0), (0 0 1))
sage: magma("AbelianGroup(EllipticCurve([1..5]))").gens()  # optional -- magma
($.1,)
```

```
>>> from sage.all import *
>>> magma("VectorSpace(RationalField(),3)").gens()  # optional - magma
((1 0 0), (0 1 0), (0 0 1))
>>> magma("AbelianGroup(EllipticCurve([1..5]))").gens()  # optional - magma
($.1,)
```

`get_magma_attribute(attrname)`

Return value of a given Magma attribute. This is like `self attrname` in Magma.

OUTPUT: MagmaElement

EXAMPLES:

```sage
sage: # optional - magma
sage: V = magma("VectorSpace(RationalField(),10)"
sage: V.set_magma_attribute('M','hello')
sage: V.get_magma_attribute('M')
hello
sage: V.M
hello
```

```
>>> from sage.all import *
>>> # optional - magma
>>> V = magma("VectorSpace(RationalField(),10)"
>>> V.set_magma_attribute('M','hello')
>>> V.get_magma_attribute('M')
hello
>>> V.M
hello
```

`ideal(gens)`

Return the ideal of self with given list of generators.

INPUT:

• gens – object or list/tuple of generators

OUTPUT:

• magma element – a Magma ideal

EXAMPLES:
```
sage: # optional - magma
sage: R = magma('PolynomialRing(RationalField())')
sage: R.assign_names(['x'])
sage: x = R.1
sage: R.ideal([x^2 - 1, x^3 - 1])
Ideal of Univariate Polynomial Ring in x over Rational Field generated by x - 1
```

```
>>> from sage.all import *
>>> # optional - magma
>>> R = magma('PolynomialRing(RationalField())')
>>> R.assign_names(['x'])
>>> x = R.gen(1)
>>> R.ideal([x**Integer(2) - Integer(1), x**Integer(3) - Integer(1)])
Ideal of Univariate Polynomial Ring in x over Rational Field generated by x - 1
```

**list_attributes()**

Return the attributes of self, obtained by calling the ListAttributes function in Magma.

**OUTPUT:** list of strings

**EXAMPLES:** We observe that vector spaces in Magma have numerous funny and mysterious attributes.

```
sage: V = magma("VectorSpace(RationalField(),2") # optional - magma
sage: v = V.list_attributes(); v.sort() # optional - magma
sage: print(v) # optional - magma
['Coroots', 'Involution', ..., 'p', 'ssbasis', 'weights']
```

```
>>> from sage.all import *
>>>
>>> V = magma("VectorSpace(RationalField(),2") # optional - magma
>>> v = V.list_attributes(); v.sort() # optional - magma
>>> print(v) # optional - magma
['Coroots', 'Involution', ..., 'p', 'ssbasis', 'weights']
```

**methods**(any=False)

Return signatures of all Magma intrinsics that can take self as the first argument, as strings.

**INPUT:**

- `any` (bool: default is False) if True, also include signatures with Any as first argument.

**OUTPUT:** list of strings

**EXAMPLES:**

```
sage: v = magma('2/3').methods() # optional - magma
sage: v[0] # optional - magma
"*...
```

```
>>> from sage.all import *
>>> v = magma('2/3').methods() # optional - magma
>>> v[Integer(0)] # optional - magma
"*...
```

**quo**(gens, **args)

Return the quotient of self by the given object or list of generators.

**INPUT:**
Interpreter Interfaces, Release 10.4

- gens – object or list/tuple of generators
- further named arguments that are ignored

OUTPUT:
- magma element – the quotient object
- magma element – mapping from self to the quotient object

EXAMPLES:

```sage```
```
sage: V = magma('VectorSpace(RationalField(),3)')  # optional - magma
sage: V.quo([[1,2,3], [1,1,2]])  # optional - magma
(Full Vector space of degree 1 over Rational Field, Mapping from: Full Vector space of degree 3 over Rational Field to Full Vector space of degree 1 over Rational Field)
```

```sage```
```
>>> from sage.all import *
>>> V = magma('VectorSpace(RationalField(),3)')  # optional - magma
>>> V.quo([[Integer(1),Integer(2),Integer(3)], [Integer(1),Integer(1), Integer(2)]]))  # optional - magma
(Full Vector space of degree 1 over Rational Field, Mapping from: Full Vector space of degree 3 over Rational Field to Full Vector space of degree 1 over Rational Field)
```

We illustrate quotienting out by an object instead of a list of generators:

```sage```
```
sage: W = V.sub([[1,2,3], [1,1,2]])  # optional - magma
sage: V.quo(W)  # optional - magma
(Full Vector space of degree 1 over Rational Field, Mapping from: Full Vector space of degree 3 over Rational Field to Full Vector space of degree 1 over Rational Field)
```

```sage```
```
>>> from sage.all import *
>>> W = V.sub([[Integer(1),Integer(2),Integer(3)], [Integer(1),Integer(1), Integer(2)]]))  # optional - magma
>>> V.quo(W)  # optional - magma
(Full Vector space of degree 1 over Rational Field, Mapping from: Full Vector space of degree 3 over Rational Field to Full Vector space of degree 1 over Rational Field)
```

We quotient a ZZ module out by a submodule.

```sage```
```
sage: V = magma.RModule(ZZ,3); V
RModule(IntegerRing(), 3)
sage: W, phi = V.quo([[1,2,3]])
sage: W
RModule(IntegerRing(), 2)
sage: phi
Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 2)
```

```sage```
```
>>> from sage.all import *
>>> W = V.sub([[1,2,3]])  # optional - magma
>>> V.quo(W)  # optional - magma
(Full Vector space of degree 1 over Rational Field, Mapping from: Full Vector space of degree 3 over Rational Field to Full Vector space of degree 1 over Rational Field)
```

```sage```
```
>>> from sage.all import *
>>> V = magma.RModule(ZZ,Integer(3)); V
RModule(IntegerRing(), 3)
>>> W, phi = V.quo([[Integer(1),Integer(2),Integer(3)]]))
>>> W
```

(continues on next page)
Interpreter Interfaces, Release 10.4

RModule(IntegerRing(), 2)
>>> phi
Mapping from: RModule(IntegerRing(), 3) to RModule(IntegerRing(), 2)

set_magma_attribute (attrname, value)

INPUT: attrname - string value - something coercible to a MagmaElement

EXAMPLES:

sage: # optional - magma
sage: V = magma("VectorSpace(RationalField(),2)"

sage: V.set_magma_attribute('M',10)

sage: V.get_magma_attribute('M')
10

sage: V.M
10

>>> from sage.all import *

>>> # optional - magma

>>> V = magma("VectorSpace(RationalField(),2)"

>>> V.set_magma_attribute('M',Integer(10))

>>> V.get_magma_attribute('M')
10

>>> V.M
10

sub (gens)

Return the sub-object of self with given gens.

INPUT:
• gens – object or list/tuple of generators

EXAMPLES:

sage: V = magma('VectorSpace(RationalField(),3)') # optional - magma

sage: W = V.sub([ [1,2,3], [1,1,2] ]); W # optional - magma
Vector space of degree 3, dimension 2 over Rational Field
Generators:
(1 2 3)
(1 1 2)
Echelonized basis:
(1 0 1)
(0 1 1)

>>> from sage.all import *

>>> V = magma('VectorSpace(RationalField(),3)') # optional - magma

>>> W = V.sub([ [Integer(1),Integer(2),Integer(3)], [Integer(1),Integer(1),
Integer(2)] ]); W # optional - magma
Vector space of degree 3, dimension 2 over Rational Field
Generators:
(1 2 3)
(1 1 2)
Echelonized basis:
(1 0 1)
(0 1 1)
class sage.interfaces.magma.MagmaFunction (parent, name)
    Bases: ExpectFunction

class sage.interfaces.magma.MagmaFunctionElement (obj, name)
    Bases: FunctionElement

class sage.interfaces.magma.MagmaGBDefaultContext (magma=None)
    Bases: object
    Context to force preservation of verbosity options for Magma’s Groebner basis computation.

class sage.interfaces.magma.MagmaGBLogPrettyPrinter (verbosity=1, style='magma')
    Bases: object
    A device which filters Magma Groebner basis computation logs.

    app_inpt = re.compile('^Append\(~_sage_, 0\);$')
    cmd_inpt = re.compile('^>>>$')
    deg_curr = re.compile('^Basis length\: (\d+), queue length\: (\d+), step degree\: (\d+), num pairs\: (\d+)')

    flush()

    EXAMPLES:

    sage: from sage.interfaces.magma import MagmaGBLogPrettyPrinter
    sage: logs = MagmaGBLogPrettyPrinter()
    sage: logs.flush()

    >>> from sage.all import *
    >>> from sage.interfaces.magma import MagmaGBLogPrettyPrinter
    >>> logs = MagmaGBLogPrettyPrinter()
    >>> logs.flush()

    pol_curr = re.compile('^Number of pair polynomials\: (\d+), at (\d+) column\(s\), .*)

    write(s)

    EXAMPLES:

    sage: P.<x, y, z> = GF(32003)[[]]
    sage: I = sage.rings.ideal.Katsura(P)
    sage: _ = I.groebner_basis('magma', prot=True) # indirect doctest, optional ~-
    magma
    *******************
    ** FAUGERE F4 ALGORITHM **
    ********************
    ...
    Total Faugere F4 time: ..., real time: ...

    >>> from sage.all import *
    >>> P = GF(Integer(32003))['x', 'y', 'z']; (x, y, z) = P._first_ngens(3)
    >>> I = sage.rings.ideal.Katsura(P)
    >>> _ = I.groebner_basis('magma', prot=True) # indirect doctest, optional ~-
    magma
    *******************
    (continues on next page)
sage.interfaces.magma.extcode_dir(iface=None)

Return directory that contains all the Magma extcode. This is put in a writable directory owned by the user, since when attached, Magma has to write sig and lck files.

EXAMPLES:

```python
sage: sage.interfaces.magma.extcode_dir()
'...dir_.../data/
```

sage.interfaces.magma.is_MagmaElement(x)

Return True if x is of type MagmaElement, and False otherwise.

INPUT:
- x -- any object

OUTPUT: bool

EXAMPLES:

```python
sage: from sage.interfaces.magma import is_MagmaElement
sage: is_MagmaElement(2)
False

sage: is_MagmaElement(magma(2))
True
```

sage.interfaces.magma.magma_console()

Run a command line Magma session.

EXAMPLES:

```python
sage: magma_console()  # not tested
Magma V2.14-9 Sat Oct 11 2008 06:36:41 on one [Seed = 1157408761]
Type ? for help. Type <Ctrl>-D to quit.
```
Interpreter Interfaces, Release 10.4

(continued from previous page)

```
>>> from sage.all import *
>>> magma_console() # not tested
Magma V2.14-9 Sat Oct 11 2008 06:36:41 on one [Seed = 1157408761]
Type ? for help.  Type <Ctrl>-D to quit.
```

sage.interfaces.magma.magma_gb_standard_options (func)

Decorator to force default options for Magma.

EXAMPLES:

```
sage: P.<a,b,c,d,e> = PolynomialRing(GF(127))
sage: J = sage.rings.ideal.Cyclic(P).homogenize()
sage: from sage.misc.sageinspect import sage_getsource
sage: "mself" in sage_getsource(J._groebner_basis_magma)
True
```

sage.interfaces.magma.reduce_load_Magma ()

Used in unpickling a Magma interface.

This functions just returns the global default Magma interface.

EXAMPLES:

```
sage: sage.interfaces.magma.reduce_load_Magma()
Magma
```

23.5. Other Examples
class sage.interfaces.magma_free.MagmaExpr
    Bases: str

class sage.interfaces.magma_free.MagmaFree
    Bases: object

Evaluate MAGMA code without requiring that MAGMA be installed on your computer by using the free online MAGMA calculator.

EXAMPLES:

sage: magma_free("Factorization(9290348092384)")  # optional - internet
[<2, 5>, <290323377887, 1> ]

>>> from sage.all import *
>>> magma_free("Factorization(9290348092384)")  # optional - internet
[<2, 5>, <290323377887, 1> ]

eval (x, **kwds)

sage.interfaces.magma_free.magma_free_eval (code, strip=True, columns=0)

Use the free online MAGMA calculator to evaluate the given input code and return the answer as a string.

LIMITATIONS: The code must evaluate in at most 20 seconds and there is a limitation on the amount of RAM.

EXAMPLES:

sage: magma_free("Factorization(9290348092384)")  # optional - internet
[<2, 5>, <290323377887, 1> ]

>>> from sage.all import *
>>> magma_free("Factorization(9290348092384)")  # optional - internet
[<2, 5>, <290323377887, 1> ]
CHAPTER
TWENTYFIVE

INTERFACE TO MAPLE

AUTHORS:

• William Stein (2005): maple interface
• Gregg Musiker (2006-02-02): tutorial
• William Stein (2006-03-05): added tab completion, e.g., maple.[tab], and help, e.g., maple.sin?.

You must have the optional commercial Maple interpreter installed and available as the command maple in your PATH in order to use this interface. You do not have to install any optional Sage packages.

Type maple.[tab] for a list of all the functions available from your Maple install. Type maple.[tab]? for Maple's help about a given function. Type maple(...) to create a new Maple object, and maple.eval(...) to run a string using Maple (and get the result back as a string).

EXAMPLES:

```sage
sage: # optional - maple
sage: maple('3 * 5')
15
sage: maple.eval('ifactor(2005)')
'AA(5)*AA(401)'
sage: maple.ifactor(2005)
AA(5)*AA(401)
sage: maple.fsolve('x^2=cos(x)+4', 'x=0..5')
1.914020619
sage: maple.factor(x^5 - y^5)
(x-y)*(x^4+x^3*y+x^2*y^2+x*y^3+y^4)
```

```python
>>> from sage.all import *
>>> # optional - maple
>>> maple('3 * 5')
15
>>> maple.eval('ifactor(2005)')
'AA(5)*AA(401)'
>>> maple.ifactor(Integer(2005))
AA(5)*AA(401)
>>> maple.fsolve('x^2=cos(x)+4', 'x=0..5')
1.914020619
>>> maple.factor('x^5 - y^5')
(x-y)*(x^4+x^3*y+x^2*y^2+x*y^3+y^4)
```

If the string “error” (case insensitive) occurs in the output of anything from Maple, a RuntimeError exception is raised.
25.1 Tutorial

AUTHORS:

This tutorial is based on the Maple Tutorial for number theory from http://www.math.mun.ca/~drdideout/m3370/numtheory.html.

There are several ways to use the Maple Interface in Sage. We will discuss two of those ways in this tutorial.

1. If you have a maple expression such as

```maple
factor( (x^5-1));
```

We can write that in sage as

```sage
sage: maple('factor(x^5-1)')
(x-1)*(x^4+x^3+x^2+x+1)
```

Notice, there is no need to use a semicolon.

2. Since Sage is written in Python, we can also import maple commands and write our scripts in a Pythonic way. For example, `factor()` is a maple command, so we can also factor in Sage using

```sage
sage: maple('factor(x^5-1)').factor()
(x-1)*(x^4+x^3+x^2+x+1)
```

where `expression.command()` means the same thing as `command(expression)` in Maple. We will use this second type of syntax whenever possible, resorting to the first when needed.

```sage
sage: maple('(x^12-1)/(x-1)').simplify()
(x+1)*(x^2+1)*(x^2+x+1)*(x^2-x+1)*(x^2+1)*(x^4-x^2+1)
```

The normal command will always reduce a rational function to the lowest terms. The factor command will factor a polynomial with rational coefficients into irreducible factors over the ring of integers. So for example,

```sage
sage: maple('(x^12-1)').factor()  # optional - maple
(x-1)*(x+1)*(x^2+x+1)*(x^2-x+1)*(x^2+1)*(x^4-x^2+1)
```
Another important feature of Maple is its online help. We can access this through Sage as well. After reading the description of the command, you can press `q` to immediately get back to your original prompt.

Incidentally you can always get into a Maple console by the command

```
sage: maple().console()  # not tested
```

Note that the above two commands are slightly different, and the first is preferred.

For example, for help on the Maple command `fibonacci`, we type

```
sage: maple.help('fibonacci') # not tested, since it uses a pager
```

We see there are two choices. Type

```
sage: maple.help('combinat, fibonacci') # not tested, since it uses a pager
```

We now see how the Maple command `fibonacci` works under the combinatorics package. Try typing in

```
sage: maple.fibonacci(10)  # optional - maple
```

You will get `fibonacci(10)` as output since Maple has not loaded the combinatorics package yet. To rectify this type

```
sage: maple('combinat[fibonacci]')(10)  # optional - maple
```

```
55
```
instead.

If you want to load the combinatorics package for future calculations, in Sage this can be done as

```sage
sage: maple.with_package('combinat')  # optional - maple
```

or

```sage
sage: maple.load('combinat')  # optional - maple
```

Now if we type `maple.fibonacci(10)`, we get the correct output:

```sage
sage: maple.fibonacci(10)  # optional - maple
55
```

Some common Maple packages include `combinat`, `linalg`, and `numtheory`. To produce the first 19 Fibonacci numbers, use the sequence command.

```sage
sage: maple('seq(fibonacci(i),i=1..19)')  # optional - maple
1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181
```

Two other useful Maple commands are `ifactor` and `isprime`. For example

```sage
sage: maple.isprime(maple.fibonacci(27))  # optional - maple
false
sage: maple.ifactor(maple.fibonacci(27))  # optional - maple
```

Note that the `isprime` function that is included with Sage (which uses PARI) is better than the Maple one (it is faster and gives a provably correct answer, whereas Maple is sometimes wrong).
Let's say we want to write a maple program now that squares a number if it is positive and cubes it if it is negative. In maple, that would look like

```maple
mysqcu := proc(x)
    if x > 0 then x^2;
    else x^3; fi;
end;
```

In Sage, we write

```sage
sage: mysqcu = maple('proc(x) if x > 0 then x^2 else x^3 fi')
```

More complicated programs should be put in a separate file and loaded.

```sage
class sage.interfaces.maple.Maple(maxread=None, script_subdirectory=None, server=None, server_tmpdir=None, logfile=None, ulimit=None):
    Bases: ExtraTabCompletion, Expect

    Interface to the Maple interpreter.

    Type maple.[tab] for a list of all the functions available from your Maple install. Type maple.[tab]? for Maple's help about a given function. Type maple(...) to create a new Maple object, and maple.eval(...) to run a string using Maple (and get the result back as a string).
```
clear\( (var) \)

Clear the variable named \( var \).

To clear a Maple variable, you must assign ‘itself’ to itself. In Maple ‘expr’ prevents expr to be evaluated.

EXAMPLES:

\[
\begin{array}{l}
sage: \text{# optional - maple} \\
sage: \text{maple.set('xx', '2')} \\
sage: \text{maple.get('xx')} \\
\text{'}2\text{'} \\
sage: \text{maple.clear('xx')} \\
sage: \text{maple.get('xx')} \\
\text{'}xx\text{'}
\end{array}
\]

completions\( (s) \)

Return all commands that complete the command starting with the string \( s \).

This is like typing \( s + \text{Ctrl} + \text{T} \) in the Maple interpreter.

EXAMPLES:

\[
\begin{array}{l}
sage: c = \text{maple.completions('di')} \quad \text{# optional - maple} \\
sage: 'divide' \text{ in } c \\
\text{True}
\end{array}
\]

console\( () \)

Spawn a new Maple command-line session.

EXAMPLES:

\[
\begin{array}{l}
sage: \text{maple.console()} \quad \text{# not tested} \\
\text{'\text{\textbackslash \text{n}/\text{n} Maple 2019 (X86 64 LINUX) \text{:\textbackslash \text{n}\textbackslash \text{n}._\textbackslash|\textbackslash \text{\textbackslash \text{n} Copyright (c) Maplesoft, a division of Waterloo Maple Inc. 2019 \text{:\textbackslash \text{n} \text{\textbackslash MAPLE} / All rights reserved. Maple is a trademark of \text{:\textbackslash \text{n} <\textbackslash\text{n}> Waterloo Maple Inc. \text{:\textbackslash \text{n} \text{\textbackslash|\text{n} Type ? for help.}
\end{array}
\]

(continues on next page)
cputime \( t=None \)

Return the amount of CPU time that the Maple session has used.

If \( t \) is not None, then it returns the difference between the current CPU time and \( t \).

EXAMPLES:

```python
sage: # optional - maple
sage: t = maple.cputime()
sage: t  # random
0.02
sage: x = maple('x')
sage: maple.diff(x^2, x)
2*x
sage: maple.cputime(t)  # random
0.0
```

```python
>>> from sage.all import *

>>> from sage.all import *
>>> # optional - maple
>>> t = maple.cputime()
>>> t  # random
0.02
>>> x = maple('x')
>>> maple.diff(x**Integer(2), x)
2*x
>>> maple.cputime(t)  # random
0.0
```

expect ()

Return the pexpect object for this Maple session.

EXAMPLES:

```python
sage: # optional - maple
sage: m = Maple()
sage: m.expect() is None
True
sage: m._start()
sage: m.expect()
Maple with PID ...
sage: m.quit()
```

```python
>>> from sage.all import *

>>> from sage.all import *
>>> # optional - maple
>>> m = Maple()
>>> m.expect() is None
True
>>> m._start()
>>> m.expect()
Maple with PID ...
>>> m.quit()
```

get (\texttt{var})

Get the value of the variable \texttt{var}. 

25.1. Tutorial
Interpreter Interfaces, Release 10.4

EXAMPLES:
sage: maple.set( xx ,
sage: maple.get( xx )
2

2 ) # optional - maple
# optional - maple

>>> from sage.all import *
>>> maple.set( xx , 2 ) # optional - maple
>>> maple.get( xx )
# optional - maple
2

help(string)
Display Maple help about string.
This is the same as typing “?string” in the Maple console.
INPUT:
• string – a string to search for in the maple help system
EXAMPLES:
sage: maple.help( Psi ) # not tested
Psi - the Digamma and Polygamma functions
...
>>> from sage.all import *
>>> maple.help( Psi ) # not tested
Psi - the Digamma and Polygamma functions
...

load(package)
Make a package of Maple procedures available in the interpreter.
INPUT:
• package – string
EXAMPLES: Some functions are unknown to Maple until you use with to include the appropriate package.
sage: # optional - maple
sage: maple.quit()
# reset maple
sage: maple( partition(10) )
partition(10)
sage: maple( bell(10) )
bell(10)
sage: maple.with_package( combinat )
sage: maple( partition(10) )
[[1, 1, 1, 1, 1, 1, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1, 1, 1, 2], [1, 1, 1, 1, 1,␣
˓→1, 2, 2], [1, 1, 1, 1, 2, 2, 2], [1, 1, 2, 2, 2, 2], [2, 2, 2, 2, 2], [1, 1,
˓→ 1, 1, 1, 1, 1, 3], [1, 1, 1, 1, 1, 2, 3], [1, 1, 1, 2, 2, 3], [1, 2, 2, 2,␣
˓→3], [1, 1, 1, 1, 3, 3], [1, 1, 2, 3, 3], [2, 2, 3, 3], [1, 3, 3, 3], [1, 1,␣
˓→1, 1, 1, 1, 4], [1, 1, 1, 1, 2, 4], [1, 1, 2, 2, 4], [2, 2, 2, 4], [1, 1, 1,
˓→ 3, 4], [1, 2, 3, 4], [3, 3, 4], [1, 1, 4, 4], [2, 4, 4], [1, 1, 1, 1, 1,␣
˓→5], [1, 1, 1, 2, 5], [1, 2, 2, 5], [1, 1, 3, 5], [2, 3, 5], [1, 4, 5], [5,␣
˓→5], [1, 1, 1, 1, 6], [1, 1, 2, 6], [2, 2, 6], [1, 3, 6], [4, 6], [1, 1, 1,␣
˓→7], [1, 2, 7], [3, 7], [1, 1, 8], [2, 8], [1, 9], [10]]
sage: maple( bell(10) )
115975
(continues on next page)

278

Chapter 25. Interface to Maple


Interpreter Interfaces, Release 10.4

(continued from previous page)

```python
sage: maple('fibonacci(10)')
55
```

```python
>>> from sage.all import *
>>> # optional - maple
>>> maple.quit()  # reset maple
>>> maple('partition(10)')
partition(10)
>>> maple('bell(10)')
bell(10)
>>> maple.with_package('combinat')
>>> maple('partition(10)')[
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1, 1, 1, 2], [1, 1, 1, 1, 1, 1, 1, 2, 2], [1, 1, 1, 1, 1, 1, 2, 2, 2], [1, 1, 1, 1, 1, 1, 2, 3], [1, 1, 1, 1, 1, 1, 3, 3], [1, 1, 1, 1, 1, 2, 3, 3], [1, 1, 1, 1, 1, 3, 3, 3], [1, 1, 1, 1, 2, 3, 4], [1, 1, 1, 1, 2, 4, 4], [1, 1, 1, 1, 3, 4, 4], [1, 1, 1, 2, 3, 4, 4], [1, 1, 1, 2, 4, 4, 4], [1, 1, 1, 3, 4, 4, 4], [1, 1, 1, 3, 5, 5], [1, 1, 1, 4, 5, 5], [1, 1, 1, 4, 6, 6], [1, 1, 1, 5, 6, 6], [1, 1, 2, 5, 6, 6], [1, 1, 2, 6, 6, 6], [1, 1, 3, 6, 6, 6], [1, 1, 3, 7, 7, 7], [1, 1, 4, 7, 7, 7], [1, 2, 7, 7, 7], [1, 8, 8, 8], [2, 8, 8, 8], [1, 9, 9, 9], [10]]
>>> maple('bell(10)')
115975
>>> maple('fibonacci(10)')
55
```

### set(var, value)

Set the variable `var` to the given value.

**EXAMPLES:**

```python
sage: maple.set('xx', 2)  # optional - maple
sage: maple.get('xx')  # optional - maple
2
```

### source(s)

Display the Maple source (if possible) about `s`.

This is the same as returning the output produced by the following Maple commands:

```plaintext
interface(verboseproc=2): print(s)
```

**INPUT:**

- `s` – a string representing the function whose source code you want

**EXAMPLES:**

```python
sage: maple.source('curry')  # not tested
... -> subs(_X = _passed[2 .. _npassed],() -> ...(_X, _passed))
```

25.1. Tutorial 279
with_package (package)

Make a package of Maple procedures available in the interpreter.

INPUT:

- package – string

EXAMPLES: Some functions are unknown to Maple until you use with to include the appropriate package.

```python
>>> from sage.all import *
>>> maple.source('curry')  # not tested
...
-> subs(_X = _passed[2 .. _npassed],() -> ...(_X, _passed))

>>> from sage.all import *
>>> # optional - maple
>>> maple.quit()  # reset maple
>>> maple('partition(10)')
partition(10)
>>> maple('bell(10)')
>>> maple.with_package('combinat')
>>> maple('partition(10)')
[[1, 1, 1, 1, 1, 1, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1, 1, 1, 2, 1], [1, 1, 1, 1, 1, 1, 1, 2, 2], [1, 1, 1, 1, 1, 1, 2, 2, 2], [1, 1, 1, 2, 2, 2, 2], [1, 1, 2, 2, 2, 2], [1, 1, 1, 1, 1, 1, 3], [1, 1, 1, 1, 1, 3, 3], [1, 1, 2, 3, 3], [1, 2, 2, 3, 3], [1, 1, 1, 1, 1, 4], [1, 1, 1, 1, 2, 4], [1, 1, 1, 2, 2, 4], [1, 1, 2, 2, 2, 4], [1, 1, 1, 1, 3, 4], [1, 1, 2, 3, 4], [1, 1, 2, 4, 4], [1, 1, 4, 4], [1, 1, 1, 1, 3, 5], [1, 1, 1, 2, 3, 5], [1, 1, 1, 3, 5], [1, 1, 2, 5], [1, 1, 3, 5], [1, 2, 5], [1, 1, 1, 4, 6], [1, 1, 1, 5, 6], [1, 1, 1, 6, 6], [1, 1, 2, 6, 6], [1, 1, 3, 6, 6], [1, 1, 4, 6, 6], [1, 1, 5, 6, 6], [1, 1, 1, 7, 6], [1, 1, 1, 6, 7], [1, 1, 2, 7, 6], [1, 1, 1, 7, 7], [1, 2, 7, 7], [2, 7, 7], [1, 1, 1, 8, 8], [2, 2, 8], [1, 1, 9, 9], [1, 1, 1, 1, 8, 10]]
```

```python
>>> maple('bell(10)')
115975
>>> maple('fibonacci(10)')
55
```
class sage.interfaces.maple.MapleElement(parent, value, is_name=False, name=None)
Bases: ExtraTabCompletion, ExpectElement

op(i=\text{None})

Return the i-th operand of this expression.

INPUT:

• \text{i} – an integer or None

EXAMPLES:

.. code-block::

   sage: V = maple(vector(QQ, [4, 5, 6]))  # optional - maple
   sage: V.op(1)  # optional - maple
   3
   sage: V.op(2)  # optional - maple
   \{1 = 4, 2 = 5, 3 = 6\}

>>> from sage.all import *

>>> V = maple(vector(QQ, [Integer(4), Integer(5), Integer(6)]))  # optional - maple

>>> V.op(Integer(1))  # optional - maple
3

>>> V.op(Integer(2))  # optional - maple
\{1 = 4, 2 = 5, 3 = 6\}

class sage.interfaces.maple.MapleFunction(parent, name)
Bases: ExpectFunction

class sage.interfaces.maple.MapleFunctionElement(obj, name)
Bases: FunctionElement

sage.interfaces.maple.maple_console()

Spawn a new Maple command-line session.

EXAMPLES:

.. code-block::

   sage: maple_console()  # not tested

    Maple 11 (IBM INTEL LINUX)
    _|
    \ MAPLE / All rights reserved. Maple is a trademark of
    <____ ____> Waterloo Maple Inc.
    | Type ? for help.

>>> from sage.all import *

>>> maple_console()  # not tested

sage.interfaces.maple.reduce_load_Maple()

Return the maple object created in sage.interfaces.maple.

EXAMPLES:
sage: from sage.interfaces.maple import reduce_load_Maple
sage: reduce_load_Maple()
Maple

>>> from sage.all import *
>>> from sage.interfaces.maple import reduce_load_Maple
>>> reduce_load_Maple()
Maple
The Mathematica interface will only work if Mathematica is installed on your computer with a command line interface that runs when you give the `math` command. The interface lets you send certain Sage objects to Mathematica, run Mathematica functions, import certain Mathematica expressions to Sage, or any combination of the above. The Sage command:

```
sage: print(mathematica._install_hints())
...
```

```
>>> from sage.all import *

>>> print(mathematica._install_hints())
...
```

prints more information on Mathematica installation.

To send a Sage object `sobj` to Mathematica, call `mathematica(sobj)`. This exports the Sage object to Mathematica and returns a new Sage object wrapping the Mathematica expression/variable, so that you can use the Mathematica variable from within Sage. You can then call Mathematica functions on the new object; for example:

```
sage: mobj = mathematica(x^2-1)  # optional - mathematica
sage: mobj.Factor()  # optional - mathematica
(-1 + x)*(1 + x)
```

```
>>> from sage.all import *

>>> mobj = mathematica(x**Integer(2)-Integer(1))  # optional - mathematica
>>> mobj.Factor()  # optional - mathematica
(-1 + x)*(1 + x)
```

In the above example the factorization is done using Mathematica's `Factor[]` function.

To see Mathematica’s output you can simply print the Mathematica wrapper object. However if you want to import Mathematica’s output back to Sage, call the Mathematica wrapper object’s `sage()` method. This method returns a native Sage object:

```
sage: # optional - mathematica
sage: mobj = mathematica(x^2-1)
sage: mobj.Factor(); mobj2
(-1 + x)*(1 + x)
sage: mobj2 = mobj.Factor(); mobj2
(-1 + x)*(1 + x)
```

```
>>> from sage.all import *

>>> mobj = mathematica(x**Integer(2)-Integer(1))  # optional - mathematica

>>> mobj.Factor()  # optional - mathematica
(-1 + x)*(1 + x)
```

Mathematica
```
sage: # optional - mathematica
sage: mobj = mathematica(x^2-1)
sage: mobj2 = mobj.Factor(); mobj2
(-1 + x)*(1 + x)
sage: mobj2.parent()
Mathematica
sage: subj = mobj2.sage(); subj
(x + 1)*(x - 1)
sage: subj.parent()
Symbolic Ring
```
If you want to run a Mathematica function and don’t already have the input in the form of a Sage object, then it might be simpler to input a string to \texttt{mathematica}(\textit{expr}). This string will be evaluated as if you had typed it into Mathematica:

\begin{verbatim}
  sage: mathematica('Factor[x^2-1]')  # optional - mathematica
  (-1 + x)*(1 + x)

  sage: mathematica('Range[3]')  # optional - mathematica
  {1, 2, 3}
\end{verbatim}

If you don’t want Sage to go to the trouble of creating a wrapper for the Mathematica expression, then you can call \texttt{mathematica}.$\texttt{eval}(\textit{expr})$, which returns the result as a Mathematica AsciiArtString formatted string. If you want the result to be a string formatted like Mathematica’s InputForm, call \texttt{repr(\textit{mobj})} on the wrapper object \textit{mobj}. If you want a string formatted in Sage style, call \textit{mobj}.$\texttt{_sage_repr()}$:

\begin{verbatim}
  sage: mathematica.eval('x^2 - 1')  # optional - mathematica
  2
  -1 + x

  sage: repr(mathematica('Range[3]'))  # optional - mathematica
  '{1, 2, 3}'

  sage: mathematica('Range[3]')._sage_repr()  # optional - mathematica
  '[1, 2, 3]'
\end{verbatim}

Finally, if you just want to use a Mathematica command line from within Sage, the function \texttt{mathematica}.$\texttt{console()}$ dumps you into an interactive command-line Mathematica session. This is an enhanced version of the usual Mathematica command-line, in that it provides readline editing and history (the usual one doesn’t!)
26.1 Tutorial

We follow some of the tutorial from http://library.wolfram.com/conferences/devconf99/withoff/Basic1.html/. For any of this to work you must buy and install the Mathematica program, and it must be available as the command math in your PATH.

26.1.1 Syntax

Now make 1 and add it to itself. The result is a Mathematica object.

```sage
m = mathematica
a = m(1) + m(1); a  # optional - mathematica
2
a.parent()          # optional - mathematica
Mathematica
m('1+1')            # optional - mathematica
2
m(3)**m(50)         # optional - mathematica
71897987691852588770249
```

The following is equivalent to `Plus[2, 3]` in Mathematica:

```sage
m = mathematica
m(2).Plus(m(3))     # optional - mathematica
5
```

We can also compute `7(2 + 3)`.

```sage
m(7).Times(m(2).Plus(m(3))) # optional - mathematica
35
m('7(2+3)')             # optional - mathematica
35
```

(continues on next page)
26.1.2 Some typical input

We solve an equation and a system of two equations:

```python
sage: eqn = mathematica('3x + 5 == 14')
sage: eqn
5 + 3*x == 14
sage: eqn.Solve('x')
{(x -> 3)}
sage: sys = mathematica({x^2 - 3y == 3, 2x - y == 1})
sage: print(sys)
{x - 3 y == 3, 2 x - y == 1}
sage: sys.Solve({x, y})
{{x -> 0, y -> -1}, {x -> 6, y -> 11}}
```

26.1.3 Assignments and definitions

If you assign the mathematica 5 to a variable \(c\) in Sage, this does not affect the \(c\) in Mathematica.

```python
sage: c = m(5)  # optional - mathematica
sage: print(m('b + c x'))  # optional - mathematica
b + c x
sage: print(m('b') + c*m('x'))  # optional - mathematica
b + 5 x
```

The Sage interfaces changes Sage lists into Mathematica lists:
26.1.4 Function definitions

Define mathematica functions by simply sending the definition to the interpreter.

```plaintext
sage: m = mathematica
sage: _ = mathematica('f[p_] = p^2');  # optional - mathematica
sage: m('f[9]')                        # optional - mathematica
81
```

26.1.5 Numerical Calculations

We find the $x$ such that $e^x - 3x = 0$.

```plaintext
sage: eqn = mathematica('Exp[x] - 3x == 0')  # optional - mathematica
sage: eqn.FindRoot({'x': 2})                # optional - mathematica
{x -> 1.512134551657842}
```

Note that this agrees with what the PARI interpreter gp produces:

```plaintext
sage: gp('solve(x=1,2,exp(x)-3*x)')
1.512134551657842473896739678 # 32-bit
1.5121345516578424738967396780720387046 # 64-bit
```
Interpreter Interfaces, Release 10.4

```python
>>> from sage.all import *
>>> gp('solve(x=1,2,exp(x)-3*x)')
1.512134551657842473896739678 # 32-bit
1.5121345516578424738967396780720387046 # 64-bit
```

Next we find the minimum of a polynomial using the two different ways of accessing Mathematica:

```python
sage: mathematica('FindMinimum[x^3 - 6x^2 + 11x - 5, {x,3}]
# optional - mathematica
{0.6150998205402516, {x -> 2.5773502699629733}}
```

```python
>>> from sage.all import *
>>> f = mathematica('x^3 - 6x^2 + 11x - 5')
# optional - mathematica
>>> f.FindMinimum({x, 3})
# optional - mathematica
{0.6150998205402516, {x -> 2.5773502699629733}}
```

26.1.6 Polynomial and Integer Factorization

We factor a polynomial of degree 200 over the integers.

```python
sage: R.<x> = PolynomialRing(ZZ)
sage: f = (x**100+17*x+5)*(x**100-5*x+20)
sage: f
x^200 + 12*x^101 + 25*x^100 - 85*x^2 + 315*x + 100
sage: g = mathematica(str(f))
# optional - mathematica
sage: print(g)
# optional - mathematica
2 100 101 200
100 + 315 x - 85 x + 25 x + 12 x + x
sage: g
# optional - mathematica
100 + 315*x - 85*x^2 + 25*x^100 + 12*x^101 + x^200
sage: print(g.Factor())
# optional - mathematica
100 100
(20 - 5 x + x ) (5 + 17 x + x )
```

We can also factor a multivariate polynomial:

```python
```

288 Chapter 26. Interface to Mathematica
We factor an integer:

Mathematica’s ECM package is no longer available.

## 26.2 Long Input

The Mathematica interface reads in even very long input (using files) in a robust manner.
26.3 Loading and saving

Mathematica has an excellent InputForm function, which makes saving and loading Mathematica objects possible. The first examples test saving and loading to strings.

```
sage: # optional - mathematica
sage: x = mathematica(pi/2)
sage: print(x)
  Pi
  --
  2
sage: loads(dumps(x)) == x
True
sage: n = x.N(50)
sage: print(n)
1.5707963267948966192313216916397514420985846996876
sage: loads(dumps(n)) == n
True
```

```
>>> from sage.all import *
>>> # optional - mathematica
>>> x = mathematica(pi/Integer(2))
>>> print(x)
  Pi
  --
  2
>>> loads(dumps(x)) == x
True
>>> n = x.N(Integer(50))
>>> print(n)
1.5707963267948966192313216916397514420985846996876
>>> loads(dumps(n)) == n
True
```

26.4 Complicated translations

The `sageobj.sage()` method tries to convert a Mathematica object to a Sage object. In many cases, it will just work. In particular, it should be able to convert expressions entirely consisting of:

- numbers, i.e. integers, floats, complex numbers;
- functions and named constants also present in Sage, where:
  - Sage knows how to translate the function or constant’s name from Mathematica’s, or
  - the Sage name for the function or constant is trivially related to Mathematica’s;
- symbolic variables whose names don’t pathologically overlap with objects already defined in Sage.

This method will not work when Mathematica’s output includes:

- strings;
- functions unknown to Sage;
- Mathematica functions with different parameters/parameter order to the Sage equivalent.
If you want to convert more complicated Mathematica expressions, you can instead call `mobj._sage_()` and supply a translation dictionary:

```python
sage: m = mathematica('NewFn[x]')  # optional - mathematica
sage: m._sage_(locals={'NewFn': sin})  # optional - mathematica
sin(x)
```

```python
>>> from sage.all import *
>>> m = mathematica('NewFn[x]')  # optional - mathematica
>>> m._sage_(locals={'NewFn': Integer(1)})  # optional - mathematica
sin(x)
```

For more details, see the documentation for `_sage_()`.

**OTHER Examples:**

```python
sage: def math_bessel_K(nu,x):
    ....: return mathematica(nu).BesselK(x).N(20)
sage: math_bessel_K(2,I)  # optional - mathematica
-2.59288617549119697817 + 0.18048997206696202663*I
```

```python
>>> from sage.all import *
>>>
>>> def math_bessel_K(nu,x):
...     return mathematica(nu).BesselK(x).N(Integer(20))
>>> math_bessel_K(Integer(2),I)  # optional - mathematica
-2.59288617549119697817 + 0.18048997206696202663*I
```

```python
sage: slist = [[1, 2], 3., 4 + I]
sage: mlist = mathematica(slist); mlist  # optional - mathematica
{{1, 2}, 3., 4 + I}
sage: slist2 = list(mlist); slist2  # optional - mathematica
[{1, 2}, 3., 4 + I]
sage: slist2[0]  # optional - mathematica
{1, 2}
sage: slist2[0].parent()  # optional - mathematica
Mathematica
sage: slist3 = mlist.sage(); slist3  # optional - mathematica
[[1, 2], 3.00000000000000, I + 4]
```

```python
>>> from sage.all import *
>>> slist = [[Integer(1), Integer(2)], RealNumber('3.'), Integer(4) + I]
>>> mlist = mathematica(slist); mlist  # optional - mathematica
{{1, 2}, 3., 4 + I}
>>> slist2 = list(mlist); slist2  # optional - mathematica
[{1, 2}, 3., 4 + I]
>>> slist2[Integer(0)]  # optional - mathematica
{1, 2}
>>> slist2[Integer(0)].parent()  # optional - mathematica
Mathematica
>>> slist3 = mlist.sage(); slist3  # optional - mathematica
[[1, 2], 3.00000000000000, I + 4]
```

```python
sage: mathematica('10.^80')  # optional - mathematica
1.*^80
sage: mathematica('10.^80').sage()  # optional - mathematica
1.00000000000000e80
```
AUTHORS:

- William Stein (2005): first version
- Felix Lawrence (2009-08-21): Added support for importing Mathematica lists and floats with exponents.

class sage.interfaces.mathematica.Mathematica(maxread=None, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, command=None, verbose_start=False)

Bases: ExtraTabCompletion, Expect

Interface to the Mathematica interpreter.

chdir(dir)
Change Mathematica's current working directory.

EXAMPLES:

```
sage: mathematica.chdir('/')  # optional - mathematica
sage: mathematica('Directory[]')  # optional - mathematica
```

```
>>> from sage.all import *
>>>
>>> mathematica.chdir('/')  # optional - mathematica
>>> mathematica('Directory[]')  # optional - mathematica
```

cache(readline=True)

eval(code, strip=True, **kwds)

get(var, ascii_art=False)
Get the value of the variable var.

AUTHORS:

- William Stein
- Kiran Kedlaya (2006-02-04): suggested using InputForm

help(cmd)

set(var, value)
Set the variable var to the given value.

class sage.interfaces.mathematica.MathematicaElement(parent, value, is_name=False, name=None)

Bases: ExpectElement
Numerical approximation by converting to Sage object first

Convert the object into a Sage object and return its numerical approximation. See documentation of the function `sage.misc.functional.n()` for details.

**EXAMPLES:**

```python
sage: mathematica('Pi').n(10) # optional -- mathematica
3.1
sage: mathematica('Pi').n() # optional -- mathematica
3.14159265358979
sage: mathematica('Pi').n(digits=10) # optional -- mathematica
3.141592654
```

```python
>>> from sage.all import *
```

```python
>>> mathematica('Pi').n(Integer(10)) # optional -- mathematica
3.1
```

```python
>>> from sage.all import *
```

```python
>>> mathematica('Pi').n() # optional -- mathematica
3.14159265358979
```

```python
>>> from sage.all import *
```

```python
>>> mathematica('Pi').n(digits=Integer(10)) # optional -- mathematica
3.141592654
```

**save_image** *(filename, ImageSize=600)*

Save a mathematica graphics

**INPUT:**

- `filename` – string. The filename to save as. The extension determines the image file format.
- `ImageSize` – integer. The size of the resulting image.

**EXAMPLES:**

```python
sage: P = mathematica('Plot[Sin[x],{x,-2Pi,4Pi}]') # optional -- mathematica
sage: filename = tmp_filename() # optional -- mathematica
sage: P.save_image(filename, ImageSize=800) # optional -- mathematica
```

```python
>>> from sage.all import *
```

```python
>>> P = mathematica('Plot[Sin[x],{x,-2Pi,4Pi}]') # optional -- mathematica
```

```python
>>> filename = tmp_filename() # optional -- mathematica
```

```python
>>> P.save_image(filename, ImageSize=Integer(800)) # optional -- mathematica
```

**show** *(ImageSize=600)*

Show a mathematica expression immediately.

This method attempts to display the graphics immediately, without waiting for the currently running code (if any) to return to the command line. Be careful, calling it from within a loop will potentially launch a large number of external viewer programs.

**INPUT:**

- `ImageSize` – integer. The size of the resulting image.

**OUTPUT:**

This method does not return anything. Use `save()` if you want to save the figure as an image.

**EXAMPLES:**
sage: Q = mathematica('Sin[x*Cos[y]]/Sqrt[1-x^2]')  # optional - mathematica
sage: show(Q)  # optional - mathematica
\[ \frac{\sin(x \cos(y))}{\sqrt{1-x^2}} \]

The following example starts a Mathematica frontend to do the rendering (Issue #28819):

```plaintext
sage: P = mathematica('Plot[Sin[x],{x,-2Pi,4Pi}]')  # optional - mathematica
sage: show(P)  # optional - mathematica
```

For more details on the `SageMath` interface to Mathematica, you can refer to the `sage.interfaces.mathematica` module, which includes classes like `MathematicaFunction` and `MathematicaFunctionElement`.

```python
str()
class sage.interfaces.mathematica.MathematicaFunction (parent, name):
    Bases: ExpectFunction
class sage.interfaces.mathematica.MathematicaFunctionElement (obj, name):
    Bases: FunctionElement
sage.interfaces.mathematica.clean_output(s)
sage.interfaces.mathematica.mathematica_console (readline=True)
sage.interfaces.mathematica.parse_moutput_from_json (page_data, verbose=False)

Return the list of outputs found in the json (with key 'moutput')

INPUT:
- page_data – json obtained from Wolfram Alpha
- verbose – bool (default: False)

OUTPUT:
list of unicode strings

EXAMPLES:
```
>>> from sage.all import *
>>> from sage.interfaces.mathematica import request_wolfram_alpha
>>> from sage.interfaces.mathematica import parse_moutput_from_json

>>> page_data = request_wolfram_alpha('integrate Sin[x]')  # optional internet
["-Cos[x]"

sage: page_data = request_wolfram_alpha('Sin[x]')  # optional internet
sage: L = parse_moutput_from_json(page_data)  # optional internet
sage: sorted(L)
['-Cos[x]', '{x == 0}', '{x == Pi C[1], Element[C[1], Integers]}']

sage: from sage.all import *

>>> L = parse_moutput_from_json(page_data)  # optional internet
>>> sorted(L)
['-Cos[x]', '{x == 0}', '{x == Pi C[1], Element[C[1], Integers]}']

sage.interfaces.mathematica.reduce_load(X)
sage.interfaces.mathematica.request_wolfram_alpha(input, verbose=False)

Request Wolfram Alpha website.

INPUT:

• input – string
• verbose – bool (default: False)

OUTPUT:

json

EXAMPLES:

sage: from sage.interfaces.mathematica import request_wolfram_alpha
sage: page_data = request_wolfram_alpha('integrate Sin[x]')  # optional internet
sage: [str(a) for a in sorted(page_data.keys())]  # optional internet
["queryresult"]

sage: [str(a) for a in sorted(page_data['queryresult'].keys())]  # optional internet
sage.interfaces.mathematica.symbolic_expression_from_mathematica_string(mexpr)

Translate a mathematica string into a symbolic expression

INPUT:

- mexpr – string

OUTPUT:

symbolic expression

EXAMPLES:

sage: from sage.interfaces.mathematica import symbolic_expression_from_mathematica_string
sage: symbolic_expression_from_mathematica_string('"-Cos[x]"')
-cos(x)

sage: from sage.all import *
sage: from sage.interfaces.mathematica import symbolic_expression_from_mathematica_string
sage: symbolic_expression_from_mathematica_string('"-Cos[x]"')
-cos(x)
Mathics is an open source interpreter for the Wolfram Language. From the introduction of its reference manual:

**Note:** Mathics — to be pronounced like “Mathematics” without the “emat” — is a general-purpose computer algebra system (CAS). It is meant to be a free, light-weight alternative to Mathematica®. It is free both as in “free beer” and as in “freedom”. There are various online mirrors running Mathics but it is also possible to run Mathics locally. A list of mirrors can be found at the Mathics homepage, http://mathics.github.io.

The programming language of Mathics is meant to resemble Wolfram’s famous Mathematica® as much as possible. However, Mathics is in no way affiliated or supported by Wolfram. Mathics will probably never have the power to compete with Mathematica® in industrial applications; yet, it might be an interesting alternative for educational purposes.

The Mathics interface will only work if the optional Sage package Mathics is installed. The interface lets you send certain Sage objects to Mathics, run Mathics functions, import certain Mathics expressions to Sage, or any combination of the above.

To send a Sage object `sobj` to Mathics, call `mathics(sobj)`. This exports the Sage object to Mathics and returns a new Sage object wrapping the Mathics expression/variable, so that you can use the Mathics variable from within Sage. You can then call Mathics functions on the new object; for example:

```python
sage: from sage.interfaces.mathics import mathics
sage: mobj = mathics(x^2-1); mobj
# optional - mathics
-1 + x ^ 2
sage: mobj.Factor()  # optional - mathics
(-1 + x) (1 + x)
```

In the above example the factorization is done using Mathics’s `Factor[]` function.

To see Mathics’s output you can simply print the Mathics wrapper object. However if you want to import Mathics’s output back to Sage, call the Mathics wrapper object’s `sage()` method. This method returns a native Sage object:

```python
sage: # optional - mathics
sage: mobj = mathics(x^2-1)
sage: mobj2 = mobj.Factor(); mobj2
(-1 + x) (1 + x)
sage: mobj2.parent()
```

(continues on next page)
Mathics

```
sage: sobj = mobj2.sage(); sobj
(x + 1)*(x - 1)
sage: sobj.parent()
Symbolic Ring
```

```
>>> from sage.all import *
>>>
# optional - mathics
>>> mobj = mathics(x**Integer(2)-Integer(1))
>>> mobj2 = mobj.Factor(); mobj2
(-1 + x) (1 + x)
>>> mobj2.parent()
Mathics
>>> sobj = mobj2.sage(); sobj
(x + 1)*(x - 1)
>>> sobj.parent()
Symbolic Ring
```

If you want to run a Mathics function and don’t already have the input in the form of a Sage object, then it might be simpler to input a string to `mathics(expr)`. This string will be evaluated as if you had typed it into Mathics:

```
sage: mathics('Factor[x^2-1]')
# optional - mathics
(-1 + x) (1 + x)
sage: mathics('Range[3]')
# optional - mathics
{1, 2, 3}
```

```
>>> from sage.all import *
>>>
# optional - mathics
>>> mathics('Factor[x^2-1]')
(-1 + x) (1 + x)
>>> mathics('Range[3]')
{1, 2, 3}
```

If you want work with the internal Mathics expression, then you can call `mathics.eval(expr)`, which returns an instance of `mathics.core.expression.Expression`. If you want the result to be a string formatted like Mathics’s InputForm, call `repr(mobj)` on the wrapper object `mobj`. If you want a string formatted in Sage style, call `mobj._sage_repr()`:

```
sage: mathics.eval('x^2 - 1')
# optional - mathics
'-1 + x ^ 2'
sage: repr(mathics('Range[3]'))
# optional - mathics
'{1, 2, 3}'
sage: mathics('Range[3]')._sage_repr()
# optional - mathics
'[1, 2, 3]'
```

```
>>> from sage.all import *
>>>
# optional - mathics
>>> mathics.eval('x^2 - 1')
'-1 + x ^ 2'
>>> repr(mathics('Range[3]'))
'{1, 2, 3}'
>>> mathics('Range[3]')._sage_repr()
'[1, 2, 3]'
```

Finally, if you just want to use a Mathics command line from within Sage, the function `mathics_console()` dumps you into an interactive command-line Mathics session.
27.1 Tutorial

We follow some of the tutorial from http://library.wolfram.com/conferences/devconf99/withoff/Basic1.html/.

27.1.1 Syntax

Now make 1 and add it to itself. The result is a Mathics object.

```sage
m = mathics
a = m(1) + m(1); a
# optional - mathics
2
a.parent()
# optional - mathics
Mathics
m('1+1')
# optional - mathics
2
m(3)**m(50)
# optional - mathics
717897987691852588770249
```

The following is equivalent to `Plus[2, 3]` in Mathics:

```sage
m(2).Plus(m(3))
# optional - mathics
5
```

We can also compute `7(2 + 3)`.

```sage
m(7).Times(m(2).Plus(m(3)))
# optional - mathics
35
m('7(2+3)')
# optional - mathics
35
```

```sage
>>> from sage.all import *

m = mathics

a = m(Integer(1)) + m(Integer(1)); a
# optional - mathics
2
a.parent()
# optional - mathics
Mathics
m('1+1')
# optional - mathics
2
m(Integer(3))**m(Integer(50))
# optional - mathics
717897987691852588770249
```

The following is equivalent to `Plus[2, 3]` in Mathics:

```sage
m(2).Plus(m(3))
# optional - mathics
5
```

We can also compute `7(2 + 3)`.

```sage
m(7).Times(m(2).Plus(m(3)))
# optional - mathics
35
m('7(2+3)')
# optional - mathics
35
```
27.1.2 Some typical input

We solve an equation and a system of two equations:

```python
sage: # optional - mathics
eqn = mathics('3x + 5 == 14')
sage: eqn
5 + 3 x == 14
sage: eqn.Solve('x')
{(x -> 3)}
sage: sys = mathics({x^2 - 3y == 3, 2x - y == 1})
sage: print(sys)
{x^2 - 3 y == 3, 2 x - y == 1}
sage: sys.Solve({'x', 'y'})
{(x -> 0, y -> -1), (x -> 6, y -> 11)}
```

27.1.3 Assignments and definitions

If you assign the mathics 5 to a variable 𝑐 in Sage, this does not affect the 𝑐 in Mathics.

```python
sage: c = m(5) # optional - mathics
sage: print(m('b + c x'))
b + c x
sage: print(m('b') + c*m('x'))
b + 5 x
```

The Sage interfaces changes Sage lists into Mathics lists:

```python
sage: m = mathics
sage: eq1 = m('x^2 - 3y == 3') # optional - mathics
sage: eq2 = m('2x - y == 1') # optional - mathics
sage: v = m([eq1, eq2]); v # optional - mathics
{x^2 - 3 y == 3, 2 x - y == 1}
sage: v.Solve(['x', 'y']) # optional - mathics
{(x -> 0, y -> -1), (x -> 6, y -> 11)}
```
>>> from sage.all import *
>>> m = mathics

>>> eq1 = m('x^2 - 3y == 3')  # optional - mathics
>>> eq2 = m('2x - y == 1')  # optional - mathics

>>> v = m([eq1, eq2]); v  # optional - mathics
{x^2 - 3 y == 3, 2 x - y == 1}

>>> v.Solve(['x', 'y'])  # optional - mathics
{(x -> 0, y -> -1), {x -> 6, y -> 11}}

27.1.4 Function definitions

Define mathics functions by simply sending the definition to the interpreter.

sage: m = mathics
sage: _ = mathics(f[\_] = p^2);  # optional - mathics
sage: m(f[9])  # optional - mathics
81

>>> from sage.all import *

>>> _ = mathics(f[\_] = p^2);  # optional - mathics

>>> m(f[9])  # optional - mathics
81

27.1.5 Numerical Calculations

We find the \( x \) such that \( e^x - 3x = 0 \).

sage: eqn = mathics('Exp[x] - 3x == 0')  # optional - mathics
sage: eqn.FindRoot(['x', 2])  # optional - mathics
{x -> 1.51213}

sage: gp(solve(x=1,2,exp(x)-3*x))
1.512134551657842473896739678 # 32-bit
1.5121345516578424738967396780720387046 # 64-bit

Note that this agrees with what the PARI interpreter gp produces:

sage: gp('solve(x=1,2,exp(x)-3*x)')
1.512134551657842473896739678 # 32-bit
1.5121345516578424738967396780720387046 # 64-bit

Next we find the minimum of a polynomial using the two different ways of accessing Mathics:

sage: mathics('FindMinimum[x^3 - 6x^2 + 11x - 5, \{x,3\}]')  # not tested (since not...

(continues on next page)
27.1.6 Polynomial and Integer Factorization

We factor a polynomial of degree 200 over the integers.

```python
sage: R.<x> = PolynomialRing(ZZ)
sage: f = (x**100 + 17*x + 5)*(x**100 - 5*x + 20)
sage: f
x^200 + 12*x^101 + 25*x^100 - 85*x + 315*x + 100
sage: g = mathics(str(f)) # optional - mathics
sage: print(g) # optional - mathics
100 + 315*x - 85*x^2 + 25*x^100 + 12*x^101 + x^200
sage: print(g.Factor()) # optional - mathics
(5 + 17*x + x^100) (20 - 5*x + x^100)
```

We can also factor a multivariate polynomial:

```python
sage: f = mathics('x^6 + (-y - 2)*x^5 + (y^3 + 2*y)*x^4 - y^4*x^3') # optional - mathics
sage: print(f.Factor()) # optional - mathics
x^3 (x - y) (-2 + x + x^2 + y^3)
```

(continues on next page)
We factor an integer:

```python
sage: n = mathics(2434500)
sage: n.FactorInteger()
{(2, 2), (3, 2), (5, 3), (541, 1)}
```

```python
sage: F = n.FactorInteger(); F
{(2, 2), (3, 2), (5, 3), (541, 1)}
```

```python
sage: F[1]
{2, 2}
```

```python
sage: F[4]
{541, 1}
```

27.2 Long Input

The Mathics interface reads in even very long input (using files) in a robust manner.

```python
sage: t = "%s" % (10**10000) # ten thousand character string.
sage: a = mathics(t) # optional - mathics
```

```python
>>> from sage.all import *
```

```python
sage: t = "%s" % Integer(10)**Integer(10000) # ten thousand character string.
sage: a = mathics(t) # optional - mathics
>>> a = mathics.eval(t) # optional - mathics
```
27.3 Loading and saving

Mathics has an excellent `InputForm` function, which makes saving and loading Mathics objects possible. The first examples test saving and loading to strings.

```sage
# optional - mathics
sage: x = mathics(pi/2)
sage: print(x)
Pi / 2
sage: loads(dumps(x)) == x
True
sage: n = x.N(50)
sage: print(n)
1.5707963267948966192313216916397514420985846996876
sage: loads(dumps(n)) == n
True
```

```python
>>> from sage.all import *

>>> x = mathics(pi/Integer(2))
>>> print(x)
Pi / 2
>>> loads(dumps(x)) == x
True
>>> n = x.N(Integer(50))
>>> print(n)
1.5707963267948966192313216916397514420985846996876
>>> loads(dumps(n)) == n
True
```

27.4 Complicated translations

The `mobj.sage()` method tries to convert a Mathics object to a Sage object. In many cases, it will just work. In particular, it should be able to convert expressions entirely consisting of:

- numbers, i.e. integers, floats, complex numbers;
- functions and named constants also present in Sage, where:
  - Sage knows how to translate the function or constant’s name from Mathics’s, or
  - the Sage name for the function or constant is trivially related to Mathics’s;
- symbolic variables whose names don’t pathologically overlap with objects already defined in Sage.

This method will not work when Mathics’s output includes:

- strings;
- functions unknown to Sage;
- Mathics functions with different parameters/parameter order to the Sage equivalent.

If you want to convert more complicated Mathics expressions, you can instead call `mobj._sage_()` and supply a translation dictionary:
sage: x = var('x')
sage: m = mathics('NewFn[x]')
# optional - mathics
sage: m._sage_(locals={'NewFn': sin, 'x':x})
# optional - mathics
sin(x)

>>> from sage.all import *
>>> x = var('x')
>>> m = mathics('NewFn[x]')
# optional - mathics
>>> m._sage_(locals={'NewFn': sin, 'x':x})
# optional - mathics
sin(x)

For more details, see the documentation for \_sage\_().

OTHER Examples:

sage: def math_bessel_K(nu,x):
....:     return mathics(nu).BesselK(x).N(20)
sage: math_bessel_K(2,I)
# optional - mathics
-2.5928861754911969782 + 0.18048997206696202663 I

>>> from sage.all import *
>>> def math_bessel_K(nu,x):
...     return mathics(nu).BesselK(x).N(Integer(20))

>>> math_bessel_K(Integer(2),I)
# optional - mathics
-2.5928861754911969782 + 0.18048997206696202663 I

sage: slist = [[1, 2], 3., 4 + I]
sage: mlist = mathics(slist)
# optional - mathics
{[1, 2], 3., 4 + I}
sage: slist2 = list(mlist); slist2
# optional - mathics
[[1, 2], 3., 4 + I]
sage: slist2[0]
# optional - mathics
{1, 2}
sage: slist2[0].parent()
# optional - mathics
Mathics
sage: slist3 = mlist.sage(); slist3
# optional - mathics
[[1, 2], 3.00000000000000, 4.00000000000000 + 1.00000000000000*I]

>>> from sage.all import *
>>> slist = [[Integer(1), Integer(2)], RealNumber('3.'), Integer(4) + I]
>>> mlist = mathics(slist)
# optional - mathics
{[1, 2], 3., 4 + I}
>>> slist2 = list(mlist); slist2
# optional - mathics
[[1, 2], 3., 4 + I]
>>> slist2[Integer(0)]
# optional - mathics
{1, 2}
>>> slist2[Integer(0)].parent()
# optional - mathics
Mathics
>>> slist3 = mlist.sage(); slist3
# optional - mathics
[[1, 2], 3.00000000000000, 4.00000000000000 + 1.00000000000000*I]

sage: mathics('10.^80')
# optional - mathics
1.*^80
sage: mathics('10.^80').sage()
# optional - mathics
1.00000000000000e80
AUTHORS:

- Sebastian Oehms (2021): first version from a copy of the Mathematica interface (see Issue #31778).

Thanks to Rocky Bernstein and Juan Mauricio Matera for their support. For further acknowledgments see this list.

```python
>>> from sage.all import *
>>> mathics('10.*^80') # optional - mathics
1.*^80
>>> mathics('10.*^80').sage() # optional - mathics
1.00000000000000e80
```

More examples can be found in the module header.
**chdir** *(dir)*

Change Mathics’s current working directory.

**EXAMPLES:**

```plaintext
sage: mathics.chdir('/') # optional - mathics
sage: mathics('Directory[]') # optional - mathics
```

```plaintext
>>> from sage.all import *
>>> mathics.chdir('/') # optional - mathics
>>> mathics('Directory[]') # optional - mathics
```

**console()**

Spawn a new Mathics command-line session.

**EXAMPLES:**

```plaintext
sage: mathics.console() # not tested
```

Mathics 2.1.1.dev0

sage:

eval (code, *args, **kwds)
Evaluates a command inside the Mathics interpreter and returns the output in printable form.

EXAMPLES:
sage: mathics.eval('1+1') # optional - mathics
2

>>> from sage.all import *
>>> mathics.eval('1+1') # optional - mathics
2

get (var)
Get the value of the variable var.

EXAMPLES:
sage: mathics.set('u', '2*x + E') # optional - mathics
sage: mathics.get('u') # optional - mathics
'E + 2 x'

>>> from sage.all import *
>>> mathics.set('u', '2*x + E') # optional - mathics
>>> mathics.get('u') # optional - mathics
'E + 2 x'

help (cmd, long=False)
Return the Mathics documentation of the given command.

EXAMPLES:
sage: mathics.help('Sin') # optional - mathics
"\n 'Sin[z]'
 returns the sine of z."
sage: print(_)# optional - mathics
'Sin[z]'
 returns the sine of z.

sage: print(mathics.help('Sin', long=True)) # optional - mathics
'Sin[z]'
 returns the sine of z.

Attributes[Sin] = {Listable, NumericFunction, Protected}

sage: print(mathics.Factorial.__doc__) # optional - mathics
'Factorial[n]'
(continues on next page)
'n!'
computes the factorial of n.

```python
sage: u = mathics('Pi')       # optional - mathics
sage: print(u.Cos.__doc__)   # optional - mathics
'Cos[z]' returns the cosine of z.
```

```python
>>> from sage.all import *
"\n'Sin[z]'' returns the sine of z."

>>> print(_)                   # optional - mathics
'Sin[z]' returns the sine of z.

>>> print(mathics.help('Sin', long=True)) # optional - mathics
'Sin[z]' returns the sine of z.

Attributes[Sin] = {Listable, NumericFunction, Protected}

>>> print(mathics.Factorial.__doc__) # optional - mathics
'Factorial[n]' 'n!' computes the factorial of n.

>>> u = mathics('Pi')           # optional - mathics
>>> print(u.Cos.__doc__)       # optional - mathics
'Cos[z]' returns the cosine of z.
```

```python
set (var, value)
Set the variable var to the given value.

EXAMPLES:

```python
sage: mathics.set('u', '2*x +E')       # optional - mathics
sage: bool(mathics('u').sage() == 2*x+e) # optional - mathics
True
```

```python
>>> from sage.all import *
"\n'set(u, 2*x +E)\n"\n
>>> mathics.set(u, 2*x +E)            # optional - mathics

>>> bool(mathics(u).sage() == Integer(2)*x+e) # optional - mathics
True
```

class sage.interfaces.mathics.MathicsElement (parent, value, is_name=False, name=None)
Bases: `ExtraTabCompletion, InterfaceElement`

Element class of the Mathics interface.

Its instances are usually constructed via the instance call of its parent. It wraps the Mathics library for this object. In a session Mathics methods can be obtained using tab completion.

EXAMPLES:

```
sage: # optional - mathics
declare_variable('x')
sage: me=mathics(e); me
E
sage: type(me)
<class 'sage.interfaces.mathics.MathicsElement'>
sage: P = me.parent(); P
Mathics
sage: type(P)
<class 'sage.interfaces.mathics.Mathics'>
```

Access to the Mathics expression objects:

```
sage: # optional - mathics
sage: res = me._mathics_result
sage: type(res)
<class 'mathics.core.evaluation.Result'>
sage: expr = res.last_eval; expr
Symbol: SystemE
sage: type(expr)
<class 'mathics.core.expression.Symbol'>
```

Applying Mathics methods:

```
sage: # optional - mathics
sage: me.to_sympy()  
E
sage: me.get_name()
...```

(continues on next page)
Conversion to Sage:

```python
sage: bool(me.sage() == e) # optional - mathics
True
```

Numerical approximation by converting to Sage object first

Convert the object into a Sage object and return its numerical approximation. See documentation of the function `sage.misc.functional.n()` for details.

**EXAMPLES:**

```python
sage: mathics('Pi').n(10) # optional -- mathics
3.1
sage: mathics('Pi').n() # optional -- mathics
3.14159265358979
sage: mathics('Pi').n(digits=10) # optional -- mathics
3.141592654
```

```python
>>> from sage.all import *
```
```python
>>> mathics('Pi').n(Integer(10)) # optional -- mathics
3.1
```
```python
>>> mathics('Pi').n() # optional -- mathics
3.14159265358979
```
```python
>>> mathics('Pi').n(digits=Integer(10)) # optional -- mathics
3.141592654
```

**save_image** *(filename, ImageSize=600)*

Save a mathics graphics

**INPUT:**

- **filename** – string. The filename to save as. The extension determines the image file format.
- **ImageSize** – integer. The size of the resulting image.
EXAMPLES:

```python
sage: P = mathics('Plot[Sin[x],{x,-2Pi,4Pi}]') # optional - mathics
sage: filename = tmp_filename() # optional - mathics
sage: P.save_image(filename, ImageSize=800) # optional - mathics

>>> from sage.all import *
>>> P = mathics('Plot[Sin[x],{x,-2Pi,4Pi}]') # optional - mathics
>>> filename = tmp_filename() # optional - mathics
>>> P.save_image(filename, ImageSize=Integer(800)) # optional - mathics
```

```python
show(ImageSize=600)
```

Show a mathics expression immediately.

This method attempts to display the graphics immediately, without waiting for the currently running code (if any) to return to the command line. Be careful, calling it from within a loop will potentially launch a large number of external viewer programs.

INPUT:

- `ImageSize` – integer. The size of the resulting image.

OUTPUT:

This method does not return anything. Use `save()` if you want to save the figure as an image.

EXAMPLES:

```python
sage: Q = mathics('Sin[x Cos[y]]/Sqrt[1-x^2]') # optional - mathics
sage: show(Q) # optional - mathics
\[\text{Sin}[x \text{Cos}[y]] / \text{Sqrt}[1 - x^2]\]

sage: P = mathics('Plot[Sin[x],{x,-2Pi,4Pi}]') # optional - mathics
sage: show(P) # optional - mathics
sage: P.show(ImageSize=800) # optional - mathics

>>> from sage.all import *
>>> Q = mathics('Sin[x Cos[y]]/Sqrt[1-x^2]') # optional - mathics
>>> show(Q) # optional - mathics
\[\text{Sin}[x \text{Cos}[y]] / \text{Sqrt}[1 - x^2]\]

>>> P = mathics('Plot[Sin[x],{x,-2Pi,4Pi}]') # optional - mathics
>>> show(P) # optional - mathics
>>> P.show(ImageSize=Integer(800)) # optional - mathics
```

```python
sage.interfaces.mathics.mathics_console()
```

Spawn a new Mathics command-line session.

EXAMPLES:

```python
sage: mathics_console() # not tested
```

Mathics 2.1.1.dev0

sage.interfaces.mathics.reduce_load(X)

Used in unpickling a Mathics element.
This function is just the __call__ method of the interface instance.

EXAMPLES:

>>> from sage.all import *
>>> sage.interfaces.mathics.reduce_load('Denominator[a / b]') # optional --
˓→mathics
b

>>> from sage.all import *
>>> sage.interfaces.mathics.reduce_load('Denominator[a / b]') # optional --
˓→mathics
b

27.4. Complicated translations
According to their website, MATLAB is “a high-level language and interactive environment that enables you to perform computationally intensive tasks faster than with traditional programming languages such as C, C++, and Fortran.”

The commands in this section only work if you have the “matlab” interpreter installed and available in your PATH. It’s not necessary to install any special Sage packages.

**EXAMPLES:**

```python
sage: matlab.eval('2+2')  # optional - matlab
'\nans =\n\n 4\n'
```

```python
from sage.all import *  

sage: matlab.eval('2+2')  # optional - matlab
'\nans =\n\n 4\n'
```

```python
sage: a = matlab(10)  # optional - matlab

sage: a**10  # optional - matlab
1.0000e+10
```

```python
from sage.all import *

sage: a = matlab(Integer(10))  # optional - matlab

sage: a**Integer(10)  # optional - matlab
1.0000e+10
```

**AUTHORS:**

- William Stein (2006-10-11)

### 28.1 Tutorial

**EXAMPLES:**

```python
sage: matlab.eval('2+2')  # optional - matlab
'\nans =\n\n 4
'
```

```python
sage: a = matlab('4+10')  # optional - matlab
14

sage: matlab('date')  # optional - matlab
18-Oct-2006

sage: matlab('5*10 + 6')  # optional - matlab
56

sage: matlab('(6+6)/3')  # optional - matlab
4
```

(continues on next page)
Interpreter Interfaces, Release 10.4

(continued from previous page)

```
sage: matlab('9')^2
81
sage: a = matlab(10); b = matlab(20); c = matlab(30)
sage: avg = (a+b+c)/3 ; avg
20
sage: parent(avg)
Matlab
```

```
>>> from sage.all import *
>>> # optional - matlab
>>> matlab('4+10')
14
>>> matlab('date')
18-Oct-2006
>>> matlab('5*10 + 6')
56
>>> matlab('(6+6)/3')
4
>>> matlab('9')**Integer(2)
81
>>> a = matlab(Integer(10)); b = matlab(Integer(20)); c = matlab(Integer(30))
>>> avg = (a+b+c)/Integer(3) ; avg
20
>>> parent(avg)
Matlab
```

```
sage: # optional - matlab
sage: my_scalar = matlab('3.1415')
sage: my_scalar
3.1415
sage: my_vector1 = matlab('[1,5,7]')
sage: my_vector1
1 5 7
sage: my_vector2 = matlab('[1;5;7]')
sage: my_vector2
1 5 7
sage: my_vector1 * my_vector2
75
```

```
>>> from sage.all import *
>>> # optional - matlab
>>> my_scalar = matlab('3.1415')
>>> my_scalar
3.1415
>>> my_vector1 = matlab('[1,5,7]')
>>> my_vector1
1 5 7
>>> my_vector2 = matlab('[1;5;7]')
>>> my_vector2
1 5 7
>>> my_vector1 * my_vector2
75
```
Interpreter Interfaces, Release 10.4

```python
sage: # optional - matlab
sage: row_vector1 = matlab('[1 2 3]')
sage: row_vector2 = matlab('[3 2 1]')
sage: matrix_from_row_vec = matlab('[[s; s]'%(row_vector1.name(), row_vector2.name()))
sage: matrix_from_row_vec
1 2 3
3 2 1

>>> from sage.all import *
>>> # optional - matlab
>>> row_vector1 = matlab('[1 2 3]')
>>> row_vector2 = matlab('[3 2 1]')
>>> matrix_from_row_vec = matlab('[[s; s]'%(row_vector1.name(), row_vector2.name()))
>>> matrix_from_row_vec
1 2 3
3 2 1

sage: # optional - matlab
sage: column_vector1 = matlab('[1;3]')
sage: column_vector2 = matlab('[2;8]')
sage: matrix_from_col_vec = matlab('[[s s]'%(column_vector1.name(), column_vector2.name()))
sage: matrix_from_col_vec
1 2
3 8

>>> from sage.all import *
>>> # optional - matlab
>>> column_vector1 = matlab('[1;3]')
>>> column_vector2 = matlab('[2;8]')
>>> matrix_from_col_vec = matlab('[[s s]'%(column_vector1.name(), column_vector2.name()))
>>> matrix_from_col_vec
1 2
3 8

sage: my_matrix = matlab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')   # optional - matlab
sage: my_matrix
8 12 19
7 3 2
12 4 23
8 1 1

>>> from sage.all import *
>>> my_matrix = matlab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')   # optional - matlab
>>> my_matrix
8 12 19
7 3 2
12 4 23
8 1 1
```

28.1. Tutorial
Matrix indexing works as follows:

```
sage: my_matrix = matlab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')  # optional - matlab
sage: my_matrix(3,2)  # optional - matlab
4
```

(continues on next page)
Setting using parenthesis cannot work (because of how the Python language works). Use square brackets or the set function:

```python
sage: my_matrix = matlab(['[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]'])  # optional - matlab
sage: my_matrix.set(2, 3, 1999)  # optional - matlab
sage: my_matrix                         # optional - matlab
```

```plaintext
8 12 19
7 3 1999
12 4 23
8 1 1
```

class `sage.interfaces.matlab.Matlab` *(maxread=None, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None)*

Bases: `Expect`

Interface to the Matlab interpreter.

EXAMPLES:

```python
sage: # optional - matlab
sage: a = matlab(['[ 1, 1, 2; 3, 5, 8; 13, 21, 33 ]'])
sage: b = matlab(['[ 1; 3; 13]'])
sage: c = a * b
sage: print(c)
```

```plaintext
30
122
505
```

```python
>>> from sage.all import *
```

```python
>>> a = matlab(['[ 1, 1, 2; 3, 5, 8; 13, 21, 33 ]'])
```

```python
>>> b = matlab(['[ 1; 3; 13]'])
```

```python
>>> c = a * b
```

```python
>>> print(c)
```

```plaintext
30
122
505
```

`chdir(directory)`

Change MATLAB’s current working directory.
### Interpreter Interfaces, Release 10.4

**EXAMPLES:**

```python
>>> from sage.all import *
>>> matlab.chdir('/')  # optional - matlab
>>> matlab.pwd()  # optional - matlab
/  
```

**console()**

**get(var)**

Get the value of the variable var.

**EXAMPLES:**

```python
>>> s = matlab.eval('a = 2')  # optional - matlab
>>> matlab.get('a')  # optional - matlab
2
```

**sage2matlab_matrix_string(A)**

Return a matlab matrix from a Sage matrix.

**INPUT:** A Sage matrix with entries in the rationals or reals.

**OUTPUT:** A string that evaluates to a Matlab matrix.

**EXAMPLES:**

```python
>>> M33 = MatrixSpace(QQ, Integer(3), Integer(3))
>>> A = M33([Integer(1), Integer(2), Integer(3), Integer(4), Integer(5),
          Integer(6), Integer(7), Integer(8)])
>>> matlab.sage2matlab_matrix_string(A)  # optional - matlab
'[[1, 2, 3; 4, 5, 6; 7, 8, 0]']
```

**set(var, value)**

Set the variable var to the given value.

**strip_answer(s)**

Returns the string s with Matlab's answer prompt removed.

**EXAMPLES:**
Interpreter Interfaces, Release 10.4

```python
sage: s = '\nans = \n
2\n'
sage: matlab.strip_answer(s)
'2'
```

```python
>>> from sage.all import *

>>> s = '\nans = \n
2\n'

>>> matlab.strip_answer(s)
'2'
```

```
version()
whos()

class sage.interfaces.matlab.MatlabElement (parent, value, is_name=False, name=None)
Bases: ExpectElement
set(i, j, x)
sage.interfaces.matlab.matlab_console()

This requires that the optional matlab program be installed and in your PATH, but no optional Sage packages need
be installed.
```

```python
sage: matlab_console()  # optional - matlab; not tested

< M A T L A B >

Copyright 1984-2006 The MathWorks, Inc.
...
>> 2+3
```

```python
>>> from sage.all import *

>>> matlab_console()  # optional - matlab; not tested

< M A T L A B >

Copyright 1984-2006 The MathWorks, Inc.
...
>> 2+3
```

```
ans =
5
quit

Typing quit exits the matlab console and returns you to Sage. matlab, like Sage, remembers its history from one
session to another.

sage.interfaces.matlab.matlab_version()

Return the version of Matlab installed.
```

```python
sage: matlab_version()  # random; optional - matlab
'7.2.0.283 (R2006a)'
```

```python
>>> from sage.all import *

>>> matlab_version()  # random; optional - matlab
'7.2.0.283 (R2006a)'
```

```
sage.interfaces.matlab.reduce_load_Matlab()
```

28.1. Tutorial 321
Maxima is a free GPL’d general purpose computer algebra system whose development started in 1968 at MIT. It contains symbolic manipulation algorithms, as well as implementations of special functions, including elliptic functions and generalized hypergeometric functions. Moreover, Maxima has implementations of many functions relating to the invariant theory of the symmetric group $S_n$. (However, the commands for group invariants, and the corresponding Maxima documentation, are in French.) For many links to Maxima documentation see http://maxima.sourceforge.net/documentation.html.

AUTHORS:

• William Stein (2005-12): Initial version
• David Joyner: Improved documentation
• William Stein (2006-01-08): Fixed bug in parsing
• William Stein (2006-02-22): comparisons (following suggestion of David Joyner)
• William Stein (2006-02-24): greatly improved robustness by adding sequence numbers to IO bracketing in _eval_line

This is the interface used by the maxima object:

```python
sage: type(maxima)
<class 'sage.interfaces.maxima.Maxima'>
```

```python
>>> from sage.all import *
>>> type(maxima)
<class 'sage.interfaces.maxima.Maxima'>
```

If the string “error” (case insensitive) occurs in the output of anything from Maxima, a `RuntimeError` exception is raised.

EXAMPLES: We evaluate a very simple expression in Maxima.

```python
sage: maxima('3 * 5')
15
```

```python
>>> from sage.all import *
>>> maxima('3 * 5')
15
```

We factor $x^5 - y^5$ in Maxima in several different ways. The first way yields a Maxima object.
sage: x,y = SR.var('x,y')
sage: F = maxima.factor('x^5 - y^5')
sage: F # not tested - depends on maxima version
-((y-x)*(y^4+x*y^3+x^2*y^2+x^3*y+x^4))
sage: actual = F.sage()
sage: expected = -(y-x)*(y^4+x*y^3+x^2*y^2+x^3*y+x^4)
sage: bool(actual == expected)
True
sage: type(F)
<class 'sage.interfaces.maxima.MaximaElement'>

>>> from sage.all import *
>>> x,y = SR.var('x,y')
>>> F = maxima.factor('x^5 - y^5')
>>> F # not tested - depends on maxima version
-((y-x)*(y^4+x*y^3+x^2*y^2+x^3*y+x^4))
>>> actual = F.sage()
>>> expected = -(y-x)*(y**Integer(4)+x*y**Integer(3)+x**Integer(2)*y**Integer(2)+x**Integer(3)*y+x**Integer(4))
>>> bool(actual == expected)
True
>>> type(F)
<class 'sage.interfaces.maxima.MaximaElement'>

Note that Maxima objects can also be displayed using “ASCII art”; to see a normal linear representation of any Maxima object x. Just use the print command: use str(x).

sage: print(F) 4 3 2 2 3 4
- (y - x) (y + x y + x y + x y + x)

>>> from sage.all import *
>>> print(F)
4 3 2 2 3 4
- (y - x) (y + x y + x y + x y + x)

You can always use repr(x) to obtain the linear representation of an object. This can be useful for moving maxima data to other systems.

sage: F = maxima('x * y')
sage: repr(F)
'x*y'
sage: F.str()
'x*y'

>>> from sage.all import *
>>> F = maxima('x * y')
>>> repr(F)
'x*y'
>>> F.str()
'x*y'

The maxima.eval command evaluates an expression in maxima and returns the result as a string not a maxima object.

sage: print(maxima.eval('factor(x^5 - 1)'))
(x-1)*(x^4+x^3+x^2+x+1)
We can create the polynomial $f$ as a Maxima polynomial, then call the factor method on it. Notice that the notation $f.factor()$ is consistent with how the rest of Sage works.

```python
sage: f = maxima('x^5 + y^5')
sage: f^2
(y^5+x^5)^2
sage: f.factor()
(y+x)*(y^4-x*y^3+x^2*y^2-x^3*y+x^4)
```

Control-C interruption works well with the maxima interface, because of the excellent implementation of maxima. For example, try the following sum but with a much bigger range, and hit control-C.

```python
sage: maxima('sum(1/x^2, x, 1, 10)')
1968329/1270080
```

29.1 Tutorial

We follow the tutorial at [http://maxima.sourceforge.net/docs/intromax/intromax.html](http://maxima.sourceforge.net/docs/intromax/intromax.html).

```python
sage: maxima('1/100 + 1/101')
201/10100
```

```python
sage: a = maxima('(1 + sqrt(2))^5'); a
(sqrt(2)+1)^5
sage: a.expand()
29*sqrt(2)+41
```

```python
>>> from sage.all import *
>>> print(maxima.eval('factor(x^5 - 1)'))
(x-1)*(x^4+x^3+x^2+x+1)
```

29.1. Tutorial
Interpreter Interfaces, Release 10.4

sage: a = maxima('(1 + sqrt(2))^5')
sage: float(a)
82.0121933088197...
sage: a.numer()
82.0121933088197...

>>> from sage.all import *
>>> a = maxima('(1 + sqrt(2))^5')
>>> float(a)
82.0121933088197...
>>> a.numer()
82.0121933088197...

sage: maxima.eval('fpprec : 100')
'100'
sage: a.bfloat()
8.0

>>> from sage.all import *
>>> maxima.eval('fpprec : 100')
'100'
>>> a.bfloat()
8.0

sage: maxima('(100!)')
933262154439441526816992388562667004907159682643816214685926389521759999322991560894146397615651828125

sage: f = maxima('(x + 3*y + x^2*y)^3')
sage: f.expand()

sage: f = maxima('(x + 3*y + x^2*y)^3')

sage: f = maxima('(x + 3*y + x^2*y)^3')

sage: f = maxima('(x + 3*y + x^2*y)^3')

sage: f = maxima('(x + 3*y + x^2*y)^3')

sage: f = maxima('(x + 3*y + x^2*y)^3')

(continues on next page)
Here is an example of solving an algebraic equation:

```python
sage: maxima('(x^2+y^2=1)').solve('y')
[y = -sqrt(1-x^2), y = sqrt(1-x^2)]
```

You can even nicely typeset the solution in LaTeX:

```latex
\[
\begin{align*}
    &a = \ldots \frac{\sqrt{79} i - 11}{4}, \ b = \ldots \frac{\sqrt{79} i + 9}{4}, \ c = \ldots \frac{\sqrt{79} i + 1}{10}, \\
\end{align*}
\]
```

To have the above appear onscreen via `xdvi`, type `view(s)`. (TODO: For OS X should create pdf output and use `preview` instead?)

```python
sage: e = maxima('sin(u + v) * cos(u)^3'); e
cos(u)^3 * sin(v+u)
```

(continues on next page)
sage: f.realpart()
%e^3*cos(k)-k^2+9

```python
from sage.all import *
sage: e = maxima('sin(u + v) * cos(u)^3'); e
cos(u)^3*sin(v+u)
sage: f = e.trigexpand(); f
cos(u)^3*(cos(u)*sin(v)+sin(u)*cos(v))
sage: f.trigreduce()
(cos(u)^3*(cos(u)*sin(v)+sin(u)*cos(v)))*(sin(v+4*u)+sin(v-2*u))/8+(3*sin(v+2*u)+3*sin(v))/8

w = maxima('3 + k%i')
f = w**Integer(2) + maxima('%%e')**w
f.realpart()
%e^3*cos(k)-k^2+9

sage: f = maxima('x^3 * %e^(k*x) * sin(w*x)'); f
x^3*%e^(k*x)*sin(w*x)
sage: f.diff('x')
k*x^3*%e^(k*x)*sin(w*x)+3*x^2*%e^(k*x)*sin(w*x)+w*x^3*%e^(k*x) *cos(w*x)
sage: f.integrate('x')
(((k*w^6+3*k^3*w^4+3*k^5*w^2+k^7)*x^3 +(3*w^6+3*k^2*w^4-3*k^4*w^2-3*k^6)*x^2+(...-... ˓→18*k*w^4)-12*k^3*w^2+6*k^5)*x-6*w^4 +36*k^2*w^2-6*k^4)*%e^(k*x)*sin(w*x) +((...(w^ ˓→7...3*k^2*w^5-3*k^4*w^3-k^6*w)*x^3+...+(6*k*w^5+12*k^3*w^3+6*k^5*w)*x^2+...+(6*w^5- ˓→12*k^2*w^3-18*k^4*w)*x-24*k^3*w +24*k^3*w)*%e^(k*x)*cos(w*x)) /(w^8+4*k^2*w^6+6*k^4*w^4+4*k^6*w^2+k^8)
```

```
sage: f = f/maxima('1/x^2')
sage: g = f/maxima('f/sinh(k*x)^4')
g.taylor('x', 0, 3)
f/(k^4*x^4)-(2*f)/((3*k^2)*x^2)+(11*f)/45-(62*k^2*f)*x^2)/945
```

```python
>>> from sage.all import *
>>> f = maxima('1/x^2')
>>> f.integrate('x', Integer(1), 'inf')
1
>>> g = maxima('f/sinh(k*x)^4')
>>> g.taylor('x', Integer(0), Integer(3))
f/(k^4*x^4)-(2*f)/((3*k^2)*x^2)+(11*f)/45-(62*k^2*f)*x^2)/945

sage: maxima.taylor('asin(x)', 'x', 0, 10)
x+x^3/6+(3*x^5)/40+(5*x^7)/112+(35*x^9)/1152
```
29.2 Examples involving matrices

We illustrate computing with the matrix whose $i,j$ entry is $i/j$, for $i,j = 1, \ldots, 4$.

```
sage: f = maxima.eval('f[i,j] := i/j')
sage: A = maxima('genmatrix(f,4,4)'); A
matrix([1,1/2,1/3,1/4],[2,1,2/3,1/2],[3,3/2,1,3/4],[4,2,4/3,1])
sage: A.determinant()
0
sage: A.echelon()
matrix([1,1/2,1/3,1/4],[0,0,0,0],[0,0,0,0],[0,0,0,0])
sage: A.eigenvalues()
[[0,4],[3,1]]
sage: A.eigenvectors()
[[[0,4],[3,1]],[[[1,0,0,-4],[0,1,0,-2],[0,0,1,-...4/3...]],[[1,2,3,4]]]]
```

We can also compute the echelon form in Sage:

```
sage: B = matrix(QQ, A)
sage: B.echelon_form()
[ 1 1/2 1/3 1/4]
[ 0 0 0 0]
[ 0 0 0 0]
[ 0 0 0 0]
sage: B.charpoly('x').factor()
(x - 4) * x^3
```

29.2. Examples involving matrices 329
29.3 Laplace Transforms

We illustrate Laplace transforms:

sage: _ = maxima.eval("f(t) := t*sin(t)")
sage: maxima("laplace(f(t),t,s)")
(2*s)/(s^2+1)^2

>>> from sage.all import *
>>> _ = maxima.eval("f(t) := t*sin(t)")
>>> maxima("laplace(f(t),t,s)")
(2*s)/(s^2+1)^2

sage: maxima("laplace(delta(t-3),t,s)"
#Dirac delta function
%e^-(3*s)

>>> from sage.all import *
>>> _ = maxima.eval("f(t) := exp(t)*sin(t)")
>>> maxima("laplace(f(t),t,s)"
1/(s^2-2*s+2)

sage: _ = maxima.eval("f(t) := exp(t)*sin(t)")
>>>
maxima("laplace(f(t),t,s)"
1/(s^2-2*s+2)

sage: _ = maxima.eval("f(t) := t^5*exp(t)*sin(t)")
sage: maxima("laplace(f(t),t,s)"
(360*(2*s-2))/(s^2-2*s+2)^4-(480*(2*s-2)^3)/(s^2-2*s+2)^5 +(120*(2*s-2)^5)/(s^2-2*s+2)^6

>>> from sage.all import *
>>> _ = maxima.eval("f(t) := t^5*exp(t)*sin(t)")
>>> maxima("laplace(f(t),t,s)"
(360*(2*s-2))/(s^2-2*s+2)^4-(480*(2*s-2)^3)/(s^2-2*s+2)^5 +(120*(2*s-2)^5)/(s^2-2*s+2)^6

sage: maxima("laplace(diff(x(t),t),t,s)"
s*t*laplace(x(t),t,s)-x(0)
>>> from sage.all import *
>>> maxima("laplace(diff(x(t),t),t,s)"
's*laplace(x(t),t,s)-x(0)

sage: maxima("laplace(diff(x(t),t,2),t,s)"
...)at('diff(x(t),t,1),t = 0))+s^2*'laplace(x(t),t,s)-x(0)*s

3.4. Continued Fractions

A continued fraction \( a + 1/(b + 1/(c + \cdots)) \) is represented in maxima by the list \([a, b, c, \ldots] \).
29.5 Special examples

In this section we illustrate calculations that would be awkward to do (as far as I know) in non-symbolic computer algebra systems like MAGMA or GAP.

We compute the gcd of $2x^{n+4} - x^{n+2}$ and $4x^{n+1} + 3x^n$ for arbitrary $n$.

```sage
f = maxima('2*x^(n+4) - x^(n+2)')
g = maxima('4*x^(n+1) + 3*x^n')
f.gcd(g)
x^n
```

You can plot 3d graphs (via gnuplot):

```sage
maxima('plot3d(x^2-y^2, [x,-2,2], [y,-2,2], [grid,12,12])')  # not tested
[displays a 3 dimensional graph]
```

You can formally evaluate sums (note the `nusum` command):

```sage
S = maxima('nusum(exp(1+2*i/n),i,1,n)')
print(S)
```

We formally compute the limit as $n \to \infty$ of $2S/n$ as follows:

```sage
T = S*maxima('2/n')
T.tlimit('n','inf')
%e^3-%e
```
29.6 Miscellaneous

Obtaining digits of $\pi$:

```
sage: maxima.eval('fpprec : 100')
'100'
sage: maxima(pi).bfloat()
3.
-14159265358979323846264338327950288419716939375105820974944592307816406286208998628034825342117068b0
```

```>>> from sage.all import * >>> maxima.eval('fpprec : 100') '100' >>> maxima(pi).bfloat() 3.
-14159265358979323846264338327950288419716939375105820974944592307816406286208998628034825342117068b0```

Defining functions in maxima:

```
sage: maxima.eval('fun[a] := a^2')
'fun[a]:=a^2'
sage: maxima('fun[10]')
100
```

```>>> from sage.all import * >>> maxima.eval('fun[a] := a^2') 'fun[a]:=a^2' >>> maxima('fun[10]') 100```

29.7 Interactivity

Unfortunately maxima doesn't seem to have a non-interactive mode, which is needed for the Sage interface. If any Sage call leads to maxima interactively answering questions, then the questions can't be answered and the maxima session may hang. See the discussion at http://www.ma.utexas.edu/pipermail/maxima/2005/011061.html for some ideas about how to fix this problem. An example that illustrates this problem is `maxima.eval('integrate (exp(a*x), x, 0, inf)')`.

29.8 Latex Output

To \TeX{} a maxima object do this:

```
sage: latex(maxima('sin(u) + sinh(v^2)')) \sinh v^2+\sin u
```

```>>> from sage.all import * >>> latex(maxima('sin(u) + sinh(v^2)')) \sinh v^2+\sin u```

Here's another example:
29.9 Long Input

The MAXIMA interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

Note: Using maxima.eval for long input is much less robust, and is not recommended.

```python
sage: t = "
```
```
10^10000 # ten thousand character string.
sage: a = maxima(t)
```
```
```
>>> from sage.all import *
```python
```python
>>> t = "
```
```
Integer(10)**Integer(10000) # ten thousand character string.
```python
```python
>>> a = maxima(t)
```

```python
class sage.interfaces.maxima.Maxima
```
```python
Bases: MaximaAbstract, Expect
```

Interface to the Maxima interpreter.

EXAMPLES:

```python
sage: m = Maxima()
sage: m == maxima
False
```
```
```
>>> from sage.all import *
```python
```python
```python
```python
```python
clear(var)

Clear the variable named var.

EXAMPLES:

```python
sage: maxima.set('xxxxx', '2')
sage: maxima.get('xxxxx')
'2'
sage: maxima.clear('xxxxx')
sage: maxima.get('xxxxx')
'xxxxx'
```
get (var)
Get the string value of the variable var.

EXAMPLES:

```sage
maxima.set('xxxxx', '2')
maxima.get('xxxxx')

maxima.clear('xxxxx')
maxima.get('xxxxx')
```

lisp (cmd)
Send a lisp command to Maxima.

Note: The output of this command is very raw - not pretty.

EXAMPLES:

```sage
maxima.lisp("(+ 2 17)

maxima.lisp("(+ 2 17)
```

set (var, value)
Set the variable var to the given value.

INPUT:
- var – string
- value – string

EXAMPLES:

```sage
maxima.set('xxxxx', '2')
maxima.get('xxxxx')
```
```python
>>> from sage.all import *
>>> maxima.set('xxxxx', '2')
>>> maxima.get('xxxxx')
'2'
```

**set_seed**(seed=None)

`make_random_state(n)` returns a new random state object created from an integer seed value equal to `n` modulo $2^{32}$. `n` may be negative.

**EXAMPLES:**

```python
sage: m = Maxima()
sage: m.set_seed(1)
1
sage: [m.random(100) for i in range(5)]
[45, 39, 24, 68, 63]
```

```python
>>> from sage.all import *
>>> m = Maxima()
>>> m.set_seed(Integer(1))
1
>>> [m.random(Integer(100)) for i in range(Integer(5))]
[45, 39, 24, 68, 63]
```

```python
class sage.interfaces.maxima.MaximaElement(parent, value, is_name=False, name=None)
```

Bases: MaximaAbstractElement, ExpectElement

Element of Maxima through Pexpect interface.

**EXAMPLES:**

Elements of this class should not be created directly. The targeted parent should be used instead:

```python
sage: maxima(3)
3
sage: maxima(cos(x)+e^234)
cos(_SAGE_VAR_x)+%e^234
```

```python
>>> from sage.all import *
>>> maxima(Integer(3))
3
>>> maxima(cos(x)+e**Integer(234))
cos(_SAGE_VAR_x)+%e^234
```

**display2d**(onscreen=True)

Return the 2d string representation of this Maxima object.

**EXAMPLES:**

```python
sage: F = maxima('x^5 - y^5').factor()
sage: F.display2d()
-(y - x) (y + x y + x y + x y + x y + x)
```

```python
>>> from sage.all import *
>>> F = maxima('x^5 - y^5').factor()
>>> F.display2d()
```

(continues on next page)
class `sage.interfaces.maxima.MaximaElementFunction` *(parent, name, defn, args, latex)*

Bases: `MaximaElement`, `MaximaAbstractElementFunction`

Maxima user-defined functions.

**EXAMPLES:**

Elements of this class should not be created directly. The method `function` of the targeted parent should be used instead:

```python
sage: maxima.function('x,y','h(x)*y')
h(x)*y
```

```python
>>> from sage.all import *

>>> maxima.function('x,y','h(x)*y')
h(x)*y
```

`sage.interfaces.maxima.is_MaximaElement(x)`

Return True if `x` is of type `MaximaElement`.

**EXAMPLES:**

```python
sage: from sage.interfaces.maxima import is_MaximaElement
sage: is_MaximaElement(1)
False
```

```python
sage: m = maxima(1)
sage: is_MaximaElement(m)
True
```

```python
>>> from sage.all import *

>>> from sage.interfaces.maxima import is_MaximaElement

>>> is_MaximaElement(Integer(1))
False

>>> m = maxima(Integer(1))

>>> is_MaximaElement(m)
True
```

`sage.interfaces.maxima.reduce_load_Maxima()`

Unpickle a Maxima Pexpect interface.

**EXAMPLES:**

```python
sage: from sage.interfaces.maxima import reduce_load_Maxima

sage: reduce_load_Maxima()
Maxima
```
sage.interfaces.maxima.reduce_load_Maxima_function (parent, defn, args, latex)
Unpickle a Maxima function.

EXAMPLES:

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima import reduce_load_Maxima
>>> reduce_load_Maxima()
Maxima

sage: from sage.interfaces.maxima import reduce_load_Maxima_function
sage: f = maxima.function('x,y','sin(x+y)')
sage: _, args = f.__reduce__()
sage: g = reduce_load_Maxima_function(*args)
sage: g == f
True
```

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima import reduce_load_Maxima_function
>>> f = maxima.function('x,y','sin(x+y)')
>>> _, args = f.__reduce__()
>>> g = reduce_load_Maxima_function(*args)
>>> g == f
True
```
Maxima is a free GPL'd general purpose computer algebra system whose development started in 1968 at MIT. It contains symbolic manipulation algorithms, as well as implementations of special functions, including elliptic functions and generalized hypergeometric functions. Moreover, Maxima has implementations of many functions relating to the invariant theory of the symmetric group $S_n$. (However, the commands for group invariants, and the corresponding Maxima documentation, are in French.) For many links to Maxima documentation see http://maxima.sourceforge.net/docs.shtml/.

AUTHORS:

- William Stein (2005-12): Initial version
- David Joyner: Improved documentation
- William Stein (2006-01-08): Fixed bug in parsing
- William Stein (2006-02-22): comparisons (following suggestion of David Joyner)
- William Stein (2006-02-24): greatly improved robustness by adding sequence numbers to IO bracketing in _eval_line

This is an abstract class implementing the functions shared between the Pexpect and library interfaces to Maxima.

```python
class sage.interfaces.maxima_abstract.MaximaAbstract (name='maxima_abstract')
    Bases: ExtraTabCompletion, Interface

Abstract interface to Maxima.

INPUT:
    • name – string

OUTPUT: the interface

EXAMPLES:

This class should not be instantiated directly, but through its subclasses Maxima (Pexpect interface) or MaximaLib (library interface):

```
**chdir** *(dir)*

Change Maxima’s current working directory.

**INPUT:**

- dir – string

**OUTPUT:** none

**EXAMPLES:**

```
sage: maxima.chdir('/')
```

```
>>> from sage.all import *
```

```
>>> maxima.chdir('/')
```

**completions** *(s, verbose=True)*

Return all commands that complete the command starting with the string s. This is like typing s[tab] in the Maxima interpreter.

**INPUT:**

- s – string
- verbose – boolean (default: True)

**OUTPUT:** array of strings

**EXAMPLES:**

```
sage: sorted(maxima.completions('gc', verbose=False))
['gcd', 'gcdex', 'gcfactor', 'gctime']
```

```
>>> from sage.all import *
```

```
>>> sorted(maxima.completions('gc', verbose=False))
['gcd', 'gcdex', 'gcfactor', 'gctime']
```

**console**

Start the interactive Maxima console. This is a completely separate maxima session from this interface. To interact with this session, you should instead use `maxima.interact()`.

**INPUT:** none

**OUTPUT:** none

**EXAMPLES:**

```
sage: maxima.console()  # not tested (since we can’t)
```

sage:
maxima.interact()  # not tested
--> Switching to Maxima <--
maxima: 2+2
4
maxima:
--> Exiting back to Sage <--

```sage```
```python```
from sage.all import *
```sage```
```
maxima.interact()  # not tested
--> Switching to Maxima <--
maxima: 2+2
4
maxima:
--> Exiting back to Sage <--
```cputime```
\( (t=None) \)

Returns the amount of CPU time that this Maxima session has used.

INPUT:

- \( t \) – float (default: None); If \( \text{var}[t] \) is not None, then it returns the difference between the current CPU time and \( \text{var}[t] \).

OUTPUT: float

EXAMPLES:

```sage```
t = maxima.cputime()
sage:
_ = maxima.de_solve('\( \text{diff}(y,x,2) + 3\times = y' \)', ['x','y'], [1,1,1])
sage: maxima.cputime(t)  # output random
0.568913

```sage```
t = maxima.cputime()
_ = maxima.de_solve('\( \text{diff}(y,x,2) + 3\times = y' \)', ['x','y'], [Integer(1),Integer(1),Integer(1)])
```sage```
```
maxima.cputime(t)  # output random
0.568913
```

de_solve\( (de,\ vars,\ ics=None) \)

Solves a 1st or 2nd order ordinary differential equation (ODE) in two variables, possibly with initial conditions.

INPUT:

- \( \text{de} \) – a string representing the ODE
- \( \text{vars} \) – a list of strings representing the two variables.
- \( \text{ics} \) – a triple of numbers [\( a,b1,b2 \)] representing \( y(a)=b1, y'(a)=b2 \)

EXAMPLES:
de_solve_laplace \( (de, \text{vars}, \text{ics}=\text{None}) \)

Solves an ordinary differential equation (ODE) using Laplace transforms.

INPUT:

- \( de \) – a string representing the ODE (e.g., \( de = \text{"diff}(f(x),x,2) = 2*\text{diff}(f(x),x)-f(x)\)"

- \( \text{vars} \) – a list of strings representing the variables (e.g., \( \text{vars} = \{ \text{"x"}, \text{"f"} \} \))

- \( \text{ics} \) – a list of numbers representing initial conditions, with symbols allowed which are represented by strings (e.g., \( f(0)=1, f'(0)=2 \) is \( \text{ics} = [0,1,2] \))

EXAMPLES:

```python
sage: maxima.clear('x'); maxima.clear('f')
sage: maxima.de_solve_laplace("diff(f(x),x,2) = 2*diff(f(x),x)-f(x)", ["x","f ->"], [0,1,2]) f(x) = x*%e^x+f(x)^2
```

```python
sage: maxima.clear('x'); maxima.clear('f')
sage: maxima.de_solve_laplace("diff(f(x),x,2) = 2*diff(f(x),x)-f(x)", ["x","f ->"], [Integer(0),Integer(1),Integer(2)]) f(x) = x*%e^x+f(x)^2
```

```python
sage: maxima.clear('x'); maxima.clear('f')
sage: f = maxima.de_solve_laplace("diff(f(x),x,2) = 2*diff(f(x),x)-f(x)", ["x ->","f ->"])
sage: f f(x) = x*%e^x*('at(diff(f(x),x,1),x = 0))-f(0)*x*%e^x+f(0)*%e^x
```

```python
sage: print(f)
!
  x  d !
!
  x  x
f(x) = x %e ( -- (f(x))! ) - f(0) x %e + f(0) %e
```
dx !
!x = 0

```python
>>> from sage.all import *
>>> maxima.clear('x'); maxima.clear('f')
>>> f = maxima.de_solve_laplace("diff(f(x),x,2) = 2*diff(f(x),x)-f(x)", ["x", "f"])
>>> f
f(x) = x*e^x*(at(diff(f(x),x,1),x = 0)) - f(0)*x*e^x + f(0)*e^x
>>> print(f)

f(x) = x d d (f(x)) x x
      x e (f(x)) e - e - f(0) x e + f(0) e
      dx x ! x = 0
```

**Note:** The second equation sets the values of $f(0)$ and $f'(0)$ in Maxima, so subsequent ODEs involving these variables will have these initial conditions automatically imposed.

demo ($s$)  
Run Maxima's demo for $s$.

INPUT:

- $s$ – string

OUTPUT: none

EXAMPLES:

```python
>>> from sage.all import *
>>> maxima.demo('cf') # not tested
```

At the '_' prompt, type ';' and <enter> to get next demonstration.

```
frac1:cf([1,2,3,4])
...
```

```python
>>> from sage.all import *
>>> maxima.demo('cf') # not tested
```

At the '_' prompt, type ';' and <enter> to get next demonstration.

```
frac1:cf([1,2,3,4])
...
```

describe ($s$)  
Return Maxima's help for $s$.

INPUT:

- $s$ – string

OUTPUT:

Maxima's help for $s$

EXAMPLES:
example(s)

Return Maxima’s examples for s.

INPUT:

- s – string

OUTPUT:

Maxima’s examples for s

EXAMPLES:

```sage
maxima.example('arrays')
a[n]:=n*a[n-1]
a := n a
    n  n - 1
a[0]:1
a[5]:
a[n]:=n

```

function(args, defn, rep=None, latex=None)

Return the Maxima function with given arguments and definition.

INPUT:

- **args** – a string with variable names separated by commas
• **defn** – a string (or Maxima expression) that defines a function of the arguments in Maxima.

• **rep** – an optional string; if given, this is how the function will print.

OUTPUT: Maxima function

EXAMPLES:

```
sage: f = maxima.function('x', 'sin(x)')
sage: f(3.2)  # abs tol 2e-16
-0.058374143427579909
sage: f = maxima.function('x,y', 'sin(x)+cos(y)')
sage: f(2, 3.5)  # abs tol 2e-16
sin(2)-0.9364566872907963
sage: f
sin(x)+cos(y)
```

```
>>> from sage.all import *
>>> f = maxima.function('x', 'sin(x)')
>>> f(RealNumber(3.2))  # abs tol 2e-16
-0.058374143427579909
>>> f = maxima.function('x,y', 'sin(x)+cos(y)')
>>> f(Integer(2), RealNumber('3.5'))  # abs tol 2e-16
sin(2)-0.9364566872907963
>>> f
sin(x)+cos(y)
```

```
sage: g = f.integrate('z')
sage: g
(cos(y)+sin(x))*z
sage: g(1,2,3)
3*(cos(2)+sin(1))
```

```
>>> from sage.all import *
>>> g = f.integrate('z')
>>> g
(cos(y)+sin(x))*z
>>> g(Integer(1),Integer(2),Integer(3))
3*(cos(2)+sin(1))
```

The function definition can be a Maxima object:

```
sage: an_expr = maxima('sin(x)*gamma(x)')
sage: t = maxima.function('x', an_expr)
sage: t
gamma(x)*sin(x)
sage: t(2)
sin(2)
sage: float(t(2))
0.9092974268256817
sage: loads(t.dumps())
gamma(x)*sin(x)
```

```
>>> from sage.all import *
>>> an_expr = maxima('sin(x)*gamma(x)')
```
help(s)

Return Maxima's help for s.

INPUT:

• s – string

OUTPUT:

Maxima's help for s

EXAMPLES:

sage: maxima.help('gcd')
-- Function: gcd (<p_1>, <p_2>, <x_1>, ...)
...

plot2d(*args)

Plot a 2d graph using Maxima / gnuplot.

maxima.plot2d(f, [var, min, max], options)

INPUT:

• f – a string representing a function (such as f="sin(x)") [var, xmin, xmax]

• options – an optional string representing plot2d options in gnuplot format

EXAMPLES:

sage: maxima.plot2d('sin(x)', '[x,-5,5]')  # not tested
sage: opts = ['[gnuplot_term, ps]', '[gnuplot_out_file, "sin-plot.eps"]'
sage: maxima.plot2d('sin(x)', '[x,-5,5]', opts)  # not tested

The eps file is saved in the current directory.
plot2d_parametric (r, var, trange, nticks=50, options=None)

Plot r = [x(t), y(t)] for t = tmin...tmax using gnuplot with options.

INPUT:

• r – a string representing a function (such as r="[x(t),y(t)]")
• var – a string representing the variable (such as var = "t")
• trange – [tmin, tmax] are numbers with tminmax
• nticks – int (default: 50)
• options – an optional string representing plot2d
  options in gnuplot format

EXAMPLES:

```
sage: maxima.plot2d_parametric(["sin(t)","cos(t)"], "t",[-3.1,3.1])  # not tested
>>> from sage.all import *
>>> maxima.plot2d_parametric(["sin(t)","cos(t)"], "t",[-RealNumber('3.1'),
RealNumber('3.1')])  # not tested
```

```
sage: opts = ['gnuplot_preamble, "set nokey"], ['gnuplot_term, ps],
['gnuplot_out_file, "circle-plot.eps"]
sage: maxima.plot2d_parametric(["sin(t)","cos(t)"], "t", [-3.1,3.1],
options=opts)  # not tested
```

The eps file is saved to the current working directory.

Here is another fun plot:

```
sage: maxima.plot2d_parametric(["sin(5*t)","cos(11*t)"], "t", [0,2*pi()],
nticks=400)  # not tested
>>> from sage.all import *
>>> maxima.plot2d_parametric(["sin(5*t)","cos(11*t)"], "t", [Integer(0),
Integer(2)*pi()], nticks=Integer(400))  # not tested
```

plot3d (*args)

Plot a 3d graph using Maxima / gnuplot.

maxima.plot3d(f, ['x, xmin, xmax'], ['y, ymin, ymax'], ['grid, nx, ny'], options)

INPUT:

• f – a string representing a function (such as f="sin(x)") [var, min, max]
• args should be of the form ['x, xmin, xmax'], ['y, ymin, ymax'], ['grid, nx, ny'], options
EXAMPLES:

```
sage: maxima.plot3d('1 + x^3 - y^2', 'x,-2,2', 'y,-2,2', 'grid,12,12')
     → # not tested
sage: maxima.plot3d('sin(x)*cos(y)', 'x,-2,2', 'y,-2,2', 'grid,30,30')
     → # not tested
sage: opts = [['gnuplot_term', ps], ['gnuplot_out_file', "sin-plot.eps"]]
sage: maxima.plot3d('sin(x+y)', 'x,-5,5', 'y,-1,1', opts)
# not tested
```

The eps file is saved in the current working directory.

```
>>> from sage.all import *
>>> maxima.plot3d('1 + x^3 - y^2', 'x,-2,2', 'y,-2,2', 'grid,12,12')
     → # not tested
>>> maxima.plot3d('sin(x)*cos(y)', 'x,-2,2', 'y,-2,2', 'grid,30,30')
     → # not tested
>>> opts = [['gnuplot_term', ps], ['gnuplot_out_file', "sin-plot.eps"]]
>>> maxima.plot3d('sin(x+y)', 'x,-5,5', 'y,-1,1', opts)
# not tested
```

Here is a torus:

```
348 Chapter 30. Abstract interface to Maxima
```
sage: _ = maxima.eval("expr_1: cos(y)*(10.0+6*cos(x)); expr_2: sin(y)*(10.0+6*cos(x)); expr_3: -6*sin(x);")
sage: maxima.plot3d_parametric(["expr_1","expr_2","expr_3"], ["x","y"],[0,6],
                          [0,6]) # not tested

Here is a Möbius strip:

sage: x = "cos(u)*(3 + v*cos(u/2))"
sage: y = "sin(u)*(3 + v*cos(u/2))"
sage: z = "v*sin(u/2)"
sage: maxima.plot3d_parametric([x,y,z],["u","v"],[-3.1,3.2],[-1/10,1/10]) # not tested

plot_list (ptsx, ptsy, options=None)
Plots a curve determined by a sequence of points.

INPUT:

• ptsx – [x1,...,xn], where the xi and yi are real,
• ptsy – [y1,...,yn]
• options – a string representing maxima plot2d options.

The points are (x1,y1), (x2,y2), etc.
This function requires maxima 5.9.2 or newer.

Note: More that 150 points can sometimes lead to the program hanging. Why?

EXAMPLES:

sage: zeta_ptsx = [(pari(1/2 + i*I/10).zeta().real()).precision(1) # needs sage.libs.pari
.....: for i in range(70,150)]
sage: zeta_ptsy = [(pari(1/2 + i*I/10).zeta().imag()).precision(1) # needs sage.libs.pari
.....: for i in range(70,150)]
sage: maxima.plot_list(zeta_ptsx, zeta_ptsy) # not tested

sage: opts=["gnuplot_preamble, "set nokey"], ["gnuplot_term, ps"], ["gnuplot_out_file, "zeta.eps"]
(continues on next page)
plot_multilist(pts_list, options=None)

Plots a list of list of points pts_list=[[pts1,pts2,...,ptsn]], where each ptsi is of the form [[x1,y1],...,[xn,yn]]
x’s must be integers and y’s reals options is a string representing maxima plot2d options.

INPUT:

- pts_lst – list of points; each point must be of the form [x,y] where x is an integer and y is a real
- var – string; representing Maxima’s plot2d options

Requires maxima 5.9.2 at least.

Note: More that 150 points can sometimes lead to the program hanging.

EXAMPLES:

sage: xx = [i/10.0 for i in range(-10,10)]
sage: yy = [i/10.0 for i in range(-10,10)]
sage: x0 = [0 for i in range(-10,10)]
sage: y0 = [0 for i in range(-10,10)]
sage: zeta_ptsx1 = [(pari(1/2+i*I/10).zeta().real()).precision(1) # needs sage.libs.pari
...: for i in range(10)]
sage: zeta_ptsy1 = [(pari(1/2+i*I/10).zeta().imag()).precision(1) # needs sage.libs.pari
...: for i in range(10)]
sage: maxima.plot_multilist([[zeta_ptsx1,zeta_ptsy1], [xx,y0], [x0,yy]]) # not tested
...: # needs sage.libs.pari
...: for i in range(10,150)]
sage: zeta_ptsx1 = [(pari(1/2+i*I/10).zeta().real()).precision(1) # needs sage.libs.pari
...: for i in range(10,150)]
sage: zeta_ptsy1 = [(pari(1/2+i*I/10).zeta().imag()).precision(1) # needs sage.libs.pari
...: for i in range(10,150)]
sage: maxima.plot_multilist([[zeta_ptsx1,zeta_ptsy1], [xx,y0], [x0,yy]], # not tested
...: for i in range(10,150)]
sage: opts=['gnuplot_preamble, "set nokey"']
sage: maxima.plot_multilist([[zeta_ptsx1,zeta_ptsy1], [xx,y0], [x0,yy]], # not tested
...: for i in range(10,150)]

(continues on next page)
solve_linear (eqns, vars)
Wraps maxima's linsolve.

INPUT:

• eqns – a list of m strings; each representing a linear question in m = n variables

• vars – a list of n strings; each representing a variable

EXAMPLES:
sage: eqns = ["x + z = y","2*a*x - y = 2*a^2","y - 2*z = 2"]
sage: vars = ["x","y","z"]
sage: maxima.solve_linear(eqns, vars)
[x = a+1,y = 2*a,z = a-1]

unit_quadratic_integer (n)
Finds a unit of the ring of integers of the quadratic number field \( \mathbb{Q}(\sqrt{n}) \), \( n > 1 \), using the qunit maxima command.

INPUT:

• n – an integer
EXAMPLES:

```python
sage: u = maxima.unit_quadratic_integer(101); u
a + 10
sage: u.parent()
Number Field in a with defining polynomial x^2 - 101 with a = 10.
˓→04987562112089?
```

```python
sage: u = maxima.unit_quadratic_integer(13)
sage: u
5*a + 18
sage: u.parent()
Number Field in a with defining polynomial x^2 - 13 with a = 3.
˓→605551275463990?
```

```python
>>> from sage.all import *

>>> u = maxima.unit_quadratic_integer(Integer(101)); u
a + 10

>>> u.parent()
Number Field in a with defining polynomial x^2 - 101 with a = 10.
˓→04987562112089?

>>> u = maxima.unit_quadratic_integer(Integer(13))

>>> u
5*a + 18

>>> u.parent()
Number Field in a with defining polynomial x^2 - 13 with a = 3.
˓→605551275463990?
```

### version()

Return the version of Maxima that Sage includes.

**INPUT:** none  
**OUTPUT:** none  
**EXAMPLES:**

```python
sage: maxima.version()  # random
'5.41.0'
```

```python
>>> from sage.all import *

>>> maxima.version()  # random
'5.41.0'
```

### class sage.interfaces.maxima_abstract.MaximaAbstractElement

**Bases:** ExtraTabCompletion, InterfaceElement

Element of Maxima through an abstract interface.

**EXAMPLES:**

Elements of this class should not be created directly. The targeted parent of a concrete inherited class should be used instead:

```python
sage: from sage.interfaces.maxima_lib import maxima_lib
sage: xp = maxima(x)
sage: type(xp)
```

(continues on next page)
comma (args)
Form the expression that would be written ‘self, args’ in Maxima.

INPUT:

• args – string

OUTPUT: Maxima object

EXAMPLES:

```
sage: maxima('sqrt(2) + I').comma('numer')
I+1.41421356237309...
sage: maxima('sqrt(2) + I*a').comma('a=5')
5*I+sqrt(2)
```

derivative (var='x', n=1)
Return the n-th derivative of self.

INPUT:

• var – variable (default: ‘x’)
• n – integer (default: 1)

OUTPUT: n-th derivative of self with respect to the variable var

EXAMPLES:

```
sage: f = maxima('x^2')
sage: f.diff()
2*x
sage: f.diff('x')
2*x
sage: f.diff('x', 2)
2
sage: maxima('sin(x^2)').diff('x', 4)
16*x^4*sin(x^2)-12*sin(x^2)-48*x^2*cos(x^2)
```
Interpreter Interfaces, Release 10.4

>>> from sage.all import *
>>> f = maxima('x^2')
>>> f.diff()
2*x
>>> f.diff('x')
2*x
>>> f.diff('x', Integer(2))
2
>>> maxima('sin(x^2)').diff('x',Integer(4))
16*x^4*sin(x^2)-12*sin(x^2)-48*x^2*cos(x^2)

sage: f = maxima('x^2 + 17*y^2')
sage: f.diff('x')
34*y*diff(y,x,1)+2*x
sage: f.diff('y')
34*y

>>> from sage.all import *
>>> f = maxima('x^2')
>>> f.diff()
2*x
>>> f.diff('x')
2*x
>>> f.diff('x', Integer(2))
2
>>> maxima('sin(x^2)').diff('x',Integer(4))
16*x^4*sin(x^2)-12*sin(x^2)-48*x^2*cos(x^2)

\textbf{diff}(\textit{var}=\textit{x}, \textit{n}=1)

Return the \textit{n}-th derivative of self.

INPUT:

- \textit{var} – variable (default: 'x')
- \textit{n} – integer (default: 1)

OUTPUT: \textit{n}-th derivative of self with respect to the variable \textit{var}

EXAMPLES:

sage: f = maxima('x^2')
sage: f.diff()
2*x
sage: f.diff('x')
2*x
sage: f.diff('x', 2)
2
sage: maxima('sin(x^2)').diff('x',4)
16*x^4*sin(x^2)-12*sin(x^2)-48*x^2*cos(x^2)
Interpreter Interfaces, Release 10.4

```python
sage: f = maxima('x^2 + 17*y^2')
sage: f.diff('x')
34*y*diff(y,x,1)+2*x
sage: f.diff('y')
34*y
```

```python
>>> from sage.all import *
>>> f = maxima('x^2 + 17*y^2')
>>> f.diff('x')
34*y*diff(y,x,1)+2*x
>>> f.diff('y')
34*y
```

dot (other)

Implements the notation self . other.

**INPUT:**
- other – matrix; argument to dot.

**OUTPUT:** Maxima matrix

**EXAMPLES:**

```python
sage: A = maxima('matrix ([a1],[a2])')
sage: B = maxima('matrix ([b1,b2])')
sage: A.dot(B)
matrix([[a1*b1,a1*b2],[a2*b1,a2*b2])
```

```python
>>> from sage.all import *
>>> A = maxima('matrix ([a1],[a2])')
>>> B = maxima('matrix ([b1,b2])')
>>> A.dot(B)
matrix([[a1*b1,a1*b2],[a2*b1,a2*b2])
```

imag()

Return the imaginary part of this Maxima element.

**INPUT:** none

**OUTPUT:** Maxima real

**EXAMPLES:**

```python
sage: maxima('2 + (2/3)*%i').imag()
2/3
```

```python
>>> from sage.all import *
>>> maxima('2 + (2/3)*%i').imag()
2/3
```

integral (var='x', min=None, max=None)

Return the integral of self with respect to the variable x.

**INPUT:**
- var – variable
- min – default: None
- max – default: None
**integrate** *(var=’x’, min=None, max=None)*

Return the integral of self with respect to the variable x.

**INPUT:**

- **var** – variable
- **min** – default: None
- **max** – default: None
OUTPUT:

- the definite integral if xmin is not None
- an indefinite integral otherwise

EXAMPLES:

```python
sage: maxima('x^2+1').integral()
x^3/3+x
sage: maxima('x^2+ 1 + y^2').integral('y')
y^3/3+x^2*y+y
sage: maxima('x / (x^2+1)').integral()
log(x^2+1)/2
sage: maxima('1/(x^2+1)').integral()
atan(x)
sage: maxima('1/(x^2+1)').integral('x', 0, infinity)
%pi/2
sage: maxima('x/(x^2+1)').integral('x', -1, 1)
0
```

```python
>>> from sage.all import *

>>> maxima('x^2+1').integral()
x^3/3+x
>>> maxima('x^2+ 1 + y^2').integral('y')
y^3/3+x^2*y+y
>>> maxima('x / (x^2+1>').integral()
log(x^2+1)/2
>>> maxima('1/(x^2+1)').integral()
atan(x)
>>> maxima('1/(x^2+1)').integral('x', Integer(0), infinity)
%pi/2
>>> maxima('x/(x^2+1)').integral('x', -Integer(1), Integer(1))
0
```

```python
sage: f = maxima('exp(x^2)').integral('x',0,1)
sage: f.sage()
-1/2*I*sqrt(pi)*erf(I)
sage: f.numer()
1.46265174590718...
```

```python
>>> from sage.all import *

>>> f = maxima('exp(x^2)').integral('x',Integer(0),Integer(1))
>>> f.sage()
-1/2*I*sqrt(pi)*erf(I)
>>> f.numer()
1.46265174590718...
```

`nintegral (var='x', a=0, b=1, desired_relative_error='1e-8', maximum_num_subintervals=200)`

Return a numerical approximation to the integral of self from a to b.

INPUT:

- var – variable to integrate with respect to
- a – lower endpoint of integration
- b – upper endpoint of integration
• **desired_relative_error** – (default: ‘1e-8’) the desired relative error

• **maximum_num_subintervals** – (default: 200) maxima number of subintervals

OUTPUT:

• approximation to the integral

• **estimated absolute error of the approximation**

• the number of integrand evaluations

• an error code:
  - 0 – no problems were encountered
  - 1 – too many subintervals were done
  - 2 – excessive roundoff error
  - 3 – extremely bad integrand behavior
  - 4 – failed to converge
  - 5 – integral is probably divergent or slowly convergent
  - 6 – the input is invalid

EXAMPLES:

```sage
maxima('exp(-sqrt(x))').nintegral('x',0,1)
(0.5284822353142306, 4.163...e-11, 231, 0)
```

```python
from sage.all import *
maxima('exp(-sqrt(x))').nintegral('x',Integer(0),Integer(1))
(0.5284822353142306, 4.163...e-11, 231, 0)
```

Note that GP also does numerical integration, and can do so to very high precision very quickly:

```sage
intnum(x=0,1,exp(-sqrt(x)))
0.5284822353142307136179049194 # 32-bit
0.52848223531423071361790491935415653022 # 64-bit
```

```python
from sage.all import *
gp('intnum(x=0,1,exp(-sqrt(x)))')
0.52848223531423071361790491935415653021675547587292866196865279321015401702040079
```

`numer()`

Return numerical approximation to self as a Maxima object.

INPUT: none
OUTPUT: Maxima object

EXAMPLES:

```python
sage: a = maxima('sqrt(2)').numer(); a
1.41421356237309...
sage: type(a)
<class 'sage.interfaces.maxima.MaximaElement'>
```

```python
>>> from sage.all import *
>>> a = maxima('sqrt(2)').numer(); a
1.41421356237309...
```

```python
partial_fraction_decomposition(var='x')
```

Return the partial fraction decomposition of self with respect to the variable var.

INPUT:

- var: string

OUTPUT: Maxima object

EXAMPLES:

```python
sage: f = maxima(1/((1+x)*(x-1)))
sage: f.partial_fraction_decomposition(x)
1/(2*(x-1))-1/(2*(x+1))
sage: print(f.partial_fraction_decomposition(x))
1
--------- - ---------
2 (x - 1) 2 (x + 1)
```

```python
>>> from sage.all import *
>>> f = maxima(1/((1+x)*(x-1)))
```

```python
>>> f.partial_fraction_decomposition(x)
1/(2*(x-1))-1/(2*(x+1))
```

```python
>>> print(f.partial_fraction_decomposition(x))
1
--------- - ---------
2 (x - 1) 2 (x + 1)
```

real()

Return the real part of this Maxima element.

INPUT: none

OUTPUT: Maxima real

EXAMPLES:

```python
sage: maxima('2 + (2/3)*%i').real()
2
```

```python
>>> from sage.all import *
>>> maxima('2 + (2/3)*%i').real()
2
```
str()

Return string representation of this Maxima object.

INPUT: none
OUTPUT: string
EXAMPLES:

```sage
maxima('sqrt(2) + 1/3').str()
'sqrt(2)+1/3'
```

```
>>> from sage.all import *
>>> maxima('sqrt(2) + 1/3').str()
'sqrt(2)+1/3'
```

subst(val)

Substitute a value or several values into this Maxima object.

INPUT:

• val – string representing substitution(s) to perform

OUTPUT: Maxima object
EXAMPLES:

```sage
maxima('a^2 + 3*a + b').subst('b=2')
a^2+3*a+2
maxima('a^2 + 3*a + b').subst('a=17')
b+340
maxima('a^2 + 3*a + b').subst('a=17, b=2')
342
```

```
>>> from sage.all import *
>>> maxima('a^2 + 3*a + b').subst('b=2')
a^2+3*a+2
>>> maxima('a^2 + 3*a + b').subst('a=17')
b+340
>>> maxima('a^2 + 3*a + b').subst('a=17, b=2')
342
```

```python
class sage.interfaces.maxima_abstract.MaximaAbstractElementFunction(parent, name, defn, args, latex)

Bases: MaximaAbstractElement

Create a Maxima function with the parent parent, name name, definition defn, arguments args and latex representation latex.

INPUT:

• parent – an instance of a concrete Maxima interface
• name – string
• defn – string
• args – string; comma separated names of arguments
• latex – string
```
OUTPUT: Maxima function

EXAMPLES:

```
sage: maxima.function('x,y','e^cos(x)')
e^cos(x)

>>> from sage.all import *
>>> maxima.function('x,y','e^cos(x)')
e^cos(x)
```

**arguments** (*split=True*)

Returns the arguments of this Maxima function.

**INPUT:**

- **split** — boolean; if True return a tuple of strings, otherwise return a string of comma-separated arguments

**OUTPUT:**

- a string if **split** is False
- a list of strings if **split** is True

**EXAMPLES:**

```
sage: f = maxima.function('x,y','sin(x+y)')
sage: f.arguments() ['x', 'y']
sage: f.arguments(split=False) 'x,y'
sage: f = maxima.function('', 'sin(x)')
sage: f.arguments() []
```

**definition** ()

Returns the definition of this Maxima function as a string.

**INPUT:** none

**OUTPUT:** string

**EXAMPLES:**

```
sage: f = maxima.function('x,y','sin(x+y)')
sage: f.definition() 'sin(x+y)'
```
```python
>>> from sage.all import *
>>> f = maxima.function('x,y','sin(x+y)')
>>> f.definition()
'sin(x+y)'
```

**integral (var)**

Returns the integral of self with respect to the variable var.

**INPUT:**

- var -- a variable

**OUTPUT:** Maxima function

Note that integrate is an alias of integral.

**EXAMPLES:**

```python
sage: x,y = var('x,y')
sage: f = maxima.function('x','sin(x)')
sage: f.integral(x)
-cos(x)
sage: f.integral(y)
sin(x)*y
```

```python
>>> from sage.all import *
>>> x,y = var('x,y')
>>> f = maxima.function('x','sin(x)')
>>> f.integral(x)
-cos(x)
>>> f.integral(y)
sin(x)*y
```

**integrate (var)**

Returns the integral of self with respect to the variable var.

**INPUT:**

- var -- a variable

**OUTPUT:** Maxima function

Note that integrate is an alias of integral.

**EXAMPLES:**

```python
sage: x,y = var('x,y')
sage: f = maxima.function('x','sin(x)')
sage: f.integral(x)
-cos(x)
sage: f.integral(y)
sin(x)*y
```
sage.interfaces.maxima_abstract.maxima_console()

Spawn a new Maxima command-line session.

EXAMPLES:

```
sage: from sage.interfaces.maxima_abstract import maxima_console
sage: maxima_console()  # not tested
Maxima 5.46.0 https://maxima.sourceforge.io ...
```

```
>>> from sage.all import *
>>> from sage.interfaces.maxima_abstract import maxima_console
>>> maxima_console()  # not tested
Maxima 5.46.0 https://maxima.sourceforge.io ...
```

sage.interfaces.maxima_abstract.maxima_version()

Return Maxima version.

Currently this calls a new copy of Maxima.

EXAMPLES:

```
sage: from sage.interfaces.maxima_abstract import maxima_version
sage: maxima_version()  # random
'5.41.0'
```

```
>>> from sage.all import *
>>> from sage.interfaces.maxima_abstract import maxima_version
>>> maxima_version()  # random
'5.41.0'
```

sage.interfaces.maxima_abstract.reduce_load_MaximaAbstract_function (parent, defn, args, latex)

Unpickle a Maxima function.

EXAMPLES:

```
sage: from sage.interfaces.maxima_abstract import reduce_load_MaximaAbstract_function
sage: f = maxima.function(x,y,sin(x+y))
sage: _,args = f.__reduce__()
sage: g = reduce_load_MaximaAbstract_function(*args)
sage: g == f
True
```

```
>>> from sage.all import *
>>> from sage.interfaces.maxima_abstract import reduce_load_MaximaAbstract_function
>>> f = maxima.function(x,y,sin(x+y))
>>> _,args = f.__reduce__()
>>> g = reduce_load_MaximaAbstract_function(*args)
>>> g == f
True
```
Maxima is a free GPL’d general purpose computer algebra system whose development started in 1968 at MIT. It contains symbolic manipulation algorithms, as well as implementations of special functions, including elliptic functions and generalized hypergeometric functions. Moreover, Maxima has implementations of many functions relating to the invariant theory of the symmetric group $S_n$. (However, the commands for group invariants, and the corresponding Maxima documentation, are in French.) For many links to Maxima documentation, see http://maxima.sourceforge.net/documentation.html.

AUTHORS:

- William Stein (2005-12): Initial version
- David Joyner: Improved documentation
- William Stein (2006-01-08): Fixed bug in parsing
- William Stein (2006-02-22): comparisons (following suggestion of David Joyner)
- William Stein (2006-02-24): greatly improved robustness by adding sequence numbers to IO bracketing in _eval_line

For this interface, Maxima is loaded into ECL which is itself loaded as a C library in Sage. Translations between Sage and Maxima objects (which are nothing but wrappers to ECL objects) is made as much as possible directly, but falls back to the string based conversion used by the classical Maxima Pexpect interface in case no new implementation has been made.

This interface is the one used for calculus by Sage and is accessible as `maxima_calculus`:

```
sage: maxima_calculus
Maxima_lib

>>> from sage.all import *
>>> maxima_calculus
Maxima_lib
```

Only one instance of this interface can be instantiated, so the user should not try to instantiate another one, which is anyway set to raise an error:

```
sage: from sage.interfaces.maxima_lib import MaximaLib
sage: MaximaLib()
Traceback (most recent call last):
...
RuntimeError: Maxima interface in library mode can only be instantiated once
```
Interpreter Interfaces, Release 10.4

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import MaximaLib

MaximaLib()
Traceback (most recent call last):
...
RuntimeError: Maxima interface in library mode can only be instantiated once
```

Changed `besselexpand` to true in `init_code` – automatically simplify Bessel functions to trig functions when appropriate when true. Examples:

For some infinite sums, a closed expression can be found. By default, “maxima” is used for that:

```python
sage: x,n,k = var("x","n","k")
sage: sum((-x)^n/(factorial(n)*factorial(n+3/2)),n,0,oo)
-1/2*(2*x*cos(2*sqrt(x)) - sqrt(x)*sin(2*sqrt(x)))/(sqrt(pi)*x^2)
```

Maxima has some flags that affect how the result gets simplified (By default, `besselexpand` is false in Maxima; however in 5.39 this test does not show any difference, as, apparently, another expansion path is used):

```python
sage: maxima_calculus("besselexpand:false")
false
sage: x,n,k = var("x","n","k")
sage: sum((-x)^n/(factorial(n)*factorial(n+3/2)),n,0,oo)
-1/2*(2*x*cos(2*sqrt(x)) - sqrt(x)*sin(2*sqrt(x)))/(sqrt(pi)*x^2)
sage: maxima_calculus("besselexpand:true")
true
```

The output is parseable (i.e. Issue #31796 is fixed):

```python
sage: foo = maxima_calculus('a and (b or c)') ; foo
a and (b or c)
sage: bar = maxima_calculus(foo) ; bar
a and (b or c)
sage: bar == foo
True
```

```python
>>> from sage.all import *

>>> foo = maxima_calculus('a and (b or c)') ; foo
a and (b or c)
```

```python
>>> bar = maxima_calculus(foo) ; bar
a and (b or c)
>>> bar == foo
True
```
class sage.interfaces.maxima_lib.MaximaLib

Bases: MaximaAbstract

Interface to Maxima as a Library.

INPUT: none

OUTPUT: Maxima interface as a Library

EXAMPLES:

```
sage: from sage.interfaces.maxima_lib import MaximaLib, maxima_lib
sage: isinstance(maxima_lib, MaximaLib)
True
```

Only one such interface can be instantiated:

```
sage: MaximaLib()
Traceback (most recent call last):
  ...:
RuntimeError: Maxima interface in library mode can only be instantiated once
```

```
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import MaximaLib, maxima_lib
>>> isinstace(maxima_lib, MaximaLib)
True
```

```
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import MaximaLib, maxima_lib
>>> MaximaLib()
Traceback (most recent call last):
  ...:
RuntimeError: Maxima interface in library mode can only be instantiated once
```

clear(var)

Clear the variable named var.

INPUT:

- var – string

OUTPUT: none

EXAMPLES:

```
sage: from sage.interfaces.maxima_lib import maxima_lib
sage: maxima_lib.set('xxxxx', '2')
sage: maxima_lib.get('xxxxx')
'2'
sage: maxima_lib.clear('xxxxx')
sage: maxima_lib.get('xxxxx')
'xxxxx'
```

```
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib
>>> maxima_lib.set('xxxxx', '2')
>>> maxima_lib.get('xxxxx')
'2'
```
eval \((line, \text{locals}=\text{None}, \text{reformat}=\text{True}, \text{**kwds})\)

Evaluate the line in Maxima.

**INPUT:**
- \(line\) – string; text to evaluate
- \(\text{locals}\) – None (ignored); this is used for compatibility with the Sage notebook's generic system interface.
- \(\text{reformat}\) – boolean; whether to strip output or not
- \(\text{**kwds}\) – All other arguments are currently ignored.

**OUTPUT:** string representing Maxima output

**EXAMPLES:**

```python
sage: from sage.interfaces.maxima_lib import maxima_lib
sage: maxima_lib._eval_line('1+1')
'2'
sage: maxima_lib._eval_line('1+1;')
'2'
sage: maxima_lib._eval_line('1+1$')
''
sage: maxima_lib._eval_line('randvar : cos(x)+sin(y)$')
''
sage: maxima_lib._eval_line('randvar')
'sin(y)+cos(x)'
```

get \((\text{var})\)

Get the string value of the variable \(\text{var}\).

**INPUT:**
- \(\text{var}\) – string

**OUTPUT:** string

**EXAMPLES:**
**lisp**(cmd)

Send a lisp command to maxima.

**INPUT:**
- cmd – string

**OUTPUT:** ECL object

**Note:** The output of this command is very raw - not pretty.

**EXAMPLES:**

```python
sage: from sage.interfaces.maxima_lib import maxima_lib
sage: maxima_lib.lisp("(+ 2 17)")
<ECL: 19>
```

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib
>>> maxima_lib.lisp("(+ 2 17)")
<ECL: 19>
```

**set**(var, value)

Set the variable var to the given value.

**INPUT:**
- var – string
- value – string

**OUTPUT:** none

**EXAMPLES:**

```python
sage: from sage.interfaces.maxima_lib import maxima_lib
sage: maxima_lib.set('xxxxx', '2')
sage: maxima_lib.get('xxxxx')
2
```

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib
>>> maxima_lib.set('xxxxx', '2')
>>> maxima_lib.get('xxxxx')
2
```
sr_integral(*args)
    Helper function to wrap calculus use of Maxima's integration.

sr_limit(expr, v, a, dir=None)
    Helper function to wrap calculus use of Maxima's limits.

sr_prod(*args)
    Helper function to wrap calculus use of Maxima's product.

sr_sum(*args)
    Helper function to wrap calculus use of Maxima's summation.

sr_tlimit(expr, v, a, dir=None)
    Helper function to wrap calculus use of Maxima's Taylor series limits.

class sage.interfaces.maxima_lib.MaximaLibElement(parent, value, is_name=False, name=None)

    Bases: MaximaAbstractElement

    Element of Maxima through library interface.

    EXAMPLES:

    Elements of this class should not be created directly. The targeted parent should be used instead:

```python
sage: from sage.interfaces.maxima_lib import maxima_lib
sage: maxima_lib(4)
4
sage: maxima_lib(log(x))
log(_SAGE_VAR_x)
```

display2d(onscreen=True)
    Return the 2d representation of this Maxima object.

    INPUT:

    • onscreen – boolean (default: True); whether to print or return

    OUTPUT:

    The representation is printed if onscreen is set to True and returned as a string otherwise.

    EXAMPLES:

```python
sage: from sage.interfaces.maxima_lib import maxima_lib
def F(x): return x**5 - y**5
sage: F = maxima_lib(F).factor()  
4 3 2 2 3 4
- (y - x) (y + x y + x y + x y + x y + x)
```
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib
>>> F = maxima_lib('x^5 - y^5').factor()
>>> F.display2d()

\[ - (y - x) \, (y + x \, y + x \, y + x \, y + x ) \]

```
ecl()
```

Return the underlying ECL object of this MaximaLib object.

**INPUT:** none

**OUTPUT:** ECL object

**EXAMPLES:**

```
sage: from sage.interfaces.maxima_lib import maxima_lib
sage: maxima_lib(x+cos(19)).ecl()
<ECL: ((MPLUS SIMP) ((%COS SIMP) 19) |$_SAGE_VAR_x|)>
```

```
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib

maxima_lib(x+cos(Integer(19))).ecl()

<ECL: ((MPLUS SIMP) ((%COS SIMP) 19) |$_SAGE_VAR_x|)>
```

to_poly_solve (vars, options='')

Use Maxima's to_poly_solver package.

**INPUT:**

- vars – symbolic expressions
- options – string (default="")

**OUTPUT:** Maxima object

**EXAMPLES:**

The zXXX below are names for arbitrary integers and subject to change:

```
sage: from sage.interfaces.maxima_lib import maxima_lib
sage: sol = maxima_lib(sin(x) == 0).to_poly_solve(x)
sage: sol.sage()
[[x == pi*z...]]
```

```
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib

sol = maxima_lib(sin(x) == Integer(0)).to_poly_solve(x)
>>> sol.sage()
[[x == pi*z...]]
```

```
class sage.interfaces.maxima_lib.MaximaLibElementFunction (parent, name, defn, args, latex)
```

**Bases:** MaximaLibElement, MaximaAbstractElementFunction

sage.interfaces.maxima_lib.dummy_integrate (expr)

We would like to simply tie Maxima's integrate to sage.calculus.calculus.dummy_integrate, but we're being imported there so to avoid circularity we define it here.

**INPUT:**
• `expr` – ECL object; a Maxima `%INTEGRATE` expression

OUTPUT: symbolic expression

EXAMPLES:

```python
sage: from sage.interfaces.maxima_lib import maxima_lib, dummy_integrate
sage: f = maxima_lib('f(x)').integrate('x')
sage: f.ecl()
<ECL: ((%INTEGRATE SIMP) (($F SIMP) $X) $X)>
sage: dummy_integrate(f.ecl())
integrate(f(x), x)
```

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib, dummy_integrate

>>> f = maxima_lib('f(x)').integrate('x')
>>> f.ecl()
<ECL: ((%INTEGRATE SIMP) (($F SIMP) $X) $X)>
>>> dummy_integrate(f.ecl())
integrate(f(x), x)
```

```python
sage: f = maxima_lib('f(x)').integrate('x',0,10)
sage: f.ecl()
<ECL: ((%INTEGRATE SIMP) (($F SIMP) $X) $X 0 10)>
sage: dummy_integrate(f.ecl())
integrate(f(x), x, 0, 10)
```

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib, is_MaximaLibElement

>>> is_MaximaLibElement(Integer(1))
False
```

```
spect.interfaces.maxima_lib.is_MaximaLibElement(x)

Return True if x is of type `MaximaLibElement`.

EXAMPLES:

```python
sage: from sage.interfaces.maxima_lib import maxima_lib, is_MaximaLibElement
sage: is_MaximaLibElement(1)
doctest:...: DeprecationWarning: the function is_MaximaLibElement is deprecated;...
use isinstance(x, sage.interfaces.abc.MaximaLibElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
False
sage: m = maxima_lib(1)
sage: is_MaximaLibElement(m)
True
```

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib, is_MaximaLibElement

>>> is_MaximaLibElement(Integer(1))
doctest:...: DeprecationWarning: the function is_MaximaLibElement is deprecated;...
use isinstance(x, sage.interfaces.abc.MaximaLibElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
False
```

(continues on next page)
sage.interfaces.maxima_lib.max_at_to_sage(expr)

Special conversion rule for AT expressions.

**INPUT:**

- expr – ECL object; a Maxima AT expression

**OUTPUT:** symbolic expression

**EXAMPLES:**

```python
>>> from sage.interfaces.maxima_lib import maxima, max_at_to_sage
>>> a=maxima('at(f(x,y,z),[x=1,y=2,z=3])')
>>> a
at(f(x,y,z),[x = 1,y = 2,z = 3])
>>> max_at_to_sage(a.ecl())
f(1, 2, 3)
```

```python
>>> a=maxima('at(f(x,y,z),x=1)')
>>> a
at(f(x,y,z),x = 1)
>>> max_at_to_sage(a.ecl())
f(1, y, z)
```

sage.interfaces.maxima_lib.max_harmonic_to_sage(expr)

**EXAMPLES:**

```python
>>> from sage.interfaces.maxima_lib import maxima, max_to_sr
>>> c=maxima(harmonic_number(x,2))
>>> c.ecl()
<ECL: (($GEN_HARMONIC_NUMBER SIMP) 2 |$_SAGE_VAR_x|)>
>>> max_to_sr(c.ecl())
harmonic_number(x, 2)
```

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima, max_to_sr
>>> c=maxima(harmonic_number(x,Integer(2)))
>>> c.ecl()
<ECL: (($GEN_HARMONIC_NUMBER SIMP) 2 |$_SAGE_VAR_x|)>
>>> max_to_sr(c.ecl())
harmonic_number(x, 2)
```
sage.interfaces.maxima_lib.max_pochhammer_to_sage(expr)

EXAMPLES:

```python
sage: from sage.interfaces.maxima_lib import maxima_lib, max_to_sr
sage: c = maxima_lib('pochhammer(x,n)')
sage: c.ecl()
<ECL: (($POCHHAMMER SIMP) $X $N)>
sage: max_to_sr(c.ecl())
gamma(n + x)/gamma(x)
```

sage.interfaces.maxima_lib.max_to_sr(expr)

Convert a Maxima object into a symbolic expression.

INPUT:

• expr – ECL object

OUTPUT: symbolic expression

EXAMPLES:

```python
sage: from sage.interfaces.maxima_lib import maxima_lib, max_to_sr
sage: f = maxima_lib('f(x)')
sage: f.ecl()
<ECL: (($F SIMP) $X)>
sage: max_to_sr(f.ecl())
f(x)
```

sage.interfaces.maxima_lib.max_to_string(s)

Return the Maxima string corresponding to this ECL object.

INPUT:

• s – ECL object

OUTPUT: string

EXAMPLES:

```python
sage: from sage.interfaces.maxima_lib import maxima_lib, max_to_string
sage: ecl = maxima_lib(cos(x)).ecl()
sage: max_to_string(ecl)
'cos(_SAGE_VAR_x)'
```
sage.interfaces.maxima_lib.mdiff_to_sage(expr)
Special conversion rule for %DERIVATIVE expressions.

INPUT:
- expr – ECL object; a Maxima %DERIVATIVE expression

OUTPUT: symbolic expression

EXAMPLES:

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib, mdiff_to_sage
>>> f = maxima_lib('f(x)').diff('x',4)
>>> f.ecl()
<ECL: ((%DERIVATIVE SIMP) ($F SIMP) $X) $X 4)>
>>> mdiff_to_sage(f.ecl())
diff(f(x), x, x, x, x)
```

sage.interfaces.maxima_lib.mlist_to_sage(expr)
Special conversion rule for MLIST expressions.

INPUT:
- expr – ECL object; a Maxima MLIST expression (i.e., a list)

OUTPUT: a Python list of converted expressions.

EXAMPLES:

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib, mlist_to_sage
>>> L=maxima_lib('[[1,2,3]]')
>>> L.ecl()
<ECL: ((MLIST SIMP) 1 2 3)>
>>> mlist_to_sage(L.ecl())
[1, 2, 3]
```
sage.interfaces.maxima_lib.mqapply_to_sage(expr)

Special conversion rule for MQAPPLY expressions.

**INPUT:**
- `expr` – ECL object; a Maxima MQAPPLY expression

**OUTPUT:** symbolic expression

MQAPPLY is used for function as li[x](y) and psi[x](y).

**EXAMPLES:**

```python
sage: from sage.interfaces.maxima_lib import maxima_lib, mqapply_to_sage
sage: c = maxima_lib(li[2](3))
sage: c.ecl()
<ECL: ((MQAPPLY SIMP) (($LI SIMP ARRAY) 2) 3)>
sage: mqapply_to_sage(c.ecl())
dilog(3)
```

sage.interfaces.maxima_lib.mrat_to_sage(expr)

Convert a Maxima MRAT expression to Sage SR.

**INPUT:**
- `expr` – ECL object; a Maxima MRAT expression

**OUTPUT:** symbolic expression

Maxima has an optimised representation for multivariate rational expressions. The easiest way to translate those to SR is by first asking Maxima to give the generic representation of the object. That is what RATDISREP does in Maxima.

**EXAMPLES:**

```python
sage: from sage.interfaces.maxima_lib import maxima_lib, mrat_to_sage
sage: var(x y z)
(x, y, z)
sage: c = maxima_lib((x+y^2+z^9)/x^6+z^8/y).rat()
sage: c
(_SAGE_VAR_y*_SAGE_VAR_z^9+_SAGE_VAR_x^6*_SAGE_VAR_z^8+_SAGE_VAR_y^3+_SAGE_VAR_x*→SAGE_VAR_y)/(_SAGE_VAR_x^6*_SAGE_VAR_y)
sage: c.ecl()
<ECL: ((MRAT SIMP (|$_SAGE_VAR_x| |$_SAGE_VAR_y| |$_SAGE_VAR_z|) |$_SAGE_VAR_y|...>
sage: mrat_to_sage(c.ecl())
(x^6*z^8 + y*z^9 + y^3 + x*y)/(x^6*y)
```

```python
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import maxima_lib, mrat_to_sage
>>> var('x y z')
(x, y, z)
```
Interpreter Interfaces, Release 10.4

(continued from previous page)

```python
>>> c = maxima_lib((x+y**Integer(2)+z**Integer(9))/x**Integer(6)+z**Integer(8)/y).
    → rat()
>>> c
(_SAGE_VAR_y*_SAGE_VAR_z^9+_SAGE_VAR_x^6*_SAGE_VAR_z^8+_SAGE_VAR_y^3+_SAGE_VAR_x*_SAGE_VAR_y)/(_SAGE_VAR_x^6*_SAGE_VAR_y)
>>> c.ecl()
<ECL: ((MRAT SIMP ($SAGE_VAR_x$ $SAGE_VAR_y$ $SAGE_VAR_z$))
...
>>> mrat_to_sage(c.ecl())
(x^6*z^8 + y*z^9 + y^3 + x*y)/(x^6*y)
```

sage.interfaces.maxima_lib.parse_max_string(s)

Evaluate string in Maxima without any further simplification.

INPUT:

- s – string

OUTPUT: ECL object

EXAMPLES:

```python
sage: from sage.interfaces.maxima_lib import parse_max_string
sage: parse_max_string('1+1')
<ECL: ((MPLUS) 1 1)>
```

sage.interfaces.maxima_lib.pyobject_to_max(obj)

Convert a (simple) Python object into a Maxima object.

INPUT:

- expr – Python object

OUTPUT: ECL object

Note: This uses functions defined in sage.libs.ecl.

EXAMPLES:

```python
sage: from sage.interfaces.maxima_lib import pyobject_to_max
sage: pyobject_to_max(4)
<ECL: 4>
sage: pyobject_to_max('z')
<ECL: Z>
sage: var('x')
x
sage: pyobject_to_max(x)
Traceback (most recent call last):
... TypeError: Unimplemented type for python_to_ecl
```
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import pyobject_to_max
>>> pyobject_to_max(Integer(4))
<ECL: 4>
>>> pyobject_to_max('z')
<ECL: Z>
>>> var('x')
x
>>> pyobject_to_max(x)
Traceback (most recent call last):
  ...
TypeError: Unimplemented type for python_to_ecl

sage.interfaces.maxima_lib.reduce_load_MaximaLib()
Unpickle the (unique) Maxima library interface.

EXAMPLES:

sage: from sage.interfaces.maxima_lib import reduce_load_MaximaLib
sage: reduce_load_MaximaLib()
Maxima_lib

sage.interfaces.maxima_lib.sage_rat(x, y)
Return quotient x/y.

INPUT:
• x – integer
• y – integer

OUTPUT: rational

EXAMPLES:

sage: from sage.interfaces.maxima_lib import sage_rat
sage: sage_rat(1, 7)
1/7

sage.interfaces.maxima_lib.sr_to_max(expr)
Convert a symbolic expression into a Maxima object.

INPUT:
• expr – symbolic expression

OUTPUT: ECL object

EXAMPLES:
Evaluate command $s$ and catch Maxima stdout (not the result of the command!) into a string.

**INPUT:**

- $s$ – string; command to evaluate

**OUTPUT:** string

This is currently used to implement $\textit{display2d()}$.

**EXAMPLES:**

```python
sage: from sage.interfaces.maxima_lib import stdout_to_string
sage: stdout_to_string('1+1')
'2

sage: stdout_to_string('disp(1+1)')
'2\n
>>> from sage.all import *
>>> from sage.interfaces.maxima_lib import stdout_to_string
>>> stdout_to_string('1+1')
'2

>>> stdout_to_string('disp(1+1)')
'2\n
```
AUTHOR:

- Mike Hansen
- William Stein

You must have the optional commercial MuPAD interpreter installed and available as the command code{mupkern} in your PATH in order to use this interface. You do not have to install any optional sage packages.

```python
class sage.interfaces.mupad.Mupad(maxread=None, script_subdirectory=None, server=None, server_tmpdir=None, logfile=None)

Bases: ExtraTabCompletion, Expect

Interface to the MuPAD interpreter.

completions (string, strip=False)

EXAMPLES:

sage: mupad.completions('linal') # optional - mupad
['linalg']

>>> from sage.all import *

>>> mupad.completions('linal') # optional - mupad
['linalg']
```

```python
console()

Spawn a new MuPAD command-line session.

EXAMPLES:

```
cputime (t=None)

EXAMPLES:

```python
sage: t = mupad.cputime()  # random, optional - MuPAD
0.11600000000000001

>>> from sage.all import *
>>> t = mupad.cputime()  # random, optional - MuPAD
0.11600000000000001
```

eval (code, strip=True, **kwds)

EXAMPLES:

```python
sage: mupad.eval('2+2')  # optional - mupad
4

>>> from sage.all import *
>>> mupad.eval('2+2')  # optional - mupad
4
```

expect ()

EXAMPLES:

```python
sage: a = mupad(1)  # optional - mupad
sage: mupad.expect()  # optional - mupad
<pexpect.spawn instance at 0x...>

>>> from sage.all import *
>>> a = mupad(Integer(1))  # optional - mupad
>>> mupad.expect()  # optional - mupad
<pexpect.spawn instance at 0x...>
```

get (var)

Get the value of the variable var.

EXAMPLES:

```python
sage: mupad.set('a', 4)  # optional - mupad
sage: mupad.get('a').strip()  # optional - mupad
'4'

>>> from sage.all import *
>>> mupad.set('a', Integer(4))  # optional - mupad
>>> mupad.get('a').strip()  # optional - mupad
'4'
```

set (var, value)

Set the variable var to the given value.

EXAMPLES:
sage: mupad.set('a', 4) # optional - mupad
sage: mupad.get('a').strip() # optional - mupad
'*4'*

>>> from sage.all import *
>>> mupad.set('a', Integer(4)) # optional - mupad
>>> mupad.get('a').strip() # optional - mupad
'*4'*

class sage.interfaces.mupad.MupadElement (parent, value, is_name=False, name=None)
Bases: ExtraTabCompletion, ExpectElement

class sage.interfaces.mupad.MupadFunction (parent, name)
Bases: ExtraTabCompletion, ExpectFunction

class sage.interfaces.mupad.MupadFunctionElement (obj, name)
Bases: ExtraTabCompletion, FunctionElement

sage.interfaces.mupad.mupad_console()

Spawn a new MuPAD command-line session.

EXAMPLES:

```python
sage: from sage.interfaces.mupad import mupad_console
sage: mupad_console() #not tested

*----* MuPAD Pro 4.0.2 -- The Open Computer Algebra System

*----* | Copyright (c) 1997 - 2007 by SciFace Software
| -*-|--*
|/ |/
*----* Licensed to: ...
```

sage.interfaces.mupad.reduce_load_mupad()

EXAMPLES:

```python
sage: from sage.interfaces.mupad import reduce_load_mupad
sage: reduce_load_mupad()
Mupad
```

```python
>>> from sage.all import *
>>> from sage.interfaces.mupad import reduce_load_mupad
>>> reduce_load_mupad()
Mupad
```
CHAPTER

THIRTYTHREE

INTERFACE TO MWRANK

sage.interfaces.mwrank.Mwrank (options='', server=None, server_tmpdir=None)

Create and return an mwrank interpreter, with given options.

INPUT:

• options – string; passed when starting mwrank. The format is:

```
-h help                          prints this info and quits
-q quiet                         turns OFF banner display and prompt
-v n verbosity                   sets verbosity to n (default=1)
-o PARI/GP output                turns ON extra PARI/GP short output (default is OFF)
-p n precision                   sets precision to n decimals (default=15)
-b n quartic bound               bound on quartic point search (default=10)
-x n n aux                       number of aux primes used for sieving (default=6)
-l list                          turns ON listing of points (default ON unless v=0)
-s selmer_only                   if set, computes Selmer rank only (default: not set)
-d skip_2nd_descent             if set, skips the second descent for curves with 2-torsion (default: not set)
-S n sat_bd                      upper bound on saturation primes (default=100, -1 for automatic)
```

Warning: Do not use the option “-q” which turns off the prompt.

EXAMPLES:

```
sage: M = Mwrank('-v 0 -l')
sage: print(M('0 0 1 -1 0'))
Curve [0,0,1,-1,0] : Rank = 1
Generator 1 is [0:-1:1]; height 0.051...
Regulator = 0.051...
```

```
>>> from sage.all import *
>>> M = Mwrank('-v 0 -l')
>>> print(M('0 0 1 -1 0'))
Curve [0,0,1,-1,0] : Rank = 1
Generator 1 is [0:-1:1]; height 0.051...
Regulator = 0.051...
```

class sage.interfaces.mwrank.Mwrank_class (options='', server=None, server_tmpdir=None)

Bases: Expect

Interface to the Mwrank interpreter.
console()

Start the mwrank console.

EXAMPLES:

```
sage: mwrank.console() # not tested: expects console input
Program mwrank: ...
```

```python
>>> from sage.all import *
```

```python
>>> mwrank.console() # not tested: expects console input
Program mwrank: ...
```

eval(s,**kwds)

Return mwrank’s output for the given input.

INPUT:

- *s* (str) – a Sage object which when converted to a string gives valid input to mwrank. The conversion is done by `validate_mwrank_input()`. Possible formats are:
  - a string representing exactly five integers separated by whitespace, for example ‘1 2 3 4 5’
  - a string representing exactly five integers separated by commas, preceded by ‘[’ and followed by ‘]’ (with arbitrary whitespace), for example ‘[1 2 3 4 5]’
  - a list or tuple of exactly 5 integers.

Note: If a `RuntimeError` exception is raised, then the mwrank interface is restarted and the command is retried once.

EXAMPLES:

```
sage: mwrank.eval('12 3 4 5 6')
'Curve [12,3,4,5,6] :...
```

```
sage: mwrank.eval('[12, 3, 4, 5, 6]')
'Curve [12,3,4,5,6] :...
```

```
sage: mwrank.eval([12, 3, 4, 5, 6])
'Curve [12,3,4,5,6] :...
```

```
sage: mwrank.eval((Integer(12), Integer(3), Integer(4), Integer(5), Integer(6)))
'Curve [12,3,4,5,6] :...
```

```
>>> from sage.all import *
```

```
>>> mwrank.eval('12 3 4 5 6')
'Curve [12,3,4,5,6] :...
```

```
>>> mwrank.eval('[12, 3, 4, 5, 6]')
'Curve [12,3,4,5,6] :...
```

```
>>> mwrank.eval([12, 3, 4, 5, 6])
'Curve [12,3,4,5,6] :...
```

```
>>> mwrank.eval((Integer(12), Integer(3), Integer(4), Integer(5), Integer(6)))
'Curve [12,3,4,5,6] :...
```

sage.interfaces.mwrank.mwrank_console()

Start the mwrank console.

EXAMPLES:
sage: mwrank_console() # not tested: expects console input
Program mwrank: ...

>>> from sage.all import *
>>> mwrank_console() # not tested: expects console input
Program mwrank: ...

sage.interfaces.mwrank.validate_mwrank_input(s)

Returns a string suitable for mwrank input, or raises an error.

INPUT:

- s – one of the following:
  - a list or tuple of 5 integers \([a_1, a_2, a_3, a_4, a_6]\) or \((a_1, a_2, a_3, a_4, a_6)\)
  - a string of the form \('[a_1, a_2, a_3, a_4, a_6]'\) or \('a_1 a_2 a_3 a_4 a_6'\) where \(a_1, a_2, a_3, a_4, a_6\) are integers

OUTPUT:

For valid input, a string of the form \('[a_1, a_2, a_3, a_4, a_6]'\. For invalid input a ValueError is raised.

EXAMPLES:

A list or tuple of 5 integers:

```python
sage: from sage.interfaces.mwrank import validate_mwrank_input
sage: validate_mwrank_input([1,2,3,4,5])
'[1, 2, 3, 4, 5]'
sage: validate_mwrank_input((-1,2,-3,4,-55))
'[-1, 2, -3, 4, -55]'
sage: validate_mwrank_input([1,2,3,4])
Traceback (most recent call last):
  ... ValueError: [1, 2, 3, 4] is not valid input to mwrank (should have 5 entries)
sage: validate_mwrank_input([1,2,3,4,i])
Traceback (most recent call last):
  ... ValueError: [1, 2, 3, 4, I] is not valid input to mwrank (entries should be integers)
```

A string of the form \('[a_1, a_2, a_3, a_4, a_6]'\) with any whitespace and integers ai:
**Example 33.1**

```python
>>> from sage.all import *
>>> validate_mwrank_input('0 -1 1 -7 6')
'\[0,-1,1,-7,6\]
>>> validate_mwrank_input('[0,-1,1,0,0]')
'\[0,-1,1,0,0\]
>>> validate_mwrank_input('0\t -1\t 1\t 0\t 0\n')
'\[0,-1,1,0,0\]
>>> validate_mwrank_input('0 -1 1 -7 ')
Traceback (most recent call last):
...
ValueError: 0 -1 1 -7 is not valid input to mwrank
```
GNU Octave is a free software (GPL) MATLAB-like program with numerical routines for integrating, solving systems of equations, special functions, and solving (numerically) differential equations. Please see http://octave.org/ for more details.

The commands in this section only work if you have the optional “octave” interpreter installed and available in your PATH. It’s not necessary to install any special Sage packages.

EXAMPLES:

```
sage: octave.eval('2+2')    # optional - octave
 'ans = 4'
sage: a = octave(10)       # optional - octave
sage: a**10                 # optional - octave
 1e+10
```

```
>>> from sage.all import *
>>> octave.eval('2+2')    # optional - octave
 'ans = 4'
>>> a = octave(Integer(10)) # optional - octave
>>> a**Integer(10)        # optional - octave
 1e+10
```

34.1 Computation of Special Functions

Octave implements computation of the following special functions (see the maxima and gp interfaces for even more special functions):

```
airy
    Airy functions of the first and second kind, and their derivatives.
    airy(0,x) = Ai(x), airy(1,x) = Ai'(x), airy(2,x) = Bi(x), airy(3,x) = Bi'(x)
besselj
    Bessel functions of the first kind.
bessely
    Bessel functions of the second kind.
besseli
    Modified Bessel functions of the first kind.
besselk
    Modified Bessel functions of the second kind.
```

(continues on next page)
besselh

  Compute Hankel functions of the first (k = 1) or second (k = 2) kind.

beta

  The Beta function,
  \[ \text{beta} (a, b) = \frac{\Gamma(a) \times \Gamma(b)}{\Gamma(a + b)} \].

betainc

  The incomplete Beta function,

erf

  The error function,

erfinv

  The inverse of the error function.

gamma

  The Gamma function,

gammainc

  The incomplete gamma function,

For example,

```
sage: # optional - octave
sage: octave("airy(3,2)")
4.10068
sage: octave("beta(2,2)")
0.166667
sage: octave("betainc(0.2,2,2)")
0.104
sage: octave("besselh(0,2)")
(0.223891, 0.510376)
sage: octave("besselh(0,1)")
(0.765198, 0.088257)
sage: octave("besseli(1,2)")
1.59064
sage: octave("besselj(1,2)")
0.576725
sage: octave("besselk(1,2)")
0.139866
sage: octave("erf(0)")
0
sage: octave("erf(1)")
0.842701
sage: octave("erfinv(0.842)")
0.998315
sage: octave("gamma(1.5)")
0.886227
sage: octave("gammainc(1.5,1)")
0.77687
```
Interpreter Interfaces, Release 10.4

34.2 Tutorial

EXAMPLES:

```python
sage: # optional - octave
sage: octave('4+10')
14
sage: octave('date')
18-Oct-2007
sage: octave('5*10 + 6')
56
sage: octave('(6+6)/3')
4
sage: octave('9')**2
81
sage: a = octave(10); b = octave(20); c = octave(30)
sage: avg = (a+b+c)/3
sage: avg
20
sage: parent(avg)
Octave
```

```python
>>> from sage.all import *
>>> # optional - octave
>>> octave('4+10')
14
>>> octave('date')
18-Oct-2007
>>> octave('5*10 + 6')
56
>>> octave('(6+6)/3')
4
>>> octave('9')**Integer(2)
81
>>> a = octave(Integer(10)); b = octave(Integer(20)); c = octave(Integer(30))
```

(continues on next page)
Interpreter Interfaces, Release 10.4

>>> avg = (a+b+c)/Integer(3)
>>> avg
20
>>> parent(avg)
Octave

sage: # optional - octave
sage: my_scalar = octave('3.1415')
sage: my_scalar
3.1415
sage: my_vector1 = octave('[1,5,7]')
sage: my_vector1
[1 5 7]
sage: my_vector2 = octave('[1;5;7]')
sage: my_vector2
[1
 5
 7]
sage: my_vector1 * my_vector2
75

>>> from sage.all import *
>>> # optional - octave
>>> my_scalar = octave('3.1415')
>>> my_scalar
3.1415
>>> my_vector1 = octave([1,5,7])
>>> my_vector1
[1 5 7]
>>> my_vector2 = octave([1;5;7])
>>> my_vector2
[1
 5
 7]
>>> my_vector1 * my_vector2
75

class sage.interfaces.octave.Octave(maxread=None, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, seed=None, command=None)

Bases: Expect

Interface to the Octave interpreter.

EXAMPLES:

sage: octave.eval("a = [ 1, 1, 2; 3, 5, 8; 13, 21, 33 ]").strip()  # optional -- octave
'a =\n\n 1 1 2
 3 5 8
 13 21 33'
sage: octave.eval("b = [ 1; 3; 13 ]").strip()  # optional -- octave
'b =\n 1
 3
 13'

>>> from sage.all import *
>>> octave.eval("a = [ 1, 1, 2; 3, 5, 8; 13, 21, 33 ]").strip()  # optional -- octave
'a =\n\n 1 1 2
 3 5 8
 13 21 33'

(continues on next page)
The following solves the linear equation: \( a \cdot c = b \):

\[
\begin{align*}
sage: \text{octave.eval}(\text{"c= a \ b"}).strip() & \quad \# \text{optional} - \text{octave} \quad \# \text{abs tol 0.01} \\
'c' = [1; -0; 0] \\
sage: \text{octave.eval}(\text{"c"}).strip() & \quad \# \text{optional} - \text{octave} \quad \# \text{abs tol 0.01} \\
'c' = [1; -0; 0]
\end{align*}
\]

```
>>> \text{octave.eval}(\text{"c= a \ b"}).strip() \quad \# \text{optional} - \text{octave} \quad \# \text{abs tol 0.01}
'c' = [1; -0; 0]
```

```
>>> \text{octave.eval}(\text{"c"}).strip() \quad \# \text{optional} - \text{octave} \quad \# \text{abs tol 0.01}
'c' = [1; -0; 0]
```

\[
\begin{align*}
\text{clear}(\text{var})
\end{align*}
\]

Clear the variable named \text{var}.

**EXAMPLES:**

```
\begin{verbatim}
sage: \text{octave.set}(\text{"x", \text{2}}) \quad \# \text{optional} - \text{octave}
sage: \text{octave.clear}(\text{"x"}) \quad \# \text{optional} - \text{octave}
sage: \text{octave.get}(\text{"x"}) \quad \# \text{optional} - \text{octave}
"\text{error: 'x' undefined near line ... column 1}"
\end{verbatim}
```

```
\begin{verbatim}
>>> \text{from sage.all import *} \\
>>> \text{octave.set}(\text{"x", \text{2}}) \quad \# \text{optional} - \text{octave} \\
>>> \text{octave.clear}(\text{"x"}) \quad \# \text{optional} - \text{octave} \\
>>> \text{octave.get}(\text{"x"}) \quad \# \text{optional} - \text{octave} \\
"\text{error: 'x' undefined near line ... column 1}"
\end{verbatim}
```

\[
\begin{align*}
\text{console}()
\end{align*}
\]

Spawn a new Octave command-line session.

This requires that the optional octave program be installed and in your PATH, but no optional Sage packages need be installed.

**EXAMPLES:**

```
\begin{verbatim}
sage: \text{octave_console()} \quad \# \text{not tested}
\end{verbatim}
```

```
\begin{verbatim}
GNU Octave, version 2.1.73 (i386-apple-darwin8.5.3).
Copyright (\text{C}) 2006 John W. Eaton.
...
octave:1> 2+3
ans = 5
octave:2> [\text{ctrl-d}]
```

```
\begin{verbatim}
>>> \text{from sage.all import *} \\
>>> \text{octave_console()} \quad \# \text{not tested}
\end{verbatim}
```

```
\begin{verbatim}
GNU Octave, version 2.1.73 (i386-apple-darwin8.5.3).
Copyright (\text{C}) 2006 John W. Eaton.
...
octave:1> 2+3
```
```
Pressing ctrl-d exits the octave console and returns you to Sage. octave, like Sage, remembers its history from one session to another.

**de_system_plot**(*f*, *ics*, *trange*)

Plot (using octave’s interface to gnuplot) the solution to a $2 \times 2$ system of differential equations.

**INPUT:**

- *f* – a pair of strings representing the differential equations; The independent variable must be called *x* and the dependent variable must be called *y*.
- *ics* – a pair $[x_0,y_0]$ such that $x(t_0) = x_0, y(t_0) = y_0$
- *trange* – a pair $[t_0,t_1]$

**OUTPUT:** A gnuplot window appears.

**EXAMPLES:**

```sage```
```
sage: octave.de_system_plot(['x+y','x-y'], [1,-1], [0,2]) # not tested -- does this actually work (on OS X it fails for me -- William Stein, 2007-10)
```

```sage```
```
>>> from sage.all import *
```
```
>>> octave.de_system_plot(['x+y','x-y'], [Integer(1),-Integer(1)], [Integer(0),Integer(2)]) # not tested -- does this actually work (on OS X it fails for me -- William Stein, 2007-10)
```
```
This should yield the two plots $(t,x(t)),(t,y(t))$ on the same graph (the $t$-axis is the horizontal axis) of the system of ODEs

$$
x' = x + y, x(0) = 1; \quad y' = x - y, y(0) = -1, \quad \text{for} \quad 0 < t < 2.
$$

**get**(*var*)

Get the value of the variable *var*.

**EXAMPLES:**

```sage```
```
sage: octave.set('x', '2') # optional - octave
sage: octave.get('x') # optional - octave
'2'
```

```sage```
```
>>> from sage.all import *
```
```
>>> octave.set('x', '2') # optional - octave
```
```
>>> octave.get('x') # optional - octave
```
```
**quit**(*verbose=False*)

**EXAMPLES:**

```sage```
```
sage: o = Octave()
sage: o._start() # optional - octave
sage: o.quit(True) # optional - octave
Exiting spawned Octave process.
```
```python
>>> from sage.all import *
>>> o = Octave()
>>> o._start()  # optional - octave
>>> o.quit(True)  # optional - octave
Exiting spawned Octave process.
```

**sage2octave_matrix_string** *(A)*

Return an octave matrix from a Sage matrix.

**INPUT:** A Sage matrix with entries in the rationals or reals.

**OUTPUT:** A string that evaluates to an Octave matrix.

**EXAMPLES:**

```python
sage: M33 = MatrixSpace(QQ,3,3)
sage: A = M33([1,2,3,4,5,6,7,8,0])
sage: octave.sage2octave_matrix_string(A)  # optional - octave
'[[1, 2, 3; 4, 5, 6; 7, 8, 0]]
```

**AUTHORS:**
- David Joyner and William Stein

**set** *(var, value)*

Set the variable *var* to the given *value*.

**EXAMPLES:**

```python
sage: octave.set('x', 2)  # optional - octave
sage: octave.get('x')  # optional - octave
2
```

**set_seed** *(seed=None)*

Set the seed for the random number generator for this octave interpreter.

**EXAMPLES:**

```python
sage: o = Octave()  # optional - octave
sage: o.set_seed(1)  # optional - octave
1
sage: [o.rand() for i in range(5)]  # optional - octave
[0.134364, 0.847434, 0.763775, 0.255069, 0.495435]
```
solve_linear_system(A, b)
Use octave to compute a solution x to A*x = b, as a list.

INPUT:
- A - mxn matrix A with entries in Q or R
- b - m-vector b entries in Q or R (resp)

OUTPUT: A list x (if it exists) which solves M*x = b

EXAMPLES:

from sage.all import *
>>> o = Octave() # optional - octave
>>> o.set_seed(Integer(1)) # optional - octave
1
>>> [o.rand() for i in range(Integer(5))] # optional - octave
[ 0.134364, 0.847434, 0.763775, 0.255069, 0.495435]

AUTHORS:
- David Joyner and William Stein

version()
Return the version of Octave.

OUTPUT: string

EXAMPLES:

sage: v = octave.version() # optional - octave
sage: v # optional - octave; random
'2.13.7'

sage: import re
sage: assert re.match(r"\d+\.\d+\.\d+", v) is not None # optional - octave

(continues on next page)
class sage.interfaces.octave.OctaveElement (parent, value, is_name=False, name=None)

Bases: ExpectElement

sage.interfaces.octave.octave_console()

Spawn a new Octave command-line session.

This requires that the optional octave program be installed and in your PATH, but no optional Sage packages need be installed.

EXAMPLES:

```
sage: octave_console()       # not tested
GNU Octave, version 2.1.73 (i386-apple-darwin8.5.3).
Copyright (C) 2006 John W. Eaton.
...
octave:1> 2+3
ans = 5
octave:2> [ct1-d]
```

```
>>> from sage.all import *
>>> octave_console()       # not tested
GNU Octave, version 2.1.73 (i386-apple-darwin8.5.3).
Copyright (C) 2006 John W. Eaton.
...
octave:1> 2+3
ans = 5
octave:2> [ct1-d]
```

Pressing ctrl-d exits the octave console and returns you to Sage. octave, like Sage, remembers its history from one session to another.

sage.interfaces.octave.reduce_load_Octave()

EXAMPLES:

```
sage: from sage.interfaces.octave import reduce_load_Octave
sage: reduce_load_Octave()
Octave
```

```
>>> from sage.all import *
>>> from sage.interfaces.octave import reduce_load_Octave
>>> reduce_load_Octave()
Octave
```

sage.interfaces.octave.to_complex (octave_string, R)

Helper function to convert octave complex number
INTERFACE TO PHC.

PHC computes numerical information about systems of polynomials over the complex numbers. PHC implements polynomial homotopy methods to exploit structure in order to better approximate all isolated solutions. The package also includes extra tools to handle positive dimensional solution components.

AUTHORS:

- PHC was written by J. Verschelde, R. Cools, and many others (?
- William Stein and Kelly ?? – first version of interface to PHC
- Marshall Hampton – second version of interface to PHC
- Marshall Hampton and Alex Jokela – third version, path tracking

class sage.interfaces.phc.PHC

Bases: object

A class to interface with PHCpack, for computing numerical homotopies and root counts.

EXAMPLES:

```python
sage: from sage.interfaces.phc import phc
sage: R.<x,y> = PolynomialRing(CDF,2)
sage: testsys = [x^2 + 1, x*y - 1]
sage: phc.mixed_volume(testsys)  # optional -- phc
2
sage: v = phc.blackbox(testsys, R)  # optional -- phc
sage: sols = v.solutions()  # optional -- phc
sage: sols.sort()  # optional -- phc
sage: sols  # optional -- phc
[[[-1.00000000000000*I, 1.00000000000000*I], [1.00000000000000*I, -1.00000000000000*I]]

sage: sol_dict = v.solution_dicts()  # optional -- phc
sage: x_sols_from_dict = [d[x] for d in sol_dict]  # optional -- phc
sage: x_sols_from_dict.sort(); x_sols_from_dict  # optional -- phc
[-1.00000000000000*I, 1.00000000000000*I]

sage: residuals  # optional -- phc
[[0, 0], [0, 0]]
```

```python
>>> from sage.all import *
>>> from sage.interfaces.phc import phc
>>> R = PolynomialRing(CDF, Integer(2), names=('x', 'y',)); (x, y) = R._first_
>>> ngens(2)
```
Interpreter Interfaces, Release 10.4

>>> testsys = [x**Integer(2) + Integer(1), x*y - Integer(1)]
>>> phc.mixed_volume(testsys)  # optional -- phc
2
>>> v = phc.blackbox(testsys, R)  # optional -- phc
>>> sols = v.solutions()  # optional -- phc
>>> sols.sort()  # optional -- phc
[([-1.00000000000000*I, 1.00000000000000*1], [1.00000000000000*1, -1.00000000000000*I])
>>> sol_dict = v.solutions_dicts()  # optional -- phc
>>> x_sols_from_dict = [d[x] for d in sol_dict]  # optional -- phc
>>> x_sols_from_dict.sort(); x_sols_from_dict  # optional -- phc
[-1.00000000000000*I, 1.00000000000000*I]
>>> residuals = [[test_equation.change_ring(CDF).subs(sol) for test_equation in testsys] for sol in v.solutions_dicts()]  # optional -- phc
>>> residuals  # optional -- phc
[[0, 0], [0, 0]]

blackbox (polys, input_ring, verbose=False)

Return as a string the result of running PHC with the given polynomials under blackbox mode (the `-b` option).

INPUT:

- polys – a list of multivariate polynomials (elements of a multivariate polynomial ring).
- input_ring – for coercion of the variables into the desired ring.
- verbose – print lots of verbose information about what this function does.

OUTPUT:

- a PHC_Object object containing the phcpack output string.

EXAMPLES:

```python
sage: from sage.interfaces.phc import *
sage: R2.<x,y> = PolynomialRing(QQ,2)
sage: start_sys = [x**2-y**2,y**5-1]
sage: sol = phc.blackbox(start_sys, R2)  # optional -- phc
sage: len(sol.solutions())  # optional -- phc
30
```

mixed_volume (polys, verbose=False)

Compute the mixed volume of the polynomial system given by the input polys.

INPUT:

- polys – a list of multivariate polynomials (elements of a multivariate polynomial ring).
- verbose – print lots of verbose information about what this function does.
OUTPUT:

• The mixed volume.

EXAMPLES:

```python
sage: from sage.interfaces.phc import *
sage: R2.<x,y,z> = PolynomialRing(QQ,3)
sage: test_sys = [(x+y+z)^2-1,x^2-x,y^2-1]
sage: phc.mixed_volume(test_sys)  # optional -- phc
4
```

```python
>>> from sage.all import *
>>> from sage.interfaces.phc import *
>>> R2 = PolynomialRing(QQ,Integer(3), names=('x', 'y', 'z'))
>>> (x, y, z,) = R2._first_ngens(3)
>>> test_sys = [(x+y+z)**Integer(2)-Integer(1),x**Integer(2)-x,y**Integer(2)-Integer(1)]
>>> phc.mixed_volume(test_sys)  # optional -- phc
4
```

**path_track** *(start_sys, end_sys, input_ring, c_skew=0.001, saved_start=None)*

This function computes homotopy paths between the solutions of start_sys and end_sys.

INPUT:

• start_sys – a square polynomial system, given as a list of polynomials

• end_sys – same type as start_sys

• input_ring – for coercion of the variables into the desired ring.

• c_skew – optional. the imaginary part of homotopy multiplier; nonzero values are often necessary to avoid intermediate path collisions

• saved_start – optional. A phc output file. If not given, start system solutions are computed via the phc.blackbox function.

OUTPUT:

• a list of paths as dictionaries, with the keys variables and t-values on the path.

EXAMPLES:

```python
sage: from sage.interfaces.phc import *
sage: R2.<x,y> = PolynomialRing(QQ,2)
sage: start_sys = [x^6-y^2,y^5-1]
sage: sol = phc.blackbox(start_sys, R2)  # optional -- phc
sage: start_save = sol.save_as_start()  # optional -- phc
sage: end_sys = [x^7-2,y^5-x^2]  # optional -- phc
sage: sol_paths = phc.path_track(start_sys, end_sys, R2, saved_start = start_save)  # optional -- phc
sage: len(sol_paths)  # optional -- phc
30
```

```python
>>> from sage.all import *
>>> from sage.interfaces.phc import *
>>> R2 = PolynomialRing(QQ,Integer(2), names=('x', 'y')); (x, y,) = R2._first_ngens(2)
>>> start_sys = [x**Integer(6)-y**Integer(2),y**Integer(5)-Integer(1)]
>>> sol = phc.blackbox(start_sys, R2)  # optional -- phc
```

(continues on next page)
Interpreter Interfaces, Release 10.4

(continued from previous page)

```python
>>> start_save = sol.save_as_start() # optional -- phc
>>> end_sys = [x**Integer(7)-Integer(2),y**Integer(5)-x**Integer(2)] # optional -- phc
>>> sol_paths = phc.path_track(start_sys, end_sys, R2, saved_start = start_save) # optional -- phc
>>> len(sol_paths) # optional -- phc
30
```

`plot_paths_2d` *(start_sys, end_sys, input_ring, c_skew=0.001, endpoints=True, saved_start=None, rand_colors=False)*

Return a graphics object of solution paths in the complex plane.

**INPUT:**

- `start_sys` – a square polynomial system, given as a list of polynomials
- `end_sys` – same type as `start_sys`
- `input_ring` – for coercion of the variables into the desired ring.
- `c_skew` – optional. the imaginary part of homotopy multiplier; nonzero values are often necessary to avoid intermediate path collisions
- `endpoints` – optional. Whether to draw in the ends of paths as points.
- `saved_start` – optional. A `phc` output file. If not given, start system solutions are computed via the `phc.blackbox` function.

**OUTPUT:**

- lines and points of solution paths

**EXAMPLES:**

```python
sage: from sage.interfaces.phc import *
sage: from sage.structure.sage_object import SageObject
sage: R2.<x,y> = PolynomialRing(QQ,2)
sage: start_sys = [x^5-y^2,y^5-1]
sage: sol = phc.blackbox(start_sys, R2) # optional -- phc
sage: start_save = sol.save_as_start() # optional -- phc
sage: end_sys = [x^5-25,y^5-x^2] # optional -- phc
sage: testing = phc.plot_paths_2d(start_sys, end_sys, R2) # optional -- phc
sage: type(testing) # optional -- phc (normally use plot here)
<class 'sage.plot.graphics.Graphics'>
```
**start_from**(*start_filename_or_string*, *polys*, *input_ring*, *path_track_file=None*, *verbose=False*)

This computes solutions starting from a phcpack solution file.

**INPUT:**

- *start_filename_or_string* – the filename for a phcpack start system, or the contents of such a file as a string. Variable names must match the inputting variables. The value of the homotopy variable t should be 1, not 0.
- *polys* – a list of multivariate polynomials (elements of a multivariate polynomial ring).
- *input_ring*: for coercion of the variables into the desired ring.
- *path_track_file*: whether to save path-tracking information
- *verbose* – print lots of verbose information about what this function does.

**OUTPUT:**

- A solution in the form of a PHCObject.

**EXAMPLES:**

```python
sage: from sage.interfaces.phc import *
sage: R2.<x, y> = PolynomialRing(QQ, 2)
sage: start_sys = [x^6-y^2, y^5-1]
sage: sol = phc.blackbox(start_sys, R2)  # optional -- phc
sage: start_save = sol.save_as_start()  # optional -- phc
sage: end_sys = [x^7-2, y^5-x^2]  # optional -- phc
sage: sol = phc.start_from(start_save, end_sys, R2)  # optional -- phc
sage: len(sol.solutions())  # optional -- phc
30
```

```python
>>> from sage.all import *
>>> from sage.interfaces.phc import *

R2 = PolynomialRing(QQ, Integer(2), names=('x', 'y',)); (x, y,) = R2._first_ngens(2)
>>> start_sys = [x**Integer(6)-y**Integer(2), y**Integer(5)-Integer(1)]
>>> sol = phc.blackbox(start_sys, R2)  # optional -- phc
>>> start_save = sol.save_as_start()  # optional -- phc
>>> end_sys = [x**Integer(7)-Integer(2), y**Integer(5)-x**Integer(2)]  # optional -- phc
>>> sol = phc.start_from(start_save, end_sys, R2)  # optional -- phc
>>> len(sol.solutions())  # optional -- phc
30
```

**class** `sage.interfaces.phc.PHC_Object` (*output_file_contents*, *input_ring*)

**Bases:** object

A container for data from the PHCpack program - lists of float solutions, etc. Currently the file contents are kept as a string; for really large outputs this would be bad.

**INPUT:**

- *output_file_contents*: the string output of PHCpack
- *input_ring*: for coercion of the variables into the desired ring.

**EXAMPLES:**
```python
sage: from sage.interfaces.phc import phc
sage: R2.<x,y> = PolynomialRing(QQ,2)
sage: start_sys = [(x-1)^2+(y-1)-1, x^2+y^2-1]
sage: sol = phc.blackbox(start_sys, R2)  # optional -- phc
sage: str(sum([x[0] for x in sol.solutions()]).real())[0:3]  # optional -- phc
'2.0'
```

### classified_solution_dicts()

Return a dictionary of lists of dictionaries of solutions.

It's not as crazy as it sounds; the keys are the types of solutions as classified by phcpack: regular vs. singular, complex vs. real

**INPUT:**

- None

**OUTPUT:**

- A dictionary of lists of dictionaries of solutions

**EXAMPLES:**

```python
sage: from sage.interfaces.phc import phc
sage: R.<x,y> = PolynomialRing(CC,2)
sage: p_sys = [x^10-y,y^2-1]
sage: sol = phc.blackbox(p_sys,R)  # optional -- phc
sage: classifieds = sol.classified_solution_dicts()  # optional -- phc
sage: str(sum([q[y] for q in classifieds['real']]))[0:3]  # optional -- phc
'2.0'
```

```python
>>> from sage.all import *
>>> from sage.interfaces.phc import phc
>>> R = PolynomialRing(CC,Integer(2), names=('x', 'y',)); (x, y,) = R._first_˓→ngens(2)
>>> p_sys = [x**Integer(10)-y,y**Integer(2)-Integer(1)]
>>> sol = phc.blackbox(p_sys,R)  # optional -- phc
>>> classifieds = sol.classified_solution_dicts()  # optional -- phc
>>> str(sum([q[y] for q in classifieds['real']]))[Integer(0):Integer(3)] ˓→# optional -- phc
'2.0'
```

### save_as_start (start_filename=None, sol_filter='')

Save a solution as a phcpack start file. The usual output is just as a string, but it can be saved to a file as well. Even if saved to a file, it still returns the output string.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.interfaces.phc import phc
>>> R = PolynomialRing(CC,Integer(2), names=('x', 'y',)); (x, y,) = R._first_˓→ngens(2)
>>> p_sys = [x**Integer(10)-y,y**Integer(2)-Integer(1)]
>>> sol = phc.blackbox(p_sys,R)  # optional -- phc
>>> classifieds = sol.classified_solution_dicts()  # optional -- phc
>>> str(sum([q[y] for q in classifieds['real']]))[Integer(0):Integer(3)] ˓→# optional -- phc
'2.0'
```
solution_dicts (get_failures=False)

Return a list of solutions in dictionary form: variable:value.

INPUT:

- self – for access to self_out_file_contents, the string of raw PHCpack output.
- get_failures (optional) – a boolean. The default (False) is to not process failed homotopies. These either lie on positive-dimensional components or at infinity.

OUTPUT:

- solution_dicts: a list of dictionaries. Each dictionary element is of the form variable:value, where the variable is an element of the input_ring, and the value is in ComplexField.

EXAMPLES:
solutions (get_failures=False)

Return a list of solutions in the ComplexField.

Use the variable_list function to get the order of variables used by PHCpack, which is usually different than the term order of the input_ring.

INPUT:

• self – for access to self_out_file_contents, the string of raw PHCpack output.
• get_failures (optional) – a boolean. The default (False) is to not process failed homotopies. These either lie on positive-dimensional components or at infinity.

OUTPUT:

• solutions: a list of lists of ComplexField-valued solutions.

EXAMPLES:

>>> from sage.interfaces.phc import *
>>> R2.<x1,x2> = PolynomialRing(QQ,2)
>>> test_sys = [x1^5-x1*x2^2-1, x2^5-x1*x2-1]
>>> sol = phc.blackbox(test_sys, R2) # optional -- phc
>>> len(sol.solutions()) # optional -- phc
25

variable_list()

Return the variables, as strings, in the order in which PHCpack has processed them.

EXAMPLES:

>>> from sage.interfaces.phc import *
>>> R2.<x1,x2> = PolynomialRing(QQ,2)
>>> test_sys = [x1^5-x1*x2^2-1, x2^5-x1*x2-1]
>>> sol = phc.blackbox(test_sys, R2) # optional -- phc
>>> sol.variable_list() # optional -- phc
['x1', 'x2']

sage.interfaces.phc.get Classified_solution_dicts (output_file_contents, input_ring, get_failures=True)
Return a dictionary of lists of dictionaries of variable:value (key:value) pairs. Only used internally; see the classified_solution_dict function in the PHC_Object class definition for details.

**INPUT:**
- output_file_contents – phc solution output as a string
- input_ring – a PolynomialRing that variable names can be coerced into

**OUTPUT:**
- a dictionary of lists if dictionaries of solutions, classifies by type

**EXAMPLES:**

```python
sage: from sage.interfaces.phc import *

sage: R2.<x1,x2> = PolynomialRing(QQ,2)
sage: test_sys = [(x1-2)^5-x2, (x2-1)^5-1]
sage: sol = phc.blackbox(test_sys, R2)  # optional -- phc
sage: sol_classes = get_classified_solution_dicts(sol.output_file_contents,R2)  # optional -- phc
sage: len(sol_classes['real'])  # optional -- phc
1

>>> from sage.all import *
>>> from sage.interfaces.phc import *
>>> R2 = PolynomialRing(QQ,Integer(2), names=('x1', 'x2',)); (x1, x2,) = R2._first_ngens(2)
>>> test_sys = [(x1-Integer(2))**Integer(5)-x2, (x2-Integer(1))**Integer(5)-Integer(1)]
>>> sol = phc.blackbox(test_sys, R2)  # optional -- phc
>>> sol_classes = get_classified_solution_dicts(sol.output_file_contents,R2)  # optional -- phc
>>> len(sol_classes['real'])  # optional -- phc
1
```

sage.interfaces.phc.get_solution_dicts(output_file_contents, input_ring, get_failures=True)

Return a list of dictionaries of variable:value (key:value) pairs. Only used internally; see the solution_dict function in the PHC_Object class definition for details.

**INPUT:**
- output_file_contents – phc solution output as a string
- input_ring – a PolynomialRing that variable names can be coerced into

**OUTPUT:**
- a list of dictionaries of solutions

**EXAMPLES:**

```python
sage: from sage.interfaces.phc import *

sage: R2.<x1,x2> = PolynomialRing(QQ,2)
sage: test_sys = [(x1-1)^5-x2, (x2-1)^5-1]
sage: sol = phc.blackbox(test_sys, R2)  # optional -- phc
sage: test = get_solution_dicts(sol.output_file_contents,R2)  # optional -- phc
sage: str(sum([q[x1].real() for q in test]))[0:4]  # optional -- phc
'25.0'
```
```python
>>> from sage.all import *
>>> from sage.interfaces.phc import *

>>> R2 = PolynomialRing(QQ,Integer(2), names=('x1', 'x2',)); (x1, x2,) = R2._first_ngens(2)
>>> test_sys = [(x1-Integer(1))**Integer(5)-x2, (x2-Integer(1))**Integer(5)-Integer(1)]
>>> sol = phc.blackbox(test_sys, R2)  # optional -- phc
>>> test = get_solution_dicts(sol.output_file_contents,R2)  # optional -- phc
>>> str(sum([q[x1].real() for q in test]))[Integer(0):Integer(4)]  # optional -- phc
25.0
```

**sage.interfaces.phc.get_variable_list**(output_file_contents)

Return the variables, as strings, in the order in which PHCpack has processed them.

**EXAMPLES:**

```python
sage: from sage.interfaces.phc import *
sage: R2.<x1,x2> = PolynomialRing(QQ,2)
sage: test_sys = [(x1-2)^5-x2, (x2-1)^5-1]
sage: sol = phc.blackbox(test_sys, R2)  # optional -- phc
sage: get_variable_list(sol.output_file_contents)  # optional -- phc
['x1', 'x2']
```

```python
>>> from sage.all import *
>>> from sage.interfaces.phc import *

>>> R2 = PolynomialRing(QQ,Integer(2), names=('x1', 'x2',)); (x1, x2,) = R2._first_ngens(2)
>>> test_sys = [(x1-Integer(2))**Integer(5)-x2, (x2-Integer(1))**Integer(5)-Integer(1)]
>>> sol = phc.blackbox(test_sys, R2)  # optional -- phc
>>> get_variable_list(sol.output_file_contents)  # optional -- phc
['x1', 'x2']
```

**sage.interfaces.phc.random**( ) → x in the interval [0, 1).
polymake (https://polymake.org) is a mature open source package for research in polyhedral geometry and related fields, developed since 1997 by Ewgenij Gawrilow and Michael Joswig and various contributors.

polymake has been described in [GJ1997], [GJ2006], [JMP2009], [GJRW2010], [GHJ2016], and [AGHJLPR2017].

```python
sage.interfaces.polymake.Polymake
alias of PolymakeJuPyMake
class sage.interfaces.polymake.PolymakeAbstract (seed=None)
    Bases: ExtraTabCompletion, Interface
    Abstract interface to the polymake interpreter.
    This class should not be instantiated directly, but through its subclasses Polymake (Pexpect interface) or Polymake-JuPyMake (JuPyMake interface).

EXAMPLES:

```python
code_snippet
We test the verbosity management with very early doctests because messages will not be repeated.

Testing the JuPyMake interface:

```python
```
Random spherical polytope of dimension 4; seed=5...

```
set_verbose(Integer(3))
p.H_VECTOR
polymake: used package ppl
The Parma Polyhedra Library ...
1 16 40 16 1
set_verbose(Integer(0))
p.F_VECTOR
```

**application**(app)

Change to a given polymake application.

**INPUT:**

- app, a string, one of “common”, “fulton”, “group”, “matroid”, “topaz”, “fan”, “graph”, “ideal”, “polytope”, “tropical”

**EXAMPLES:**

We expose a computation that uses both the ‘polytope’ and the ‘fan’ application of polymake. Let us start by defining a polytope $q$ in terms of inequalities. Polymake knows to compute the f- and h-vector and finds that the polytope is very ample:

```
sage: q = polymake.new_object("Polytope", INEQUALITIES=[[5,-4,0,1], [-3,0,-4,-1], [-2,1,0,0], [-4,4,4,-1], [0,0,1,0], [8,0,0,-1], [1,0,-1,0], [3,-1,0,0]])
sage: q.H_VECTOR
1 5 5 1
sage: q.F_VECTOR
8 14 8
sage: q.VERY_AMPLE
true
```

In the application ‘fan’, polymake can now compute the normal fan of $q$ and its (primitive) rays:

```
sage: q = polymake.application('fan')
sage: q.RAYS
```

(continues on next page)
>>> from sage.all import *

>>> # optional - jupymake
>>> polymake.application('fan')

>>> g = q.normal_fan()

>>> g.RAYS

sage: g.RAYS.primitive()

Notethatthelistoffunctionsavailablebytabcompletiondependsontheapplication.

<table>
<thead>
<tr>
<th>clear(var)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clear the variable named var.</td>
</tr>
</tbody>
</table>

**Note:** This is implicitly done when deleting an element in the interface.

<table>
<thead>
<tr>
<th>console()</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raise an error, pointing to interact() and polymake_console().</td>
</tr>
</tbody>
</table>

**EXAMPLES:**

```python
sage: polymake.console()
Traceback (most recent call last):
```
Interpreter Interfaces, Release 10.4

NotImplementedError: Please use polymake_console() function or the .
→ interact() method

>>> from sage.all import *

polymake.console()
Traceback (most recent call last):
...
NotImplementedError: Please use polymake_console() function or the .
→ interact() method

function_call (function, args=None, kwds=None)

EXAMPLES:

sage: polymake.rand_sphere(4, 30, seed=15) # optional - jupymake # indirect doctest
Random spherical polytope of dimension 4; seed=15...

>>> from sage.all import *

polymake.rand_sphere(Integer(4), Integer(30), seed=Integer(15)) # optional - jupymake # indirect doctest
Random spherical polytope of dimension 4; seed=15...

get (cmd)

Return the string representation of an object in the polymake interface.

EXAMPLES:

sage: polymake.get('cube(3)') # optional - jupymake
'Polymake::polytope::Polytope__Rational=ARRAY(...)'

>>> from sage.all import *

polymake.get('cube(3)') # optional - jupymake
'Polymake::polytope::Polytope__Rational=ARRAY(...)'

Note that the above string representation is what polymake provides. In our interface, we use what polymake calls a "description":

sage: polymake('cube(3)') # optional - jupymake
cube of dimension 3

>>> from sage.all import *

polymake('cube(3)') # optional - jupymake
cube of dimension 3

help (topic, pager=True)

Displays polymake's help on a given topic, as a string.

INPUT:

• topic, a string

• pager, optional bool, default True: When True, display help, otherwise return as a string.

EXAMPLES:
objects/Polytope:
Not necessarily bounded or unbounded polyhedron.
Nonetheless, the name "Polytope" is used for two reasons:
Firstly, combinatorially we always deal with polytopes; see the description
of VERTICES_IN_FACETS for details.
The second reason is historical.
We use homogeneous coordinates, which is why Polytope is derived from Cone.
Note that a pointed polyhedron is projectively equivalent to a polytope.
Scalar is the numeric data type used for the coordinates.

In some cases, polymake expects user interaction to choose from different available help topics. In these
cases, a warning is given, and the available help topics are displayed resp. printed, without user interaction:

UserWarning: Polymake expects user interaction. We abort and return the
options that Polymake provides.
There are 5 help topics matching 'TRIANGULATION':
1: objects/Visualization/Visual::Polytope/methods/TRIANGULATION
2: objects/Visualization/Visual::PointConfiguration/methods/TRIANGULATION
3: objects/Cone/properties/Triangulation and volume/TRIANGULATION
4: objects/PointConfiguration/properties/Triangulation and volume/
   TRIANGULATION
5: objects/Polytope/properties/Triangulation and volume/TRIANGULATION
If an unknown help topic is requested, a `PolymakeError` results:

```python
sage: polymake.help('Triangulation')                          # optional - jupymake
Traceback (most recent call last):
...
PolymakeError: unknown help topic 'Triangulation'
```

```python
>>> from sage.all import *

sage: polymake.help('Triangulation')                          # optional - jupymake
Traceback (most recent call last):
...
PolymakeError: unknown help topic 'Triangulation'
```

`new_object(name, *args, **kwds)`

Return a new instance of a given polymake type, with given positional or named arguments.

**INPUT:**

- name of a polymake class (potentially templated), as string.
- further positional or named arguments, to be passed to the constructor.

**EXAMPLES:**

```python
sage: # optional - jupymake
sage: q = polymake.new_object("Polytope<Rational>", INEQUALITIES=[[4,-4,0,1],
→[-4,0,-4,1],[-2,1,0,0],[-4,4,4,-1],[0,0,1,0],[8,0,0,-1]])

sage: q.N_VERTICES
4
sage: q.BOUNDED
true
sage: q.VERTICES
1 2 0 4
1 3 0 8
1 2 1 8
1 3 1 8

sage: q.full_typename()
'Polytope<Rational>'
```

```python
>>> from sage.all import *

>>> q = polymake.new_object("Polytope<Rational>", INEQUALITIES=[[Integer(4),-
→-Integer(4),Integer(0),Integer(1)],[Integer(0),-Integer(4),-Integer(4),
→Integer(1)],[Integer(2),Integer(1),Integer(0),Integer(0)],[Integer(4),
→Integer(4),Integer(4),-Integer(1)],[Integer(0),Integer(0),Integer(0),
→Integer(0)],})

>>> q.N_VERTICES
4

>>> q.BOUNDED
true

>>> q.VERTICES
1 2 0 4
1 3 0 8
1 2 1 8
1 3 1 8

>>> q.full_typename()
'Polytope<Rational>'
```
**set** (var, value)

Set the variable var to the given value.

Eventually, var is a reference to value.

**Warning:** This method, although it doesn’t start with an underscore, is an internal method and not part of the interface. So, please do not try to call it explicitly. Instead, use the polymake interface as shown in the examples.

**REMARK:**

Polymake’s user language is Perl. In Perl, if one wants to assign the return value of a function to a variable, the syntax to do so depends on the type of the return value. While this is fine in compiled code, it seems quite awkward in user interaction.

To make this polymake pexpect interface a bit more user friendly, we treat all variables as arrays. A scalar value (most typically a reference) is thus interpreted as the only item in an array of length one. It is, of course, possible to use the interface without knowing these details.

**EXAMPLES:**

```sage
sage: c = polymake('cube(3)')
# optional - jupymake
˓→indirect doctest
sage: d = polymake.cube(3)  # optional - jupymake

>>> from sage.all import *
>>> c = polymake('cube(3)')  # optional - jupymake
˓→indirect doctest
>>> d = polymake.cube(Integer(3))  # optional -
˓→jupymake
```

Equality is, for “big” objects such as polytopes, comparison by identity:

```sage
sage: c == d  # optional - jupymake
False

>>> from sage.all import *
>>> c == d  # optional - jupymake
False
```

However, the list of vertices is equal:

```sage
sage: c.VERTICES == d.VERTICES  # optional - jupymake
True

>>> from sage.all import *
>>> c.VERTICES == d.VERTICES  # optional - jupymake
True
```

**version()**

Version of the polymake installation.

**EXAMPLES:**

```sage
sage: polymake.version()  # optional - jupymake # random
'4...
```
```python
>>> from sage.all import *
polymake.version()  # optional - jupymake # random '4...
```

class sage.interfaces.polymake.PolymakeElement (parent, value, is_name=False, name=None)

Elements in the polymake interface.

EXAMPLES:

We support all “big” polymake types, Perl arrays of length different from one, and Perl scalars:

```python
sage: p = polymake.rand_sphere(4, 20, seed=5)  # optional - jupymake
sage: p.typename()  # optional - jupymake
'Polytope'
sage: p  
Polytope
Random spherical polytope of dimension 4; seed=5...
```

Now, one can work with that element in Python syntax, for example:

```python
sage: p.VERTICES[2][2]  # optional - jupymake
1450479926727001/2251799813685248
```

```python
>>> from sage.all import *
>>> p = polymake.rand_sphere(Integer(4), Integer(20), seed=Integer(5))
>>> p.typename()  # optional - jupymake
'Polytope'
>>> p  
Polytope
Random spherical polytope of dimension 4; seed=5...
```

```python
full_typename ()
The name of the specialised type of this element.

EXAMPLES:

```python
sage: c = polymake.cube(4)  # optional - jupymake
sage: c.full_typename()  # optional - jupymake
'Polytope<Rational>'
sage: c.VERTICES.full_typename()  # optional - jupymake
'Matrix<Rational, NonSymmetric>'
```

```python
>>> from sage.all import *
>>> c = polymake.cube(Integer(4))  # optional - jupymake
>>> c.full_typename()  # optional - jupymake
'Polytope<Rational>'
>>> c.VERTICES.full_typename()  # optional - jupymake
'Matrix<Rational, NonSymmetric>'
```

```python
get_member (attrname)
Get a member/property of this element.
```
Note: Normally, it should be possible to just access the property in the usual Python syntax for attribute access. However, if that fails, one can request the member explicitly.

EXAMPLES:

```python
sage: p = polymake.rand_sphere(4, 20, seed=5)  # optional - jupymake

>>> from sage.all import *

>>> p = polymake.rand_sphere(Integer(4), Integer(20), seed=Integer(5))  #...
˓→optional - jupymake

Normally, a property would be accessed as follows:

```python
sage: p.F_VECTOR                     # optional - jupymake
20 94 148 74

```python
>>> from sage.all import *

```python
>>> p.F_VECTOR                       # optional - jupymake
20 94 148 74

However, explicit access is possible as well:

```python
sage: p.get_member('F_VECTOR')       # optional - jupymake
20 94 148 74

```python
>>> from sage.all import *

```python
>>> p.get_member('F_VECTOR')         # optional - jupymake
20 94 148 74

In some cases, the explicit access works better:

```python
sage: p.type                              # optional - jupymake
Member function 'type' of Polymake::polytope::Polytope__Rational object

```python
sage: p.get_member('type')                # optional - jupymake
Polytope<Rational>[SAGE...]

```python
sage: p.get_member('type').get_member('name')  # optional - jupymake
Polytope

```python
>>> from sage.all import *

```python
>>> p.type                              # optional - jupymake
Member function 'type' of Polymake::polytope::Polytope__Rational object

```python
>>> p.get_member('type')                # optional - jupymake
Polytope<Rational>[SAGE...]

```python
>>> p.get_member('type').get_member('name')  # optional - jupymake
Polytope

Note that in the last example calling the erroneously constructed member function type still works:

```python
sage: p.type()                           # optional - jupymake
Polytope<Rational>[SAGE...]

```python
>>> from sage.all import *

```python
>>> p.type()                           # optional - jupymake
Polytope<Rational>[SAGE...]
**get_member_function**(*attrname*)

Request a member function of this element.

**Note:** It is not checked whether a member function with the given name exists.

**EXAMPLES:**

```
sage: # optional - jupymake
sage: c = polymake.cube(2)
sage: c.contains
Member function 'contains' of Polymake::polytope::Polytope__Rational object
sage: V = polymake.new_object('Vector', [1,0,0])
sage: V
1 0 0
sage: c.contains(V)
true
```

Whether a member function of the given name actually exists for that object will only be clear when calling it:

```
sage: c.get_member_function("foo")
"Py"Member function 'foo' of Polymake::polytope::Polytope__Rational object
sage: c.get_member_function("foo")()
Traceback (most recent call last):
... TypeError: Can't locate object method "foo" via package "Polymake::polytope::Polytope__Rational"
```

```
>>> from sage.all import *
>>> # optional - jupymake
>>> c = polymake.cube(Integer(2))
>>> c.contains
Member function 'contains' of Polymake::polytope::Polytope__Rational object
>>> V = polymake.new_object('Vector', [Integer(1),Integer(0),Integer(0)])
>>> V
1 0 0
>>> c.contains(V)
true
```

**known_properties**()

List the names of properties that have been computed so far on this element.
Note: This is in many cases equivalent to use polymake’s `list_properties`, which returns a blank separated string representation of the list of properties. However, on some elements, `list_properties` would simply result in an error.

EXAMPLES:

```sage
c = polymake.cube(4)  # optional - jupymake
sage: c.known_properties()  # optional - jupymake
['AFFINE_HULL',
 'BOUNDED',
 'CONE_AMBIENT_DIM',
 'CONE_DIM',
 ...
 'VERTICES_IN_FACETS']
sage: c.list_properties()  # optional - jupymake
CONE_AMBIENT_DIM, CONE_DIM, FACETS, AFFINE_HULL, VERTICES_IN_FACETS, BOUNDED...
```

```python
>>> from sage.all import *
>>> c = polymake.cube(Integer(4))  # optional - jupymake
```

A computation can change the list of known properties:

```sage
c.F_VECTOR  # optional - jupymake
16 32 24 8
sage: c.known_properties()  # optional - jupymake
['AFFINE_HULL',
 'BOUNDED',
 'COMBINATORIAL_DIM',
 'CONE_AMBIENT_DIM',
 'CONE_DIM',
 ...
 'VERTICES_IN_FACETS']
```

```python
>>> c.F_VECTOR  # optional - jupymake
16 32 24 8
```

```python
>>> from sage.all import *
>>> c.F_VECTOR  # optional - jupymake
16 32 24 8
>>> c.known_properties()  # optional - jupymake
['AFFINE_HULL',
 'BOUNDED',
 'COMBINATORIAL_DIM',
 'CONE_AMBIENT_DIM',
 'CONE_DIM',
 ...
 'VERTICES_IN_FACETS']
```
qualified_typename()

The qualified name of the type of this element.

EXAMPLES:

```python
sage: c = polymake.cube(4)  # optional - jupymake
sage: c.qualified_typename()  # optional - jupymake
'polytope::Polytope<Rational>'
sage: c.VERTICES.qualified_typename()  # optional - jupymake
'common::Matrix<Rational, NonSymmetric>'
```

typename()

The name of the underlying base type of this element in polymake.

EXAMPLES:

```python
sage: c = polymake.cube(4)  # optional - jupymake
sage: c.typename()  # optional - jupymake
'Polytope'
sage: c.VERTICES.typename()  # optional - jupymake
'Matrix'
```

typeof()

Return the type of a polymake “big” object, and its underlying Perl type.

Note: This is mainly for internal use.

EXAMPLES:

```python
sage: p = polymake.rand_sphere(3, 13, seed=12)
sage: p.typeof()  # optional - jupymake
('Polymake::polytope::Polytope__Rational', 'ARRAY')
sage: p.VERTICES.typeof()  # optional - jupymake
('Polymake::common::Matrix_A_Rational_I_NonSymmetric_Z', 'ARRAY')
sage: p.get_schedule("F_VECTOR").typeof()  # optional - jupymake
('Polymake::Core::Scheduler::RuleChain', 'ARRAY')
```

(continues on next page)
On “small” objects, it just returns empty strings:

```python
sage: p.N_VERTICES.typeof()                                 # optional ~--
    __jupymake__
('', '')
```

```python
sage: p.list_properties().typeof()                           # optional ~--
    __jupymake__
('', '')
```

```
>>> from sage.all import *
>>> p.N_VERTICES.typeof()                                  # optional ~--
    __jupymake__
(('', '')
```

```
>>> p.list_properties().typeof()                            # optional ~--
    __jupymake__
(('', '')
```

```python
exception sage.interfaces.polymake.PolymakeError
Bases: RuntimeError

Raised if polymake yields an error message.
```

```python
class sage.interfaces.polymake.PolymakeFunctionElement (obj, name, memberfunction=False)
Bases: InterfaceFunctionElement

A callable (function or member function) bound to a polymake element.
```

EXAMPLES:

```python
sage: # optional -- jupymake
sage: c = polymake.cube(2)
sage: V = polymake.new_object('Vector', [1,0,0])
sage: V
1 0 0
sage: c.contains
Member function 'contains' of Polymake::polytope::Polytope__Rational object
sage: c.contains(V)
true
```

```
>>> from sage.all import *
>>> # optional -- jupymake
>>> c = polymake.cube(Integer(2))
>>> V = polymake.new_object('Vector', [Integer(1),Integer(0),Integer(0)])
>>> V
1 0 0
>>> c.contains
Member function 'contains' of Polymake::polytope::Polytope__Rational object
>>> c.contains(V)
true
```
class sage.interfaces.polymake.PolymakeJuPyMake (seed=None, verbose=False)

Bases: PolymakeAbstract

Interfacl to the polymake interpreter using JuPyMake.

In order to use this interface, you need to either install the optional polymake package for Sage, or install polymake system-wide on your computer; it is available from https://polymake.org. Also install the jupymake Python package.

Type polymake.[tab] for a list of most functions available from your polymake install. Type polymake.Function? for polymake's help about a given Function. Type polymake(...) to create a new polymake object, and polymake.eval(...) to run a string using polymake and get the result back as a string.

EXAMPLES:

```
sage: from sage.interfaces.polymake import polymake_jupymake as polymake
sage: type(polymake)
<...sage.interfaces.polymake.PolymakeJuPyMake...>
sage: p = polymake.rand_sphere(4, 20, seed=5)  # optional - jupymake
sage: p
Random spherical polytope of dimension 4; seed=5...
sage: p.H_VECTOR;  # optional - jupymake # random
used package ppl
   The Parma Polyhedra Library ...
   1 16 40 16 1
sage: p.F_VECTOR
20 94 148 74
```

You can perform algebraic operations such as addition or scalar multiplication.

You can create a new Vector by entering its elements, e.g.:

```
$v = new Vector<Int>(1,2,3);
```

or

```
$v = new Vector<Int>([1,2,3]);
```
Interpreter Interfaces, Release 10.4

>>> print(p.F_VECTOR._sage_doc_())
property_types/Algebraic Types/Vector:
A type for vectors with entries of type Element.

You can perform algebraic operations such as addition or scalar multiplication.

You can create a new Vector by entering its elements, e.g.:
   $v = \text{new Vector}(<\text{Int}>)(1,2,3);
or
   $v = \text{new Vector}(<\text{Int}>)([1,2,3]);

Python strings are translated to polymake (Perl) identifiers. To obtain Perl strings, use strings containing double-quote characters. Python dicts are translated to Perl hashes.

```
sage: # long time, optional - internet jupymake perl_mongodb
sage: L = polymake.db_query({"_id": "F.4D.0047"},
                        ...
                        db="LatticePolytopes",
                        ...
                        collection="SmoothReflexive"); L
BigObjectArray
sage: len(L)
1
sage: P = L[0]
```
```
>>> from sage.all import *
```  

```
sage: # long time, optional - internet jupymake perl_mongodb
sage: L = polymake.db_query({"_id": "F.4D.0047"},
                        ...
                        db="LatticePolytopes",
                        ...
                        collection="SmoothReflexive"); L
BigObjectArray
sage: len(L)
1
sage: P = L[Integer(0)]
```
```
>>> from sage.all import *
>>> L = polymake.db_query({"_id": "F.4D.0047"},
                        ...
                        db="LatticePolytopes",
                        ...
                        collection="SmoothReflexive"); L
BigObjectArray
>>> len(L)
1
>>> P = L[Integer(0)]
```
```
eval(code, **kwds)
Evaluate a command.

INPUT:

   • code – a command (string) to be evaluated

Different reaction types of polymake, including warnings, comments, errors, request for user interaction, and yielding a continuation prompt, are taken into account.

EXAMPLES:

```
sage: from sage.interfaces.polymake import polymake_jupymake as polymake
sage: p = polymake.cube(3) # optional - jupymake # indirect...
←doctest
```
Here we see that remarks printed by polymake are displayed if the verbosity is positive:

```python
sage: set_verbose(1)
sage: p.N_LATTICE_POINTS # optional - jupymake # random
used package latte
LattE (Lattice point Enumeration) is a computer software dedicated to the
problems of counting lattice points and integration inside convex polytopes.
Copyright by Matthias Köppe, Jesus A. De Loera and others.
http://www.math.ucdavis.edu/~latte/27
sage: set_verbose(0)
```

If polymake raises an error, the polymake interface raises a `PolymakeError`:

```python
sage: polymake.eval('FOOBAR(3);') # optional - jupymake
Traceback (most recent call last):
... PolymakeError: Undefined subroutine &Polymake::User::FOOBAR called...
```

If a command is incomplete, then polymake returns a continuation prompt. In that case, we raise an error:

```python
sage: polymake.eval('print 3') # optional - jupymake
Traceback (most recent call last):
... SyntaxError: Incomplete polymake command 'print 3'
```

```python
sage: polymake.eval('print 3;') # optional - jupymake
'3'
```
However, if the command contains line breaks but eventually is complete, no error is raised:

```
sage: print(polymake.eval('tmp="abc";\nprint $tmp;'))  # optional - jupymake
abc
```

```
>>> from sage.all import *
>>> print(polymake.eval('tmp="abc";\nprint $tmp;'))  # optional - jupymake
abc
```

When requesting help, polymake sometimes expects the user to choose from a list. In that situation, we abort with a warning, and show the list from which the user can choose; we could demonstrate this using the `help()` method, but here we use an explicit code evaluation:

```
sage: print(polymake.eval('help "TRIANGULATION";'))  # optional - jupymake
←# random
doctest:warning...

UserWarning: Polymake expects user interaction. We abort and return the options that Polymake provides.
There are 5 help topics matching 'TRIANGULATION':
1: objects/Cone/properties/Triangulation and volume/TRIANGULATION
2: objects/Polytope/properties/Triangulation and volume/TRIANGULATION
3: objects/Visualization/Visual::PointConfiguration/methods/TRIANGULATION
4: objects/Visualization/Visual::Polytope/methods/TRIANGULATION
5: objects/PointConfiguration/properties/Triangulation and volume/
←TRIANGULATION
```

```
>>> from sage.all import *
>>> print(polymake.eval('help "TRIANGULATION";'))  # optional - jupymake
←# random
doctest:warning...

UserWarning: Polymake expects user interaction. We abort and return the options that Polymake provides.
There are 5 help topics matching 'TRIANGULATION':
1: objects/Cone/properties/Triangulation and volume/TRIANGULATION
2: objects/Polytope/properties/Triangulation and volume/TRIANGULATION
3: objects/Visualization/Visual::PointConfiguration/methods/TRIANGULATION
4: objects/Visualization/Visual::Polytope/methods/TRIANGULATION
5: objects/PointConfiguration/properties/Triangulation and volume/
←TRIANGULATION
```

By default, we just wait until polymake returns a result. However, it is possible to explicitly set a timeout. The following usually does work in an interactive session and often in doc tests, too. However, sometimes it hangs, and therefore we remove it from the tests, for now:

```
sage: c = polymake.cube(15)  # optional - jupymake
sage: polymake.eval('print {}).format(c.name()), timeout=1))  # not...
←# tested # optional - jupymake
Traceback (most recent call last):
...
RuntimeError: Polymake fails to respond timely
```

```
>>> from sage.all import *
>>> c = polymake.cube(Integer(15))  # optional - jupymake
>>> polymake.eval('print {}.format(c.name()), timeout=Integer(1))
```

(continues on next page)
We verify that after the timeout, polymake is still able to give answers:

```
sage: c  # optional - jupymake
cube of dimension 15
sage: c.N_VERTICES  # optional - jupymake
32768
```

Note, however, that the recovery after a timeout is not perfect. It may happen that in some situation the interface collapses and thus polymake would automatically be restarted, thereby losing all data that have been computed before.

```
is_running()
Return True if self is currently running.
```

```
sage.interfaces.polymake.polymake_console(command='')
Spawn a new polymake command-line session.
```

EXAMPLES:

```
sage: from sage.interfaces.polymake import polymake_console
sage: polymake_console()  # not tested
Welcome to polymake version ...

```
sage.interfaces.polymake.reduce_load_Polymake()
```

Return the polymake interface object defined in `sage.interfaces.polymake`.

**EXAMPLES:**

```
sage: from sage.interfaces.polymake import reduce_load_Polymake
sage: reduce_load_Polymake()
Polymake

>>> from sage.all import *
>>> from sage.interfaces.polymake import reduce_load_Polymake
>>> reduce_load_Polymake()
Polymake
```
POV-Ray, THE PERSISTENCE OF VISION RAY TRACER

```python
class sage.interfaces.povray.POVRay
    Bases: object
    
    POV-Ray The Persistence of Vision Ray Tracer

    INPUT:
    • pov_file – complete path to the .pov file you want to be rendered
    • outfile – the filename you want to save your result to
    • **kwargs – additionally keyword arguments you want to pass to POVRay

    OUTPUT:
    Image is written to the file you specified in outfile

    EXAMPLES:

    AUTHOR:
    Sage interface written by Yi Qiang (yqiang_atNOSPAM_gmail.com)

    POVRay: http://www.povray.org

    usage()
```
PARALLEL INTERFACE TO THE SAGE INTERPRETER

This is an expect interface to a multiple copy of the Sage interpreter, which can all run simultaneous calculations. A PSage object does not work as well as the usual Sage object, but does have the great property that when you construct an object in a PSage you get back a prompt immediately. All objects constructed for that PSage print << currently executing code >> until code execution completes, when they print as normal.

note { BUG – currently non-idle PSage subprocesses do not stop when sage exits. I would very much like to fix this but don't know how. }

EXAMPLES:

We illustrate how to factor 3 integers in parallel. First startup 3 parallel Sage interfaces:

```
sage: v = [PSage() for _ in range(3)]
```

```
>>> from sage.all import *
>>> v = [PSage() for _ in range(Integer(3))]
```

Next, request factorization of one random integer in each copy.

```
sage: w = [x(factor(2**%s-1) % randint(250,310)) for x in v] # long time (5s on sage.math, 2011)
```

```
>>> from sage.all import *
>>> w = [x(factor(2**%s-1) % randint(Integer(250),Integer(310))) for x in v] # long time (5s on sage.math, 2011)
```

Print the status:

```
sage: w # long time, random output (depends on timing)
[3 * 11 * 31^2 * 311 * 11161 * 11471 * 73471 * 715827883 * 2147483647 * 4649919401 *
   \ldots 18158209813151 * 5947603221397891 * 29126056043168521,
   \ldots << currently executing code >>,
   9623 * 68492481833 *
   \ldots 23579543011798993222850893929565870383844167873851502677311057483194673]
```

```
>>> from sage.all import *
>>> w # long time, random output (depends on timing)
[3 * 11 * 31^2 * 311 * 11161 * 11471 * 73471 * 715827883 * 2147483647 * 4649919401 *
   \ldots 18158209813151 * 5947603221397891 * 29126056043168521,
   \ldots << currently executing code >>,
   9623 * 68492481833 *
   \ldots 23579543011798993222850893929565870383844167873851502677311057483194673]
```
Note that at the point when we printed two of the factorizations had finished but a third one hadn’t. A few seconds later all three have finished:

```plaintext
sage: w   # long time, random output
[3 * 11 * 31^2 * 311 * 11161 * 11471 * 73471 * 715827883 * 2147483647 * 4649919401 *␣→18158209813151 * 5947603221397891 * 29126056043168521,
 23^2 * 47 * 89 * 178481 * 4103188409 * 199957736328435366769577 *␣→44667711762797798403039426178361,
 9623 * 68492481833 *␣→23579543011798993222850893929565870383844167873851502677311057483194673]
```

```python
>>> from sage.all import *
>>> w   # long time, random output
[3 * 11 * 31^2 * 311 * 11161 * 11471 * 73471 * 715827883 * 2147483647 * 4649919401 *␣→18158209813151 * 5947603221397891 * 29126056043168521,

    set (var, value)
    Set the variable var to the given value.

class sage.interfaces.psage.PSageElement (parent, value, is_name=False, name=None)
    Bases: SageElement
    is_locked ()
```
The basic function of QEPCAD is to construct cylindrical algebraic decompositions (CADs) of $\mathbb{R}^k$, given a list of polynomials. Using this CAD, it is possible to perform quantifier elimination and formula simplification.

A CAD for a set $A$ of $k$-variate polynomials decomposes $\mathbb{R}^j$ into disjoint cells, for each $j$ in $0 \leq j \leq k$. The sign of each polynomial in $A$ is constant in each cell of $\mathbb{R}^k$, and for each cell in $\mathbb{R}^j$ ($j > 1$), the projection of that cell into $\mathbb{R}^{j-1}$ is a cell of $\mathbb{R}^{j-1}$. (This property makes the decomposition ‘cylindrical’.)

Given a formula $\exists x. P(a, b, x) = 0$ (for a polynomial $P$), and a cylindrical algebraic decomposition for $P$, we can eliminate the quantifier (find an equivalent formula in the two variables $a, b$ without the quantifier $\exists$) as follows. For each cell $C$ in $\mathbb{R}^2$, find the cells of $\mathbb{R}^3$ which project to $C$. (This collection is called the stack over $C$.) Mark $C$ as true if some member of the stack has sign = 0; otherwise, mark $C$ as false. Then, construct a polynomial formula in $a, b$ which specifies exactly the true cells (this is always possible). The same technique works if the body of the quantifier is any boolean combination of polynomial equalities and inequalities.

Formula simplification is a similar technique. Given a formula which describes a simple set of $\mathbb{R}^k$ in a complicated way as a boolean combination of polynomial equalities and inequalities, QEPCAD can construct a CAD for the polynomials and recover a simple equivalent formula.

Note that while the following documentation is tutorial in nature, and is written for people who may not be familiar with QEPCAD, it is documentation for the sage interface rather than for QEPCAD. As such, it does not cover several issues that are very important to use QEPCAD efficiently, such as variable ordering, the efficient use of the alternate quantifiers and _root_ expressions, the measure-zero-error command, etc. For more information on QEPCAD, see the online documentation at url{http://www.cs.usna.edu/~qepcad/B/QEPCAD.html} and Chris Brown’s tutorial handout and slides from url{http://www.cs.usna.edu/~wcbrown/research/ISSAC04/Tutorial.html}. (Several of the examples in this documentation came from these sources.)

The examples below require that the optional qepcad package is installed.

QEPCAD can be run in a fully automatic fashion, or interactively. We first demonstrate the automatic use of QEPCAD.

Since sage has no built-in support for quantifiers, this interface provides qepcad_formula which helps construct quantified formulas in the syntax QEPCAD requires.

```sage
sage: var('a,b,c,d,x,y,z')
(a, b, c, d, x, y, z)
sage: qf = qepcad_formula

>> from sage.all import *
>> var('a,b,c,d,x,y,z')
(a, b, c, d, x, y, z)
>> qf = qepcad_formula
```

We start with a simple example. Consider an arbitrarily-selected ellipse:
What is the projection onto the $x$ axis of this ellipse? First we construct a formula asking this question.

```python
sage: F = qf.exists(y, ellipse == 0); F
(E y)\[3 x^2 + 2 x y + y^2 - x + y - 7 = 0\]
```

Then we run qepcad to get the answer:

```python
sage: qepcad(F) # optional - qepcad
8 x^2 - 8 x - 29 <= 0
```

How about the projection onto the $y$ axis?

```python
sage: qepcad(qf.exists(x, ellipse == 0)) # optional - qepcad
8 y^2 + 16 y - 85 <= 0
```

QEPCAD deals with more quantifiers than just ‘exists’, of course. Besides the standard ‘forall’, there are also ‘for infinitely many’, ‘forall but finitely many’, ‘for a connected subset’, and ‘for exactly k’. The `qepcad()` documentation has examples of all of these; here we will just give one example.

First we construct a circle:

```python
sage: circle = x^2 + y^2 - 3
```

For what values $k$ does a vertical line $x = k$ intersect the combined figure of the circle and ellipse exactly three times?

```python
sage: F = qf.exactly_k(3, y, circle * ellipse == 0); F
(X3 y)\[(3 x^2 + 2 x y + y^2 - x + y - 7) (x^2 + y^2 - 3) = 0\]
```

(continues on next page)
Here we see that the solutions are among the eight \((4 + 2 + 2)\) roots of the three polynomials inside the brackets, but not all of these roots are solutions; the polynomial inequalities outside the brackets are needed to select those roots that are solutions.

QEPCAD also supports an extended formula language, where \(_\text{root}_k P(\bar{x}, y)\) refers to a particular zero of \(P(\bar{x}, y)\) (viewed as a polynomial in \(y\)). If there are \(n\) roots, then \(_\text{root}_1\) refers to the least root and \(_\text{root}_n\) refers to the greatest. Also, \(_\text{root}_{-n}\) refers to the least root and \(_\text{root}_{-1}\) refers to the greatest.

This extended language is available both on input and output; see the QEPCAD documentation for more information on how to use this syntax on input. We can request output that is intended to be easy to interpret geometrically; then QEPCAD will use the extended language to produce a solution formula without the selection polynomials.

We then see that the 6 solutions correspond to the vertical tangent on the left side of the ellipse, the four intersections between the ellipse and the circle, and the vertical tangent on the right side of the circle.

Let us do some basic formula simplification and visualization. We will look at the region which is inside both the ellipse and the circle:

We get back the same formula we put in. This is not surprising (we started with a pretty simple formula, after all), but it is not very enlightening either. Again, if we ask for a ‘geometric’ output, then we see an output that lets us understand something about the shape of the solution set.
There is another reason to prefer output using \_root\_ expressions; not only does it sometimes give added insight into the geometric structure, it also can be more efficient to construct. Consider this formula for the projection of a particular semicircle onto the \(x\) axis:

```python
>>> from sage.all import *
>>> qepcad(F, solution='geometric') # not tested (random order)
[ [ x = _root_-2 8 x^4 - 26 x^2 - 4 x + 13
  \ \
  x < _root_-2 8 x^4 - 26 x^2 - 4 x + 13
  \ \
  y^2 + x^2 - 3 < 0 ]
]```

There is another reason to prefer output using \_root\_ expressions; not only does it sometimes give added insight into the geometric structure, it also can be more efficient to construct. Consider this formula for the projection of a particular semicircle onto the \(x\) axis:

```python
sage: F = qf.exists(y, qf.and_(circle == 0, x + y > 0)); F
(E y)[x^2 + y^2 - 3 = 0 /\ x + y > 0]
sage: qepcad(F) # not tested (random order)
x^2 - 3 <= 0 /\ [ x > 0 /\ 2 x^2 - 3 < 0 ]
```
Here, the formula \( x > 0 \) had to be introduced in order to get a solution formula; the original CAD of \( F \) did not include the polynomial \( x \). To avoid having QEPCAD do the extra work to come up with a solution formula, we can tell it to use the extended language; it is always possible to construct a solution formula in the extended language without introducing new polynomials.

```
sage: qepcad(F, solution='extended')  # not tested (random order)
x^2 - 3 <= 0 /\ x > _root_1 2 x^2 - 3
```

Up to this point, all the output we have seen has basically been in the form of strings; there is no support (yet) for parsing these outputs back into Sage polynomials (partly because Sage does not yet have support for symbolic conjunctions and disjunctions). The function \texttt{qepcad()} supports three more output types that give numbers which can be manipulated in Sage: any-point, all-points, and cell-points.

These output types give dictionaries mapping variable names to values. With any-point, \texttt{qepcad()} either produces a single dictionary specifying a point where the formula is true, or raises an exception if the formula is false everywhere. With all-points, \texttt{qepcad()} either produces a list of dictionaries for all points where the formula is true, or raises an exception if the formula is true on infinitely many points. With cell-points, \texttt{qepcad()} produces a list of dictionaries with one point for each cell where the formula is true. (This means you will have at least one point in each connected component of the solution, although you will often have many more points than that.)

Let us revisit some of the above examples and get some points to play with. We will start by finding a point on our ellipse.

```
sage: p = qepcad(ellipse == 0, solution='any-point'); p  # optional - qepcad
{'x': -1.468501968502953?, 'y': 0.9685019685029527?}
```

(Note that despite the decimal printing and the question marks, these are really exact numbers.)

We can verify that this point is a solution. To do so, we create a copy of ellipse as a polynomial over \( \mathbb{Q} \) (instead of a symbolic expression).

```
sage: pellipse = QQ['x','y'](ellipse)
sage: pellipse(**p) == 0  # optional - qepcad
True
```

For cell-points, let us look at points \textit{not} on the ellipse.

```
sage: pts = qepcad(ellipse != 0, solution='cell-points'); pts  # optional - qepcad
[{'x': 4, 'y': 0},
```
For the points here which are in full-dimensional cells, QEPCAD has the freedom to choose rational sample points, and it does so.

And, of course, all these points really are not on the ellipse.

Finally, for all-points, let us look again at finding vertical lines that intersect the union of the circle and the ellipse exactly three times.

Since $y$ is bound by the quantifier, the solutions only refer to $x$. We can substitute one of these solutions into the original equation:
sage: intersections = pcombo(y=polygen(AA, 'y'), **pt); intersections  # optional - gecad
y^4 + 4.464101615137755*y^3 + 0.2679491924311227*y^2

>>> from sage.all import *
>>> pt = pts[Integer(0)]  # optional - qepcad
>>> pcombo = QQ[x,y](circle * ellipse)
>>> intersections = pcombo(y=polygen(AA, 'y'), **pt); intersections  # optional - gecad
y^4 + 4.464101615137755*y^3 + 0.2679491924311227*y^2

and verify that it does have three roots:

sage: intersections.roots()  # optional - gecad
[(−4.403249005600958?, 1), (−0.06085260953679653?, 1), (0, 2)]

Let us check all six solutions.

sage: [len(pcombo(y=polygen(AA, 'y'), **p).roots()) for p in pts]  # optional - gecad
[3, 3, 3, 3, 3, 3]

We said earlier that we can run QEPCAD either automatically or interactively. Now that we have discussed the automatic modes, let us turn to interactive uses.

If the qepcad() function is passed interact=True, then instead of returning a result, it returns an object of class Qepcad representing a running instance of QEPCAD that you can interact with. For example:

```
sage: qe = qepcad(qf.forall(x, x^2 + b*x + c > 0), interact=True); qe  # optional - gecad
QEPCAD object in phase 'Before Normalization'
```

This object is a fairly thin wrapper over QEPCAD; most QEPCAD commands are available as methods on the Qepcad object. Given a Qepcad object qe, you can type qe.[tab] to see the available QEPCAD commands; to see the documentation for an individual QEPCAD command, for example d_setting, you can type qe.d_setting?. (In QEPCAD, this command is called d-setting. We systematically replace hyphens with underscores for this interface.)

The execution of QEPCAD is divided into four phases. Most commands are not available during all phases. We saw above that QEPCAD starts out in phase 'Before Normalization'. We see that the d_cell command is not available in this phase:
We will focus here on the fourth (and last) phase, 'Before Solution', because this interface has special support for some operations in this phase. Consult the QEPCAD documentation for information on the other phases.

We can tell QEPCAD to finish off the current phase and move to the next with its `go` command. (There is also the `step` command, which partially completes a phase for phases that have multiple steps, and the `finish` command, which runs QEPCAD to completion.)

Let us pick a nice, simple example, return to phase 4, and explore the resulting `qe` object.
We said before that QEPCAD creates ‘cylindrical algebraic decompositions’; since we have a bivariate polynomial, we get decompositions of \( \mathbb{R}^0 \), \( \mathbb{R}^1 \), and \( \mathbb{R}^2 \). In this case, where our example is a circle of radius \( \sqrt{3} \) centered on the origin, these decompositions are as follows:

The decomposition of \( \mathbb{R}^0 \) is trivial (of course). The decomposition of \( \mathbb{R}^1 \) has five cells: \( x < -\sqrt{3}, x = -\sqrt{3}, -\sqrt{3} < x < \sqrt{3}, x = \sqrt{3}, \) and \( x > \sqrt{3} \). These five cells comprise the stack over the single cell in the trivial decomposition of \( \mathbb{R}^0 \).

These five cells give rise to five stacks in \( \mathbb{R}^2 \). The first and fifth stack have just one cell apiece. The second and fourth stacks have three cells: \( y < 0, y = 0, \) and \( y > 0 \). The third stack has five cells: below the circle, the lower semicircle, the interior of the circle, the upper semicircle, and above the circle.

QEPCAD (and this QEPCAD interface) number the cells in a stack starting with 1. Each cell has an index, which is a tuple of integers describing the path to the cell in the tree of all cells. For example, the cell ‘below the circle’ has index \((3,1)\) (the first cell in the stack over the third cell of \( \mathbb{R}^1 \)) and the interior of the circle has index \((3,3)\).

We can view these cells with the QEPCAD command `d_cell`. For instance, let us look at the cell for the upper semicircle:

```
sage: qe.d_cell(3, 4)  # optional - qepcad
--------- Information about the cell (3,4) ---------
Level    : 2
Dimension : 1
Number of children : 0
Truth value  : T by trial evaluation.
Degrees after substitution : Not known yet or No polynomial.
Multiplicities   : ((1,1))
Signs of Projection Factors
Level 1 : (-)
Level 2 : (0)
--------- Sample point ----------
The sample point is in a PRIMITIVE representation.

alpha = the unique root of x^2 - 3 between 0 and 4
       = 1.7320508076-

Coordinate 1 = 0
              = 0.0000000000
Coordinate 2 = alpha
              = 1.7320508076-
```

```
>>> from sage.all import *

>>> qe.d_cell(Integer(3), Integer(4))  # optional - qepcad
--------- Information about the cell (3,4) ---------
Level    : 2
Dimension : 1
Number of children : 0
Truth value  : T by trial evaluation.
Degrees after substitution : Not known yet or No polynomial.
Multiplicities   : ((1,1))
Signs of Projection Factors
Level 1 : (-)
```
Level 2 : (0)
--------- Sample point ---------
The sample point is in a PRIMITIVE representation.
alpha = the unique root of $x^2 - 3$ between 0 and 4
  $\approx 1.7320508076$-
Coordinate 1 = 0
  $\approx 0.0000000000$
Coordinate 2 = alpha
  $\approx 1.7320508076$-

We see that, the level of this cell is 2, meaning that it is part of the decomposition of $\mathbb{R}^2$. The dimension is 1, meaning that the cell is homeomorphic to a line (rather than a plane or a point). The sample point gives the coordinates of one point in the cell, both symbolically and numerically.

For programmatic access to cells, we have defined a sage wrapper class $\texttt{QepcadCell}$. These cells can be created with the $\texttt{cell()}$ method; for example:

```python
sage: c = qe.cell(3, 4); c
# optional - qepcad
QEPCAD cell (3, 4)
```

```python
>>> from sage.all import *

>>> c = qe.cell(Integer(3), Integer(4)); c
# optional - qepcad
QEPCAD cell (3, 4)
```

A $\texttt{QepcadCell}$ has accessor methods for the important state held within a cell. For instance:

```python
sage: # optional - qepcad
sage: c.level()
2
sage: c.index()
(3, 4)
sage: qe.cell(3).number_of_children()
5
sage: len(qe.cell(3))
5
```

```python
>>> from sage.all import *

>>> # optional - qepcad

>>> c.level()
2
>>> c.index()
(3, 4)
>>> qe.cell(Integer(3)).number_of_children()
5
>>> len(qe.cell(Integer(3)))
5
```

One particularly useful thing we can get from a cell is its sample point, as sage algebraic real numbers.

```python
sage: c.sample_point()
# optional - qepcad
(0, 1.732050807568878?)
sage: c.sample_point_dict()
# optional - qepcad
{'x': 0, 'y': 1.732050807568878?}
```
We have seen that we can get cells using the `cell()` method. There are several QEPCAD commands that print lists of cells; we can also get cells using the `make_cells()` method, passing it the output of one of these commands.

```python
sage: qe.make_cells(qe.d_true_cells())  # optional - qepcad
[QEPCAD cell (4, 2), QEPCAD cell (3, 4), QEPCAD cell (3, 2),
 QEPCAD cell (2, 2)]
```

Also, the cells in the stack over a given cell can be accessed using array subscripting or iteration. (Remember that cells in a stack are numbered starting with one; we preserve this convention in the array-subscripting syntax.)

```python
sage: c = qe.cell(3)  # optional - qepcad
sage: c[1]  # optional - qepcad
QEPCAD cell (3, 1)
sage: [c2 for c2 in c]  # optional - qepcad
[QEPCAD cell (3, 1), QEPCAD cell (3, 2), QEPCAD cell (3, 3),
 QEPCAD cell (3, 4), QEPCAD cell (3, 5)]
```

We can do one more thing with a cell: we can set its truth value. Once the truth values of the cells have been set, we can get QEPCAD to produce a formula which is true in exactly the cells we have selected. This is useful if QEPCAD's quantifier language is insufficient to express your problem.

For example, consider again our combined figure of the circle and the ellipse. Suppose you want to find all vertical lines that intersect the circle twice, and also intersect the ellipse twice. The vertical lines that intersect the circle twice can be found by simplifying:

```python
sage: F = qf.exactly_k(2, y, circle == 0); F
(X2 y)[x^2 + y^2 - 3 = 0]
```

and the vertical lines that intersect the ellipse twice are expressed by:

```python
sage: G = qf.exactly_k(2, y, ellipse == 0); G
(X2 y)[3 x^2 + 2 x y + y^2 - x + y - 7 = 0]
```
and the lines that intersect both figures would be:

```python
>>> from sage.all import *

>>> G = qf.exactly_k(Integer(2), y, ellipse == Integer(0)); G
(X2 y)[3 x^2 + 2 x y + y^2 - x + y - 7 = 0]
```

...except that QEPCAD does not support formulas like this; in QEPCAD input, all logical connectives must be inside all quantifiers.

Instead, we can get QEPCAD to construct a CAD for our combined figure and set the truth values ourselves. (The exact formula we use doesn’t matter, since we’re going to replace the truth values in the cells; we just need to use a formula that uses both polynomials.)

```python
sage: qe = qepcad(qf.and_(ellipse == 0, circle == 0), interact=True)  # optional - qepcad
sage: qe.go(); qe.go(); qe.go()  # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
```

Now we want to find all cells \( c \) in the decomposition of \( \mathbb{R}^1 \) such that the stack over \( c \) contains exactly two cells on the ellipse, and also contains exactly two cells on the circle.

Our input polynomials are ‘level-2 projection factors’, we see:

```python
sage: qe.d_proj_factors()  # optional - qepcad

P_1,1 = fac(J_1,1) = fac(dis(A_2,1))
  = 8 x^2 - 8 x - 29
P_1,2 = fac(J_1,2) = fac(dis(A_2,2))
  = x^2 - 3
P_1,3 = fac(J_1,3) = fac(res(A_2,1|A_2,2))
  = 8 x^4 - 26 x^2 - 4 x + 13
A_2,1 = input
  = y^2 + 2 x y + y + 3 x^2 - x - 7
A_2,2 = input
  = y^2 + x^2 - 3
```
so we can test whether a cell is on the ellipse by checking that the sign of the corresponding projection factor is 0 in our cell. For instance, the cell (12,2) is on the ellipse:

```
sage: qe.cell(12,2).signs()[1][0] # optional - qepcad
0
```

So we can update the truth values as desired like this:

```
sage: for c in qe.cell():
    count_ellipse = 0
    count_circle = 0
    for c2 in c:
        count_ellipse += (c2.signs()[1][0] == 0)
        count_circle += (c2.signs()[1][1] == 0)
    c.set_truth(count_ellipse == 2 and count_circle == 2)
```

and then we can get our desired solution formula. (The 'G' stands for 'geometric', and gives solutions using the same rules as solution='geometric' described above.)

```
sage: qe.solution_extension('G') # not tested (random order)
8 x^2 - 8 x - 29 < 0
\/
x^2 - 3 < 0
```
**AUTHORS:**

- Carl Witty (2008-03): initial version
- Thierry Monteil (2015-07) repackaging + noncommutative doctests.

```python
class sage.interfaces.qepcad.Qepcad(formula, vars=None, logfile=None, verbose=False, memcells=None, server=None)
```

**Bases:** object

The wrapper for QEPCAD.

**answer()**

For a QEPCAD instance which is finished, return the simplified quantifier-free formula that it printed just before exiting.

**EXAMPLES:**

```python
sage: qe = qepcad(x^3 - x == 0, interact=True)  # optional - qepcad
sage: qe.finish()  # not tested (random order)
x - 1 <= 0 /
x + 1 >= 0 /
[x = 0 /
x - 1 = 0 /
x + 1 = 0 ]
sage: qe.answer()  # not tested (random order)
x - 1 <= 0 /
x + 1 >= 0 /
[x = 0 /
x - 1 = 0 /
x + 1 = 0 ]
```

```python
>>> from sage.all import *

>>> var('a,b,c,x')
(a, b, c, x)

>>> qf = qepcad_formula

>>> qe = qepcad(qf.exists(x, a*x**Integer(3) + b*x + c == 0), interact=True)  # optional - qepcad
>>> qe.finish()  # not tested (random order)
x - 1 <= 0 /
x + 1 >= 0 /
[x = 0 /
x - 1 = 0 /
x + 1 = 0 ]
```

**assume(assume)**

The following documentation is from qepcad.help.

Add an assumption to the problem. These will not be included in the solution formula.

For example, with input (E x)[ a x^2 + b x + c = 0], if we issue the command

```python
assume [ a /= 0 ]
```

we will get the solution formula b^2 - 4 a c => 0. Without the assumption we'd get something like [a = 0 /b /= 0] / [a /= 0 /a c - b^2 <= 0 /a = 0 /b = 0 /c = 0].

**EXAMPLES:**

```python
sage: var('a,b,c,x')
(a, b, c, x)

sage: qf = qepcad_formula

sage: qe = qepcad(qf.exists(x, a*x^2 + b*x + c == 0), interact=True)  # optional - qepcad

sage: qe.assume(a != 0)  # optional - qepcad

sage: qe.finish()  # optional - qepcad
4 a c - b^2 <= 0
```

```python
>>> from sage.all import *

>>> var('a,b,c,x')
(a, b, c, x)

>>> qf = qepcad_formula

>>> qe = qepcad(qf.exists(x, a*x**2 + b*x + c == 0), interact=True)  # optional - qepcad
```
cell(*index*)

Given a cell index, returns a QepcadCell wrapper for that cell. Uses a cache for efficiency.

EXAMPLES:

```python
>>> from sage.all import *
```
make_cells(text)

Given the result of some QEPCAD command that returns cells (such as d_cell(), d_witness_list(), etc.), return a list of cell objects.

EXAMPLES:

```sage
var('x,y')
(qe, y)
sage: qe = qepcad(x^2 + y^2 == 1, interact=True) # optional - qepcad
sage: qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
sage: qe.make_cells(qe.d_false_cells()) # optional - qepcad
[QEPCAD cell (5, 1), QEPCAD cell (4, 3), QEPCAD cell (4, 1), QEPCAD cell (3, 5), QEPCAD cell (3, 3), QEPCAD cell (3, 1), QEPCAD cell (2, 3), QEPCAD cell (2, 1), QEPCAD cell (1, 1)]
```

```
>>> from sage.all import *

>>> var('x,y')

(x, y)
>>> qe = qepcad(x**Integer(2) + y**Integer(2) == Integer(1), interact=True) # optional - qepcad
>>> qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
>>> qe.make_cells(qe.d_false_cells()) # optional - qepcad
[QEPCAD cell (5, 1), QEPCAD cell (4, 3), QEPCAD cell (4, 1), QEPCAD cell (3, 5), QEPCAD cell (3, 3), QEPCAD cell (3, 1), QEPCAD cell (2, 3), QEPCAD cell (2, 1), QEPCAD cell (1, 1)]
```

phase()

Return the current phase of the QEPCAD program.

EXAMPLES:

```sage
# optional - qepcad
sage: qe = qepcad(x > 2/3, interact=True)
sage: qe.phase()
'Before Normalization'
sage: qe.go()
QEPCAD object has moved to phase 'At the end of projection phase'
sage: qe.phase()
'At the end of projection phase'
sage: qe.go()
QEPCAD object has moved to phase 'Before Choice'
sage: qe.phase()
'Before Choice'
sage: qe.go()
QEPCAD object has moved to phase 'Before Solution'
```

(continues on next page)
Interpreter Interfaces, Release 10.4

(continued from previous page)

```sage
sage: qe.phase()
'Before Solution'
sage: qe.go()
3 x - 2 > 0
tsage: qe.phase()
'EXITED'
```

```python
>>> from sage.all import *
>>> # optional - qepcad
>>> qe = qepcad(x > Integer(2)/Integer(3), interact=True)
>>> qe.phase()
'Before Normalization'
>>> qe.go()
QEPCAD object has moved to phase 'At the end of projection phase'
>>> qe.phase()
'At the end of projection phase'
>>> qe.go()
QEPCAD object has moved to phase 'Before Choice'
>>> qe.phase()
'Before Choice'
>>> qe.go()
QEPCAD object has moved to phase 'Before Solution'
>>> qe.phase()
'Before Solution'
>>> qe.go()
3 x - 2 > 0
>>> qe.phase()
'EXITED'
```

**set_truth_value** *(index, nv)*

Given a cell index (or a cell) and an integer, set the truth value of the cell to that integer.

Valid integers are 0 (false), 1 (true), and 2 (undetermined).

**EXAMPLES:**

```sage
sage: qe = qepcad(x == 1, interact=True) # optional - qepcad
sage: qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'At the end of projection phase'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
sage: qe.set_truth_value(1, 1) # optional - qepcad
```

```python
>>> from sage.all import *
>>> # optional - qepcad
>>> qe = qepcad(x == Integer(1), interact=True) # optional - qepcad
>>> qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'At the end of projection phase'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
>>> qe.set_truth_value(Integer(1), Integer(1)) # optional - qepcad
```

**solution_extension** *(kind)*

The following documentation is modified from qepcad.help:

solution-extension x

Use an alternative solution formula construction method. The parameter x is allowed to be T,E, or G. If x is
T, then a formula in the usual language of Tarski formulas is produced. If x is E, a formula in the language of Extended Tarski formulas is produced. If x is G, then a geometry-based formula is produced.

EXAMPLES:

```python
sage: var('x,y')
(x, y)
sage: qf = qepcad_formula
sage: qe = qepcad(qf.and_(x**Integer(2) + y**Integer(2) - Integer(3) == Integer(0), x + y > Integer(0)), interact=True) # optional - qepcad
sage: qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
sage: qe.solution_extension('E')                # not tested (random order)
x > _root_1 2 x^2 - 3 /\ y^2 + x^2 - 3 = 0 /
  [ 2 x^2 - 3 > 0 /\ y = _root_-1 2 x^2 - 3]

sage: qe.solution_extension('G')                # not tested (random order)
[ [ 2 x^2 - 3 < 0
    / y = _root_-1 y^2 + x^2 - 3
  ] /\ y^2 + x^2 - 3 = 0
   ] /\
  [ x^2 - 3 <= 0
    /\
    x > _root_-1 2 x^2 - 3
    /\
    y^2 + x^2 - 3 = 0
  ]

sage: qe.solution_extension('T')                # not tested (random order)
y + x > 0 /\ y^2 + x^2 - 3 = 0

>>> from sage.all import *
>>> var('x,y')
(x, y)
>>> qf = qepcad_formula
>>> qe = qepcad(qf.and_(x**Integer(2) + y**Integer(2) - Integer(3) == Integer(0), x + y > Integer(0)), interact=True) # optional - qepcad
>>> qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
>>> qe.solution_extension('E')                # not tested (random order)
x > _root_1 2 x^2 - 3 /\ y^2 + x^2 - 3 = 0 /
  [ 2 x^2 - 3 > 0 /\ y = _root_-1 2 x^2 - 3]
>>> qe.solution_extension('G')                # not tested (random order)
[ [ 2 x^2 - 3 < 0
```

(continues on next page)
/\  2 x^2 - 3  \\
| \   \  x = _root_-1 x^2 - 3  \\
| \   \  y = _root_-1 y^2 + x^2 - 3  \\
| [ \  x^2 - 3 <= 0  \\
| [ \  x > _root_-1 2 x^2 - 3  \\
| [ \  y^2 + x^2 - 3 = 0  \\

>>> qe.solution_extension('T')    # not tested (random order)
y + x > 0 /\ y^2 + x^2 - 3 = 0

class sage.interfaces.qepcad.QepcadCell (parent, lines)

Bases: object

A wrapper for a QEPCAD cell.

index()

Give the index of a QEPCAD cell.

EXAMPLES:

sage: var('x,y')
(x, y)

sage: qe = qepcad(x^2 + y^2 == 1, interact=True) # optional - qepcad
sage: qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'

sage: qe.cell().index() # optional - qepcad ()
sage: qe.cell(1).index() # optional - qepcad (1,)
sage: qe.cell(2, 2).index() # optional - qepcad (2, 2)

>>> from sage.all import *
>>> var('x,y')
(x, y)

>>> qe = qepcad(x**Integer(2) + y**Integer(2) == Integer(1), interact=True) # _
 optional - qepcad
>>> qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'

>>> qe.cell().index() # optional - qepcad ()
>>> qe.cell(Integer(1)).index() # optional - qepcad (1,)
>>> qe.cell(Integer(2), Integer(2)).index() # optional - qepcad (2, 2)
level()  
Return the level of a QEPCAD cell.

EXAMPLES:

```python
sage: var('x,y')
(x, y)
sage: qe = qepcad(x^2 + y^2 == 1, interact=True) # optional - qepcad
sage: qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
sage: qe.cell().level() # optional - qepcad
0
sage: qe.cell(1).level() # optional - qepcad
1
sage: qe.cell(2, 2).level() # optional - qepcad
2
```

number_of_children()  
Return the number of elements in the stack over a QEPCAD cell. (This is always an odd number, if the stack has been constructed.)

EXAMPLES:

```python
>>> from sage.all import *
>>> var('x,y')
(x, y)
>>> qe = qepcad(x**Integer(2) + y**Integer(2) == Integer(1), interact=True) # optional - qepcad
>>> qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
>>> qe.cell().level() # optional - qepcad
0
>>> qe.cell(Integer(1)).level() # optional - qepcad
1
>>> qe.cell(Integer(2), Integer(2)).level() # optional - qepcad
2
```

(continues on next page)
Interpreter Interfaces, Release 10.4

(continued from previous page)

```python
>>> qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
>>> qe.cell().number_of_children() # optional - qepcad
5
>>> [c.number_of_children() for c in qe.cell()] # optional - qepcad
[1, 3, 5, 3, 1]
```

**sample_point()**

Return the coordinates of a point in the cell, as a tuple of Sage algebraic reals.

**EXAMPLES:**

```python
sage: qe = qepcad(x^2 - x - 1 == 0, interact=True)
sage: qe.go(); qe.go(); qe.go()
QEPCAD object has moved to phase 'At the end of projection phase'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
sage: v1 = qe.cell(2).sample_point()[0]; v1
-0.618033988749895?
sage: v2 = qe.cell(4).sample_point()[0]; v2
1.618033988749895?
sage: v1 + v2 == 1
True
```

```python
>>> from sage.all import *
>>> qe = qepcad(x**Integer(2) - x - Integer(1) == Integer(0), interact=True)
>>> qe.go(); qe.go(); qe.go()
QEPCAD object has moved to phase 'At the end of projection phase'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
>>> v1 = qe.cell(Integer(2)).sample_point()[0]; v1
-0.618033988749895?
>>> v2 = qe.cell(Integer(4)).sample_point()[0]; v2
1.618033988749895?
>>> v1 + v2 == Integer(1)
True
```

**sample_point_dict()**

Return the coordinates of a point in the cell, as a dictionary mapping variable names (as strings) to Sage algebraic reals.

**EXAMPLES:**

```python
sage: qe = qepcad(x^2 - x - 1 == 0, interact=True) # optional - qepcad
sage: qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'At the end of projection phase'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
sage: qe.cell(4).sample_point_dict() # optional - qepcad
{'x': 1.618033988749895?}
```
set_truth(v)

Set the truth value of this cell, as used by QEPCAD for solution formula construction.

The argument v should be either a boolean or None (which will set the truth value to 'undetermined').

EXAMPLES:

```python
sage: var('x,y')
(x, y)
sage: qe = qepcad(x**2 + y**2 == 1, interact=True) # optional - qepcad
sage: qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
sage: qe.cell(3, 3).set_truth(True) # optional - qepcad
sage: qe.solution_extension(T) # optional - qepcad
y^2 + x^2 - 1 <= 0
```

signs()

Return the sign vector of a QEPCAD cell.

This is a list of lists. The outer list contains one element for each level of the cell; the inner list contains one element for each projection factor at that level. These elements are either -1, 0, or 1.

EXAMPLES:

```python
sage: var('x,y')
(x, y)
sage: qe = qepcad(x**2 + y**2 == 1, interact=True) # optional - qepcad
sage: qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'
```
 QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'
sage: from sage.interfaces.qepcad import QepcadCell
sage: all_cells = flatten(qe.cell(), ltypes=QepcadCell, max_level=1) #
#optional - qepcad
sage: [(c, c.signs()[0]) for c in all_cells] # optional - qepcad
[(QEPCAD cell (1, 1), 1), (QEPCAD cell (2, 1), 1), (QEPCAD cell (2, 2), 0),
 (QEPCAD cell (2, 3), 1), (QEPCAD cell (3, 1), 1), (QEPCAD cell (3, 2), 0),
 (QEPCAD cell (3, 3), -1), (QEPCAD cell (3, 4), 0), (QEPCAD cell (3, 5), 1),
 (QEPCAD cell (4, 1), 1), (QEPCAD cell (4, 2), 0), (QEPCAD cell (4, 3), 1),
 (QEPCAD cell (5, 1), 1)]

>>> from sage.all import *

>>> var('x,y')
(x, y)

>>> qe = qepcad(x**Integer(2) + y**Integer(2) == Integer(1), interact=True) #
#optional - qepcad

>>> qe.go(); qe.go(); qe.go() # optional - qepcad
QEPCAD object has moved to phase 'Before Projection (y)'  
QEPCAD object has moved to phase 'Before Choice'
QEPCAD object has moved to phase 'Before Solution'

>>> from sage.interfaces.qepcad import QepcadCell

>>> all_cells = flatten(qe.cell(), ltypes=QepcadCell, max_level=Integer(1)) #
#optional - qepcad

>>> [(c, c.signs()[1][0]) for c in all_cells] # optional - qepcad
[(QEPCAD cell (1, 1), 1), (QEPCAD cell (2, 1), 1), (QEPCAD cell (2, 2), 0),
 (QEPCAD cell (2, 3), 1), (QEPCAD cell (3, 1), 1), (QEPCAD cell (3, 2), 0),
 (QEPCAD cell (3, 3), -1), (QEPCAD cell (3, 4), 0), (QEPCAD cell (3, 5), 1),
 (QEPCAD cell (4, 1), 1), (QEPCAD cell (4, 2), 0), (QEPCAD cell (4, 3), 1),
 (QEPCAD cell (5, 1), 1)]

class sage.interfaces.qepcad.QepcadFunction (parent, name)

    Bases: ExpectFunction

    A wrapper for a QEPCAD command.

class sage.interfaces.qepcad.Qepcad_expect (memcells=None, maxread=None, logfile=None, server=None)

    Bases: ExtraTabCompletion, Expect

    The low-level wrapper for QEPCAD.

sage.interfaces.qepcad.qepcad (formula, assume=None, interact=False, solution=None, vars=None, **kwargs)

    Quantifier elimination and formula simplification using QEPCAD B.
    If assume is specified, then the given formula is 'assumed', which is taken into account during final solution formula construction.
    If interact=True is given, then a Qepcad object is returned which can be interacted with either at the command line or programmatically.

    The type of solution returned can be adjusted with solution. The options are 'geometric', which tries to construct a solution formula with geometric meaning; 'extended', which gives a solution formula in an extended language that may be more efficient to construct; 'any-point', which returns any point where the formula is true; 'all-points', which returns a list of all points where the formula is true (or raises an exception if there are infinitely many); and 'cell-points', which returns one point in each cell where the formula is true.
All other keyword arguments are passed through to the `qepcad` constructor.

For much more documentation and many more examples, see the module docstring for this module (type `sage.interfaces.qepcad?` to read this docstring from the sage command line).

The examples below require that the optional qepcad package is installed.

EXEMPLARY:

```python
sage: qf = qepcad_formula

sage: var('a,b,c,d,x,y,z,long_with_underscore_314159')
(a, b, c, d, x, y, z, long_with_underscore_314159)

sage: K.<q,r> = QQ[]

sage: qepcad('(E x)[a x + b > 0]', vars='(a,b,x)')  # not tested (random order)
a /= 0 \( b > 0 

sage: qepcad(a > b)  # optional - qepcad
b - a < 0

sage: qepcad(qf.exists(x, a*x^2 + b*x + c == 0))  # not tested (random order)
4 a c - b^2 <= 0 \[ c = 0 \( a /= 0 \( 4 a c - b^2 < 0 \]

sage: qepcad(qf.exists(x, a*x^2 + b*x + c == 0), assume=(a != 0))  # optional - qepcad
4 a c - b^2 <= 0

>>> from sage.all import *

>>> qf = qepcad_formula

>>> var('a,b,c,d,x,y,z,long_with_underscore_314159')
(a, b, c, d, x, y, z, long_with_underscore_314159)

>>> K = QQ['q, r']; (q, r) = K._first_ngens(2)

>>> qepcad('(E x)[a x + b > 0]', vars='(a,b,x)')  # not tested (random order)
a /= 0 \( b > 0

>>> qepcad(a > b)  # optional - qepcad
b - a < 0

>>> qepcad(qf.exists(x, a*x**Integer(2) + b*x + c == Integer(0)))  # not tested (random order)
4 a c - b^2 <= 0 \[ c = 0 \( a /= 0 \( 4 a c - b^2 < 0 \]

>>> qepcad(qf.exists(x, a*x**Integer(2) + b*x + c == Integer(0)), assume=(a != Integer(0)))  # optional - qepcad
4 a c - b^2 <= 0

For which values of \( a, b, c \) does \( ax^2 + bx + c \) have 2 real zeroes?

```
one real zero?

```python
>>> from sage.all import *
>>> exact2 = qepcad(qf.exactly_k(Integer(2), x, a*x**2 + b*x + c == Integer(0))); exact2
# not tested (random order)
a /= 0 \land 4 a c - b^2 < 0
```

No real zeroes?

```python
>>> from sage.all import *
>>> exact1 = qepcad(qf.exactly_k(1, x, a*x**2 + b*x + c == 0)); exact1
# not tested (random order)
[ a > 0 \land 4 a c - b^2 = 0 ] \lor [ a < 0 \land 4 a c - b^2 = 0 ] \lor [ a = 0 \land 4 a c - b^2 < 0 ]
```

3^{75} real zeroes?

```python
>>> from sage.all import *
>>> exact0 = qepcad(qf.forall(x, a*x**2 + b*x + c != 0)); exact0
# not tested (random order)
4 a c - b^2 >= 0 \land c /= 0 \land [ b = 0 \lor 4 a c - b^2 > 0 ]
```

We can check that the results don’t overlap:

```python
>>> from sage.all import *
>>> qepcad(\texttt{r'}[\texttt{[[s]} / \texttt{[s]}]' \% (exact0, exact1), \texttt{vars='a,b,c'})
# not tested (random order)
FALSE
>>> qepcad(\texttt{r'}[\texttt{[[s]} / \texttt{[s]}]' \% (exact0, exact2), \texttt{vars='a,b,c'})
# not tested (random order)
FALSE
>>> qepcad(\texttt{r'}[\texttt{[[s]} / \texttt{[s]}]' \% (exact1, exact2), \texttt{vars='a,b,c'})
# not tested (random order)
FALSE
```
and that the union of the results is as expected:

```python
sage: qepcad(r'[$s] \lor [s] \lor [$s]' % (exact0, exact1, exact2), vars=(a,b,c))
# not tested
b /= 0 \ a /= 0 \ c /= 0
```

So we have finitely many zeroes if $a$, $b$, or $c$ is nonzero; which means we should have infinitely many zeroes if they are all zero.

```python
sage: qepcad(qf.ininitely_many(x, a*x^2 + b*x + c == 0))
# not tested
a = 0 \ b = 0 \ c = 0
```

The polynomial is nonzero almost everywhere iff it is not identically zero.

```python
sage: qepcad(qf.all_but_finitely_many(x, a*x^2 + b*x + c != 0))
# not tested
b /= 0 \ a /= 0 \ c /= 0
```

The non-zeroes are continuous iff there are no zeroes or if the polynomial is zero.

```python
sage: qepcad(qf.connected_subset(x, a*x^2 + b*x + c != 0))
# not tested
4 a c - b^2 >= 0 \ [ a = 0 \ 4 a c - b^2 > 0 ]
```

The zeroes are continuous iff there are no or one zeroes, or if the polynomial is zero:

```python
sage: qepcad(qf.connected_subset(x, a*x^2 + b*x + c == 0))
# not tested
```
Since polynomials are continuous and $y > 0$ is an open set, they are positive infinitely often iff they are positive at least once.

However, since $y \geq 0$ is not open, the equivalence does not hold if you replace ‘positive’ with ‘nonnegative’. (We assume $a \neq 0$ to get simpler formulas.)

sage.interfaces.qepcad.qepcad_banner()

Return the QEPCAD startup banner.

EXAMPLES:
sage: from sage.interfaces.qepcad import qepcad_banner
sage: qepcad_banner() # optional - qepcad

===================================================================

sage.interfaces.qepcad.qepcad_console (memcells=None)
Run QEPCAD directly. To exit early, press Control + C.

EXAMPLES:

sage: qepcad_console() # not tested
...
Enter an informal description between ['[ and ']':

>>> from sage.all import *
>>> qepcad_console() # not tested
...
Enter an informal description between ['[ and ']':

class sage.interfaces.qepcad.qepcad_formula_factory
Bases: object
Contains routines to help construct formulas in QEPCAD syntax.
A \((v, \text{formula})\)
Given a variable (or list of variables) and a formula, returns the universal quantification of the formula over the variables.

This method is available both as `forall()` and `A()` (the QEPCAD name for this quantifier).

The input formula may be a qformula as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial \(p\) (meaning \(p = 0\)).

EXAMPLES:

```python
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.forall(a, a^2 + b > b^2 + a)
(A a)[a^2 + b > b^2 + a]
sage: qf.forall((a, b), a^2 + b^2 > 0)
(A a)(A b)[a^2 + b^2 > 0]
sage: qf.A(b, b^2 != a)
(A b)[b^2 /= a]
>>> from sage.all import *
>>>
```

C \((v, \text{formula}, \text{allow_multi=False})\)
Given a variable and a formula, returns a new formula which is true iff the set of values for the variable at which the original formula was true is connected (including cases where this set is empty or is a single point).

This method is available both as `connected_subset()` and `C()` (the QEPCAD name for this quantifier).

The input formula may be a qformula as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial \(p\) (meaning \(p = 0\)).

EXAMPLES:

```python
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.connected_subset(a, a^2 + b > b^2 + a)
(C a)[a^2 + b > b^2 + a]
sage: qf.C(b, b^2 != a)
(C b)[b^2 /= a]
>>> from sage.all import *
>>>
```
Given a variable (or list of variables) and a formula, returns the existential quantification of the formula over the variables.

This method is available both as `exists()` and `E()` (the QEPCAD name for this quantifier).

The input formula may be a `qformula` as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial $p$ (meaning $p = 0$).

**EXAMPLES:**

```python
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.exists(a, a^2 + b > b^2 + a)
(E a)[a^2 + b > b^2 + a]
sage: qf.exists((a, b), a^2 + b^2 < 0)
(E a)(E b)[a^2 + b^2 < 0]
sage: qf.E(b, b^2 == a)
(E b)[b^2 = a]
```

Given a variable and a formula, returns a new formula which is true iff the original formula was true for infinitely many values of the variable.

This method is available both as `infinitely_many()` and `F()` (the QEPCAD name for this quantifier).

The input formula may be a `qformula` as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial $p$ (meaning $p = 0$).

**EXAMPLES:**

```python
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.infinitely_many(a, a^2 + b > b^2 + a)
(F a)[a^2 + b > b^2 + a]
sage: qf.F(b, b^2 != a)
(F b)[b^2 /= a]
```

```python
>>> from sage.all import *
>>>
>>> var('a,b')
(a, b)
>>> qf = qepcad_formula
>>> qf.infinitely_many(a, a**Integer(2) + b > b**Integer(2) + a)
(F a)[a^2 + b > b^2 + a]
>>> qf.F(b, b**Integer(2) != a)
(F b)[b^2 /= a]
```
**G** *(v, formula)*

Given a variable and a formula, returns a new formula which is true iff the original formula was true for all but finitely many values of the variable.

This method is available both as `all_but_finitely_many()` and `G()` (the QEPCAD name for this quantifier).

The input formula may be a `qformula` as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial \( p \) (meaning \( p = 0 \)).

**EXAMPLES:**

```sage
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.all_but_finitely_many(a, a^2 + b > b^2 + a)
(G a)[a^2 + b > b^2 + a]
sage: qf.G(b, b^2 != a)
(G b)[b^2 /= a]
```

**X** *(k, v, formula, allow_multi=False)*

Given a nonnegative integer \( k \), a variable, and a formula, returns a new formula which is true iff the original formula is true for exactly \( k \) values of the variable.

This method is available both as `exactly_k()` and `X()` (the QEPCAD name for this quantifier).

(Note that QEPCAD does not support \( k = 0 \) with this syntax, so if \( k = 0 \) is requested we implement it with `forall()` and `not_()`.)

The input formula may be a `qformula` as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial \( p \) (meaning \( p = 0 \)).

**EXAMPLES:**

```sage
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.exactly_k(1, x, x^2 + a*x + b == 0)
(X1 x)[a x + x^2 + b = 0]
sage: qf.exactly_k(0, b, a*b == 1)
(A b)[~a b = 1]
```

```python
>>> from sage.all import *
>>> var('a,b')
(a, b)
>>> qf = qepcad_formula
>>> qf.exactly_k(Integer(1), x, x^Integer(2) + a*x + b == Integer(0))
(X1 x)[a x + x^2 + b = 0]
>>> qf.exactly_k(Integer(0), b, a*b == Integer(1))
(A b)[~a b = 1]
```
all but finitely many \((v, \text{formula})\)

Given a variable and a formula, returns a new formula which is true iff the original formula was true for all but finitely many values of the variable.

This method is available both as `all_but_finitely_many()` and `G()` (the QEPCAD name for this quantifier).

The input formula may be a `qformula` as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial \(p\) (meaning \(p = 0\)).

**EXAMPLES:**

```sage
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.all_but_finitely_many(a, a^2 + b > b^2 + a)
(G a)[a^2 + b > b^2 + a]
sage: qf.G(b, b^2 != a)
(G b)[b^2 /= a]
```

and_ \((*\text{formulas})\)

Return the conjunction of its input formulas.

(This method would be named ‘and’ if that were not a Python keyword.)

Each input formula may be a `qformula` as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial \(p\) (meaning \(p = 0\)).

**EXAMPLES:**

```sage
sage: var('a,b,c,x')
(a, b, c, x)
sage: qf = qepcad_formula
sage: qf.and_(a*b, a*c, b*c != 0)
[a b = 0 /\ a c = 0 /\ b c /= 0]
sage: qf.and_(a*x^2 == 3, qf.or_(a > b, b > c))
[a x^2 = 3 /\ [a > b \lor b > c]]
```

atomic \((lhs, op=‘=’, rhs=0)\)

Construct a QEPCAD formula from the given inputs.
INPUT:

- **lhs** – a polynomial, or a symbolic equality or inequality
- **op** – a relational operator, default ‘=’
- **rhs** – a polynomial, default 0

If **lhs** is a symbolic equality or inequality, then **op** and **rhs** are ignored.

This method works by printing the given polynomials, so we do not care what ring they are in (as long as they print with integral or rational coefficients).

EXAMPLES:

```
sage: qf = qepcad_formula
sage: var('a,b,c')
(a, b, c)
sage: K.<x,y> = QQ[]
sage: def test_qf(qf):
....:     return qf, qf.vars
sage: test_qf(qf.atomic(a^2 + 17))
(a^2 + 17 = 0, frozenset({a}))
sage: test_qf(qf.atomic(a*b*c <= c^3))
(a b c <= c^3, frozenset({a', 'b', 'c'}))
sage: test_qf(qf.atomic(x+y^2, !=, a+b))
(y^2 + x /= a + b, frozenset({a', 'b', 'x', 'y'}))
sage: test_qf(qf.atomic(x, operator.lt))
(x < 0, frozenset({x'}))
```

```python
>>> from sage.all import *
>>> qf = qepcad_formula
>>> var('a,b,c')
(a, b, c)
>>> K = QQ['x, y']; (x, y) = K._first_ngens(2)
>>> def test_qf(qf):
...     return qf, qf.vars
>>> test_qf(qf.atomic(a**Integer(2) + Integer(17)))
(a^2 + 17 = 0, frozenset({a'}))
>>> test_qf(qf.atomic(a*b*c <= c**Integer(3)))
(a b c <= c^3, frozenset({a', 'b', 'c'}))
>>> test_qf(qf.atomic(x+y**Integer(2), !=, a+b))
(y^2 + x /= a + b, frozenset({a', 'b', 'x', 'y'}))
>>> test_qf(qf.atomic(x, operator.lt))
(x < 0, frozenset({x'}))
```

**connected_subset** *(v, formula, allow_multi=False)*

Given a variable and a formula, returns a new formula which is true iff the set of values for the variable at which the original formula was true is connected (including cases where this set is empty or is a single point).

This method is available both as **connected_subset()** and **C()** (the QEPCAD name for this quantifier).

The input formula may be a **gformula** as returned by the methods of **qepcad_formula**, a symbolic equality or inequality, or a polynomial **p** (meaning **p** = 0).

EXAMPLES:

```
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
```

(continues on next page)
sage: qf.connected_subset(a, a^2 + b > b^2 + a)
(C a) [a^2 + b > b^2 + a]
sage: qf.C(b, b^2 != a)
(C b) [b^2 /= a]

>>> from sage.all import *
>>> var('a,b')
(a, b)
>>> qf = qepcad_formula
>>> qf.connected_subset(a, a**Integer(2) + b > b**Integer(2) + a)
(C a) [a^2 + b > b^2 + a]
>>> qf.C(b, b**Integer(2) != a)
(C b) [b^2 /= a]

exactly_k (k, v, formula, allow_multi=False)

Given a nonnegative integer k, a variable, and a formula, returns a new formula which is true iff the original formula is true for exactly k values of the variable.

This method is available both as exactly_k() and X() (the EPECAD name for this quantifier).

(Note that QEPCAD does not support k = 0 with this syntax, so if k = 0 is requested we implement it with forall() and not_.)

The input formula may be a qformula as returned by the methods of qepcad_formula, a symbolic equality or inequality, or a polynomial p (meaning p = 0).

EXAMPLES:

sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.exactly_k(1, x, x^2 + a*x + b == 0)
(X1 x) [a x + x^2 + b = 0]
sage: qf.exactly_k(0, b, a*b == 1)
(A b) [~a b = 1]

exists (v, formula)

Given a variable (or list of variables) and a formula, returns the existential quantification of the formula over the variables.

This method is available both as exists() and E() (the QEPCAD name for this quantifier).

The input formula may be a qformula as returned by the methods of qepcad_formula, a symbolic equality or inequality, or a polynomial p (meaning p = 0).

EXAMPLES:
forall (v, formula)

Given a variable (or list of variables) and a formula, returns the universal quantification of the formula over the variables.

This method is available both as `forall()` and `A()` (the QEPCAD name for this quantifier).

The input formula may be a `qformula` as returned by the methods of `qepcad_formula`, a symbolic equality or inequality, or a polynomial \( p \) (meaning \( p = 0 \)).

**EXAMPLES:**

```python
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.exists(a, a^2 + b > b^2 + a)
(E a)[a^2 + b > b^2 + a]
sage: qf.exists((a, b), a^2 + b^2 < 0)
(E a)(E b)[a^2 + b^2 < 0]
sage: qf.E(b, b^2 == a)
(E b)[b^2 = a]
```

```python
>>> from sage.all import *

>>> var('a,b')
(a, b)

>>> qf = qepcad_formula

>>> qf.exists(a, a^2 + b > b^2 + a)
(E a)[a^2 + b > b^2 + a]

>>> qf.exists((a, b), a^2 + b^2 < 0)
(E a)(E b)[a^2 + b^2 < 0]

>>> qf.E(b, b^2 == a)
(E b)[b^2 = a]
```

**formula (formula)**

Constructs a QEPCAD formula from the given input.

**INPUT:**
Interpreter Interfaces, Release 10.4

• formula – a polynomial, a symbolic equality or inequality, or a list of polynomials, equalities, or inequalities

A polynomial $p$ is interpreted as the equation $p = 0$. A list is interpreted as the conjunction (‘and’) of the elements.

EXAMPLES:

\[
\text{sage: } \text{var('a,b,c,x')} \\
(a, b, c, x) \\
\text{sage: } \text{qf = qepcad_formula} \\
\text{sage: } \text{qf.formula(a*x + b)} \\
a * x + b = 0 \\
\text{sage: } \text{qf.formula((a*x^2 + b*x + c, a != 0))} \\
[a \times 2 + b \times x + c = 0 \land a \neq 0]
\]

\[
\text{if} (f_1, f_2) \\
\text{Return the equivalence of its input formulas (that is, given formulas } P \text{ and } Q, \text{ returns ‘} P \text{ iff } Q \text{’).}
\]

The input formulas may be a $\text{qformula}$ as returned by the methods of $\text{qepcad_formula}$, a symbolic equality or inequality, or a polynomial $p$ (meaning $p = 0$).

EXAMPLES:

\[
\text{sage: } \text{var('a,b')} \\
(a, b) \\
\text{sage: } \text{qf = qepcad_formula} \\
\text{sage: } \text{qf.iff(a, b)} \\
[a = 0 <==> b = 0] \\
\text{sage: } \text{qf.iff(a^2 < b, b^2 < a)} \\
[a^2 < b <==> b^2 < a]
\]

\[
\text{implies}(f_1, f_2) \\
\text{Return the implication of its input formulas (that is, given formulas } P \text{ and } Q, \text{ returns ‘} P \text{ implies } Q \text{’).}
\]

The input formulas may be a $\text{qformula}$ as returned by the methods of $\text{qepcad_formula}$, a symbolic equality or inequality, or a polynomial $p$ (meaning $p = 0$).

EXAMPLES:
**infinitely_many** *(v, formula)*

Given a variable and a formula, returns a new formula which is true iff the original formula was true for infinitely many values of the variable.

This method is available both as *infinitely_many()* and *F()* (the QEPCAD name for this quantifier).

The input formula may be a *qformula* as returned by the methods of *qepcad_formula*, a symbolic equality or inequality, or a polynomial *p* (meaning *p* = 0).

**EXAMPLES:**

```
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula
sage: qf.implies(a, b)
[a = 0 ==> b = 0]
sage: qf.implies(a^2 < b, b^2 < a)
[a^2 < b ==> b^2 < a]

>>> from sage.all import *
>>> var('a,b')
(a, b)
>>> qf = qepcad_formula
>>> qf.implies(a, b)
[a = 0 ==> b = 0]
>>> qf.implies(a**Integer(2) < b, b**Integer(2) < a)
[a^2 < b ==> b^2 < a]
```

**not_** *(formula)*

Return the negation of its input formula.

(This method would be named ‘not’ if that were not a Python keyword.)

The input formula may be a *qformula* as returned by the methods of *qepcad_formula*, a symbolic equality or inequality, or a polynomial *p* (meaning *p* = 0).

**EXAMPLES:**

```
sage: var('a,b')
(a, b)
sage: qf = qepcad_formula

(continues on next page)```
quantifier(kind, v, formula, allow_multi=True)

A helper method for building quantified QEPCAD formulas; not expected to be called directly.

Takes the quantifier kind (the string label of this quantifier), a variable or list of variables, and a formula, and returns the quantified formula.

EXAMPLES:

sage: var('a, b')
(a, b)
sage: qf = qepcad_formula
sage: qf.quantifier('NOT_A_REAL_QEPCAD_QUANTIFIER', a, a*b==0)
sage.interfaces.qepcad.qepcad_version()  
Return a string containing the current QEPCAD version number.

EXAMPLES:

```python
sage: qepcad_version() # random, optional - qepcad
'Version B 1.69, 16 Mar 2012'
```

```python
>>> from sage.all import *
... var('a,b')
(a, b)
>>> qf = qepcad_formula
>>> qf.quantifier('NOT_A_REAL_QEPCAD_QUANTIFIER', a, a*b==Integer(0))
(NOT_A_REAL_QEPCAD_QUANTIFIER a)[a b = 0]
>>> qf.quantifier('FOO', (a, b), a*b)
(FOO a)(FOO b)[a b = 0]
```

class sage.interfaces.qepcad.qformula(formula, vars, qvars=[])
    Bases: object

A qformula holds a string describing a formula in QEPCAD's syntax, and a set of variables used.
INTERFACES TO R

This is the reference to the Sagemath R interface, usable from any Sage program.

The %r interface creating an R cell in the sage notebook is described in the Notebook manual.

The %R and %%%R interface creating an R line or an R cell in the Jupyter notebook are briefly described at the end of this page. This documentation will be expanded and placed in the Jupyter notebook manual when this manual exists.

The following examples try to follow “An Introduction to R” which can be found at http://cran.r-project.org/doc/manuals/R-intro.html.

EXAMPLES:

Simple manipulations; numbers and vectors

The simplest data structure in R is the numeric vector which consists of an ordered collection of numbers. To create a vector named \( x \) using the R interface in Sage, you pass the R interpreter object a list or tuple of numbers:

```
sage: x = r([10.4,5.6,3.1,6.4,21.7]); x
[1] 10.4 5.6 3.1 6.4 21.7
```

You can invert elements of a vector \( x \) in R by using the invert operator or by doing \( 1/x \):

```
sage: ~x
[1] 0.09615385 0.17857143 0.32258065 0.15625000 0.04608295
```

```
sage: 1/x
[1] 0.09615385 0.17857143 0.32258065 0.15625000 0.04608295
```

The following assignment creates a vector \( y \) with 11 entries which consists of two copies of \( x \) with a 0 in between:

```
sage: y = r([x,0,x]); y
[1] 10.4 5.6 3.1 6.4 21.7 0.0 10.4 5.6 3.1 6.4 21.7
```
Vector Arithmetic

The following command generates a new vector $v$ of length 11 constructed by adding together (element by element) $2x$ repeated 2.2 times, $y$ repeated just once, and 1 repeated 11 times:

```python
sage: v = 2*x+y+1; v
[1] 32.2 17.8 10.3 20.2 66.1 21.8 22.6 12.8 16.9 50.8 43.5
```

One can compute the sum of the elements of an R vector in the following two ways:

```python
sage: sum(x)
[1] 47.2
sage: x.sum()
[1] 47.2
```

One can calculate the sample variance of a list of numbers:

```python
sage: ((x-x.mean())**2/(x.length()-1)).sum()
[1] 53.853
sage: x.var()
[1] 53.853
sage: x.sort()
[1] 3.1 5.6 6.4 10.4 21.7
sage: x.min()
[1] 3.1
sage: x.max()
sage: x
[1] 10.4 5.6 3.1 6.4 21.7
sage: r(-17).sqrt()
[1] NaN
sage: r(-17+0i).sqrt()
[1] 0+4.123106i
```

(continues on next page)
>>> x.sort()
[1] 3.1 5.6 6.4 10.4 21.7
>>> x.min()
[1] 3.1
>>> x.max()
>>> x
[1] 10.4 5.6 3.1 6.4 21.7

>>> r(-Integer(17)).sqrt()
[1] NaN

>>> r(-17+0i).sqrt()
[1] 0+4.123106i

Generating an arithmetic sequence:

```
sage: r('1:10')
[1] 1 2 3 4 5 6 7 8 9 10
```

```
>>> from sage.all import *
```

```
>>> r('1:10')
[1] 1 2 3 4 5 6 7 8 9 10
```

Because `from` is a keyword in Python, it can’t be used as a keyword argument. Instead, `from_` can be passed, and R will recognize it as the correct thing:

```
sage: r.seq(length=10, from_=-1, by=.2)
[1] -1.0 -0.8 -0.6 -0.4 -0.2 0.0 0.2 0.4 0.6 0.8

sage: x = r([10.4,5.6,3.1,6.4,21.7])
sage: x.rep(2)
[1] 10.4 5.6 3.1 6.4 21.7 10.4 5.6 3.1 6.4 21.7
sage: x.rep(times=2)
[1] 10.4 5.6 3.1 6.4 21.7 10.4 5.6 3.1 6.4 21.7
sage: x.rep(each=2)
[1] 10.4 10.4 5.6 5.6 3.1 3.1 6.4 6.4 21.7 21.7
```

```
>>> from sage.all import *
```

```
>>> r.seq(length=Integer(10), from_=-Integer(1), by=RealNumber(.2))
[1] -1.0 -0.8 -0.6 -0.4 -0.2 0.0 0.2 0.4 0.6 0.8
```

```
>>> x = r([RealNumber(10.4),RealNumber(5.6),RealNumber(3.1),RealNumber(6.4),
        -> RealNumber(21.7)])
```

```
>>> x.rep(Integer(2))
[1] 10.4 5.6 3.1 6.4 21.7 10.4 5.6 3.1 6.4 21.7
```

```
>>> x.rep(times=Integer(2))
[1] 10.4 5.6 3.1 6.4 21.7 10.4 5.6 3.1 6.4 21.7
>>>
```

```
>>> x.rep(each=Integer(2))
[1] 10.4 10.4 5.6 5.6 3.1 3.1 6.4 6.4 21.7 21.7
```

Missing Values:

```
sage: na = r('NA')
sage: z = r([1,2,3,na])
sage: z
[1] 1 2 3 NA
```

(continues on next page)
sage: ind = r.is_na(z)
sage: ind
[1] FALSE FALSE FALSE TRUE
sage: zero = r(0)
sage: zero / zero
[1] NaN
sage: inf = r('Inf')
sage: inf-inf
[1] NaN
sage: r.is_na(inf)
[1] FALSE
sage: r.is_na(inf-inf)
[1] TRUE
sage: r.is_na(zero/zero)
[1] TRUE
sage: r.is_na(na)
[1] TRUE
sage: r.is_nan(inf-inf)
[1] TRUE
sage: r.is_nan(zero/zero)
[1] TRUE
sage: r.is_nan(na)
[1] FALSE

>>> from sage.all import *
>>> na = r('NA')
>>> z = r([Integer(1),Integer(2),Integer(3),na])
>>> z
[1] 1 2 3 NA
>>> ind = r.is_na(z)
>>> ind
[1] FALSE FALSE FALSE TRUE
>>> zero = r(Integer(0))
>>> zero / zero
[1] NaN
>>> inf = r('Inf')
>>> inf-inf
[1] NaN
>>> r.is_na(inf)
[1] FALSE
>>> r.is_na(inf-inf)
[1] TRUE
>>> r.is_na(zero/zero)
[1] TRUE
>>> r.is_na(na)
[1] TRUE
>>> r.is_nan(inf-inf)
[1] TRUE
>>> r.is_nan(zero/zero)
[1] TRUE
>>> r.is_nan(na)
[1] FALSE

Character Vectors:

sage: labs = r.paste('c("X","Y")', '1:10', sep=''''''); labs
[1] "X1" "Y2" "X3" "Y4" "X5" "Y6" "X7" "Y8" "X9" "Y10"
Index vectors; selecting and modifying subsets of a data set:

```python
>>> from sage.all import *
>>> labs = r.paste(c("X","Y"), '1:10', sep=""); labs
[1] "X1" "Y2" "X3" "Y4" "X5" "Y6" "X7" "Y8" "X9" "Y10"
```

```python
sage: na = r(NA)
sage: x = r([10.4,5.6,3.1,6.4,21.7,na]); x
[1] 10.4 5.6 3.1 6.4 21.7
sage: x[!is.na(self)]
[1] 10.4 5.6 3.1 6.4 21.7
```

```python
>>> from sage.all import *
>>> na = r(NA)
>>> x = r([RealNumber(10.4),RealNumber(5.6),RealNumber(3.1),RealNumber(6.4),RealNumber(21.7),na]); x
[1] 10.4 5.6 3.1 6.4 21.7
>>> (x+1)[(!is.na(self)) & self>0]
[1] 11.4 6.6 4.1 7.4 22.7
```

```python
>>> from sage.all import *
>>> na = r(NA)
>>> x = r([10.4,-2,3.1,-0.5,21.7,na]); x
[1] 10.4 -2.0 3.1 -0.5 21.7
>>> (x+1)[(!is.na(self)) & self>0]
[1] 11.4 4.1 0.5 22.7
```

Distributions:

```python
sage: r.options(width="60")
$width
[1] 80
sage: rr = r.dnorm(r.seq(-3,3,0.1))

Convert R Data Structures to Python/Sage:

```python
sage: rr = r.dnorm(r.seq(-3,3,0.1))
sage: sum(rr._sage_())
sage: rs = r.summary(r.c(1,4,3,4,3,2,5,1))
```

Or you get a dictionary to be able to access all the information:

```python
sage: rs = r.summary(r.c(1,4,3,4,3,2,5,1))
sage: d = rs._sage_()
sage: d['_r_class']
summaryDefault, 'table'
```
>>> from sage.all import *

>>> rs = r.summary(r.c(Integer(1),Integer(4),Integer(3),Integer(4),Integer(3),
→ Integer(2),Integer(5),Integer(1)))

>>> rs
 Min. 1st Qu. Median Mean 3rd Qu. Max.
1.000 1.750 3.000 2.875 4.000 5.000

>>> d = rs._sage_()

>>> d['DATA']
 [1, 1.75, 3, 2.875, 4, 5]

>>> d['_Names']
 ['Min.', '1st Qu.', 'Median', 'Mean', '3rd Qu.', 'Max. ']

>>> d['_r_class']
 ['summaryDefault', 'table']

It is also possible to access the plotting capabilities of R through Sage. For more information see the documentation of r.plot() or r.png().

THE JUPYTER NOTEBOOK INTERFACE (work in progress).

The %r interface described in the Sage notebook manual is not useful in the Jupyter notebook: it creates a inferior R interpreter which cannot be escaped.

The RPy2 library allows the creation of an R cell in the Jupyter notebook analogous to the %r escape in command line or %r cell in a Sage notebook.

The interface is loaded by a cell containing the sole code:

```
"%load_ext rpy2.ipython"
```

After execution of this code, the %R and %%%R magics are available:

- **%R allows the execution of a single line of R code. Data exchange is**
  possible via the -i and -o options. Do “%R?” in a standalone cell to get the documentation.

- **%%R allows the execution in R of the whole text of a cell, with**
  similar options (do “%%R?” in a standalone cell for documentation).

A few important points must be noted:

- The R interpreter launched by this interface IS (currently) DIFFERENT from the R interpreter used by other R… functions.

- Data exchanged via the -i and -o options have a format DIFFERENT from the format used by the r… functions
  (RPy2 mostly uses arrays, and bugs the user to use the pandas Python package).

- R graphics are (beautifully) displayed in output cells, but are not directly importable. You have to save them as
  .png, .pdf or .svg files and import them in Sage for further use.

In its current incarnation, this interface is mostly useful to statisticians needing Sage for a few symbolic computations but
mostly using R for applied work.

class sage.interfaces.r.HelpExpression
    Bases: str

    Used to improve printing of output of r.help.

class sage.interfaces.r.R(maxread=None, logfile=None, init_list_length=1024, seed=None)
    Bases: ExtraTabCompletion, Interface

    An interface to the R interpreter.

    R is a comprehensive collection of methods for statistics, modelling, bioinformatics, data analysis and much more.
    For more details, see http://www.r-project.org/about.html

    Resources:
    • http://r-project.org/ provides more information about R.
    • http://rseek.org/ R’s own search engine.

    EXAMPLES:

    sage: r.summary(r.c(1,2,3,111,2,3,2,3,2,5,4))
    Min. 1st Qu. Median Mean 3rd Qu. Max.
    1.00  2.00  3.00 12.55  3.50 111.00

    >>> from sage.all import *
    >>> r.summary(r.c(Integer(1),Integer(2),Integer(3),Integer(111),Integer(2),
    ... Integer(3),Integer(2),Integer(3),Integer(2),Integer(5),Integer(4)))
    Min. 1st Qu. Median Mean 3rd Qu. Max.
    1.00  2.00  3.00 12.55  3.50 111.00

    available_packages()
    Returns a list of all available R package names.

    This list is not necessarily sorted.

    OUTPUT: list of strings

    Note: This requires an internet connection. The CRAN server is that is checked is defined at the top of
da directory.

    EXAMPLES:

    sage: ap = r.available_packages() # optional - internet
    sage: len(ap) > 20 # optional - internet
    True

    >>> from sage.all import *
    >>> ap = r.available_packages() # optional - internet
    >>> len(ap) > Integer(20) # optional -
    True

call (function_name, *args, **kwds)
    This is an alias for function_call().

    EXAMPLES:
sage: r.call('length', [1, 2, 3])
[1] 3

>>> from sage.all import *
>>> r.call('length', [Integer(1), Integer(2), Integer(3)])
[1] 3

chdir(dir)

Changes the working directory to dir

INPUT:

- dir – the directory to change to.

EXAMPLES:

sage: import tempfile
sage: tmpdir = tempfile.mkdtemp()
sage: r.chdir(tmpdir)

Check that tmpdir and r.getwd() refer to the same directory. We need to use realpath() in case $TMPDIR (by default /tmp) is a symbolic link (see Issue #10264).

sage: os.path.realpath(tmpdir) == sageobj(r.getwd())  # known bug (issue #9970)
True

completions(s)

Return all commands names that complete the command starting with the string s. This is like typing s[Ctrl-T] in the R interpreter.

INPUT:

- s – string

OUTPUT: list – a list of strings

EXAMPLES:

sage: dummy = r._tab_completion(use_disk_cache=False)  # clean doctest
sage: 'testInheritedMethods' in r.completions('tes')
True

>>> from sage.all import *
>>> dummy = r._tab_completion(use_disk_cache=False)  # clean doctest
>>> 'testInheritedMethods' in r.completions('tes')
True
console()

Runs the R console as a separate new R process.

EXAMPLES:

```python
sage: r.console() # not tested
R version 2.6.1 (2007-11-26)
Copyright (C) 2007 The R Foundation for Statistical Computing
ISBN 3-900051-07-0
...
```

```python
>>> from sage.all import *

r.console() # not tested
R version 2.6.1 (2007-11-26)
Copyright (C) 2007 The R Foundation for Statistical Computing
ISBN 3-900051-07-0
...
```

convert_r_list(l)

Converts an R list to a Python list.

EXAMPLES:

```python
sage: s = c(".GlobalEnv", "package:stats", "package:graphics",
       "Autoloads", "package:base")

sage: r.convert_r_list(s)
['.GlobalEnv',
 'package:stats',
 'package:graphics',
 'package:grDevices',
 'package:utils',
 'package:datasets',
 'package:methods',
 'Autoloads',
 'package:base']
```

```python
>>> from sage.all import *

>>> s = c(".GlobalEnv", "package:stats", "package:graphics",
       "Autoloads", "n"package:base")

>>> r.convert_r_list(s)
['.GlobalEnv',
 'package:stats',
 'package:graphics',
 'package:grDevices',
 'package:utils',
 'package:datasets',
 'package:methods',
 'Autoloads',
 'package:base']
```

eval (code, *args, **kwds)

Evaluates a command inside the R interpreter and returns the output as a string.

EXAMPLES:
Interpreter Interfaces, Release 10.4

```python
sage: r.eval('1+1')
'[1] 2'
```

```python
>>> from sage.all import *
```

```python
>>> r.eval('1+1')
'[1] 2'
```

**function_call** (*function*, *args=None*, *kwds=None*)

Return the result of calling an R function, with given args and keyword args.

OUTPUT: RElement – an object in R

EXAMPLES:

```python
sage: r.function_call('length', args=[ [1,2,3] ])  
[1] 3
```

```python
>>> from sage.all import *
```

```python
>>> r.function_call('length', args=[ [Integer(1),Integer(2),Integer(3)] ])  
[1] 3
```

**get** (*var*)

Returns the string representation of the variable var.

INPUT:

- var – a string

OUTPUT: string

EXAMPLES:

```python
sage: r.set('a', 2)
sage: r.get('a')
'[1] 2'
```

```python
>>> from sage.all import *
```

```python
>>> r.set('a', Integer(2))
>>> r.get('a')
'[1] 2'
```

**help** (*command*)

Returns help string for a given command.

INPUT: - command – a string

OUTPUT: HelpExpression – a subclass of string whose __repr__ method is __str__, so it prints nicely

EXAMPLES:

```python
sage: r.help('c')
title
------
Combine Values into a Vector or List
```
c
...

```python
>>> from sage.all import *
>>> r.help('c')
title
-----

Combine Values into a Vector or List

name
-----

library (library_name)

Load the library library_name into the R interpreter.

This function raises an ImportError if the given library is not known.

INPUT:

- library_name – string

EXAMPLES:

```python
sage: r.library('grid')
sage: 'grid' in r.eval('.packages()')
True
sage: r.library('foobar')
Traceback (most recent call last):
...
ImportError: ...
```
>>> from sage.all import *
>>> r.library('grid')
'grid' in r.eval('.packages()')
True
>>> r.library('foobar')
Traceback (most recent call last):
... ImportError: ...

na()

Returns the NA in R.

OUTPUT: RElement – an element of R

EXAMPLES:

sage: r.na()
[1] NA

plot (*args, **kwds)

The R plot function. Type r.help('plot') for much more extensive documentation about this function. See also below for a brief introduction to more plotting with R.

If one simply wants to view an R graphic, using this function is is sufficient (because it calls dev.off() to turn off the device).

However, if one wants to save the graphic to a specific file, it should be used as in the example below to write the output.

EXAMPLES:

This example saves a plot to the standard R output, usually a filename like Rplot001.png - from the command line, in the current directory, and in the cell directory in the notebook. We use a temporary directory in this example while doctesting this example, but you should use something persistent in your own code:

```python
>>> from tempfile import TemporaryDirectory
>>> with TemporaryDirectory() as d:
...     _ = r.setwd(d)
...     r.plot("1:10")
null device
1
```

To save to a specific file name, one should use `png()` to set the output device to that file. If this is done in the notebook, it must be done in the same cell as the plot itself:
sage: filename = tmp_filename() + '.png'
sage: r.png(filename='"%s"%filename')                       # optional - rgraphics
sage: x = r([1,2,3])
sage: y = r([4,5,6])
sage: r.plot(x,y)                                          # optional - rgraphics
null device
sage: import os; os.unlink(filename)                        # optional - rgraphics

>>> from sage.all import *
>>> filename = tmp_filename() + '.png'
>>> r.png(filename='"%s"%filename')                       # optional - rgraphics
>>> x = r([Integer(1),Integer(2),Integer(3)])
>>> y = r([Integer(4),Integer(5),Integer(6)])
>>> r.plot(x,y)                                          # optional - rgraphics
null device
>>> import os; os.unlink(filename)                        # optional - rgraphics

Please note that for more extensive use of R’s plotting capabilities (such as the lattices package), it is advisable to either use an interactive plotting device or to use the notebook. The following examples are not tested, because they differ depending on operating system:

sage: # not tested
sage: r.X11()
sage: r.quartz()
sage: r.hist("rnorm(100)")
sage: r.library("lattice")
sage: r.histogram(x = "~ wt | cyl", data="mtcars")
sage: r.dev_off()

>>> from sage.all import *
>>> # not tested
>>> r.X11()
>>> r.quartz()
>>> r.hist("rnorm(100)")
>>> r.library("lattice")
>>> r.histogram(x = "~ wt | cyl", data="mtcars")
>>> r.dev_off()

In the notebook, one can use r.png() to open the device, but would need to use the following since R lattice graphics do not automatically print away from the command line:

sage: filename = tmp_filename() + '.png'  # not needed in notebook, used for doctesting
sage: r.png(filename='"%s"%filename')                       # optional - rgraphics
sage: r.library("lattice")
sage: r("print(histogram(~ wt | cyl, data=mtcars))")        # optional - rgraphics
sage: import os; os.unlink(filename)                        # optional - rgraphics

>>> from sage.all import *
>>> filename = tmp_filename() + '.png'  # not needed in notebook, used for doctesting
png(*args, **kwargs)

Creates an R PNG device.

This should primarily be used to save an R graphic to a custom file. Note that when using this in the notebook, one must plot in the same cell that one creates the device. See r.plot() documentation for more information about plotting via R in Sage.

These examples won’t work on the many platforms where R still gets built without graphics support.

EXAMPLES:

```python
sage: filename = tmp_filename() + '.png'
sage: r.png(filename='"%s"' % filename) # optional - rgraphics
NULL
sage: x = r([1,2,3])
sage: y = r([4,5,6])
sage: r.plot(x,y) # optional - rgraphics
null device
1
sage: import os
sage: os.unlink(filename) # optional - rgraphics
```

We want to make sure that we actually can view R graphics, which happens differently on different platforms:

```python
sage: s = r.eval('capabilities("png")') # should be on Linux and Solaris
sage: t = r.eval('capabilities("aqua")') # should be on all supported Mac...

"TRUE" in s+t # optional - rgraphics
True
```

read(filename)

Read filename into the R interpreter by calling R's `source()` function on a read-only file connection.
EXAMPLES:

```python
sage: filename = tmp_filename()
sage: f = open(filename, 'w')
sage: _ = f.write('a <- 2+2

sage: f.close()
sage: r.read(filename)
sage: r.get('a')
'[1] 4'
```

```python
>>> from sage.all import *
>>> filename = tmp_filename()
>>> f = open(filename, 'w')
>>> _ = f.write('a <- 2+2

>>> f.close()
>>> r.read(filename)
>>> r.get('a')
'[1] 4'
```

`require(library_name)`

Load the library `library_name` into the R interpreter.

This function raises an ImportError if the given library is not known.

**INPUT:**

- `library_name` – string

**EXAMPLES:**

```python
sage: r.library('grid')
sage: 'grid' in r.eval('.packages()')
True
sage: r.library('foobar')
Traceback (most recent call last):
... ImportError: ...
```

```python
>>> from sage.all import *
>>> r.library('grid')
>>> 'grid' in r.eval('.packages()')
True
>>> r.library('foobar')
Traceback (most recent call last):
... ImportError: ...
```

`set(var, value)`

Set the variable `var` in R to what the string `value` evaluates to in R.

**INPUT:**

- `var` – a string
- `value` – a string

**EXAMPLES:**
sage: r.set('a', '2 + 3')
sage: r.get('a')
'[1] 5'

>>> from sage.all import *
>>> r.set('a', '2 + 3')
>>> r.get('a')
'[1] 5'

set_seed (seed=None)
Set the seed for R interpreter.
The seed should be an integer.

EXAMPLES:

sage: r = R()
sage: r.set_seed(1)
1
sage: r.sample("1:10", 5) # random
[1] 3 4 5 7 2

>>> from sage.all import *
>>> r = R()
>>> r.set_seed(Integer(1))
1
>>> r.sample("1:10", Integer(5)) # random
[1] 3 4 5 7 2

source (s)
Display the R source (if possible) about the function named s.

INPUT:

• s – a string representing the function whose source code you want to see

OUTPUT: string – source code

EXAMPLES:

sage: print(r.source("c"))
function (...) .Primitive("c")

>>> from sage.all import *
>>> print(r.source("c"))
function (...) .Primitive("c")

version ()
Return the version of R currently running.

OUTPUT: tuple of ints; string

EXAMPLES:

sage: r.version()  # not tested
((3, 0, 1), 'R version 3.0.1 (2013-05-16)')
sage: rint, rstr = r.version()
sage: rint[0] >= 3
(continues on next page)
rstr.startswith('R version')
True

>>> from sage.all import *
>>> r.version()  # not tested
((3, 0, 1), 'R version 3.0.1 (2013-05-16)')
>>> rint, rstr = r.version()
>>> rint[Integer(0)] >= Integer(3)
True
>>> rstr.startswith('R version')
True

class sage.interfaces.r.RElement (parent, value, is_name=False, name=None)
Bases: ExtraTabCompletion, InterfaceElement
dot_product (other)

Implements the notation self . other.

INPUT:

• self, other – R elements

OUTPUT: R element

EXAMPLES:

sage: c = r.c(1, 2, 3, 4)
sage: c.dot_product(c.t())

\[
\begin{bmatrix}
1 & 2 & 3 & 4 \\
2 & 4 & 6 & 8 \\
3 & 6 & 9 & 12 \\
4 & 8 & 12 & 16
\end{bmatrix}
\]

sage: v = r([3, -1, 8])
sage: v.dot_product(v)

\[
\begin{bmatrix}
28
\end{bmatrix}
\]

>>> from sage.all import *
>>> c = r.c(Integer(1), Integer(2), Integer(3), Integer(4))
>>> c.dot_product(c.t())

\[
\begin{bmatrix}
1 & 2 & 3 & 4 \\
2 & 4 & 6 & 8 \\
3 & 6 & 9 & 12 \\
4 & 8 & 12 & 16
\end{bmatrix}
\]

>>> v = r([Integer(3), -Integer(1), Integer(8)])
>>> v.dot_product(v)

\[
\begin{bmatrix}
28
\end{bmatrix}
\]

is_string()

Tell whether this element is a string.

EXAMPLES:
sage: r("abc").is_string()
True
sage: r([1,2,3]).is_string()
False

>>> from sage.all import *
>>> r("abc").is_string()
True
>>> r([Integer(1),Integer(2),Integer(3)]).is_string()
False

\texttt{stat\_model}(x)

The tilde regression operator in R.

\textbf{EXAMPLES:}

sage: x = r([1,2,3,4,5])
sage: y = r([3,5,7,9,11])
sage: a = r.lm( y.tilde(x) )  # \texttt{lm( y \sim x )}
sage: d = a._sage_()
sage: d['DATA']['coefficients']['DATA'][1]
2

\textit{tilde}(x)

The tilde regression operator in R.

\textbf{EXAMPLES:}

sage: x = r([1,2,3,4,5])
sage: y = r([3,5,7,9,11])
sage: a = r.lm( y.tilde(x) )  # \texttt{lm( y \sim x )}
sage: d = a._sage_()
sage: d['DATA']['coefficients']['DATA'][Integer(1)]
2

\texttt{class} sage.interfaces.r.RFunction (parent, name, r_name=None)

\textbf{Bases:} InterfaceFunction

A Function in the R interface.

\textbf{INPUT:}
• parent – the R interface
• name – the name of the function for Python
• r_name – the name of the function in R itself (which can have dots in it)

EXAMPLES:

```
sage: length = r.length
sage: type(length)
<class 'sage.interfaces.r.RFunction'>
sage: loads(dumps(length))
length
```

```
>>> from sage.all import *
>>> length = r.length
>>> type(length)
<class 'sage.interfaces.r.RFunction'>
>>> loads(dumps(length))
length
```

class sage.interfaces.r.RFunctionElement(obj, name)

Bases: InterfaceFunctionElement

sage.interfaces.r.is_RElement(x)

Return True if x is an element in an R interface.

INPUT:
• x – object

OUTPUT: bool

EXAMPLES:

```
sage: from sage.interfaces.r import is_RElement
sage: is_RElement(2)
False
sage: is_RElement(r(2))
True
```

```
>>> from sage.all import *
>>> from sage.interfaces.r import is_RElement

>>> is_RElement(Integer(2))
False

>>> is_RElement(r(Integer(2)))
True
```

sage.interfaces.r.r_console()

Spawn a new R command-line session.

EXAMPLES:
sage: r_console()  # not tested

R version 2.6.1 (2007-11-26)

...

sage.interfaces.r.r_version()

Return the R version.

EXAMPLES:

sage: r_version()  # not tested
((3, 0, 1), 'R version 3.0.1 (2013-05-16)')
sage: rint, rstr = r_version()
sage: rint[0] >= 3
True
sage: rstr.startswith('R version')
True

>>> from sage.all import *
>>> from sage.interfaces.r import reduce_load_R

sage.interfaces.r.reduce_load_R()

Used for reconstructing a copy of the R interpreter from a pickle.

EXAMPLES:

sage: from sage.interfaces.r import reduce_load_R
sage: reduce_load_R()
R Interpreter

>>> from sage.all import *
>>> from sage.interfaces.r import reduce_load_R
>>> reduce_load_R()
R Interpreter
The first is by Michael Reid, and tries to find an optimal solution given the cube’s state, and may take a long time. See http://www.math.ucf.edu/~reid/Rubik/optimal_solver.html

The second is by Eric Dietz, and uses a standard (?) algorithm to solve the cube one level at a time. It is extremely fast, but often returns a far from optimal solution. See https://web.archive.org/web/20121212175710/http://www.wrongway.org/?rubiksource

The third is by Dik Winter and implements Kociemba’s algorithm which finds reasonable solutions relatively quickly, and if it is kept running will eventually find the optimal solution.

AUTHOR:

– Optimal was written by Michael Reid <reid@math.ucf.edu> (2004) – Cubex was written by Eric Dietz <root@wrongway.org> (2003) – Kociemba was written by Dik T. Winter <dik.winter@cwi.nl> (1993) – Initial interface by Robert Bradshaw (2007-08)

class sage.interfaces.rubik.CubexSolver
    Bases: object

    format_cube(facets)

    solve(facets)

EXAMPLES:

```python
sage: # optional - rubiks
sage: from sage.interfaces.rubik import *

sage: C = RubiksCube("R U")
'R U'
sage: CubexSolver().solve(C.facets())
'R U'
sage: C = RubiksCube("R U F L B D")
"R U F L B D"
sage: sol = CubexSolver().solve(C.facets()); sol
sage: RubiksCube(sol) == C
True
sage: C = RubiksCube("R2 F'")
"R2 F'"
sage: CubexSolver().solve(C.facets())
"R' R' F'"
sage: C = RubiksCube().scramble()
sage: sol = CubexSolver().solve(C.facets())
sage: C == RubiksCube(sol)
True
```
>>> from sage.all import *
>>> # optional - rubiks
>>> from sage.interfaces.rubik import *

>>> C = RubiksCube("R U")
>>> CubexSolver().solve(C.facets())
'R U'

>>> C = RubiksCube("R U F L B D")
>>> sol = CubexSolver().solve(C.facets()); sol
"U' L' U L U' L U D L L D' L D L' U L D' L U L' B' U' L' U B...
→L D L D' U' L' U L B L B' L' U L U' L' F' L' F L' F L' F L' F L' L' D' L' D D L D'...
→B L B' L B' L B F' L F F B' L F' B D' D' L D B' B L' D' B U' U' L' B' D' F
→' F' L D F'" 

>>> RubiksCube(sol) == C
True

>>> C = RubiksCube("R2 F'")
>>> CubexSolver().solve(C.facets())
"R' R' F'"

>>> C = RubiksCube().scramble()

>>> sol = CubexSolver().solve(C.facets())

>>> C == RubiksCube(sol)
True

496 Chapter 41. Interface to several Rubik’s cube solvers.

```python
class sage.interfaces.rubik.DikSolver
    Bases: object

    facet_map = [1, 2, 3, 4, 0, 5, 6, 7, 8, 9, 10, 11, 17, 18, 19, 25, 26, 27,
                 33, 34, 35, 12, 0, 13, 20, 0, 21, 28, 0, 29, 36, 0, 37, 14, 15, 16, 22, 23,
                 24, 30, 31, 32, 38, 39, 40, 41, 42, 43, 44, 0, 45, 46, 47, 48]

    format_cube(facets)

    rot_map = {'B': 'U', 'D': 'B', 'F': 'D', 'L': 'L', 'R': 'R', 'U': 'F'}

    solve(facets, timeout=10, extra_time=2)

    EXAMPLES:
```
class sage.interfaces.rubik.OptimalSolver(verbosel=False, wait=True)

Bases: object

Interface to Michael Reid's optimal Rubik's Cube solver.

format_cube(facets)

ready()

solve(facets)

The initial startup and precomputation are substantial...

Todo: Let it keep searching once it found a solution?

EXAMPLES:

```python
sage: # optional - rubiks
sage: from sage.interfaces.rubik import *

sage: solver = DikSolver()

sage: solver = OptimalSolver() # long time (28s on sage.math, 2012)
Initializing tables...
Done.

sage: C = RubiksCube("R U")

sage: solver.solve(C.facets())
'R U'

sage: C = RubiksCube("R U F L B D")

sage: solver.solve(C.facets())
'R U F L B D'

sage: C = RubiksCube("R2 D2")

sage: solver.solve(C.facets())
'R2 D2'
```

```python
>>> from sage.all import *

>>> from sage.interfaces.rubik import *

>>> solver = DikSolver()

>>> solver = OptimalSolver() # long time (28s on sage.math, 2012)
Initializing tables...
Done.

>>> C = RubiksCube("R U")

>>> solver.solve(C.facets())
'R U'

>>> C = RubiksCube("R U F L B D")

>>> solver.solve(C.facets())
'R U F L B D'

>>> C = RubiksCube("R2 D2")

>>> solver.solve(C.facets())
'R2 D2'
```

start()
class sage.interfaces.rubik.SingNot(s)
    Bases: object

    This class is to resolve difference between various Singmaster notation.
    Case is ignored, and the second and third letters may be swapped.

    EXAMPLES:

    sage: from sage.interfaces.rubik import SingNot
    sage: SingNot("acb") == SingNot("ACB")
    True
    sage: SingNot("acb") == SingNot("bca")
    False

    >>> from sage.all import *
    >>> from sage.interfaces.rubik import SingNot
    >>> SingNot("acb") == SingNot("ACB")
    True
    >>> SingNot("acb") == SingNot("bca")
    False
INTERFACE TO SAGE

This is an expect interface to another copy of the Sage interpreter.

```python
class sage.interfaces.sage0.Sage (logfile=None, preparse=True, python=False, init_code=None, server=None, server_tmpdir=None, remote_cleaner=True, **kwds)

Bases: ExtraTabCompletion, Expect

Expect interface to the Sage interpreter itself.

INPUT:

* server – (optional); if specified runs Sage on a remote machine with address. You must have ssh keys setup so you can login to the remote machine by typing “ssh remote_machine” and no password, call _install_hints_ssh() for hints on how to do that.

The version of Sage should be the same as on the local machine, since pickling is used to move data between the two Sage process.

EXAMPLES: We create an interface to a copy of Sage. This copy of Sage runs as an external process with its own memory space, etc.
```
sage: s = Sage()

```
Note that $V$ is a not a vector space, it’s a wrapper around an object (which happens to be a vector space), in another running instance of Sage.

```
sage: type(V)
<class 'sage.interfaces.sage0.SageElement'>
sage: V.parent()
Sage
sage: g = V.0; g
(1, 0, 0, 0)
sage: g.parent()
Sage
```

We can still get the actual parent by using the name attribute of $g$, which is the variable name of the object in the child process.

```
sage: s('%s.parent()' % g.name())
Vector space of dimension 4 over Rational Field
```

Note that the memory space is completely different.

```
sage: x = 10
sage: s('x = 5')
5
sage: x
10
sage: s('x')
5
```

```
>>> from sage.all import *
>>> x = Integer(10)
>>> s('x = 5')
5
>>> x
10
>>> s('x')
5
```

We can have the child interpreter itself make another child Sage process, so now three copies of Sage are running:
sage: s3 = s('Sage()')
sage: a = s3(10)
sage: a
10

>>> from sage.all import *
>>> s3 = s('Sage()')
>>> a = s3(Integer(10))
>>> a
10

This $a = 10$ is in a subprocess of a subprocess of your original Sage.

sage: _ = s.eval('%s.eval("x=8") % s3.name()')
sage: s3('x')
8
sage: s('x')
5
sage: x
10

>>> from sage.all import *
>>> _ = s.eval('%s.eval("x=8") % s3.name()')
>>> s3('x')
8
>>> s('x')
5
>>> x
10

The double quotes are needed because the call to s3 first evaluates its arguments using the s interpreter, so the call to s3 is passed \texttt{s('"x"')}, which is the string "x" in the s interpreter.

clear(var)

Clear the variable named \texttt{var}.

Note that the exact format of the NameError for a cleared variable is slightly platform dependent, see Issue \texttt{#10539}.

EXAMPLES:

sage: sage0.set('x', '2')
sage: sage0.get('x')
'2'
sage: sage0.clear('x')
sage: 'NameError in sage0.get('x')
True

>>> from sage.all import *
>>> sage0.set('x', '2')
>>> sage0.get('x')
'2'
>>> sage0.clear('x')
>>> 'NameError' in sage0.get('x')
True

console()
Spawn a new Sage command-line session.

EXEMPLARY:

```python
sage: sage0.console() #not tested
```

```python
| SageMath version ..., Release Date: ... |
| Using Python .... Type "help()" for help. |
```

```python
>>> from sage.all import *
```

```python
>>> sage0.console() #not tested
```

```python
| SageMath version ..., Release Date: ... |
| Using Python .... Type "help()" for help. |
```

```python
cputime(t=None)
```

Return cputime since this Sage subprocess was started.

EXEMPLARY:

```python
sage: sage0.cputime()  # random output
1.3530439999999999
sage: sage0('factor(2^157-1)')
852133201 * 60726444167 * 1654058017289 * 2134387368610417
sage: sage0.cputime()  # random output
1.6462939999999999
```

```python
eval(line, strip=True, **kwds)
```

Send the code `x` to a second instance of the Sage interpreter and return the output as a string.

This allows you to run two completely independent copies of Sage at the same time in a unified way.

INPUT:

- `line` – input line of code
- `strip` – ignored

EXEMPLARY:

```python
sage: sage0.eval('2+2')
'4'
```

```python
>>> from sage.all import *
```

```python
>>> sage0.eval('2+2')
'4'
```
**get (var)**

Get the value of the variable var.

**EXAMPLES:**

```python
sage: sage0.set('x', '2')
sage: sage0.get('x')
'2'
```

```python
>>> from sage.all import *
>>> sage0.set('x', '2')
>>> sage0.get('x')
'2'
```

**new (x)**

**EXAMPLES:**

```python
sage: sage0.new(2)
2
sage: _.parent()
Sage
```

```python
>>> from sage.all import *
>>> sage0.new(Integer(2))
2
>>> _.parent()
Sage
```

**preparse (x)**

Returns the preparsed version of the string s.

**EXAMPLES:**

```python
sage: sage0.preparse(2+2)
'Integer(2)+Integer(2)'
```

```python
>>> from sage.all import *
>>> sage0.preparse(2+2)
'Integer(2)+Integer(2)'
```

**set (var, value)**

Set the variable var to the given value.

**EXAMPLES:**

```python
sage: sage0.set('x', '2')
sage: sage0.get('x')
'2'
```

```python
>>> from sage.all import *
>>> sage0.set('x', '2')
>>> sage0.get('x')
'2'
```

**version ()**

**EXAMPLES:**
sage: sage0.version()
'SageMath version ..., Release Date: ...'
sage: sage0.version() == version()
True

>>> from sage.all import *
>>> sage0.version()
'SageMath version ..., Release Date: ...'
>>> sage0.version() == version()
True

class sage.interfaces.sage0.SageElement (parent, value, is_name=False, name=None)
    Bases: ExpectElement
class sage.interfaces.sage0.SageFunction (obj, name)
    Bases: FunctionElement

sage.interfaces.sage0.reduce_load_Sage()
    EXAMPLES:

sage: from sage.interfaces.sage0 import reduce_load_Sage
sage: reduce_load_Sage()
Sage

>>> from sage.all import *
>>> from sage.interfaces.sage0 import reduce_load_Sage
>>> reduce_load_Sage()
Sage

sage.interfaces.sage0.reduce_load_element(s)
    EXAMPLES:

sage: from sage.interfaces.sage0 import reduce_load_element
sage: s = dumps(1/2)
sage: half = reduce_load_element(s); half
1/2
sage: half.parent()
Sage

>>> from sage.all import *
>>> from sage.interfaces.sage0 import reduce_load_element
>>> s = dumps(Integer(1)/Integer(2))
>>> half = reduce_load_element(s); half
1/2
>>> half.parent()
Sage

sage.interfaces.sage0.sage0_console()
    Spawn a new Sage command-line session.
    EXAMPLES:

sage: sage0_console() # not tested
SageMath version ..., Release Date: ... |
<table>
<thead>
<tr>
<th>Using Python .... Type &quot;help()&quot; for help.</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

```python
>>> from sage.all import *
>>> sage0_console() #not tested
```

<table>
<thead>
<tr>
<th>SageMath version ..., Release Date: ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using Python .... Type &quot;help()&quot; for help.</td>
</tr>
<tr>
<td>----------------------------------------</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

sage.interfaces.sage0.sage0_version()

**EXAMPLES:**

```python
sage: from sage.interfaces.sage0 import sage0_version
sage: sage0_version() == version()
True
```

```python
>>> from sage.all import *
>>> from sage.interfaces.sage0 import sage0_version
>>> sage0_version() == version()
True
```
Scilab is a scientific software package for numerical computations providing a powerful open computing environment for engineering and scientific applications. Scilab includes hundreds of mathematical functions with the possibility to add interactively programs from various languages (C, C++, Fortran…). It has sophisticated data structures (including lists, polynomials, rational functions, linear systems…), an interpreter and a high level programming language.

The commands in this section only work if you have the “scilab” interpreter installed and available in your PATH. It’s not necessary to install any special Sage packages.

EXAMPLES:

```
sage: # optional - scilab
sage: scilab.eval('2+2')
'ans =\n 4.'
sage: scilab('2+2')
4.
sage: a = scilab(10)
sage: a**10
1.000D+10
```

```
>>> from sage.all import *

>>> # optional - scilab
>>> scilab.eval('2+2')
'ans =\n 4.'
>>> scilab('2+2')
4.
>>> a = scilab(Integer(10))
>>> a**Integer(10)
1.000D+10
```

Tutorial based the MATLAB interface tutorial:

EXAMPLES:

```
sage: # optional - scilab
sage: scilab('4+10')
14.
sage: scilab('date')
15-Feb-2010
sage: scilab('5*10 + 6')
56.
sage: scilab('(6+6)/3')
4.
sage: scilab('9')^2
81.
```

(continues on next page)
sage: a = scilab(10); b = scilab(20); c = scilab(30)
sage: avg = (a+b+c)/3
sage: avg
20.
sage: parent(avg)
Scilab

sage: # optional - scilab
sage: my_scalar = scilab('3.1415')
sage: my_scalar
3.1415
sage: my_vector1 = scilab('[1,5,7]')
sage: my_vector1
1. 5. 7.
sage: my_vector2 = scilab('[1;5;7]')
sage: my_vector2
1. 5. 7.
sage: my_vector1 * my_vector2
75.

sage: # optional - scilab
sage: row_vector1 = scilab([1 2 3])
sage: row_vector2 = scilab([3 2 1])
sage: matrix_from_row_vec = scilab(['%s; %s'%(row_vector1.name(), row_vector2.name())])
sage: matrix_from_row_vec
1. 2. 3.
3. 2. 1.

sage: # optional - scilab
sage: column_vector1 = scilab('[1;3]')
sage: column_vector2 = scilab('[2;8]')
sage: matrix_from_col_vec = scilab(['%s %s'%(column_vector1.name(), column_vector2.name())])
sage: matrix_from_col_vec
1. 2.
3. 8.

sage: my_matrix = scilab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')  # optional - scilab
sage: my_matrix
8. 12. 19.
7. 3. 2.
12. 4. 23.
8. 1. 1.

sage: combined_matrix = scilab(['%s %s'%(my_matrix.name(), my_matrix.name())])  # optional - scilab
sage: combined_matrix
7. 3. 2. 7. 3. 2.
12. 4. 23. 12. 4. 23.
8. 1. 1. 8. 1. 1.

sage: tm = scilab('0.5:2:10')  # optional - scilab
(continues on next page)
sage: tm # optional - scilab
0.5  2.5  4.5  6.5  8.5

sage: # optional - scilab
sage: my_vector1 = scilab('[1,5,7]')
sage: my_vector1(1)
1.
sage: my_vector1(2)
5.
sage: my_vector1(3)
7.

>>> from sage.all import *
>>> # optional - scilab
>>> scilab('4+10')
14.
>>> scilab('date')
15-Feb-2010
>>> scilab('5*10 + 6')
56.
>>> scilab('(6+6)/3')
4.
>>> scilab('9')**Integer(2)
81.
>>> a = scilab(Integer(10)); b = scilab(Integer(20)); c = scilab(Integer(30))
>>> avg = (a+b+c)/Integer(3)
>>> avg
20.
>>> parent(avg)
Scilab

>>> # optional - scilab
>>> my_scalar = scilab('3.1415')
>>> my_scalar
3.1415
>>> my_vector1 = scilab('[1,5,7]')
>>> my_vector1
1.  5.  7.
>>> my_vector2 = scilab('[1;5;7]')
>>> my_vector2
1.  5.  7.
>>> my_vector1 * my_vector2
75.

>>> # optional - scilab
>>> row_vector1 = scilab('[1 2 3]')
>>> row_vector2 = scilab('[3 2 1]')
>>> matrix_from_row_vec = scilab('[$s; $s]'%(row_vector1.name(), row_vector2.name()))
>>> matrix_from_row_vec
1.  2.  3.
3.  2.  1.

>>> # optional - scilab
>>> column_vector1 = scilab('[1;3]')
Matrix indexing works as follows:

```
>>> column_vector2 = scilab('[2;8]')
>>> matrix_from_col_vec = scilab(['$s$ $s$' % (column_vector1.name(), column_vector2.name())])
>>> matrix_from_col_vec
1.  2.
3.  8.

>>> my_matrix = scilab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')  # optional - scilab
>>> my_matrix
 8. 12. 19.
 7. 3.  2.
12. 4. 23.
 8. 1.  1.

>>> combined_matrix = scilab(['$s$, $s$' % (my_matrix.name(), my_matrix.name())])  # optional - scilab
>>> combined_matrix
 7. 3.  2.  7.  3.  2.
12. 4. 23. 12.  4. 23.
 8. 1.  1.  8.  1.  1.

>>> tm = scilab('0.5:2:10')  # optional - scilab
>>> tm
0.5  2.5  4.5  6.5  8.5

>>> my_vector1 = scilab('[1,5,7]')
>>> my_vector1(Integer(1))
1.
>>> my_vector1(Integer(2))
5.
>>> my_vector1(Integer(3))
7.
```

One can also use square brackets:

```
sage: my_matrix = scilab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')  # optional - scilab
sage: my_matrix(3,2)  # optional - scilab
4.
```
Setting using parenthesis cannot work (because of how the Python language works). Use square brackets or the set function:

```
>>> from sage.all import *
>>> my_matrix[Integer(3),Integer(2)]  # optional --
...scilab
4.
```

```
sage: # optional - scilab
sage: my_matrix = scilab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')
sage: my_matrix.set(2,3, 1999)
sage: my_matrix
8. 12. 19.
7. 3. 1999.
12. 4. 23.
8. 1. 1.
sage: my_matrix[2,3] = -126
sage: my_matrix
8. 12. 19.
7. 3. -126.
12. 4. 23.
8. 1. 1.
```

```
>>> from sage.all import *
>>> # optional - scilab
>>> my_matrix = scilab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')
>>> my_matrix.set(Integer(2),Integer(3), Integer(1999))
>>> my_matrix
8. 12. 19.
7. 3. 1999.
12. 4. 23.
8. 1. 1.
```

```
>>> from sage.all import *
>>> # optional - scilab
>>> my_matrix = scilab('[8, 12, 19; 7, 3, 2; 12, 4, 23; 8, 1, 1]')
>>> my_matrix.set(Integer(2),Integer(3), Integer(1999))
>>> my_matrix
8. 12. 19.
7. 3. -126.
12. 4. 23.
8. 1. 1.
```

AUTHORS:

class sage.interfaces.scilab.Scilab(maxread=None, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, seed=None)

Bases: Expect

Interface to the Scilab interpreter.

EXAMPLES:

```
sage: # optional - scilab
sage: a = scilab('[ 1, 1, 2; 3, 5, 8; 13, 21, 33 ]')
sage: b = scilab('[ 1; 3; 13 ]')
sage: c = a * b
sage: print(c)
30.
```
console()

Starts Scilab console.

EXAMPLES:

sage: scilab.console() # optional - scilab; not tested

>>> from sage.all import *

>>> scilab.eval("5") # optional - scilab

ans = 5.'

sage: scilab.eval("d=44") # optional - scilab 'd =

44.'

get(var)

Get the value of the variable var.

EXAMPLES:

sage: scilab.eval('b=124;') # optional - scilab

'sage: scilab.get('b') # optional - scilab

' (continues on next page)
sage2scilab_matrix_string(A)

Return a Scilab matrix from a Sage matrix.

**INPUT:**
A Sage matrix with entries in the rationals or reals.

**OUTPUT:**
A string that evaluates to a Scilab matrix.

**EXAMPLES:**

```python
sage: M33 = MatrixSpace(QQ, 3, 3)  # optional - scilab
sage: A = M33([[1, 2, 3], [4, 5, 6], [7, 8, 0]])  # optional - scilab
sage: scilab.sage2scilab_matrix_string(A)  # optional - scilab
'[[1, 2, 3; 4, 5, 6; 7, 8, 0]]
```

```python
>>> from sage.all import *
```

```python
sage: M33 = MatrixSpace(QQ, Integer(3), Integer(3))  # optional - scilab
sage: A = M33([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5), Integer(6)], [Integer(7), Integer(8), Integer(0)]]))  # optional - scilab
sage: scilab.sage2scilab_matrix_string(A)  # optional - scilab
'[[1, 2, 3; 4, 5, 6; 7, 8, 0]]
```

**set (var, value)**

Set the variable var to the given value.

**EXAMPLES:**

```python
sage: scilab.set('a', 123)  # optional - scilab
sage: scilab.get('a')  # optional - scilab

>>> from sage.all import *
```

```python
sage: scilab.set('a', Integer(123))  # optional - scilab
sage: scilab.get('a')  # optional - scilab
```

**set_seed (seed=None)**

Set the seed for gp interpreter.

The seed should be an integer.

**EXAMPLES:**

```python
sage: # optional - scilab
sage: from sage.interfaces.scilab import Scilab
sage: s = Scilab()
```

```python
sage: s.set_seed(1)
```

(continues on next page)
sage: [s.rand() for i in range(5)]
[0.6040239,
 0.0079647,
 0.6643966,
 0.9832111,
 0.5321420]

>>> from sage.all import *
>>> # optional - scilab
>>> from sage.interfaces.scilab import Scilab
>>> s = Scilab()
>>> s.set_seed(Integer(1))
1
>>> [s.rand() for i in range(Integer(5))]
[0.6040239,
 0.0079647,
 0.6643966,
 0.9832111,
 0.5321420]

version()
Returns the version of the Scilab software used.

EXAMPLES:

sage: scilab.version()  # optional - scilab
'scilab-...'

whos (name=None, typ=None)
Returns information about current objects. Arguments: nam: first characters of selected names typ: name of selected Scilab variable type

EXAMPLES:

sage: scilab.whos("core")  # optional - scilab
'Name Type Size Bytes...'

sage: scilab.whos(typl='function')  # optional - scilab
'Name Type Size Bytes...'
```python
>>> from sage.all import *

>>> scilab.whos("core")  # optional - scilab
'Name'    'Type'    'Size'    'Bytes...'  

>>> scilab.whos(typ='function')  # optional - scilab
'Name'    'Type'    'Size'    'Bytes...'  

class sage.interfaces.scilab.ScilabElement (parent, value, is_name=False, name=None)
Bases: ExpectElement

set (i, j, x)

Set the variable var to the given value.

EXAMPLES:

```
sage: scilab.set('c', 125)  # optional - scilab
sage: scilab.get('c')  # optional - scilab
```

```
>>> from sage.all import *

>>> scilab.set('c', Integer(125))  # optional - scilab

>>> scilab.get('c')  # optional - scilab
```

125.'

sage.interfaces.scilab.scilab_console()

This requires that the optional Scilab program be installed and in your PATH, but no optional Sage packages need to be installed.

EXAMPLES:

```
sage: from sage.interfaces.scilab import scilab_console  # optional - scilab
sage: scilab_console()  # optional - scilab; not tested
```

```
```
```
```
```

```
```
```
```
```
```
Startup execution:
   loading initial environment

-->2+3
ans =
  5.
-->quit

Typing quit exits the Scilab console and returns you to Sage. Scilab, like Sage, remembers its history from one
session to another.

sage.interfaces.scilab.scilab_version()

Return the version of Scilab installed.

EXAMPLES:

```
sage: from sage.interfaces.scilab import scilab_version # optional - scilab
sage: scilab_version() # optional - scilab
'scilab-...'
```

```
>>> from sage.all import *
>>> from sage.interfaces.scilab import scilab_version # optional - scilab
>>> scilab_version() # optional - scilab
'scilab-...'
```
44.1 Introduction

This interface is extremely flexible, since it’s exactly like typing into the Singular interpreter, and anything that works there should work here.

The Singular interface will only work if Singular is installed on your computer; this should be the case, since Singular is included with Sage. The interface offers three pieces of functionality:

1. `singular_console()` – A function that dumps you into an interactive command-line Singular session.

2. `singular(expr, type='def')` – Creation of a Singular object. This provides a Pythonic interface to Singular. For example, if `f=singular(10)`, then `f.factorize()` returns the factorization of 10 computed using Singular.

3. `singular.eval(expr)` – Evaluation of arbitrary Singular expressions, with the result returned as a string.

Of course, there are polynomial rings and ideals in Sage as well (often based on a C-library interface to Singular). One can convert an object in the Singular interpreter interface to Sage by the method `sage()`.

44.2 Tutorial

EXAMPLES: First we illustrate multivariate polynomial factorization:

```python
sage: R1 = singular.ring(0, '(x,y)', 'dp')
sage: R1
polynomial ring, over a field, global ordering
// coefficients: QQ
// number of vars : 2
// block 1 : ordering dp
// : names x y
// block 2 : ordering C
sage: f = singular('9*x^16 - 18*x^13*y^2 - 9*x^12*y^3 + 9*x^10*y^4 - 18*x^11*y^2 + 36*x^8*y^4 + 18*x^7*y^5 - 18*x^5*y^6 + 9*x^6*y^4 - 18*x^3*y^6 - 9*x^2*y^7 + 9*y^8')
sage: f
9*x^16-18*x^13*y^2-9*x^12*y^3+9*x^10*y^4-18*x^11*y^2+36*x^8*y^4+18*x^7*y^5-18*x^5*y^6+9*x^6*y^4-18*x^3*y^6-9*x^2*y^7+9*y^8
sage: f.parent()
Singular
```

```python
>>> from sage.all import *
>>>
>>> R1 = singular.ring(Integer(0), '(x,y)', 'dp')
(continues on next page)
```
```python
>>> R1
polynomial ring, over a field, global ordering
// coefficients: QQ
// number of vars : 2
// block 1 : ordering dp
// : names x y
// block 2 : ordering C
>>> f = singular('9x16 - 18x13y2 - 9x12y3 + 9x10y4 - 18x11y2 + 36x8y4 + 18x7y5 -
˓→18x5y6 + 9x6y4 - 18x3y6 - 9x2y7 + 9y8')
>>> f
9*x^16-18*x^13*y^2-9*x^12*y^3+9*x^10*y^4-18*x^11*y^2+36*x^8*y^4+18*x^7*y^5-18*x^5*y^6+9*x^6*y^4-18*x^3*y^6-9*x^2*y^7+9*y^8
>>> f.parent()
Singular
```

```python
sage: F = f.factorize(); F
[1]:
  _[1]=9
  _[2]=x^6-2*x^3*y^2-x^2*y^3+y^4
  _[3]=-x^5+y^2
[2]:
  1,1,2

>>> from sage.all import *

```sage```

```
>>> F = f.factorize(); F
[1]:
  _[1]=9
  _[2]=x^6-2*x^3*y^2-x^2*y^3+y^4
  _[3]=-x^5+y^2
[2]:
  1,1,2
```

```python
sage: F[1][2].sage()
x^6 - 2*x^3*y^2 - x^2*y^3 + y^4
```

```python
sage: g = f.sage(); g
9*x^16 - 18*x^13*y^2 - 9*x^12*y^3 + 9*x^10*y^4 - 18*x^11*y^2 + 36*x^8*y^4 + 18*x^7*y^˓→5 - 18*x^5*y^6 + 9*x^6*y^4 - 18*x^3*y^6 - 9*x^2*y^7 + 9*y^8
```

```python
sage: F[1][2].sage()
x^6 - 2*x^3*y^2 - x^2*y^3 + y^4
```

We can convert \( f \) and each exponent back to Sage objects as well.

```python
sage: F[Integer(1)]
9,
x^6-2*x^3*y^2-x^2*y^3+y^4,
-x^5+y^2
```

```python
sage: g.parent()
```

(continues on previous page)
Multivariate Polynomial Ring in x, y over Rational Field

```
>>> from sage.all import *
>>> g = f.sage(); g
9*x^16 - 18*x^13*y^2 - 9*x^12*y^3 + 9*x^10*y^4 - 18*x^11*y^2 + 36*x^8*y^4 + 18*x^7*y^5 - 18*x^5*y^6 + 9*x^6*y^4 - 18*x^3*y^6 - 9*x^2*y^7 + 9*y^8
>>> F[Integer(1)][Integer(2)].sage()
F
>>> g.parent()
Multivariate Polynomial Ring in x, y over Rational Field
```

This example illustrates polynomial GCD's:

```
sage: R2 = singular.ring(0, (x,y,z), lp)
sage: a = singular.new('3x^2*(x+y)')
sage: b = singular.new('9x*(y^2-x^2)')
sage: g = a.gcd(b)
sage: g
x^2+x*y
```

This example illustrates computation of a Groebner basis:

```
sage: R3 = singular.ring(0, '(a,b,c,d)’, ’lp’)  
sage: I = singular.ideal([a + b + c + d, a*b + a*d + b*c + c*d, a*b*c + a*b*d +__-a*c*d + b*c*d, ’a*b*c*d - 1’])
sage: I2 = I.groebner()
sage: I2
a^2*d^6-a^2*d^2-d^4+1,
a^3*d^2+c^2*d^3-c-d,
b*d^4-b*d^5-d,
b*c-b*d^5+c^2*d^4+c*d-d^6-d^2,
b^2+2*b*d^2,
a+b+c+d
```

The following example is the same as the one in the Singular - Gap interface documentation:
This example illustrates moving a polynomial from one ring to another. It also illustrates calling a method of an object with an argument.

We can calculate the Milnor number of $f$:

```python
sage: R = singular.ring(0, '(x,y,z)', 'dp')
sage: f = singular('x^3*y^2-x^2*y^3+x^3+y^3+z^2')
sage: f
x^3*y^2-x^2*y^3+x^3+y^3+z^2
sage: R1 = singular.ring(Integer(0), '(x,y,z)', 'ds')
sage: f = R.fetch(f)
sage: f
z^2+x^3+y^3+x^3*y^2-x^2*y^3
```

```python
>>> from sage.all import *
>>> R = singular.ring(Integer(0), '(x,y,z)', 'dp')
>>> f = singular('x^3*y^2-x^2*y^3+x^3+y^3+z^2')
>>> f
x^3*y^2-x^2*y^3+x^3+y^3+z^2
>>> R1 = singular.ring(Integer(0), '(x,y,z)', 'ds')
>>> f = R.fetch(f)
>>> f
z^2+x^3+y^3+x^3*y^2-x^2*y^3
```

```python
>>> from sage.all import *
>>> R = singular.ring(Integer(0), '(x,y,z)', 'dp')
>>> f = singular('x^3*y^2-x^2*y^3+x^3+y^3+z^2')
>>> f
x^3*y^2-x^2*y^3+x^3+y^3+z^2
>>> R1 = singular.ring(Integer(0), '(x,y,z)', 'ds')
>>> f = R.fetch(f)
>>> f
z^2+x^3+y^3+x^3*y^2-x^2*y^3
```

We can calculate the Milnor number of $f$:

```python
sage: __=singular.LIB('sing.lib')  # assign to __ to suppress printing
sage: f.milnor()
4
```
The Jacobian applied twice yields the Hessian matrix of $f$, with which we can compute.

```
sage: H = f.jacob().jacob()
sage: H
6*x+6*x*y^2-2*y^3, 6*x^2*y-6*x*y^2, 0,
6*x^2*y-6*x*y^2, 6*y+2*x^3-6*x^2*y,0,
0, 0, 2
sage: H.sage()
[6*x + 6*x*y^2 - 2*y^3 6*x^2*y - 6*x*y^2 0]
[ 6*x^2*y - 6*x*y^2 6*y + 2*x^3 - 6*x^2*y 0]
[ 0 0 2]
sage: H.det() # This is a polynomial in Singular
72*x*y+24*x^4-72*x^3*y+72*x*y^3-24*y^4-48*x^4*y^2+64*x^3*y^3-48*x^2*y^4
sage: H.det().sage() # This is the corresponding polynomial in Sage
72*x*y + 24*x^4 - 72*x^3*y + 72*x*y^3 - 24*y^4 - 48*x^4*y^2 + 64*x^3*y^3 - 48*x^2*y^4
```

The 1x1 and 2x2 minors:

```
sage: H.minor(1)
2,
6*y+2*x^3-6*x^2*y,
6*x^2*y-6*x*y^2,
6*x+6*x*y^2-2*y^3,
0, 0, 0
sage: H.minor(2)
12*y^4*x^3-12*x^2*y,
12*x^2*y-12*x*y^2,
12*x^2*y-12*x*y^2,
12*x+12*x*y^2-4*y^3,
-36*x*y-12*x^4+36*x^3*y-36*x*y^3+12*y^4+24*x^4*y^2-32*x^3*y^3+24*x^2*y^4,
0, 0, 0
```

(continues on next page)
>>> from sage.all import *
>>> H.minor(Integer(1))
2,
6*y^2+2*x^3-6*x^2*y,
6*x^2*y-6*x*y^2,

6*x+6*x*y^2-2*y^3,
0,
0,
0,
0

>>> H.minor(Integer(2))
12*y+4*x^3-12*x^2*y,
12*x^2*y-12*x*y^2,
12*x^2*y-12*x*y^2,
12*x+12*x*y^2-4*y^3,
-36*x*y-12*x^4+36*x^3*y-36*x*y^3+12*y^4+24*x^4*y^2-32*x^3*y^3+24*x^2*y^4,
0,
0,
0,
0

>>> from sage.all import *
>>> _=singular.eval('option(redSB)')
>>> H.minor(1).groebner()
1

>>> from sage.all import *
>>> _=singular.eval('option(redSB)')
>>> H.minor(Integer(1)).groebner()
1

44.3 Computing the Genus

We compute the projective genus of ideals that define curves over \( \mathbb{Q} \). It is very important to load the normal.lib library before calling the genus command, or you'll get an error message.

EXAMPLES:

```python
sage: singular.lib('normal.lib')
sage: R = singular.ring(0,'(x,y)','dp')
sage: i2 = singular.ideal('y^9 - x^2*(x-1)^9 + x')
sage: i2.genus()
40
```

```python
>>> from sage.all import *
>>> singular.lib('normal.lib')
>>> R = singular.ring(Integer(0),'(x,y)','dp')
>>> i2 = singular.ideal('y^9 - x^2*(x-1)^9 + x')
>>> i2.genus()
40
```

Note that the genus can be much smaller than the degree:
44.4 An Important Concept

The following illustrates an important concept: how Sage interacts with the data being used and returned by Singular. Let's compute a Groebner basis for some ideal, using Singular through Sage.

```
sage: singular.lib('polylib.lib')
sage: singular.ring(32003, '(a,b,c,d,e,f)', 'lp')
   polynomial ring, over a field, global ordering
   // coefficients: ZZ/32003
   // number of vars : 6
   // block 1 : ordering lp
   // : names    a b c d e f
   // block 2 : ordering C
sage: I = singular.ideal('cyclic(6)')
sage: g = singular('groebner(I)')
Traceback (most recent call last):
  ... TypeError: Singular error: ...
```

We restart everything and try again, but correctly.

```
sage: singular.quit()
sage: singular.lib('polylib.lib'); R = singular.ring(32003, '(a,b,c,d,e,f)', 'lp')
sage: I = singular.ideal('cyclic(6)')
sage: I.groebner()
f^48-2554*f^42-15674*f^36+12326*f^30-12326*f^18+15674*f^12+2554*f^6-1,
```

44.4 An Important Concept
It's important to understand why the first attempt at computing a basis failed. The line where we gave Singular the input `groebner(I)` was useless because Singular has no idea what `I` is! Although `I` is an object that we computed with calls to Singular functions, it actually lives in Sage. As a consequence, the name `I` means nothing to Singular. When we called `I.groebner()`, Sage was able to call the groebner function on `I` in Singular, since `I` actually means something to Sage.

### 44.5 Long Input

The Singular interface reads in even very long input (using files) in a robust manner, as long as you are creating a new object.

```python
sage: t = r"%s"%10^15000 # 15 thousand character string (note that normal Singular input must be at most 10000)
sage: a = singular.eval(t)
sage: a = singular(t)
```

AUTHORS:
- David Joyner and William Stein (2005): first version
- Neal Harris (unknown): perhaps added “An Important Concept”
- Martin Albrecht (2006-03-05): code so singular.[tab] and x = singular(…). x.[tab] includes all singular commands.
- Martin Albrecht (2006-03-06): This patch adds the equality symbol to singular. Also fix a problem in which “ “ as prompt means comparison will break all further communication with Singular.
- Martin Albrecht (2006-03-13): added current_ring() and current_ring_name()
- Simon King (2010-11-23): Reduce the overhead caused by waiting for the Singular prompt by doing garbage collection differently.
- Simon King (2011-06-06): Make conversion from Singular to Sage more flexible.

```python
class sage.interfaces.singular.Singular(maxread=None, script_subdirectory=None, logfile=None, server=None, server_tmpdir=None, seed=None):
    Bases: ExtraTabCompletion, Expect
```

Chapter 44. Interface to Singular
Interface to the Singular interpreter.

EXAMPLES: A Groebner basis example.

```python
sage: R = singular.ring(0, '(x0,x1,x2)', 'lp')
sage: I = singular.ideal([ 'x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2', 'x0*x1-x0*x2-x1*x2'])
sage: I.groebner()
x1^2*x2^2,
x0*x2^3-x1^2*x2^2+x1*x2^3,
x0*x1-x0*x2-x1*x2,
x0^2*x2-x0*x2^2-x1*x2^2
```

AUTHORS:

- David Joyner and William Stein

**LIB**(lib, reload=False)

Load the Singular library named lib.

Note that if the library was already loaded during this session it is not reloaded unless the optional reload argument is True (the default is False).

EXAMPLES:

```python
sage: singular.lib('sing.lib')
sage: singular.lib('sing.lib', reload=True)
```

**clear**(var)

Clear the variable named var.

EXAMPLES:

```python
sage: singular.set('int', 'x', '2')
sage: singular.get('x')
'2'
sage: singular.clear('x')
```
“Clearing the variable” means to allow to free the memory that it uses in the Singular sub-process. However, the actual deletion of the variable is only committed when the next element in the Singular interface is created:

```
sage: singular.get('x')
'2'
sage: a = singular(3)
sage: singular.get('x')
'
```

```
>>> from sage.all import *
>>> singular.get('x')
'2'
>>> a = singular(Integer(3))
>>> singular.get('x')
'
```

console()

EXAMPLES:

```
sage: singular_console() #not tested
SINGULAR / Development
A Computer Algebra System for Polynomial Computations / version 3-0-4
0<
FB Mathematik der Universitaet, D-67653 Kaiserslautern \

>>> from sage.all import *
>>> singular_console() #not tested
SINGULAR / Development
A Computer Algebra System for Polynomial Computations / version 3-0-4
0<
FB Mathematik der Universitaet, D-67653 Kaiserslautern \
```

```
cputime(t=None)

Return the amount of CPU time that the Singular session has used. If t is not None, then it returns the difference between the current CPU time and t.

EXAMPLES:

```
sage: t = singular.cputime()
sage: R = singular.ring(0, '(x0,x1,x2)', 'lp')
sage: I = singular.ideal(['x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2', 'x0*x1-x0*x2-x1*x2'])
sage: gb = I.groebner()
sage: singular.cputime(t) #random
0.02

>>> from sage.all import *
>>> t = singular.cputime()
>>> R = singular.ring(Integer(0), '(x0,x1,x2)', 'lp')
>>> I = singular.ideal(['x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2', 'x0*x1-x0*x2-x1*x2'])
>>> gb = I.groebner()
>>> singular.cputime(t) #random
0.02
```
current_ring()

Return the current ring of the running Singular session.

EXAMPLES:

```sage
sage: r = PolynomialRing(GF(127), 3, 'xyz', order='invlex')
sage: r._singular_()
polynomial ring, over a field, global ordering
// coefficients: ZZ/127
// number of vars : 3
// block 1 : ordering ip
// : names x y z
// block 2 : ordering C
```

```sage
sage: singular.current_ring()
polynomial ring, over a field, global ordering
// coefficients: ZZ/127
// number of vars : 3
// block 1 : ordering ip
// : names x y z
// block 2 : ordering C
```

```sage
>>> from sage.all import *

>>> r = PolynomialRing(GF(Integer(127)), Integer(3), 'xyz', order='invlex')

>>> r._singular_().name() == singular.current_ring_name()
True
```

current_ring_name()

Return the Singular name of the currently active ring in Singular.

OUTPUT: currently active ring’s name

EXAMPLES:

```sage
sage: r = PolynomialRing(GF(127), 3, 'xyz')
sage: r._singular_().name() == singular.current_ring_name()
True
```

```sage
>>> from sage.all import *

>>> r = PolynomialRing(GF(Integer(127)), Integer(3), 'xyz')

>>> r._singular_().name() == singular.current_ring_name()
True
```

eval(x, allow_semicolon=True, strip=True, **kwds)

Send the code x to the Singular interpreter and return the output as a string.

INPUT:
- `x` – string (of code)
- `allow_semicolon` – default: False; if False then raise a `TypeError` if the input line contains a semicolon.
- `strip` – ignored

**EXAMPLES:**

```python
sage: singular.eval('2 > 1')
'1'
sage: singular.eval('2 + 2')
'4'
```

```python
>>> from sage.all import *

>>> singular.eval('2 > 1')
'1'

>>> singular.eval('2 + 2')
'4'
```

If the verbosity level is > 1 comments are also printed and not only returned.

```python
sage: r = singular.ring(0,'(x,y,z)','dp')
sage: i = singular.ideal(['x^2','y^2','z^2'])
sage: s = i.std()
sage: singular.eval(hilb('%s')%(s.name()))
'...// dimension (affine) = 0
// degree (affine) = 8'
```

```python
>>> from sage.all import *

>>> from sage.misc.verbose import set_verbose

>>> set_verbose(1)

>>> o = singular.eval(hilb('%s')%(s.name()))
'...// dimension (affine) = 0
// degree (affine) = 8
...
```

```python
>>> from sage.misc.verbose import set_verbose

>>> set_verbose(Integer(1))

>>> o = singular.eval(hilb('%s')%(s.name()))
'...// dimension (affine) = 0
// degree (affine) = 8

```

This is mainly useful if this method is called implicitly. Because then intermediate results, debugging outputs and printed statements are printed.

```python
sage: o = s.hilb()
'...// dimension (affine) = 0
// degree (affine) = 8
// ** right side is not a datum, assignment ignored
...'
```
>>> from sage.all import *
>>> o = s.hilb()
...// dimension (affine) = 0
// degree (affine) = 8
// ** right side is not a datum, assignment ignored
...

rather than ignored

sage: set_verbose(0)
sage: o = s.hilb()

>>> from sage.all import *
>>> set_verbose(Integer(0))
>>> o = s.hilb()

get(var)
Get string representation of variable named var.

EXAMPLES:

sage: singular.set('int', 'x', '2')
sage: singular.get('x')
'2'

ideal(*gens)
Return the ideal generated by gens.

INPUT:

• gens – list or tuple of Singular objects (or objects that can be made into Singular objects via evaluation)

OUTPUT: the Singular ideal generated by the given list of gens

EXAMPLES: A Groebner basis example done in a different way.

sage: _ = singular.eval("ring R=0,(x0,x1,x2),lp")
sage: i1 = singular.ideal([ 'x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-
\rightarrow x0*x1*x2^2', 'x0*x1-x0*x2-x1*x2'])
sage: i1
-x0^2*x2+x0*x1*x2,
x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2,
x0*x1-x0*x2-x1*x2

>>> from sage.all import *
>>> _ = singular.eval("ring R=0,(x0,x1,x2),lp")
>>> i1 = singular.ideal([ 'x0*x1*x2 -x0^2*x2', 'x0^2*x1*x2-x0*x1^2*x2-
\rightarrow x0*x1*x2^2', 'x0*x1-x0*x2-x1*x2'])
>>> i1
-x0^2*x2+x0*x1*x2,
x0^2*x1*x2-x0*x1^2*x2-x0*x1*x2^2,
x0*x1-x0*x2-x1*x2
Interpreter Interfaces, Release 10.4

```
sage: i2 = singular.ideal('groebner(%s);\%il.name())
sage: i2
x1^2*x2^2,
x0*x2^3-x1^2*x2^2+x1*x2^3,
x0^2*x2-x0*x2^2-x1*x2^2

>>> from sage.all import *
>>> i2 = singular.ideal('groebner(%s);\%il.name())
>>> i2
x1^2*x2^2,
x0*x2^3-x1^2*x2^2+x1*x2^3,
x0^2*x2-x0*x2^2-x1*x2^2
```

**lib**(*lib*, **reload=False**)

Load the Singular library named *lib*.

Note that if the library was already loaded during this session it is not reloaded unless the optional reload argument is True (the default is False).

**EXAMPLES:**

```
sage: singular.lib('sing.lib')
sage: singular.lib('sing.lib', reload=True)
```

```
>>> from sage.all import *
>>> singular.lib('sing.lib')
>>> singular.lib('sing.lib', reload=True)
```

**list**(*x*)

Creates a list in Singular from a Sage list *x*.

**EXAMPLES:**

```
sage: singular.list([1,2])
[1]:
  1
[2]:
  2

sage: singular.list([[1,2],[3,4]])
[1]:
  1
[2]:
  2
[3]:
  [1]:
    3
  [2]:
    4

sage: R.<x,y> = QQ[]
sage: singular.list({1,2,[x,ideal(x,y)]})
[1]:
  1
[2]:
```

(continues on next page)
>>> from sage.all import *
>>> singular.list([Integer(1), Integer(2)])
[1]:
   1
[2]:
   2

>>> singular.list([Integer(1), Integer(2), [Integer(3), Integer(4)]])
[1]:
   1
[2]:
   2
[3]:
   [1]:
      3
   [2]:
      4

>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> singular.list([Integer(1), Integer(2), [x, ideal(x, y)]]])
[1]:
   1
[2]:
   2
[3]:
   [1]:
      x
   [2]:
      _[1]=x
      _[2]=y

Strings have to be escaped before passing them to this method:

sage: singular.list([1, 2, "hi"])
[1]:
   1
[2]:
   2
[3]:
   hi

>>> from sage.all import *
>>> singular.list([Integer(1), Integer(2), "hi"])
[1]:
   1
[2]:
   2
[3]:
   hi

(continues on next page)
load(lib, reload=False)

Load the Singular library named lib.

Note that if the library was already loaded during this session it is not reloaded unless the optional reload argument is True (the default is False).

EXAMPLES:

sage: singular.lib('sing.lib')
sage: singular.lib('sing.lib', reload=True)

matrix(nrows, ncols, entries=None)

EXAMPLES:

sage: singular.lib("matrix")
sage: R = singular.ring(0, '(x,y,z)', 'dp')
sage: A = singular.matrix(3,2,'1,2,3,4,5,6')
sage: A
1,2,
3,4,
5,6
sage: A.gauss_col() 2,-1,
1,0,
0,1

AUTHORS:
• Martin Albrecht (2006-01-14)

option(cmd=None, val=None)

Access to Singular's options as follows:

Syntax: option() Returns a string of all defined options.
Syntax: option('option_name') Sets an option. Note to disable an option, use the prefix no.
Syntax: option('get') Returns an intvec of the state of all options.
Syntax: option( 'set', intvec_expression ) Restores the state of all options from an intvec (produced by option('get')).

EXAMPLES:

```
sage: singular.option()
//options: redefine loadLib usage prompt
sage: singular.option('get')
0, 10321
sage: old_options = _
sage: singular.option('noredefine')
//options: loadLib usage prompt
sage: singular.option('set', old_options)
sage: singular.option('get')
0, 10321

>>> from sage.all import *
>>> singular.option()
//options: redefine loadLib usage prompt
>>> singular.option('get')
0, 10321
>>> old_options = _
>>> singular.option('noredefine')
>>> singular.option()
//options: loadLib usage prompt
>>> singular.option('set', old_options)
>>> singular.option('get')
0, 10321
```

```
ring (char=0, vars='(x)', order='lp', check=None)
Create a Singular ring and makes it the current ring.

INPUT:

- char (string) – a string specifying the characteristic of the base ring, in the format accepted by Singular (see examples below).
- vars – a tuple or string defining the variable names
- order (string) – the monomial order (default: “lp”)

OUTPUT: a Singular ring

Note: This function is not identical to calling the Singular ring function. In particular, it also attempts to “kill” the variable names, so they can actually be used without getting errors, and it sets printing of elements for this range to short (i.e., with *'s and carets).

EXAMPLES: We first declare \( \mathbb{Q}[x, y, z] \) with degree reverse lexicographic ordering.

```
sage: R = singular.ring(0, '(x,y,z)', 'dp')
sage: R
polynomial ring, over a field, global ordering
// coefficients: QQ
```

(continues on next page)
Interpreter Interfaces, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
>>> R = singular.ring(Integer(0), (x,y,z), dp)
>>> R
polynomial ring, over a field, global ordering
// coefficients: QQ
// number of vars : 3
// block 1 : ordering dp
// : names x y z
// block 2 : ordering C
```

```python
sage: R1 = singular.ring(32003, (x,y,z), dp)
sage: R2 = singular.ring(32003, (a,b,c,d), lp)
```

This is a ring in variables named x(1) through x(10) over the finite field of order 7:

```python
sage: R3 = singular.ring(7, (x(1..10)), ds)
```

This is a polynomial ring over the transcendental extension $\mathbb{Q}(a)$ of $\mathbb{Q}$:

```python
sage: R4 = singular.ring('(0,a)', '(mu,nu)', 'lp')
```

This is a ring over the field of single-precision floats:

```python
sage: R5 = singular.ring('real', '(a,b)', 'lp')
```

This is over 50-digit floats:

```python
sage: R6 = singular.ring('(real,50)', '(a,b)', 'lp')
sage: R7 = singular.ring('(complex,50,i)', '(a,b)', 'lp')
```

To use a ring that you’ve defined, use the set_ring() method on the ring. This sets the ring to be the “current ring”. For example,
Interpreter Interfaces, Release 10.4

```python
sage: R = singular.ring(7, '(a,b)', 'ds')
sage: S = singular.ring('real', '(a,b)', 'lp')
sage: singular.new('10*a')
(1.000e+01)*a
sage: R.set_ring()
sage: singular.new('10*a')
3*a
```

```python
>>> from sage.all import *

>>> R = singular.ring(Integer(7), '(a,b)', 'ds')

>>> S = singular.ring('real', '(a,b)', 'lp')

>>> singular.new('10*a')
(1.000e+01)*a

>>> R.set_ring()

>>> singular.new('10*a')
3*a
```

**set** *(type, name, value)*

Set the variable with given name to the given value.

**REMARK:**

If a variable in the Singular interface was previously marked for deletion, the actual deletion is done here, before the new variable is created in Singular.

**EXAMPLES:**

```python
sage: singular.set('int', 'x', '2')
sage: singular.get('x')
'2'
```

```python
>>> from sage.all import *

>>> singular.set('int', 'x', '2')

>>> singular.get('x')
'2'
```

We test that an unused variable is only actually deleted if this method is called:

```python
sage: a = singular(3)
sage: n = a.name()
sage: del a
sage: singular.eval(n)
3
sage: singular.set('int', 'y', '5')
sage: singular.eval('defined($s')?n')
0
```

```python
>>> from sage.all import *

>>> a = singular(Integer(3))

>>> n = a.name()

>>> del a

>>> singular.eval('int', 'y', '5')

>>> singular.eval('defined($s')?n')
0
```

44.5. Long Input 535
**set_ring** (*R*)

Sets the current Singular ring to *R*.

**EXAMPLES:**

```
sage: R = singular.ring(7, '(a,b)', 'ds')
sage: S = singular.ring('real', '(a,b)', 'lp')
sage: singular.current_ring()
// coefficients: Float()
// number of vars : 2
// block 1 : ordering lp
// : names a b
// block 2 : ordering C
```

```
sage: singular.set_ring(R)
sage: singular.current_ring()
// coefficients: ZZ/7
// number of vars : 2
// block 1 : ordering ds
// : names a b
// block 2 : ordering C
```

```
>>> from sage.all import *
>>> R = singular.ring(Integer(7), (a,b), ds)
>>> S = singular.ring(real, (a,b), lp)
>>> singular.current_ring()
// coefficients: Float()
// number of vars : 2
// block 1 : ordering lp
// : names a b
// block 2 : ordering C
```

**set_seed** (*seed= None*)

Set the seed for Singular interpreter.

**EXAMPLES:**

```
sage: s = Singular()
sage: s.set_seed(1)
1
sage: [s.random(1,10) for i in range(5)]
[8, 10, 4, 9, 1]
```

```
>>> from sage.all import *
>>> s = Singular()
```

(continues on next page)
>>> s.set_seed(Integer(1))
1
>>> [s.random(Integer(1), Integer(10)) for i in range(Integer(5))]
[8, 10, 4, 9, 1]

\textbf{setring} (R)

Sets the current Singular ring to $R$.

\textbf{EXAMPLES:}

\begin{verbatim}
    sage: R = singular.ring(7, '(a,b)', 'ds')
    sage: S = singular.ring('real', '(a,b)', 'lp')
    sage: singular.current_ring()
    polynomial ring, over a field, global ordering
    // coefficients: Float()
    // number of vars : 2
    // block 1 : ordering lp
    // : names a b
    // block 2 : ordering C
    sage: singular.set_ring(R)
    sage: singular.current_ring()
    polynomial ring, over a field, local ordering
    // coefficients: ZZ/7
    // number of vars : 2
    // block 1 : ordering ds
    // : names a b
    // block 2 : ordering C

    >>> from sage.all import *
    >>> R = singular.ring(Integer(7), '(a,b)', 'ds')
    >>> S = singular.ring('real', '(a,b)', 'lp')
    >>> singular.current_ring()
    polynomial ring, over a field, global ordering
    // coefficients: Float()
    // number of vars : 2
    // block 1 : ordering lp
    // : names a b
    // block 2 : ordering C
    >>> singular.set_ring(R)
    >>> singular.current_ring()
    polynomial ring, over a field, local ordering
    // coefficients: ZZ/7
    // number of vars : 2
    // block 1 : ordering ds
    // : names a b
    // block 2 : ordering C
\end{verbatim}

\textbf{string} ($x$)

Creates a Singular string from a Sage string. Note that the Sage string has to be “double-quoted”.

\textbf{EXAMPLES:}

\begin{verbatim}
    sage: singular.string("Sage")
    Sage
\end{verbatim}
version()

Return the version of Singular being used.

EXAMPLES:

```python
sage: singular.version()
*Singular ... version 4...
```

```
>>> from sage.all import *
>>> singular.version()
*Singular ... version 4...
```

class sage.interfaces.singular.SingularElement (parent, type, value, is_name=False)

Bases: ExtraTabCompletion, ExpectElement, SingularElement

EXAMPLES:

```python
sage: a = singular(2)
sage: loads(dumps(a))
2
```

```python
>>> from sage.all import *
>>> a = singular(Integer(2))
>>> loads(dumps(a))
2
```

attrib (name, value=None)

Get and set attributes for self.

INPUT:

- name – string to choose the attribute
- value – boolean value or None for reading, (default:None)

VALUES: isSB - the standard basis property is set by all commands computing a standard basis like groebner, std, stdhilb etc.; used by lift, dim, degree, mult, hilb, vdim, kbase isHomog - the weight vector for homogeneous or quasihomogeneous ideals/modules isCI - complete intersection property isCM - Cohen-Macaulay property rank - set the rank of a module (see nrows) withSB - value of type ideal, resp.
module, is std withHilb - value of type intvec is Hilb(_,1) (see hilb) withRes - value of type list is a free resolution withDim - value of type int is the dimension (see dim) withMult - value of type int is the multiplicity

(see mult)

EXAMPLES:

```python
sage: P.<x,y,z> = PolynomialRing(QQ)
sage: I = Ideal([z^2, y*z, y^2, x*z, x*y, x^2])
sage: Ibar = I._singular_()
sage: Ibar.attrib('isSB')
0
```

```python
sage: singular.eval(vdim\$(\%s)\%Ibar.name()) \# sage7 name is random
// ** sage7 is no standard basis
4
```

(continues on next page)
sage: Ibar.attrib('isSB',1)
sage: singular.eval('vdim($s')%Ibar.name()')
'4'

>>> from sage.all import *
>>> P = PolynomialRing(QQ, names=('x', 'y', 'z')); (x, y, z) = P._first_classnings(3)
>>> I = Ideal([z**Integer(2), y*z, y**Integer(2), x*z, x*y, x**Integer(2)])
>>> Ibar = I._singular_()
>>> Ibar.attrib('isSB')
0
>>> singular.eval('vdim($s')%Ibar.name()) # sage7 name is random
// ** sage7 is no standard basis
4
>>> Ibar.attrib('isSB',Integer(1))
>>> singular.eval('vdim($s')%Ibar.name()')
'4'

is_string()
Tell whether this element is a string.

EXAMPLES:

sage: singular("abc").is_string()
True
sage: singular('1').is_string()
False

>>> from sage.all import *
>>> singular("abc").is_string()
True
>>> singular('1').is_string()
False

sage_flattened_str_list()

EXAMPLES:

sage: R=singular.ring(0,(x,y),dp)
sage: RL = R.ringlist()
sage: RL.sage_flattened_str_list()
[0, x, y, dp, 1,1, C, 0, _[1]=0]

>>> from sage.all import *
>>> R=singular.ring(Integer(0),(x,y),dp)
>>> RL = R.ringlist()
>>> RL.sage_flattened_str_list()
[0, x, y, dp, 1,1, C, 0, _[1]=0]

sage_global_ring()
Return the current basering in Singular as a polynomial ring or quotient ring.

EXAMPLES:

sage: singular.eval('ring r1 = (9,x),(a,b,c,d,e,f), (M((1,2,3,0)),wp(2,3),lp)')
''

(continues on next page)
Real and complex fields in both Singular and Sage are defined with a precision. The precision in Singular is
given in terms of digits, but in Sage it is given in terms of bits. So, the digit precision is internally converted to a reasonable bit precision:

```plaintext
sage: singular.eval('ring r4 = (real,20),(a,b,c),dp')
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```

In our last example, the base ring is a quotient ring:

```plaintext
sage: singular.eval('ring r6 = (9,a), (x,y,z),lp')

sage: Q = singular('std(ideal(x^2,x+y^2+z^3)), type=qring')

Quotient of Multivariate Polynomial Ring in x, y, z over Finite Field in a of size 3^2 by the ideal (y^4 - y^2*z^3 + z^6, x + y^2 + z^3)
```

AUTHOR:

• Simon King (2011-06-06)

`sage_matrix(R, sparse=True)`

Return Sage matrix for self.

INPUT:

• `R` – (default: None); an optional ring, over which the resulting matrix is going to be defined. By default, the output of `sage_global_ring()` is used.

• `sparse` – (default: True); determines whether the resulting matrix is sparse or not.

EXAMPLES:

```plaintext
sage: R = singular.ring(0, '(x,y,z)', 'dp')

sage: A = singular.matrix(2,2)

sage: A.sage_matrix(ZZ)

[0 0]
[0 0]

sage: A.sage_matrix(RDF)

[0.0 0.0]
[0.0 0.0]

>>> from sage.all import *

>>> R = singular.ring(Integer(0), '(x,y,z)', 'dp')

>>> A = singular.matrix(Integer(2),Integer(2))

>>> A.sage_matrix(ZZ)

[0 0]
[0 0]

>>> A.sage_matrix(RDF)

[0.0 0.0]
[0.0 0.0]
```

542 Chapter 44. Interface to Singular
sage_poly \( (R=None, kcache=None) \)

Return a Sage polynomial in the ring \( r \) matching the provided \( \text{poly} \) which is a singular polynomial.

**INPUT:**

- \( R \) – (default: None); an optional polynomial ring. If it is provided, then you have to make sure that it matches the current singular ring as, e.g., returned by \( \text{singular.current_ring()} \). By default, the output of \( \text{sage_global_ring()} \) is used.
- \( kcache \) – (default: None); an optional dictionary for faster finite field lookups, this is mainly useful for finite extension fields

**OUTPUT:** MPolynomial

**EXAMPLES:**

```python
sage: R = PolynomialRing(GF(2^8, 'a'), ['x', 'y'])
sage: f = R('a^20*x^2*y+a^10+x')
sage: f._singular_().sage_poly(R) == f
True
sage: R = PolynomialRing(GF(2^8, 'a'), ['x'], implementation="singular")
sage: f = R('a^20*x^3+x^2+a^10')
sage: f._singular_().sage_poly(R) == f
True

>>> from sage.all import *
>>> R = PolynomialRing(GF(Integer(2)**Integer(8), 'a'), ['x', 'y'])
>>> f = R('a^20*x^3+x^2+a^10')
>>> f._singular_().sage_poly(R) == f
True

sage: P.<x,y> = PolynomialRing(QQ, 2)
sage: f = x*y^3 - 1/9 * x + 1; f
x*y^3 - 1/9*x + 1
sage: singular(f)
x*y^3-1/9*x+1
sage: P(singular(f))
x*y^3 - 1/9*x + 1

>>> from sage.all import *
>>> P = PolynomialRing(QQ, Integer(2), names=('x', 'y'),); (x, y,) = P._first_ngens(2)
>>> f = x*y**Integer(3) - Integer(1)/Integer(9) * x + Integer(1); f
x*y^3 - 1/9*x + 1
>>> singular(f)
x*y^3-1/9*x+1
>>> P(singular(f))
x*y^3 - 1/9*x + 1
```

**AUTHORS:**

- Martin Albrecht (2006-05-18)
- Simon King (2011-06-06): Deal with Singular’s short polynomial representation, automatic construction of a polynomial ring, if it is not explicitly given.

44.5. Long Input 543
Note: For very simple polynomials `eval(SingularElement.sage_polystring())` is faster than `SingularElement.sage_poly(R)`, maybe we should detect the crossover point (in dependence of the string length) and choose an appropriate conversion strategy.

**sage_polystring()**

If this Singular element is a polynomial, return a string representation of this polynomial that is suitable for evaluation in Python. Thus `*` is used for multiplication and `**` for exponentiation. This function is primarily used internally.

The short=0 option must be set for the parent ring or this function will not work as expected. This option is set by default for rings created using `singular.ring` or set using `ring_name.set_ring()`.

**EXAMPLES:**

```
sage: R = singular.ring(0,'(x,y)')
sage: f = singular('x^3 + 3*y^11 + 5')
sage: f
x^3+3*y^11+5
sage: f.sage_polystring()
'x**3+3*y**11+5'
```

```
>>> from sage.all import *
>>> R = singular.ring(Integer(0),'(x,y)')
>>> f = singular('x^3 + 3*y^11 + 5')
>>> f
x^3+3*y^11+5
>>> f.sage_polystring()
'x**3+3*y**11+5'
```

**sage_structured_str_list()**

If self is a Singular list of lists of Singularelements, returns corresponding Sage list of lists of strings.

**EXAMPLES:**

```
sage: R=singular.ring(0,'(x,y)','dp')
sage: RL=R.ringlist()
sage: RL
[1]:
  0
[2]:
  [1]:
   x
  [2]:
   y
[3]:
  [1]:
   [1]:
    dp
   [2]:
    1,1
  [2]:
   [1]:
    C
   [2]:
    0
[4]:
```

(continues on next page)
sage: RL.sage_structured_str_list()
[0, ['x', 'y'], [[dp, 1, 1], [C, 0]], 0]

>>> from sage.all import *
>>> R = singular.ring(Integer(7), (a,b), ds)
>>> RL = R.ringlist()

set_ring()

Sets the current ring in Singular to be self.

EXAMPLES:

sage: R = singular.ring(7, '(a,b)', 'ds')
sage: S = singular.ring('real', '(a,b)', 'lp')
sage: singular.current_ring()

polynomial ring, over a field, global ordering
// coefficients: Float()
// number of vars : 2
//    block 1 : ordering lp
//      : names   a b
//    block 2 : ordering C
sage: R.set_ring()

sage: singular.current_ring()

polynomial ring, over a field, local ordering
// coefficients: ZZ/7
// number of vars : 2
//    block 1 : ordering ds
//      : names   a b
//    block 2 : ordering C

>>> from sage.all import *
>>> R = singular.ring(Integer(7), '(a,b)', 'ds')
(continues on next page)
Interpreter Interfaces, Release 10.4

```plaintext
>>> S = singular.ring('real', '(a,b)', 'lp')
>>> singular.current_ring()
polynomial ring, over a field, global ordering
  // coefficients: Float()
  // number of vars : 2
  //   block 1 : ordering lp
  //             : names a b
  // block 2 : ordering C
>>> R.set_ring()
>>> singular.current_ring()
polynomial ring, over a field, local ordering
  // coefficients: ZZ/7
  // number of vars : 2
  //   block 1 : ordering ds
  //             : names a b
  // block 2 : ordering C
```

**type()**

Return the internal type of this element.

**EXAMPLES:**

```plaintext
sage: R = PolynomialRing(GF(2^8,a),2,'x')
sage: R._singular_().type()
'ring'
sage: fs = singular('x0^2','poly')
sage: fs.type()
'poly'
```

**exception** `sage.interfaces.singular.SingularError`

Bases: `RuntimeError`

Raised if Singular printed an error message

**class** `sage.interfaces.singular.SingularFunction (parent, name)`

Bases: `ExpectFunction`

**class** `sage.interfaces.singular.SingularFunctionElement (obj, name)`

Bases: `FunctionElement`

**class** `sage.interfaces.singular.SingularGBDefaultContext (singular=None)`

Bases: `object`

Within this context all Singular Groebner basis calculations are reduced automatically.

**AUTHORS:**

- Martin Albrecht
- Simon King

546 Chapter 44. Interface to Singular
class sage.interfaces.singular.SingularGBLogPrettyPrinter (verbosity=1)

Bases: object

A device which prints Singular Groebner basis computation logs more verbatim.

cri_hilb = re.compile('h')
crt_lne1 = re.compile('product criterion: (\d+) chain criterion: (\d+)')
crt_lne2 = re.compile('NF: (\d+) product criterion: (\d+), ext_product criterion: (\d+)')
deg_lead = re.compile('d+')

flush()

EXAMPLES:

sage: from sage.interfaces.singular import SingularGBLogPrettyPrinter
sage: s3 = SingularGBLogPrettyPrinter(verbosity=3)
sage: s3.flush()

>>> from sage.all import *
>>> from sage.interfaces.singular import SingularGBLogPrettyPrinter
>>> s3 = SingularGBLogPrettyPrinter(verbosity=Integer(3))
>>> s3.flush()

global_pattern = re.compile('(\\[\d+:\d+]|s|-|\.|H|H(\\d+)|\(\d+|M[\d+,[b,e]*\d+]|b|e).*)')
hig_corn = re.compile('H(\\d+)')
new_elem = re.compile('s')
non_mini = re.compile('e')
num_crit = re.compile('d+')
pat_sync = re.compile('1+(\d+);')
red_betr = re.compile('b')
red_num = re.compile('S:\d+\')
red_para = re.compile('M[\d+,[\d+])
red_post = re.compile('\.')
red_zero = re.compile('-')
rng_chng = re.compile('\\[\d+:\d+\]')

write(s)

EXAMPLES:

sage: from sage.interfaces.singular import SingularGBLogPrettyPrinter
sage: s3 = SingularGBLogPrettyPrinter(verbosity=3)
sage: s3.write('(S:1337)')
Performing complete reduction of 1337 elements.
sage: s3.write('M[389,12]')
Parallel reduction of 389 elements with 12 non-zero output elements.
sage.interfaces.singular.generate_docstring_dictionary()

Generate global dictionaries which hold the docstrings for Singular functions.

EXAMPLES:

```python
sage: from sage.interfaces.singular import generate_docstring_dictionary
sage: generate_docstring_dictionary()
```

sage.interfaces.singular.get_docstring(name)

Return the docstring for the function name.

INPUT:

- name – a Singular function name

EXAMPLES:

```python
sage: from sage.interfaces.singular import get_docstring
sage: 'groebner' in get_docstring('groebner')
True
sage: 'standard.lib' in get_docstring('groebner')
True
```

sage.interfaces.singular.is_SingularElement(x)

Return True if x is of type `SingularElement`.

This function is deprecated; use `isinstance()` (of `sage.interfaces.abc.SingularElement`) instead.

EXAMPLES:

```python
sage: from sage.interfaces.singular import is_SingularElement
sage: is_SingularElement(singular(2))
...: DeprecationWarning: the function is_SingularElement is deprecated;...
...: use isinstance(x, sage.interfaces.abc.SingularElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
True
sage: is_SingularElement(2)
False
```
from sage.all import *
from sage.interfaces.singular import is_SingularElement
is_SingularElement(singular(Integer(2)))
doctest:...: DeprecationWarning: the function is_SingularElement is deprecated;…
→use isinstance(x, sage.interfaces.abc.SingularElement) instead
See https://github.com/sagemath/sage/issues/34804 for details.
True
is_SingularElement(Integer(2))
False

sage.interfaces.singular.reduce_load_Singular()

EXAMPLES:

sage: from sage.interfaces.singular import reduce_load_Singular
sage: reduce_load_Singular()
Singular

sage.interfaces.singular.singular_console()

Spawn a new Singular command-line session.

EXAMPLES:

sage: singular_console()  #not tested
SINGULAR / Development
A Computer Algebra System for Polynomial Computations / version 3-0-4
0<
FB Mathematik der Universitaet, D-67653 Kaiserslautern \\n
sage.interfaces.singular.singular_gb_standard_options(func)

Decorator to force a reduced Singular groebner basis.

Note: This decorator is used automatically internally so the user does not need to use it manually.

sage.interfaces.singular.singular_version()

Return the version of Singular being used.

EXAMPLES:

sage: singular.version()
"Singular ... version 4..."
>>> from sage.all import *
>>> singular.version()
"Singular ... version 4..."
SYMPY -> SAGE CONVERSION

The file consists of _sage_() methods that are added lazily to the respective SymPy objects. Any call of the _sympy_() method of a symbolic expression will trigger the addition. See sage.symbolic.expression_conversion.SymPyConverter for the conversion to SymPy.

Only Function objects where the names differ need their own _sage_() method. There are several functions with differing name that have an alias in Sage that is the same as the name in SymPy, so no explicit translation is needed for them:

```python
sage: from sympy import Symbol, Si, Ci, Shi, Chi, sign
sage: sx = Symbol('x')
sage: assert sin_integral(x)._sympy_() == Si(sx)
sage: assert sin_integral(x) == Si(sx)._sage_()
sage: assert sinh_integral(x)._sympy_() == Shi(sx)
sage: assert sinh_integral(x) == Shi(sx)._sage_()
sage: assert cos_integral(x)._sympy_() == Ci(sx)
sage: assert cos_integral(x) == Ci(sx)._sage_()
sage: assert cosh_integral(x)._sympy_() == Chi(sx)
sage: assert cosh_integral(x) == Chi(sx)._sage_()
sage: assert sgn(x)._sympy_() == sign(sx)
sage: assert sgn(x) == sign(sx)._sage_()
```

```python
>>> from sage.all import *
>>> from sympy import Symbol, Si, Ci, Shi, Chi, sign
>>> sx = Symbol('x')
>>> assert sin_integral(x)._sympy_() == Si(sx)
>>> assert sin_integral(x) == Si(sx)._sage_()
>>> assert sinh_integral(x)._sympy_() == Shi(sx)
>>> assert sinh_integral(x) == Shi(sx)._sage_()
>>> assert cos_integral(x)._sympy_() == Ci(sx)
>>> assert cos_integral(x) == Ci(sx)._sage_()
>>> assert cosh_integral(x)._sympy_() == Chi(sx)
>>> assert cosh_integral(x) == Chi(sx)._sage_()
>>> assert sgn(x)._sympy_() == sign(sx)
>>> assert sgn(x) == sign(sx)._sage_()
```

AUTHORS:

- Ralf Stephan (2017-10)

```python
class sage.interfaces.sympy.UndefSageHelper
    Bases: object
    Helper class to convert sympy function objects to sage functions

EXAMPLES:
```
sage: `from sympy import Function
sage: f = function('f')

sage: assert f._sympy_() == F
sage: assert f == F._sage_()

>>> `from sage.all import *
>>> `from sympy import Function

>>> f = function('f')

>>> assert f._sympy_() == F

sage.interfaces.sympy.check_expression(expr, var_symbols, only_from_sympy=False)
Does `eval(expr)` both in Sage and SymPy and does other checks.

EXAMPLES:

sage: from sage.interfaces.sympy import check_expression
sage: check_expression("1.123*x", "x")

sage.interfaces.sympy.sympy_init(*args, **kwargs)
Add `_sage_()` methods to SymPy objects where needed.
This gets called with every call to `Expression._sympy_()` so there is only need to call it if you bypass `_sympy_()` to create SymPy objects. Note that SymPy objects have `_sage_()` methods hard installed but having them inside Sage as one file makes them easier to maintain for Sage developers.

EXAMPLES:

sage: from sage.interfaces.sympy import sympy_init
sage: from sympy import Symbol, Abs

sage: sympy_init()

sage: assert abs(x) == Abs(Symbol('x'))._sage_()

sage.interfaces.sympy.sympy_set_to_list(set, vars)
Convert all set objects that can be returned by SymPy’s solvers.

sage.interfaces.sympy.test_all()
Call some tests that were originally in SymPy.

EXAMPLES:

sage: `from sage.interfaces.sympy import test_all
sage: test_all()
>>> from sage.all import *
>>> from sage.interfaces.sympy import test_all
>>> test_all()
Chapter Forty-Six

The Tachyon Ray Tracer

Author:

- John E. Stone

This documentation, which was written by John Stone, describes how to create scene files.

At the present time, scene description files are very simple. The parser can’t handle multiple file scene descriptions, although they may be added in the future. Most of the objects and their scene description are closely related to the RAY API. (See the API docs for additional info.)

46.1 Basic Scene Requirements

Unlike some other ray tracers out there, RAY requires that you specify most of the scene parameters in the scene description file itself. If users would rather specify some of these parameters at the command line, then I may add that feature in the future. A scene description file contains keywords, and values associated or grouped with a keyword. All keywords can be in caps, lower case, or mixed case for the convenience of the user. File names and texture names are normally case-sensitive, although the behavior for file names is operating system-dependent. All values are either character strings, or floating point numbers. In some cases, the presence of one keyword will require additional keyword / value pairs.

At the moment there are several keywords with values, that must appear in every scene description file. Every scene description file must begin with the BEGIN_SCENE keyword, and end with the END_SCENE keyword. All definitions and declarations of any kind must be inside the BEGIN_SCENE, END_SCENE pair. The RESOLUTION keyword is followed by an x resolution and a y resolution in terms of pixels on each axis. There are currently no limits placed on the resolution of an output image other than the computer’s available memory and reasonable execution time. An example of a simple scene description skeleton is show below:

BEGIN_SCENE
  RESOLUTION 1024 1024
  ...
  ...
  Camera definition..
  ...
  ...
  Other objects, etc..
  ...

END_SCENE
46.2 Camera and viewing parameters

One of the most important parts of any scene, is the camera position and orientation. Having a good angle on a scene can make the difference between an average looking scene and a strikingly interesting one. There may be multiple camera definitions in a scene file, but the last camera definition overrides all previous definitions. There are several parameters that control the camera in, PROJECTION, ZOOM, ASPECTRATIO, ANTIALIASING, CENTER, RAYDEPTH, VIEWDIR, and UPDIR.

The first and last keywords required in the definition of a camera are the CAMERA and END_CAMERA keywords. The PROJECTION keyword is optional, the remaining camera keywords are required, and must be written in the sequence they are listed in the examples in this section.

46.2.1 Camera projection modes

The PROJECTION keyword must be followed by one of the supported camera projection mode identifiers PERSPECTIVE, PERSPECTIVE_DOF, ORTHOGRAPHIC, or FISHEYE. The FISHEYE projection mode requires two extra parameters FOCALLENGTH and APERTURE which precede the regular camera options.

```
Camera
  projection perspective_dof
  focallength 0.75
  aperture 0.02
  Zoom 0.666667
  Aspectratio 1.000000
  Antialiasing 128
  Raydepth 30
  Center 0.000000 0.000000 -2.000000
  Viewdir -0.000000 -0.000000 2.000000
  Updir 0.000000 1.000000 -0.000000
End_Camera
```

46.2.2 Common camera parameters

The ZOOM parameter controls the camera in a way similar to a telephoto lens on a 35mm camera. A zoom value of 1.0 is standard, with a 90 degree field of view. By changing the zoom factor to 2.0, the relative size of any feature in the frame is twice as big, while the field of view is decreased slightly. The zoom effect is implemented as a scaling factor on the height and width of the image plane relative to the world.

The ASPECTRATIO parameter controls the aspect ratio of the resulting image. By using the aspect ratio parameter, one can produce images which look correct on any screen. Aspect ratio alters the relative width of the image plane, while keeping the height of the image plane constant. In general, most workstation displays have an aspect ratio of 1.0. To see what aspect ratio your display has, you can render a simple sphere, at a resolution of 512x512 and measure the ratio of its width to its height.

The ANTIALIASING parameter controls the maximum level of supersampling used to obtain higher image quality. The parameter given sets the number of additional rays to trace per-pixel to attain higher image quality.

The RAYDEPTH parameter tells RAY what the maximum level of reflections, refraction, or in general the maximum recursion depth to trace rays to. A value between 4 and 12 is usually good. A value of 1 will disable rendering of reflective or transmissive objects (they’ll be black).

The remaining three camera parameters are the most important, because they define the coordinate system of the camera, and its position in the scene. The CENTER parameter is an X, Y, Z coordinate defining the center of the camera (also known as the Center of Projection). Once you have determined where the camera will be placed in the scene, you need to tell RAY what the camera should be looking at. The VIEWDIR parameter is a vector indicating the direction the camera...
is facing. It may be useful for me to add a “Look At” type keyword in the future to make camera aiming easier. If people want or need the “Look At” style camera, let me know. The last parameter needed to completely define a camera is the “up” direction. The UPDIR parameter is a vector which points in the direction of the “sky”. I wrote the camera so that VIEWDIR and UPDIR don’t have to be perpendicular, and there shouldn’t be a need for a “right” vector although some other ray tracers require it. Here’s a snippet of a camera definition:

```
CAMERA
    ZOOM 1.0
    ASPECTRATIO 1.0
    ANTIALIASING 0
    RAYDEPTH 12
    CENTER 0.0 0.0 2.0
    VIEWDIR 0 0 -1
    UPDIR 0 1 0
END_CAMERA
```

### 46.2.3 Viewing frustum

An optional FRUSTUM parameter provides a means for rendering sub-images in a larger frame, and correct stereoscopic images. The FRUSTUM keyword must be followed by four floating parameters, which indicate the top, bottom, left and right coordinates of the image plane in eye coordinates. When the projection mode is set to FISHEYE, the frustum parameters correspond to spherical coordinates specified in radians.

```
CAMERA
    ZOOM 1.0
    ASPECTRATIO 1.0
    ANTIALIASING 0
    RAYDEPTH 4
    CENTER 0.0 0.0 -6.0
    VIEWDIR 0.0 0.0 1.0
    UPDIR 0.0 1.0 0.0
    FRUSTUM -0.5 0.5 -0.5 0.5
END_CAMERA
```

### 46.3 Including Files

The INCLUDE keyword is used anywhere after the camera description, and is immediately followed by a valid filename, for a file containing additional scene description information. The included file is opened, and processing continues as if it were part of the current file, until the end of the included file is reached. Parsing of the current file continues from where it left off prior to the included file.

### 46.4 Scene File Comments

The # keyword is used anywhere after the camera description, and will cause RAY to ignore all characters from the # to the end of the input line. The # character must be surrounded by whitespace in order to be recognized. A sequence such as ### will not be recognized as a comment.
46.5 Lights

The most frequently used type of lights provided by RAY are positional point light sources. The lights are actually small spheres, which are visible. A point light is composed of three pieces of information, a center, a radius (since it's a sphere), and a color. To define a light, simply write the \texttt{LIGHT} keyword, followed by its \texttt{CENTER} (a \(X, Y, Z\) coordinate), its \texttt{RAD} (radius, a scalar), and its \texttt{COLOR} (a Red Green Blue triple). The radius parameter will accept any value of 0.0 or greater. Lights of radius 0.0 will not be directly visible in the rendered scene, but contribute light to the scene normally. For a light, the color values range from 0.0 to 1.0, any values outside this range may yield unpredictable results. A simple light definition looks like this:

\begin{verbatim}
LIGHT CENTER 4.0 3.0 2.0
  RAD 0.2
  COLOR 0.5 0.5 0.5
\end{verbatim}

This light would be gray colored if seen directly, and would be 50\% intensity in each RGB color component.

RAY supports simple directional lighting, commonly used in CAD and scientific visualization programs for its performance advantages over positional lights. Directional lights cannot be seen directly in scenes rendered by RAY, only their illumination contributes to the final image.

\begin{verbatim}
DIRECTIONAL_LIGHT
  DIRECTION 0.0 -1.0 0.0
  COLOR 1.0 0.0 0.0
\end{verbatim}

RAY supports spotlights, which are described very similarly to a point light, but they are attenuated by angle from the direction vector, based on a “falloff start” angle and “falloff end” angle. Between the starting and ending angles, the illumination is attenuated linearly. The syntax for a spotlight description in a scene file is as follows.

\begin{verbatim}
SPOTLIGHT
  CENTER 0.0 3.0 17.0
  RAD 0.2
  DIRECTION 0.0 -1.0 0.0
  FALLOFF_START 20.0
  FALLOFF_END 45.0
  COLOR 1.0 0.0 0.0
\end{verbatim}

The lighting system implemented by RAY provides various levels of distance-based lighting attenuation. By default, a light is not attenuated by distance. If the \texttt{attenuation} keywords is present immediately prior to the light's color, RAY will accept coefficients which are used to calculate distance-based attenuation, which is applied the light by multiplying with the resulting value. The attenuation factor is calculated from the equation

\[ 1/(K_c + K_l d + k_q d^2) \]

This attenuation equation should be familiar to some as it is the same lighting attenuation equation used by OpenGL. The constant, linear, and quadratic terms are specified in a scene file as shown in the following example.

\begin{verbatim}
LIGHT
  CENTER -5.0 0.0 10.0
  RAD 1.0
  ATTENUATION CONSTANT 1.0 LINEAR 0.2 QUADRATIC 0.05
  COLOR 1.0 0.0 0.0
\end{verbatim}
46.6 Atmospheric effects

RAY currently only implements one atmospheric effect, simple distance-based fog.

46.6.1 Fog

RAY provides a simple distance-based fog effect intended to provide functionality similar to that found in OpenGL, for compatibility with software that requires an OpenGL-like fog implementation. Much like OpenGL, RAY provides linear, exponential, and exponential-squared fog.

```
FOG
LINEAR START 0.0 END 50.0 DENSITY 1.0 COLOR 1.0 1.0 1.0
```

```
FOG
EXP START 0.0 END 50.0 DENSITY 1.0 COLOR 1.0 1.0 1.0
```

```
FOG
EXP2 START 0.0 END 50.0 DENSITY 1.0 COLOR 1.0 1.0 1.0
```

46.7 Objects

46.7.1 Spheres

Spheres are the simplest object supported by RAY and they are also the fastest object to render. Spheres are defined as one would expect, with a CENTER, RAD (radius), and a texture. The texture may be defined along with the object as discussed earlier, or it may be declared and assigned a name. Here’s a sphere definition using a previously defined “NitrogenAtom” texture:

```
SPHERE CENTER 26.4 27.4 -2.4 RAD 1.0 NitrogenAtom
```

A sphere with an inline texture definition is declared like this:

```
Sphere center 1.0 0.0 10.0
  Rad 1.0
  Texture Ambient 0.2 Diffuse 0.8 Specular 0.0 Opacity 1.0
  Color 1.0 0.0 0.5
  TexFunc 0
```

Notice that in this example I used mixed case for the keywords, this is allowable… Review the section on textures if the texture definitions are confusing.
46.7.2 Triangles

Triangles are also fairly simple objects, constructed by listing the three vertices of the triangle, and its texture. The order of the vertices isn’t important, the triangle object is “double sided”, so the surface normal is always pointing back in the direction of the incident ray. The triangle vertices are listed as V1, V2, and V3 each one is an X, Y, Z coordinate. An example of a triangle is shown below:

```
TRI
V0 0.0 -4.0 12.0
V1 4.0 -4.0 8.0
V2 -4.0 -4.0 8.0
TEXTURE
  AMBIENT 0.1 DIFFUSE 0.2 SPECULAR 0.7 OPACITY 1.0
  COLOR 1.0 1.0 1.0
  TEXFUNC 0
```

46.7.3 Smoothed Triangles

Smoothed triangles are just like regular triangles, except that the surface normal for each of the three vertices is used to determine the surface normal across the triangle by linear interpolation. Smoothed triangles yield curved looking objects and have nice reflections.

```
STRI
V0 1.4 0.0 2.4
V1 1.35 -0.37 2.4
V2 1.36 -0.32 2.45
N0 -0.9 -0.0 -0.4
N1 -0.8 0.23 -0.4
N2 -0.9 0.27 -0.15
TEXTURE
  AMBIENT 0.1 DIFFUSE 0.2 SPECULAR 0.7 OPACITY 1.0
  COLOR 1.0 1.0 1.0
  TEXFUNC 0
```

46.7.4 Infinite Planes

Useful for things like desert floors, backgrounds, skies etc, the infinite plane is pretty easy to use. An infinite plane only consists of two pieces of information, the CENTER of the plane, and a NORMAL to the plane. The center of the plane is just any point on the plane such that the point combined with the surface normal define the equation for the plane. As with triangles, planes are double sided. Here is an example of an infinite plane:

```
PLANE
  CENTER 0.0 -5.0 0.0
  NORMAL 0.0 1.0 0.0
  TEXTURE
    AMBIENT 0.1 DIFFUSE 0.9 SPECULAR 0.0 OPACITY 1.0
    COLOR 1.0 1.0 1.0
    TEXFUNC 1
    CENTER 0.0 -5.0 0.0
    ROTATE 0. 0.0 0.0
    SCALE 1.0 1.0 1.0
```
46.7.5 Rings

Rings are a simple object, they are really a not-so-infinite plane. Rings are simply an infinite plane cut into a washer shaped ring, infinitely thin just like a plane. A ring only requires two more pieces of information than an infinite plane does, an inner and outer radius. Here's an example of a ring:

```
Ring
  Center 1.0 1.0 1.0
  Normal 0.0 1.0 0.0
  Inner 1.0
  Outer 5.0
  MyNewRedTexture
```

46.7.6 Infinite Cylinders

Infinite cylinders are quite simple. They are defined by a center, an axis, and a radius. An example of an infinite cylinder is:

```
Cylinder
  Center 0.0 0.0 0.0
  Axis 0.0 1.0 0.0
  Rad 1.0
  SomeRandomTexture
```

46.7.7 Finite Cylinders

Finite cylinders are almost the same as infinite ones, but the center and length of the axis determine the extents of the cylinder. The finite cylinder is also really a shell, it doesn't have any caps. If you need to close off the ends of the cylinder, use two ring objects, with the inner radius set to 0.0 and the normal set to be the axis of the cylinder. Finite cylinders are built this way to enhance speed.

```
FCylinder
  Center 0.0 0.0 0.0
  Axis 0.0 9.0 0.0
  Rad 1.0
  SomeRandomTexture
```

This defines a finite cylinder with radius 1.0, going from 0.0 0.0 0.0, to 0.0 9.0 0.0 along the Y axis. The main difference between an infinite cylinder and a finite cylinder is in the interpretation of the AXIS parameter. In the case of the infinite cylinder, the length of the axis vector is ignored. In the case of the finite cylinder, the axis parameter is used to determine the length of the overall cylinder.

46.7.8 Axis Aligned Boxes

Axis aligned boxes are fast, but of limited usefulness. As such, I'm not going to waste much time explaining 'em. An axis aligned box is defined by a MIN point, and a MAX point. The volume between the min and max points is the box. Here's a simple box:

```
BOX
  MIN -1.0 -1.0 -1.0
  MAX 1.0 1.0 1.0
  Boxtexture1
```
**46.7.9 Fractal Landscapes**

Currently fractal landscapes are a built-in function. In the near future I'll allow the user to load an image map for use as a heightfield. Fractal landscapes are currently forced to be axis aligned. Any suggestion on how to make them more appealing to users is welcome. A fractal landscape is defined by its “resolution” which is the number of grid points along each axis, and by its scale and center. The “scale” is how large the landscape is along the X, and Y axes in world coordinates. Here's a simple landscape:

```
SCAPE
RES 30 30
SCALE 80.0 80.0
CENTER 0.0 -4.0 20.0
TEXTURE
  AMBIENT 0.1 DIFFUSE 0.9 SPECULAR 0.0 OPACITY 1.0
  COLOR 1.0 1.0 1.0
  TEXFUNC 0
```

The landscape shown above generates a square landscape made of 1,800 triangles. When time permits, the heightfield code will be rewritten to be more general and to increase rendering speed.

**46.7.10 Arbitrary Quadric Surfaces**

Docs soon. I need to add these into the parser, must have forgotten before ;-) 

**46.7.11 Volume Rendered Scalar Voxels**

These are a little trickier than the average object :-) These are likely to change substantially in the very near future so I'm not going to get too detailed yet. A volume rendered data set is described by its axis aligned bounding box, and its resolution along each axis. The final parameter is the voxel data file. If you are seriously interested in messing with these, get hold of me and I'll give you more info. Here's a quick example:

```
SCALARVOL
MIN -1.0 -1.0 -0.4
MAX 1.0 1.0 0.4
DIM 256 256 100
FILE /cfs/johns/vol/engine.256x256x110
TEXTURE
  AMBIENT 1.0 DIFFUSE 0.0 SPECULAR 0.0 OPACITY 8.1
  COLOR 1.0 1.0 1.0
  TEXFUNC 0
```

**46.8 Texture and Color**

**46.8.1 Simple Texture Characteristics**

The surface textures applied to an object drastically alter its overall appearance, making textures and color one of the most important topics in this manual. As with many other renderers, textures can be declared and associated with a name so that they may be used over and over again in a scene definition with less typing. If a texture is only need once, or it is unique to a particular object in the scene, then it may be declared along with the object it is applied to, and does not need a name.
The simplest texture definition is a solid color with no image mapping or procedural texture mapping. A solid color texture is defined by the AMBIENT, DIFFUSE, SPECULAR, OPACITY, and COLOR parameters. The AMBIENT parameter defines the ambient lighting coefficient to be used when shading the object. Similarly, the DIFFUSE parameter is the relative contribution of the diffuse shading to the surface appearance. The SPECULAR parameter is the contribution from perfectly reflected rays, as if on a mirrored surface. OPACITY defines how transparent a surface is. An OPACITY value of 0.0 renders the object completely invisible. An OPACITY value of 1.0 makes the object completely solid, and non-transmissive. In general, the values for the ambient, diffuse, and specular parameters should add up to 1.0, if they don't then pixels may be over or underexposed quite easily. These parameters function in a manner similar to that of other ray tracers. The COLOR parameter is an RGB triple with each value ranging from 0.0 to 1.0 inclusive. If the RGB values stray from 0.0 to 1.0, results are undefined. In the case of solid textures, a final parameter, TEXFUNC is set to zero (integer).

### 46.8.2 Texture Declaration and Aliasing

To define a simple texture for use on several objects in a scene, the TEXDEF keyword is used. The TEXDEF keyword is followed by a case sensitive texture name, which will subsequently be used while defining objects. If many objects in a scene use the same texture through texture definition, a significant amount of memory may be saved since only one copy of the texture is present in memory, and its shared by all of the objects. Here is an example of a solid texture definition:

```plaintext
TEXDEF MyNewRedTexture
    AMBIENT 0.1 DIFFUSE 0.9 SPECULAR 0.0 OPACITY 1.0
    COLOR 1.0 0.0 0.0 TEXFUNC 0
```

When this texture is used in an object definition, it is referenced only by name. Be careful not to use one of the other keywords as a defined texture, this will probably cause the parser to explode, as I don’t check for use of keywords as texture names.

When a texture is declared within an object definition, it appears in an identical format to the TEXDEF declaration, but the TEXTURE keyword is used instead of TEXDEF. If it is useful to have several names for the same texture (when you are too lazy to actually finish defining different variations of a wood texture for example, and just want to be approximately correct for example) aliases can be constructed using the TEXALIAS keyword, along with the alias name, and the original name. An example of a texture alias is:

```plaintext
TEXALIAS MyNewestRedTexture MyNewRedTexture
```

This line would alias MyNewestRedTexture to be the same thing as the previously declared MyNewRedTexture. Note that the source texture must be declared before any aliases that use it.

### 46.8.3 Image Maps and Procedural Textures

Image maps and procedural textures are very useful in making realistic looking scenes. A good image map can do as much for the realism of a wooden table as any amount of sophisticated geometry or lighting. Image maps are made by wrapping an image on to an object in one of three ways, a spherical map, a cylindrical map, and a planar map. Procedural textures are used in a way similar to the image maps, but they are on the fly and do not use much memory compared to the image maps. The main disadvantage of the procedural maps is that they must be hard-coded into RAY when it is compiled.

The syntax used for all texture maps is fairly simple to learn. The biggest problem with the way that the parser is written now is that the different mappings are selected by an integer, which is not very user friendly. I expect to rewrite this section of the parser sometime in the near future to alleviate this problem. When I rewrite the parser, I may also end up altering the parameters that are used to describe a texture map, and some of them may become optional rather than required.
# Texture Mapping Functions

<table>
<thead>
<tr>
<th>Value for TEXFUNC</th>
<th>Mapping and Texture Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No special texture, plain shading</td>
</tr>
<tr>
<td>1</td>
<td>3D checkerboard function, like a Rubik’s cube</td>
</tr>
<tr>
<td>2</td>
<td>Grit Texture, randomized surface color</td>
</tr>
<tr>
<td>3</td>
<td>3D marble texture, uses object’s base color</td>
</tr>
<tr>
<td>4</td>
<td>3D wood texture, light and dark brown, not very good yet</td>
</tr>
<tr>
<td>5</td>
<td>3D gradient noise function (can’t remember what it look like)</td>
</tr>
<tr>
<td>6</td>
<td>Don’t remember</td>
</tr>
<tr>
<td>7</td>
<td>Cylindrical Image Map, requires ppm filename</td>
</tr>
<tr>
<td>8</td>
<td>Spherical Image Map, requires ppm filename</td>
</tr>
<tr>
<td>9</td>
<td>Planar Image Map, requires ppm filename</td>
</tr>
</tbody>
</table>

Here’s an example of a sphere, with a spherical image map applied to its surface:

```
SPHERE
   CENTER 2.0 0.0 5.0
   RAD 2.0
TEXTURE
   AMBIENT 0.4 DIFFUSE 0.8 SPECULAR 0.0 OPACITY 1.0
   COLOR 1.0 1.0 1.0
   TEXFUNC 7 /cfs/johns/imaps/fire644.ppm
   CENTER 2.0 0.0 5.0
   ROTATE 0.0 0.0 0.0
   SCALE 2.0 -2.0 1.0
```

Basically, the image maps require the center, rotate and scale parameters so that you can position the image map on the object properly.

```python
class sage.interfaces.tachyon.TachyonRT
    Bases: SageObject

The Tachyon Ray Tracer

Usage: tachyon_rt(model, outfile='sage.png', verbose=1, block=True, extra_opts='')

INPUT:
- model – a string that describes a 3d model in the Tachyon modeling format. Type sage.interfaces.tachyon? for a description of this format.
- outfile – (default: 'sage.png') output filename; the extension of the filename determines the type. Supported types include:
  - tga – 24-bit (uncompressed)
  - bmp – 24-bit Windows BMP (uncompressed)
  - ppm – 24-bit PPM (uncompressed)
  - rgb – 24-bit SGI RGB (uncompressed)
  - png – 24-bit PNG (compressed, lossless)
- verbose – integer; (default: 1)
  - 0 – silent
  - 1 – some output
```
- 2 – very verbose output

- block – bool (default: True); if False, run the rendering command in the background.

- extra_opts – passed directly to tachyon command line. Use tachyon_rt.usage() to see some of the possibilities.

OUTPUT:

- Some text may be displayed onscreen.
- The file outfile is created.

EXAMPLES:

```python
__call__(model, outfile='sage.png', verbose=1, extra_opts='')
```

This executes the tachyon program, given a scene file input.

INPUT:

- model – string. The tachyon model.
- outfile – string, default 'sage.png'. The filename to save the model to.
- verbose – 0, 1, (default) or 2. The verbosity level.
- extra_opts – string (default: empty string). Extra options that will be appended to the tachyon commandline.

EXAMPLES:

```python
sage: from sage.interfaces.tachyon import TachyonRT
sage: tgen = Tachyon()
sage: tgen.texture('t1')
```

```python
sage: tgen.sphere((0,0,0),1,'t1')
```

```python
sage: tgen.str()[30:40] 'resolution'
```

```python
sage: t = TachyonRT()
```

```python
import os
```

```python
t(tgen.str(), outfile=os.devnull)
tachyon ...
```

```python
Tachyon Parallel/Multiprocessor Ray Tracer...
```

```python
>>> from sage.all import *
>>> from sage.interfaces.tachyon import TachyonRT
```

```python
>>> tgen = Tachyon()
```

```python
>>> tgen.texture('t1')
```

```python
>>> tgen.sphere((Integer(0),Integer(0),Integer(0)),Integer(1),'t1')
```

```python
>>> tgen.str()[Integer(30):Integer(40)] 'resolution'
```

```python
>>> t = TachyonRT()
```

```python
>>> import os
```

```python
>>> t(tgen.str(), outfile=os.devnull)
tachyon ...
```

```python
Tachyon Parallel/Multiprocessor Ray Tracer...
```

```python
help(use_pager=True)
```

Deprecated: type `sage.interfaces.tachyon?' for help

```python
usage(use_pager=True)
```

Returns the basic description of using the Tachyon raytracer (simply what is returned by running tachyon with no input). The output is paged unless use_pager=False.
version()

Returns the version of the Tachyon raytracer being used.
CHAPTER
FORTYSEVEN

INTERFACE TO TIDES

This module contains tools to write the .c files needed for TIDES [TIDES].

Tides is an integration engine based on the Taylor method. It is implemented as a c library. The user must translate its initial value problem (IVP) into a pair of .c files that will then be compiled and linked against the TIDES library. The resulting binary will produce the desired output. The tools in this module can be used to automate the generation of these files from the symbolic expression of the differential equation.

AUTHORS:
• Miguel Marco (06-2014) - Implementation of tides solver
• Marcos Rodriguez (06-2014) - Implementation of tides solver
• Alberto Abad (06-2014) - tides solver
• Roberto Barrio (06-2014) - tides solver

REFERENCES:
• [ABBR2012]
• [TIDES]

sage.interfaces.tides.genfiles_mintides(integrator, driver, f, ics, initial, final, delta, tolrel=1e-16, tolabsl=1e-16, output='')

Generate the needed files for the min_tides library.

INPUT:
• integrator – the name of the integrator file.
• driver – the name of the driver file.
• f – the function that determines the differential equation.
• ics – a list or tuple with the initial conditions.
• initial – the initial time for the integration.
• final – the final time for the integration.
• delta – the step of the output.
• tolrel – the relative tolerance.
• tolabs – the absolute tolerance.
• output – the name of the file that the compiled integrator will write to

This function creates two files, integrator and driver, that can be used later with the min_tides library [TIDES].

```python
sage.interfaces.tides.genfiles_mpfr(integrator, driver, f, ics, initial, final, delta, parameters=None, parameter_values=None, dig=20, tolrel=1e-16, tolabs=1e-16, output='')
```

Generate the needed files for the mpfr module of the tides library.

INPUT:
• integrator – the name of the integrator file.
• driver – the name of the driver file.
• f – the function that determines the differential equation.
• ics – a list or tuple with the initial conditions.
• initial – the initial time for the integration.
• final – the final time for the integration.
• delta – the step of the output.
• parameters – the variables inside the function that should be treated as parameters.
• parameter_values – the values of the parameters for the particular initial value problem.
• dig – the number of digits of precision that will be used in the integration
• tolrel – the relative tolerance.
• tolabs – the absolute tolerance.
• output – the name of the file that the compiled integrator will write to

This function creates two files, integrator and driver, that can be used later with the tides library ([TIDES]).

```python
sage.interfaces.tides.remove_constants(l1, l2)
```

Given two lists, remove the entries in the first that are real constants, and also the corresponding elements in the second one.

EXAMPLES:
```python
sage: from sage.interfaces.tides import subexpressions_list, remove_constants
sage: f(a)=[1+cos(7)*a]
sage: l1, l2 = subexpressions_list(f)
sage: l1, l2
([sin(7), cos(7), a*cos(7), a*cos(7) + 1],
[['sin', 7], ['cos', 7], ['mul', cos(7), a], ['add', 1, a*cos(7)]])
sage: remove_constants(l1,l2)
sage: l1, l2
([a*cos(7), a*cos(7) + 1], [['mul', cos(7), a], ['add', 1, a*cos(7)]])
```
```python
>>> from sage.all import *
>>> from sage.interfaces.tides import subexpressions_list, remove_constants
>>> __tmp__=var("a"); f = symbolic_expression([Integer(1)+cos(Integer(7))*a]).function(a)
>>> l1, l2 = subexpressions_list(f)
>>> l1, l2
([sin(7), cos(7), a*cos(7), a*cos(7) + 1],
 [\('\text{sin}', 7), (\'\text{cos}', 7), (\'\text{mul}', \text{cos}(7), a), (\'\text{add}', 1, a*\text{cos}(7))])
>>> remove_constants(l1,l2)
>>> l1, l2
([a*cos(7), a*cos(7) + 1], [(\'\text{mul}', \text{cos}(7), a), (\'\text{add}', 1, a*\text{cos}(7))])
```

```python
sage.interfaces.tides.remove_repeated(l1,l2)
```

Given two lists, remove the repeated elements in l1, and the elements in l2 that are on the same position.

**EXAMPLES:**

```python
sage: from sage.interfaces.tides import (subexpressions_list, remove_repeated)
sage: f(a)=[1 + a^2, arcsin(a)]
sage: l1, l2 = subexpressions_list(f)
sage: l1, l2
([a^2, a^2 + 1, -a^2 + 1, sqrt(-a^2 + 1), arcsin(a)],
 [\('\text{mul}', a, a),
 (\'add', 1, a^2),
 (\'mul', a, a),
 (\'mul', -1, a^2),
 (\'add', 1, -a^2),
 (\'pow', -a^2 + 1, 0.5),
 (\'asin', a)])
sage: remove_repeated(l1, l2)
sage: l1, l2
([a^2, a^2 + 1, -a^2, -a^2 + 1, sqrt(-a^2 + 1), arcsin(a)],
 [\('\text{mul}', a, a),
 (\'add', 1, a^2),
 (\'mul', -1, a^2),
 (\'add', 1, -a^2),
 (\'pow', -a^2 + 1, 0.5),
 (\'asin', a)])
```

(continues on next page)
sage.interfaces.tides.subexpressions_list(f, pars=None)

Construct the lists with the intermediate steps on the evaluation of the function.

INPUT:

- \( f \) – a symbolic function of several components.
- \( \text{pars} \) – a list of the parameters that appear in the function this should be the symbolic constants that appear in \( f \) but are not arguments.

OUTPUT:

- a list of the intermediate subexpressions that appear in the evaluation of \( f \).
- a list with the operations used to construct each of the subexpressions. each element of this list is a tuple, formed by a string describing the operation made, and the operands.

For the trigonometric functions, some extra expressions will be added. These extra expressions will be used later to compute their derivatives.

EXAMPLES:

```python
sage: from sage.interfaces.tides import subexpressions_list
sage: var('x,y')
(x, y)

sage: f(x,y) = [x^2+y, cos(x)/log(y)]

sage: subexpressions_list(f)
([x^2, x^2 + y, sin(x), cos(x), log(y), cos(x)/log(y)],
 ['(mul, x, x),
  '(add, y, x^2),
  '(sin, x),
  '(cos, x),
  '(log, y),
  '(div, log(y), cos(x))])

sage: f(a)=[cos(a), arctan(a)]

sage: from sage.interfaces.tides import subexpressions_list
```
sage: subexpressions_list(f)
([\sin(a), \cos(a), a^2, a^2 + 1, \arctan(a)],
[(\sin', a), (\cos', a), (\mul', a, a), (\add', 1, a^2), (\atan', a)])

>>> from sage.all import *

>>> __tmp__=var("a"); f = symbolic_expression([\cos(a), \arctan(a)]).function(a)

>>> from sage.interfaces.tides import subexpressions_list

>>> subexpressions_list(f)
([\sin(a), \cos(a), a^2, a^2 + 1, \arctan(a)],
[(\sin', a), (\cos', a), (\mul', a, a), (\add', 1, a^2), (\atan', a)])

sage: from sage.interfaces.tides import subexpressions_list

sage: var(s,b,r)

(s, b, r)

sage: f(t,x,y,z)= [s*(y-x),x*(r-z)-y,x*y-b*z]

sage: subexpressions_list(f,[s,b,r])
([-y, x - y, s*(x - y), -s*(x - y), -z, r - z, (r - z)*x, -y, (r - z)*x - y, x*y, b*z, -b*z, x*y - b*z],
[(\mul', -1, y), (\add', -y, x), (\mul', x - y, s), (\mul', -1, s*(x - y)), (\mul', -1, z), (\add', -z, r), (\mul', x, r - z), (\mul', -1, y), (\add', -y, (r - z)*x), (\mul', y, x), (\mul', z, b), (\mul', -1, b*z), (\add', -b*z, x*y)])

>>> from sage.all import *

>>> from sage.interfaces.tides import subexpressions_list

>>> var(s,b,r)

(s, b, r)

>>> __tmp__=var("t,x,y,z"); f = symbolic_expression([s*(y-x),x*(r-z)-y,x*y-b*z]).function(t,x,y,z)

>>> subexpressions_list(f,[s,b,r])
([-y, x - y, s*(x - y), -s*(x - y), -z, r - z,
(continues on next page)
(r - z)*x, 
-y, 
(r - z)*x - y, 
x*y, 
b*z, 
-b*z, 
x*y - b*z], 
[[('mul', -1, y), 
('add', -y, x), 
('mul', x - y, z), 
('mul', -1, s), 
('mul', -1, s*(x - y)), 
('mul', -1, z), 
('add', -z, r), 
('mul', x, r - z), 
('mul', -1, y), 
('add', -y, (r - z)*x), 
('mul', y, x), 
('mul', z, b), 
('mul', -1, b*z), 
('add', -b*z, x*y))]

sage: var('x, y')
(x, y)
sage: f(x,y)=[exp(x^2+sin(y))]
sage: from sage.interfaces.tides import *
sage: subexpressions_list(f)
([x^2, sin(y), cos(y), x^2 + sin(y), e^(x^2 + sin(y))],
[['mul', x, x],
('sin', y),
('cos', y),
('add', sin(y), x^2),
('exp', x^2 + sin(y))])

>>> from sage.all import *
>>> var('x, y')
(x, y)
>>> __tmp__=var("x,y"); f = symbolic_expression([exp(x+Integer(2)+sin(y))]).
function(x,y)
>>> from sage.interfaces.tides import *
>>> subexpressions_list(f)
([x^2, sin(y), cos(y), x^2 + sin(y), e^(x^2 + sin(y))],
[['mul', x, x],
('sin', y),
('cos', y),
('add', sin(y), x^2),
('exp', x^2 + sin(y))])
INTERFACE TO THE SAGE CLEANER

Trivia Note: For the name “sage-cleaner”, think of the “The Cleaner” from Pulp Fiction:  
http://www.frankjankowski.de/quiz/illus/keitel.jpg

sage.interfaces.cleaner.start_cleaner()

Start sage-cleaner in a new process group.
QUITTING INTERFACES

sage.interfaces.quit.expect_quitall(verbosetrue)

EXAMPLES:

```python
sage: sage.interfaces.quit.expect_quitall()
sage: gp.eval('a=10')  #...
  → needs sage.libs.pari '10'
sage: gp('a')  #...
  → needs sage.libs.pari 10
sage: sage.interfaces.quit.expect_quitall()
sage: gp('a')  #...
  → needs sage.libs.pari
a
sage: sage.interfaces.quit.expect_quitall(verbosetrue)  #...
  → needs sage.libs.pari
Exiting PARI/GP interpreter with PID ... running .../gp --fast --emacs --quiet --
  → stacksize 10000000
```

```python
>>> from sage.all import *
>>> sage.interfaces.quit.expect_quitall()
>>> gp.eval('a=10')  #...
  → needs sage.libs.pari '10'
>>> gp('a')  #...
  → needs sage.libs.pari 10
>>> sage.interfaces.quit.expect_quitall()
>>> gp('a')  #...
  → needs sage.libs.pari
a
>>> sage.interfaces.quit.expect_quitall(verbosetrue)  #...
  → needs sage.libs.pari
Exiting PARI/GP interpreter with PID ... running .../gp --fast --emacs --quiet --
  → stacksize 10000000
```

sage.interfaces.quit.invalidate_all()

Invalidate all of the expect interfaces.

This is used, e.g., by the fork-based @parallel decorator.

EXAMPLES:
Interpreter Interfaces, Release 10.4

```
sage: # needs sage.libs.pari sage.symbolic
sage: a = maxima(2); b = gp(3)
sage: a, b
(2, 3)
sage: sage.interfaces.quit.invalidate_all()
sage: a
(invalid Maxima object -- The maxima session in which this object was defined is...no longer running.)
sage: b
(invalid PARI/GP interpreter object -- The pari session in which this object was defined is no longer running.)
```

```
>>> from sage.all import *
>>> # needs sage.libs.pari sage.symbolic
>>> a = maxima(Integer(2)); b = gp(Integer(3))
>>> a, b
(2, 3)
>>> sage.interfaces.quit.invalidate_all()
>>> a
(invalid Maxima object -- The maxima session in which this object was defined is...no longer running.)
>>> b
(invalid PARI/GP interpreter object -- The pari session in which this object was defined is no longer running.)
```

However, the maxima and gp sessions should still work out, though with their state reset:

```
sage: a = maxima(2); b = gp(3) #...

```

```
>>> from sage.all import *
>>> # needs sage.libs.pari sage.symbolic
>>> a = maxima(Integer(2)); b = gp(Integer(3)) ...
    # needs sage.libs.pari sage.symbolic
>>> a, b
# needs sage.libs.pari sage.symbolic
(2, 3)
```

```
sage.interfaces.quit.is_running(pid)
```

Return True if and only if there is a process with id pid running.

```
sage.interfaces.quit.kill_spawned_jobs(verbose=False)
```

**INPUT:**

- `verbose` – bool (default: False); if True, display a message each time a process is sent a kill signal

**EXAMPLES:**

```
sage: gp.eval('a=10') #...

```

```
sage: sage.interfaces.quit.kill_spawned_jobs(verbose=False)
sage: sage.interfaces.quit.expect_quitall()
sage: gp.eval('a=10') #...
```

(continues on next page)
After doing the above, we do the following to avoid confusion in other doctests:

```python
data: sage.interfaces.quit.expect_quitall()

>>> from sage.all import *
>>> sage.interfaces.quit.expect_quitall()
```

`sage.interfaces.quit.register_spawned_process(pid, cmd='')`

Write a line to the spawned_processes file with the given pid and cmd.

`sage.interfaces.quit.sage_spawned_process_file()`

EXAMPLES:

```python
data: from sage.interfaces.quit import sage_spawned_process_file
data: len(sage_spawned_process_file()) > 1
True

>>> from sage.all import *
>>> from sage.interfaces.quit import sage_spawned_process_file
>>> len(sage_spawned_process_file()) > Integer(1)
True
```
sage.interfaces.read_data.read_data(f, t)

Read data from file 'f' and class 't' (one element per line), and returns a list of elements.

INPUT:

- 'f' – a file name
- 't' – a class (objects will be coerced to that class)

OUTPUT:

a list of elements of class 't'

EXAMPLES:

```python
sage: indata = tmp_filename()
sage: f = open(indata, "w")
sage: _ = f.write("17
42
")
sage: f.close()
sage: l = read_data(indata, ZZ); l
[17, 42]
sage: f = open(indata, "w")
sage: _ = f.write("1.234
5.678
")
sage: f.close()
sage: l = read_data(indata, RealField(17)); l
[1.234, 5.678]
```

```python
>>> from sage.all import *
>>> indata = tmp_filename()
>>> f = open(indata, "w")
>>> _ = f.write("17\n42\n")
>>> f.close()
>>> l = read_data(indata, ZZ); l
[17, 42]
>>> f = open(indata, "w")
>>> _ = f.write("1.234\n5.678\n")
>>> f.close()
>>> l = read_data(indata, RealField(Integer(17))); l
[1.234, 5.678]
```
