Python Module Index 1083
Index 1085
Sage provides native support for working with matrices over any commutative or noncommutative ring. The parent object for a matrix is a matrix space \texttt{MatrixSpace}(R, n, m) of all $n \times m$ matrices over a ring $R$.

To create a matrix, either use the \texttt{matrix(...)} function or create a matrix space using the \texttt{MatrixSpace} command and coerce an object into it.

Matrices also act on row vectors, which you create using the \texttt{vector(...)} command or by making a \texttt{VectorSpace} and coercing lists into it. The natural action of matrices on row vectors is from the right. Sage currently does not have a column vector class (on which matrices would act from the left), but this is planned.

In addition to native Sage matrices, Sage also includes the following additional ways to compute with matrices:

- Several math software systems included with Sage have their own native matrix support, which can be used from Sage. E.g., PARI, GAP, Maxima, and Singular all have a notion of matrices.
- The GSL C-library is included with Sage, and can be used via Cython.
- The \texttt{scipy} module provides support for \textit{sparse} numerical linear algebra, among many other things.
- The \texttt{numpy} module, which you load by typing \texttt{import numpy} is included standard with Sage. It contains a very sophisticated and well developed array class, plus optimized support for \textit{numerical linear algebra}. Sage's matrices over RDF and CDF (native floating-point real and complex numbers) use numpy.

Finally, this module contains some data-structures for matrix-like objects like operation tables (e.g. the multiplication table of a group).
You can create any space $\text{Mat}_{n \times m}(R)$ of either dense or sparse matrices with given number of rows and columns over any commutative or noncommutative ring.

EXAMPLES:

```sage
sage: MS = MatrixSpace(QQ, 6,6, sparse=True); MS
Full MatrixSpace of 6 by 6 sparse matrices over Rational Field
sage: MS.base_ring()
Rational Field
sage: MS = MatrixSpace(ZZ, 3,5, sparse=False); MS
Full MatrixSpace of 3 by 5 dense matrices over Integer Ring
```

```python
>>> from sage.all import *

>>> MS = MatrixSpace(QQ, Integer(6),Integer(6), sparse=True); MS
Full MatrixSpace of 6 by 6 sparse matrices over Rational Field

>>> MS = MatrixSpace(ZZ, Integer(3),Integer(5), sparse=False); MS
Full MatrixSpace of 3 by 5 dense matrices over Integer Ring
```

```
```

class sage.matrix.matrix_space.MatrixSpace(base_ring, nrows, ncols, sparse, implementation)

Bases: UniqueRepresentation, Parent

The space of matrices of given size and base ring.

INPUT:

- `base_ring` – a ring
- `nrows` or `row_keys` – (nonnegative integer) the number of rows, or a finite family of arbitrary objects that index the rows of the matrix
- `ncols` or `column_keys` – (nonnegative integer, default `nrows`) the number of columns, or a finite family of arbitrary objects that index the columns of the matrix
- `sparse` – (boolean, default `False`) whether or not matrices are given a sparse representation
- `implementation` – (optional, a string or a matrix class) a possible implementation. Depending on the base ring, the string can be
  - 'generic' – on any base rings
  - 'flint' – for integers and rationals
  - 'meataxe' – finite fields using the optional package meataxe: Library for computing with modular representations
Matrices and Spaces of Matrices, Release 10.4

- 'm4ri' – for characteristic 2 using the m4ri: fast arithmetic with dense matrices over GF(2) library
- 'linbox-float' – for integer mod rings up to $2^8 = 256$
- 'linbox-double' – for integer mod rings up to $\floor{2^{26} \cdot \sqrt{2} + 1/2} = 94906266$
- 'numpy' – for real and complex floating point numbers

OUTPUT: a matrix space or, more generally, a homspace between free modules

This factory function creates instances of various specialized classes depending on the input. Not all combinations of options are implemented.

- If the parameters row_keys or column_keys are provided, they must be finite families of objects. In this case, instances of \texttt{CombinatorialFreeModule} are created via the factory function \texttt{FreeModule()}. Then the homspace between these modules is returned.

**EXAMPLES:**

```python
sage: MatrixSpace(QQ, 2)
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: MatrixSpace(ZZ, 3, 2)
Full MatrixSpace of 3 by 2 dense matrices over Integer Ring
sage: MatrixSpace(ZZ, 3, sparse=False)
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
sage: MatrixSpace(ZZ, 10, 5)
Full MatrixSpace of 10 by 5 dense matrices over Integer Ring
sage: MatrixSpace(ZZ, 10, 10).category()
Category of infinite enumerated finite dimensional modules with basis over
  (Dedekind domains and euclidean domains
  and noetherian rings
  and infinite enumerated sets and metric spaces)
sage: MatrixSpace(ZZ, 10, 10).category()
Category of infinite enumerated finite dimensional algebras with basis over
  (Dedekind domains and euclidean domains
  and noetherian rings
  and infinite enumerated sets and metric spaces)
sage: MatrixSpace(QQ, 10).category()
Category of infinite finite dimensional algebras with basis over
  (number fields and quotient fields and metric spaces)
```

```python
>>> from sage.all import *

Full MatrixSpace of 2 by 2 dense matrices over Rational Field
>>> MatrixSpace(ZZ, Integer(2))
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring
>>> MatrixSpace(ZZ, Integer(3), Integer(2))
Full MatrixSpace of 3 by 2 dense matrices over Integer Ring
>>> MatrixSpace(ZZ, Integer(3), sparse=False)
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
>>> MatrixSpace(ZZ, Integer(10), Integer(5))
Full MatrixSpace of 10 by 5 dense matrices over Integer Ring
>>> MatrixSpace(ZZ, Integer(10), Integer(5)).category()
Category of infinite enumerated finite dimensional modules with basis over
  (Dedekind domains and euclidean domains
  and noetherian rings
  and infinite enumerated sets and metric spaces)
>>> MatrixSpace(ZZ, Integer(10), Integer(10)).category()
Category of infinite enumerated finite dimensional algebras with basis over
  (Dedekind domains and euclidean domains
```

(continues on next page)
and noetherian rings
and infinite enumerated sets and metric spaces)

```python
MatrixSpace(QQ, Integer(10)).category()
```
Category of infinite finite dimensional algebras with basis over
(number fields and quotient fields and metric spaces)

Some examples of square 2 by 2 rational matrices:

```python
sage: MS = MatrixSpace(QQ, 2)
sage: MS.dimension()
4
sage: MS.dims()
(2, 2)
sage: B = MS.basis()
sage: list(B)
[[1 0] [0 1] [0 0] [0 0]
 [0 0], [0 0], [1 0], [0 1]]
sage: B[0,0]
[1 0]
[0 0]
sage: B[0,1]
[0 1]
[0 0]
sage: B[1,0]
[0 0]
[1 0]
sage: B[1,1]
[0 0]
[0 1]
sage: A = MS.matrix([1,2,3,4]); A
[1 2]
[3 4]
```

```python
>>> from sage.all import *
```

```python
>>> MS = MatrixSpace(QQ, Integer(2))
```

```python
>>> MS.dimension()
4
```

```python
>>> MS.dims()
(2, 2)
```

```python
>>> B = MS.basis()
```

```python
>>> list(B)
[[1 0] [0 1] [0 0] [0 0]
 [0 0], [0 0], [1 0], [0 1]]
```

```python
>>> B[Integer(0),Integer(0)]
[1 0]
[0 0]
```

```python
>>> B[Integer(0),Integer(1)]
[0 1]
[0 0]
```

```python
>>> B[Integer(1),Integer(0)]
[0 0]
[1 0]
```

(continues on next page)
The above matrix $A$ can be multiplied by a 2 by 3 integer matrix:

```python
sage: MS2 = MatrixSpace(ZZ, 2, 3)
sage: B = MS2.matrix([1,2,3,4,5,6])
sage: A * B
[ 9 12 15]
[19 26 33]
```

Using `row_keys` and `column_keys`:

```python
sage: MS = MatrixSpace(ZZ, ['u', 'v'], ['a', 'b', 'c']); MS
Set of Morphisms
from Free module generated by {'a', 'b', 'c'} over Integer Ring
to Free module generated by {'u', 'v'} over Integer Ring
in Category of finite dimensional modules with basis over Integer Ring
```

Check categories:

```python
sage: MatrixSpace(ZZ, 10, 5)
Full MatrixSpace of 10 by 5 dense matrices over Integer Ring
sage: MatrixSpace(ZZ, 10, 5).category()
Category of infinite enumerated finite dimensional modules with basis over
(Dedekind domains and euclidean domains
and noetherian rings
and infinite enumerated sets and metric spaces)
sage: MatrixSpace(ZZ, 10, 10).category()
Category of infinite enumerated finite dimensional algebras with basis over
(Dedekind domains and euclidean domains
and noetherian rings
and infinite enumerated sets and metric spaces)
sage: MatrixSpace(QQ, 10).category()
Category of infinite finite dimensional algebras with basis over
(number fields and quotient fields and metric spaces)
```
Matrices and Spaces of Matrices, Release 10.4

>>> from sage.all import *

>>>
MatrixSpace(ZZ, Integer(10), Integer(5))
Full MatrixSpace of 10 by 5 dense matrices over Integer Ring

>>> MatrixSpace(ZZ, Integer(10), Integer(5)).category()
Category of infinite enumerated finite dimensional modules with basis over
(Dedekind domains and euclidean domains
and noetherian rings
and infinite enumerated sets and metric spaces)

>>>
MatrixSpace(ZZ, Integer(10), Integer(10)).category()
Category of infinite enumerated finite dimensional algebras with basis over
(Dedekind domains and euclidean domains
and noetherian rings
and infinite enumerated sets and metric spaces)

>>>
MatrixSpace(QQ, Integer(10)).category()
Category of infinite finite dimensional algebras with basis over
(number fields and quotient fields and metric spaces)

\[\text{base\_extend}(R)\]

Return base extension of this matrix space to \(R\).

**INPUT:**

- \(R\) – ring

**OUTPUT:** a matrix space

**EXAMPLES:**

sage: Mat(ZZ, 3, 5).base_extend(QQ)
Full MatrixSpace of 3 by 5 dense matrices over Rational Field

sage: Mat(QQ, 3, 5).base_extend(GF(7))
Traceback (most recent call last):
  ...
  TypeError: no base extension defined

\[\text{basis}()\]

Return a basis for this matrix space.

**Warning:** This will of course compute every generator of this matrix space. So for large dimensions, this could take a long time, waste a massive amount of memory (for dense matrices), and is likely not very useful. Don’t use this on large matrix spaces.

**EXAMPLES:**

sage: list(Mat(ZZ, 2, 2).basis())
[\[1 0\] \[0 1\] \[0 0\] \[0 0\]]
cached_method (f, name=None, key=None, do_pickle=None)

A decorator for cached methods.

EXAMPLES:

In the following examples, one can see how a cached method works in application. Below, we demonstrate what is done behind the scenes:

```python
>>> from sage.all import *
>>> list(Mat(ZZ,Integer(2),Integer(2)).basis())
[[1 0] [0 1], [0 0], [1 0], [0 1]]
```

When calling a cached method for the second time with the same arguments, the value is gotten from the cache, so that a new computation is not needed:

```python
>>> from sage.all import *
>>> class C:
...     @cached_method
...     def __hash__(self):
...         print("compute hash")
...         return int(5)
...     @cached_method
...     def f(self, x):
...         print("computing cached method")
...         return x*2

sage: c = C()
sage: type(C.__hash__)
<class 'sage.misc.cachefunc.CachedMethodCallerNoArgs'>
sage: hash(c)
compute hash
5

When calling a cached method for the second time with the same arguments, the value is gotten from the cache, so that a new computation is not needed:

```python
>>> from sage.all import *
>>> class C:
...     @cached_method
...     def __hash__(self):
...         print("compute hash")
...         return int(Integer(5))
...     @cached_method
...     def f(self, x):
...         print("computing cached method")
...         return x*Integer(2)

>>> c = C()
>>> type(C.__hash__)
<class 'sage.misc.cachefunc.CachedMethodCallerNoArgs'>
>>> hash(c)
compute hash
5
```
Different instances have distinct caches:

```python
sage: d = C()
sage: d.f(4) is c.f(4)
False
sage: d.f.clear_cache()
sage: c.f(4)
8
sage: d.f(4)
computing cached method
8
```

Using cached methods for the hash and other special methods was implemented in Issue #12601, by means of `CachedSpecialMethod`. We show that it is used behind the scenes:

```python
sage: cached_method(c.__hash__)
<sage.misc.cachefunc.CachedSpecialMethod object at ...>
sage: cached_method(c.f)
<sage.misc.cachefunc.CachedMethod object at ...>
```

```python
>>> from sage.all import *

>>> cached_method(c.__hash__)
<sage.misc.cachefunc.CachedSpecialMethod object at ...>
>>> cached_method(c.f)
<sage.misc.cachefunc.CachedMethod object at ...>
```

The parameter `do_pickle` can be used if the contents of the cache should be stored in a pickle of the cached method. This can be dangerous with special methods such as `__hash__`:
sage: class C:
....:     @cached_method(do_pickle=True)
....:     def __hash__(self):
....:         return id(self)

sage: import __main__
sage: __main__.C = C
sage: c = C()
sage: hash(c)  # random output
sage: d = loads(dumps(c))
sage: hash(d) == hash(c)
True

>>> from sage.all import *
>>> class C:
...     @cached_method(do_pickle=True)
...     def __hash__(self):
...         return id(self)

>>> import __main__
>>> __main__.C = C
>>> c = C()
>>> hash(c)  # random output
>>> d = loads(dumps(c))
>>> hash(d) == hash(c)
False

However, the contents of a method’s cache are not pickled unless do_pickle is set:

sage: class C:
....:     @cached_method
....:     def __hash__(self):
....:         return id(self)

sage: __main__.C = C
sage: c = C()
sage: hash(c)  # random output
sage: d = loads(dumps(c))
sage: hash(d) == hash(c)
False

>>> from sage.all import *
>>> class C:
...     @cached_method
...     def __hash__(self):
...         return id(self)

>>> __main__.C = C
>>> c = C()
>>> hash(c)  # random output
>>> d = loads(dumps(c))
>>> hash(d) == hash(c)
False

cardinality()

Return the number of elements in self.
EXAMPLES:

```
sage: MatrixSpace(GF(3), 2, 3).cardinality()
729

sage: MatrixSpace(ZZ, 2).cardinality()
+Infinity

sage: MatrixSpace(ZZ, 0, 3).cardinality()
1
```

```python
>>> from sage.all import *

>>> MatrixSpace(GF(Integer(3)), Integer(2), Integer(3)).cardinality()
729

>>> MatrixSpace(ZZ, Integer(2)).cardinality()
+Infinity

>>> MatrixSpace(ZZ, Integer(0), Integer(3)).cardinality()
1
```

`change_ring(R)`

Return matrix space over R with otherwise same parameters as `self`.

INPUT:

- R – ring

OUTPUT: a matrix space

EXAMPLES:

```
sage: Mat(QQ, 3, 5).change_ring(GF(7))
Full MatrixSpace of 3 by 5 dense matrices over Finite Field of size 7

>>> from sage.all import *

>>> Mat(QQ, Integer(3), Integer(5)).change_ring(GF(Integer(7)))
Full MatrixSpace of 3 by 5 dense matrices over Finite Field of size 7
```

`characteristic()`

Return the characteristic.

EXAMPLES:

```
sage: MatrixSpace(ZZ, 2).characteristic()
0

sage: MatrixSpace(GF(9), 0).characteristic()  # needs sage.rings.finite_rings
3

>>> from sage.all import *

>>> MatrixSpace(ZZ, Integer(2)).characteristic()
0

>>> MatrixSpace(GF(Integer(9)), Integer(0)).characteristic()  # needs sage.rings.finite_rings
3
```

`column_space()`

Return the module spanned by all columns of matrices in this matrix space. This is a free module of rank the number of columns. It will be sparse or dense as this matrix space is sparse or dense.
EXAMPLES:

```python
sage: M = Mat(GF(9,'a'), 20, 5, sparse=True); M.column_space()  # needs sage.rings.finite_rings
Sparse vector space of dimension 20 over Finite Field in a of size 3^2
```

```python
>>> from sage.all import *
>>> M = Mat(GF(Integer(9),'a'), Integer(20), Integer(5), sparse=True); M.
˓→column_space()  # needs sage.rings.finite_rings
Sparse vector space of dimension 20 over Finite Field in a of size 3^2
```

class MatrixSpace(construction())

EXAMPLES:

```python
sage: A = matrix(ZZ, 2, [1..4], sparse=True)
sage: A.parent().construction()
(MatrixFunctor, Integer Ring)
sage: A.parent().construction()[0](QQ['x'])
Full MatrixSpace of 2 by 2 sparse matrices over Univariate Polynomial Ring in x over Rational Field
sage: parent(A/2)
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
```

```python
>>> from sage.all import *
>>> A = matrix(ZZ, Integer(2), (ellipsis_range(Integer(1),Ellipsis,
˓→Integer(4))), sparse=True)
>>> A.parent().construction()
(MatrixFunctor, Integer Ring)
>>> A.parent().construction()[Integer(0)](QQ['x'])
Full MatrixSpace of 2 by 2 sparse matrices over Univariate Polynomial Ring in x over Rational Field
>>> parent(A/Integer(2))
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
```

diagonal_matrix(entries)

Create a diagonal matrix in self using the specified elements

INPUT:

- entries – the elements to use as the diagonal entries

self must be a space of square matrices. The length of entries must be less than or equal to the matrix dimensions. If the length of entries is less than the matrix dimensions, entries is padded with zeroes at the end.

EXAMPLES:

```python
sage: MS1 = MatrixSpace(ZZ,4)
sage: MS2 = MatrixSpace(QQ,3,4)
sage: I = MS1.diagonal_matrix([1, 2, 3, 4])
sage: I
[1 0 0 0]
[0 2 0 0]
[0 0 3 0]
[0 0 0 4]
sage: MS2.diagonal_matrix([1, 2])
Traceback (most recent call last):
...
```

(continues on next page)
TypeError: diagonal matrix must be square
```
sage: MS1.diagonal_matrix([1, 2, 3, 4, 5])
Traceback (most recent call last):
...
ValueError: number of diagonal matrix entries (5) exceeds the matrix size (4)
```
sage: MS1.diagonal_matrix([1/2, 2, 3, 4])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer

```
>>> from sage.all import *

>>>'MS1 = MatrixSpace(ZZ,Integer(4))

>>> I = MS1.diagonal_matrix([Integer(1), Integer(2), Integer(3), Integer(4)])

>>> I
[1 0 0 0]
[0 2 0 0]
[0 0 3 0]
[0 0 0 4]

>>> MS2.diagonal_matrix([Integer(1), Integer(2)])
Traceback (most recent call last):
...
TypeError: diagonal matrix must be square
```

```
>>> MS1.diagonal_matrix([Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)])
Traceback (most recent call last):
...
ValueError: number of diagonal matrix entries (5) exceeds the matrix size (4)
```

```
>>> MS1.diagonal_matrix([Integer(1)/Integer(2), Integer(2), Integer(3), Integer(4)])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

Check different implementations:

```
sage: M1 = MatrixSpace(ZZ, 2, implementation='flint')
# needs sage.libs.linbox

sage: M2 = MatrixSpace(ZZ, 2, implementation='generic')

sage: type(M1.diagonal_matrix([1, 2]))
# needs sage.libs.linbox
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>

sage: type(M2.diagonal_matrix([1, 2]))
<class 'sage.matrix.matrix_generic_dense.Matrix_generic_dense'>
```

```
>>> from sage.all import *

>>> M1 = MatrixSpace(ZZ, Integer(2), implementation='flint')
# needs sage.libs.linbox

>>> M2 = MatrixSpace(ZZ, Integer(2), implementation='generic')

>>> type(M1.diagonal_matrix([Integer(1), Integer(2)]))
# needs sage.libs.linbox
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>

>>> type(M2.diagonal_matrix([Integer(1), Integer(2)]))
<class 'sage.matrix.matrix_generic_dense.Matrix_generic_dense'>
```
**dimension()**

Return \((m\ \text{rows})\times(n\ \text{cols})\) of \texttt{self} as \texttt{Integer}.

**EXAMPLES:**

```sage
sage: MS = MatrixSpace(ZZ,4,6)
sage: u = MS.dimension()
sage: u - 24 == 0
True
```

```python
from sage.all import *
MS = MatrixSpace(ZZ,Integer(4),Integer(6))
u = MS.dimension()
u - Integer(24) == Integer(0)
True
```

**dims()**

Return \((m\ \text{row}, n\ \text{col})\) representation of \texttt{self} dimension.

**EXAMPLES:**

```sage
sage: MS = MatrixSpace(ZZ,4,6)
sage: MS.dims()
(4, 6)
```

```python
from sage.all import *
MS = MatrixSpace(ZZ,Integer(4),Integer(6))
MS.dims()
(4, 6)
```

**from_vector**(vector, order=None, coerce=True)

Build an element of \texttt{self} from a vector.

**EXAMPLES:**

```sage
sage: A = matrix([[1,2,3], [4,5,6]])
sage: v = vector(A); v
(1, 2, 3, 4, 5, 6)
sage: MS = A.parent()
sage: MS.from_vector(v)
[1 2 3]
[4 5 6]
sage: order = [(1,2), (1,0), (0,1), (0,2), (0,0), (1,1)]
sage: MS.from_vector(v, order=order)
[5 3 4]
[2 6 1]
```

```python
A = matrix([[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5),
Integer(6)]]
>>> v = vector(A); v
(1, 2, 3, 4, 5, 6)
>>> MS = A.parent()
>>> MS.from_vector(v)
[1 2 3]
[4 5 6]
>>> order = [(Integer(1),Integer(2)), (Integer(1),Integer(0)), (0,1),
(0,2), (0,0), (1,1)]
>>> MS.from_vector(v, order=order)
```
gen\((n)\)

Return the \(n\)-th generator of this matrix space.

This does not compute all basis matrices, so it is reasonably intelligent.

EXAMPLES:

```
sage: M = Mat(GF(7), 10000, 5); M.ngens()
50000
sage: a = M.10
sage: a[:4]
[0 0 0 0 0]
[0 0 0 0 0]
[1 0 0 0 0]
[0 0 0 0 0]
```

```
>>> from sage.all import *
```

```
>>> M = Mat(GF(Integer(7)), Integer(10000), Integer(5)); M.ngens()
50000
```

```
>>> a = M.gen(10)
```

```
>>> a[:Integer(4)]
[0 0 0 0 0]
[0 0 0 0 0]
[1 0 0 0 0]
[0 0 0 0 0]
```

identity_matrix()

Return the identity matrix in \(self\).

\(self\) must be a space of square matrices. The returned matrix is immutable. Please use \copy\ if you want a modified copy.

EXAMPLES:

```
sage: MS1 = MatrixSpace(ZZ,4)
sage: MS2 = MatrixSpace(QQ,3,4)
sage: I = MS1.identity_matrix()
sage: I
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: Er = MS2.identity_matrix()
Traceback (most recent call last):
...
TypeError: identity matrix must be square
```

```
>>> from sage.all import *
```

```
>>> MS1 = MatrixSpace(ZZ,Integer(4))
```

```
>>> MS2 = MatrixSpace(QQ,Integer(3),Integer(4))
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

>>> I = MS1.identity_matrix()
>>> I
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

>>> Er = MS2.identity_matrix()
Traceback (most recent call last):
...
TypeError: identity matrix must be square

**is_dense()**

Return whether matrices in `self` are dense.

**EXAMPLES:**

```sage
sage: Mat(RDF, 2, 3).is_sparse()
False
sage: Mat(RR, 123456, 22, sparse=True).is_sparse()
True
```

```sage
>>> from sage.all import *
```

```sage
>>> Mat(RDF, Integer(2), Integer(3)).is_sparse()
False
```

```sage
>>> Mat(RR, Integer(123456), Integer(22), sparse=True).is_sparse()
True
```

**is_finite()**

Return whether this matrix space is finite.

**EXAMPLES:**

```sage
sage: MatrixSpace(GF(101), 10000).is_finite()
True
sage: MatrixSpace(QQ, 2).is_finite()
False
```

```sage
>>> from sage.all import *
```

```sage
>>> MatrixSpace(GF(Integer(101)), Integer(10000)).is_finite()
True
```

```sage
>>> MatrixSpace(QQ, Integer(2)).is_finite()
False
```

**is_sparse()**

Return whether matrices in `self` are sparse.

**EXAMPLES:**

```sage
sage: Mat(GF(2011), 10000).is_sparse() # needs sage.rings.finite_rings
False
sage: Mat(GF(2011), 10000, sparse=True).is_sparse() # needs sage.rings.finite_rings
True
```

16 Chapter 1. Matrix Spaces
matrix($x$=None, **kwds)

Create a matrix in self.

INPUT:

- $x$ – data to construct a new matrix from. See matrix()
- coerce – (default: True) if False, assume without checking that the values in $x$ lie in the base ring

OUTPUT:

- a matrix in self.

EXAMPLES:

```python
sage: M = MatrixSpace(ZZ, 2)
sage: M.matrix([[1,0],[0,-1]])
[ 1 0]
[ 0 -1]
sage: M.matrix([1,0,0,-1])
[ 1 0]
[ 0 -1]
sage: M.matrix([1,2,3,4])
[1 2]
[3 4]
```

Note that the last “flip” cannot be performed if $x$ is a matrix, no matter what is rows (it used to be possible but was fixed by Issue #10793):

```python
sage: projection = matrix(ZZ,[[1,0,0],[0,1,0]])
sage: projection
[1 0 0]
[0 1 0]
sage: projection.parent()  # Full MatrixSpace of 2 by 3 dense matrices over Integer Ring
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring
sage: M = MatrixSpace(ZZ, 3, 2)
sage: M
Full MatrixSpace of 3 by 2 dense matrices over Integer Ring
sage: M(projection)
```

(continues on next page)
Traceback (most recent call last):
...
ValueError: inconsistent number of rows: should be 3 but got 2

If you really want to make from a matrix another matrix of different dimensions, use either transpose method or explicit conversion to a list:

```
sage: M(projection.list())
[1 0]
[0 0]
[1 0]
```

```
>>> from sage.all import *

>>> M(projection.list())
[1 0]
[0 0]
[1 0]
```

```
matrix_space(nrows=None, ncols=None, sparse=False)
```

Return the matrix space with given number of rows, columns and sparsity over the same base ring as self, and defaults the same as self.

EXAMPLES:

```
sage: M = Mat(GF(7), 100, 200)
sage: M.matrix_space(5000)
Full MatrixSpace of 5000 by 200 dense matrices over Finite Field of size 7
```
```
sage: M.matrix_space(ncols=5000)
Full MatrixSpace of 100 by 5000 dense matrices over Finite Field of size 7
```
```
sage: M.matrix_space(sparse=True)
Full MatrixSpace of 100 by 200 sparse matrices over Finite Field of size 7
```
```
>>> from sage.all import *

>>> M = Mat(GF(Integer(7)), Integer(100), Integer(200))

>>> M.matrix_space(Integer(5000))
Full MatrixSpace of 5000 by 200 dense matrices over Finite Field of size 7
```
```
>>> M.matrix_space(ncols=Integer(5000))
Full MatrixSpace of 100 by 5000 dense matrices over Finite Field of size 7
```
```
>>> M.matrix_space(sparse=True)
Full MatrixSpace of 100 by 200 sparse matrices over Finite Field of size 7
```
**ncols()**

Return the number of columns of matrices in this space.

**EXAMPLES:**

```python
sage: M = Mat(ZZ['x'], 200000, 500000, sparse=True)
sage: M.ncols()
500000
```

```python
>>> from sage.all import *

>>> M = Mat(ZZ['x'], Integer(200000), Integer(500000), sparse=True)
```

**ngens()**

Return the number of generators of this matrix space.

This is the number of entries in the matrices in this space.

**EXAMPLES:**

```python
sage: M = Mat(GF(7), 100, 200); M.ngens()
20000
```

```python
>>> from sage.all import *

>>> M = Mat(GF(Integer(7)), Integer(100), Integer(200)); M.ngens()
20000
```

**nrows()**

Return the number of rows of matrices in this space.

**EXAMPLES:**

```python
sage: M = Mat(ZZ, 200000, 500000)
sage: M.nrows()
200000
```

```python
>>> from sage.all import *

>>> M = Mat(ZZ, Integer(200000), Integer(500000))
```

**one()**

Return the identity matrix in `self`.

`self` must be a space of square matrices. The returned matrix is immutable. Please use `copy` if you want a modified copy.

**EXAMPLES:**

```python
sage: MS1 = MatrixSpace(ZZ,4)
sage: MS2 = MatrixSpace(QQ,3,4)
sage: I = MS1.identity_matrix()
sage: I
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
```

(continues on next page)
random_element (density=None, *args, **kwds)

Return a random element from this matrix space.

INPUT:

- density – float or None (default: None): rough measure of the proportion of nonzero entries in the random matrix; if set to None, all entries of the matrix are randomized, allowing for any element of the underlying ring, but if set to a float, a proportion of entries is selected and randomized to non-zero elements of the ring

- *args, **kwds – remaining parameters, which may be passed to the random_element function of the base ring. (“maybe”, since this function calls the randomize function on the zero matrix, which need not call the random_element function of the base ring at all in general.)

OUTPUT:

- Matrix

Note: This method will randomize a proportion of roughly density entries in a newly allocated zero matrix.

By default, if the user sets the value of density explicitly, this method will enforce that these entries are set to non-zero values. However, if the test for equality with zero in the base ring is too expensive, the user can override this behaviour by passing the argument nonzero=False to this method.

Otherwise, if the user does not set the value of density, the default value is taken to be 1, and the option nonzero=False is passed to the randomize method.

EXAMPLES:

```
sage: M = Mat(ZZ, 2, 5).random_element()
sage: TestSuite(M).run()
sage: M = Mat(QQ, 2, 5).random_element(density=0.5)
sage: TestSuite(M).run()
```
row_space()

Return the module spanned by all rows of matrices in this matrix space. This is a free module of rank the number of rows. It will be sparse or dense as this matrix space is sparse or dense.

EXAMPLES:

```
sage: M = Mat(ZZ, 20, 5, sparse=False).row_space()
Ambient free module of rank 5 over the principal ideal domain Integer Ring
```

```python
>>> from sage.all import *
>>> M = Mat(ZZ, Integer(20), Integer(5), sparse=False).row_space()
Ambient free module of rank 5 over the principal ideal domain Integer Ring
```

some_elements()

Return some elements of this matrix space.

See TestSuite for a typical use case.

OUTPUT:

An iterator.

EXAMPLES:

```
sage: M = MatrixSpace(ZZ, 2, 2)
sage: tuple(M.some_elements())
( [ 0 1], [1 0], [0 1], [0 0], [0 0], [1 0], [0 1] )
sage: M = MatrixSpace(QQ, 2, 3)
```

(continues on next page)
submodule (gens, check=True, already_echelonized=False, unitriangular=False, support_order=None, category=None, *args, **opts)

The submodule spanned by a finite set of matrices.

INPUT:

- **gens** – a list or family of elements of self
- **check** – (default: True) whether to verify that the elements of gens are in self
- **already_echelonized** – (default: False) whether the elements of gens are already in (not necessarily reduced) echelon form
- **unitriangular** – (default: False) whether the lift morphism is unitriangular
- **support_order** – (optional) either something that can be converted into a tuple or a key function

If already_echelonized is False, then the generators are put in reduced echelon form using echelonize(), and reindexed by 0,1,...
**Warning:** At this point, this method only works for finite dimensional submodules and if matrices can be echelonized over the base ring.

If in addition `unitriangular` is `True`, then the generators are made such that the coefficients of the pivots are 1, so that lifting map is unitriangular.

The basis of the submodule uses the same index set as the generators, and the lifting map sends $y_i$ to $gens[i]$.

**See also:**

`ModulesWithBasis.ParentMethods.submodule()`

**EXAMPLES:**

```python
sage: M = MatrixSpace(QQ, 2)
sage: mat = M.matrix([[1, 2], [3, 4]])
sage: X = M.submodule([mat], already_echelonized=True); X
Free module generated by {0} over Rational Field
sage: mat2 = M.matrix([[1, 0], [-3, 2]])
sage: X = M.submodule([mat, mat2])
sage: [X.lift(b) for b in X.basis()]
[[1 0]
 [0 1],
[-3 2], [3 1]]
sage: A = matrix([[1, 1], [0, -1]])
sage: B = matrix([[0, 1], [0, 2]])
sage: X = M.submodule([A, B])
sage: Xp = M.submodule([A, B], support_order=[(0,1), (1,1), (0,0)])
sage: [X.lift(b) for b in X.basis()]
[[1 0]
 [0 -3], [0 2]]
sage: [Xp.lift(b) for b in Xp.basis()]
[[ 2/3  1]
 [-1/3  0],
[ 0  0], [ 0  1]]
```

```python
>>> from sage.all import *

>>> M = MatrixSpace(QQ, Integer(2))
>>> mat = M.matrix([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]))
>>> X = M.submodule([mat], already_echelonized=True); X
Free module generated by {0} over Rational Field
>>> mat2 = M.matrix([[Integer(1), Integer(0)], [-Integer(3), Integer(2)]]))
>>> X = M.submodule([mat, mat2])
>>> [X.lift(b) for b in X.basis()]
[[1 0]
 [0 1],
[-3 2], [3 1]]

>>> A = matrix([[Integer(1), Integer(1)], [Integer(0), -Integer(1)]]))
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> B = matrix([[Integer(0), Integer(1)], [Integer(0), Integer(2)]])
>>> X = M.submodule([A, B])
>>> Xp = M.submodule([A, B], support_order=[(Integer(0),Integer(1)), (Integer(1),Integer(1)), (Integer(0),Integer(0))])
```

```python
>>> [X.lift(b) for b in X.basis()]
[1 0]
[0 -3],

>>> [Xp.lift(b) for b in Xp.basis()]
[2/3 1]
[-1/3 0]
```

**transposed()**

The transposed matrix space, having the same base ring and sparseness, but number of columns and rows is swapped.

**EXAMPLES:**

```python
sage: MS = MatrixSpace(GF(3), 7, 10)
sage: MS.transposed
Full MatrixSpace of 10 by 7 dense matrices over Finite Field of size 3
sage: MS = MatrixSpace(GF(3), 7, 7)
sage: MS.transposed is MS
True
sage: M = MatrixSpace(ZZ, 2, 3)
sage: M.transposed
Full MatrixSpace of 3 by 2 dense matrices over Integer Ring
```

```python
>>> from sage.all import *
```

```python
>>> MS = MatrixSpace(GF(Integer(3)), Integer(7), Integer(10))
>>> MS.transposed
Full MatrixSpace of 10 by 7 dense matrices over Finite Field of size 3
>>> MS = MatrixSpace(GF(Integer(3)), Integer(7), Integer(7))
>>> MS.transposed is MS
True
>>> M = MatrixSpace(ZZ, Integer(2), Integer(3))
>>> M.transposed
Full MatrixSpace of 3 by 2 dense matrices over Integer Ring
```

**zero()**

Return the zero matrix in self.

self must be a space of square matrices. The returned matrix is immutable. Please use copy if you want a modified copy.

**EXAMPLES:**

```python
sage: z = MatrixSpace(GF(7), 2, 4).zero_matrix(); z
[0 0 0 0]
[0 0 0 0]
sage: z.is_mutable()
False
```

24 Chapter 1. Matrix Spaces
```python
>>> from sage.all import *
>>> z = MatrixSpace(GF(Integer(7)), Integer(2), Integer(4)).zero_matrix(); z
[[0 0 0 0]
 [0 0 0 0]]
>>> z.is_mutable()
False
```

### zero_matrix()

Return the zero matrix in self.

self must be a space of square matrices. The returned matrix is immutable. Please use copy if you want a modified copy.

**EXAMPLES:**

```python
sage: z = MatrixSpace(GF(7), 2, 4).zero_matrix(); z
[[0 0 0 0]
 [0 0 0 0]]
sage: z.is_mutable()
False
```

```python
>>> from sage.all import *
>>> from sage.matrix.matrix_space import dict_to_list
>>> d = {}
>>> d[(Integer(0),Integer(0))] = Integer(1)
>>> d[(Integer(1),Integer(1))] = Integer(2)
>>> dict_to_list(d, Integer(2), Integer(2))
[[1, 0, 0, 2]
 [1, 0, 0, 0]]
```

### dict_to_list(entries, nrows, ncols)

Given a dictionary of coordinate tuples, return the list given by reading off the nrows*ncols matrix in row order.

**EXAMPLES:**

```python
sage: from sage.matrix.matrix_space import dict_to_list
sage: d = {}
```

```python
>>> from sage.all import *
>>> from sage.matrix.matrix_space import dict_to_list
>>> d = {}
>>> d[(Integer(0),Integer(0))] = Integer(1)
>>> d[(Integer(1),Integer(1))] = Integer(2)
>>> dict_to_list(d, Integer(2), Integer(2))
[[1, 0, 0, 2]
 [1, 0, 0, 0]]
```

### get_matrix_class(R, nrows, ncols, sparse, implementation)

Return a matrix class according to the input.

**Note:** This returns the base class without the category.
INPUT:

- \(R\) – a base ring
- \(\text{nrows}\) – number of rows
- \(\text{ncols}\) – number of columns
- \(\text{sparse}\) – (boolean) whether the matrix class should be sparse
- \(\text{implementation}\) – (None or string or a matrix class) a possible implementation. See the documentation of the constructor of \(\text{MatrixSpace}\).

EXAMPLES:

```python
sage: from sage.matrix.matrix_space import get_matrix_class

sage: get_matrix_class(ZZ, 4, 5, False, None)  # needs sage.libs.linbox
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>

# optional - meataxe, needs sage.rings.finite_rings
<class 'sage.matrix.matrix_gfpn_dense.Matrix_gfpn_dense'>
```

```python
sage.matrix.matrix_space.is_MatrixSpace(x)
```
Return whether `self` is an instance of `MatrixSpace`.

**EXAMPLES:**

```python
sage: from sage.matrix.matrix_space import is_MatrixSpace
sage: MS = MatrixSpace(QQ,2)
sage: A = MS.random_element()
sage: is_MatrixSpace(MS)
doctest:warning... DeprecationWarning: the function is_MatrixSpace is deprecated; use 'isinstance(..., MatrixSpace)' instead
See https://github.com/sagemath/sage/issues/37924 for details.
True
sage: is_MatrixSpace(A)
False
sage: is_MatrixSpace(5)
False
```
CHAPTER TWO

GENERAL MATRIX CONSTRUCTOR AND DISPLAY OPTIONS

`sage.matrix.constructor.Matrix(*args, **kwds)`

Create a matrix.

This implements the `matrix` constructor:

```python
sage: matrix([[1,2],[3,4]])
[1 2]
[3 4]
```

```python
>>> from sage.all import *

>>> matrix([[Integer(1),Integer(2)],[Integer(3),Integer(4)]])
[1 2]
[3 4]
```

It also contains methods to create special types of matrices, see `matrix` for more options. For example:

```python
sage: matrix.identity(2)
[1 0]
[0 1]
```

```python
>>> from sage.all import *

>>> matrix.identity(Integer(2))
[1 0]
[0 1]
```

INPUT:

The `matrix()` command takes the entries of a matrix, optionally preceded by a ring and the dimensions of the matrix, and returns a matrix.

The entries of a matrix can be specified as a flat list of elements, a list of lists (i.e., a list of rows), a list of Sage vectors, a callable object, or a dictionary having positions as keys and matrix entries as values (see the examples). If you pass in a callable object, then you must specify the number of rows and columns. You can create a matrix of zeros by passing an empty list or the integer zero for the entries. To construct a multiple of the identity (cf), you can specify square dimensions and pass in c. Calling `matrix()` with a Sage object may return something that makes sense. Calling `matrix()` with a NumPy array will convert the array to a matrix.

All arguments (even the positional ones) are optional.

Positional and keyword arguments:

- `base_ring` — parent of the entries of the matrix (despite the name, this is not a priori required to be a ring).
  By default, determine this from the given entries, falling back to `ZZ` if no entries are given.
• **nrows** – the number of rows in the matrix, or a finite or enumerated family of arbitrary objects that index the rows of the matrix

• **ncols** – the number of columns in the matrix, or a finite or enumerated family of arbitrary objects that index the columns of the matrix

• **entries** – see examples below.

If any of **nrows**, **ncols**, **row_keys**, **column_keys** is given as keyword argument, then none of these may be given as positional arguments.

Keyword-only arguments:

• **sparse** – (boolean) create a sparse matrix. This defaults to **True** when the entries are given as a dictionary, otherwise defaults to **False**.

• **row_keys** – a finite or enumerated family of arbitrary objects that index the rows of the matrix

• **column_keys** – a finite or enumerated family of arbitrary objects that index the columns of the matrix

• **space** – matrix space which will be the parent of the output matrix. This determines **base_ring**, **nrows**, **row_keys**, **ncols**, **column_keys**, and **sparse**.

• **immutable** – (boolean) make the matrix immutable. By default, the output matrix is mutable.

**OUTPUT:** a matrix or, more generally, a homomorphism between free modules

**EXAMPLES:**

```python
sage: m = matrix(2); m; m.parent()
[0 0]
[0 0]
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring

>>> from sage.all import *
>>> m = matrix(Integer(2)); m; m.parent()
[0 0]
[0 0]

  x3 & x4 & x5 \\
  x6 & x7 & x8 \\
\end{bmatrix} \]
```
```
sage: det(A)
-x2*x4*x6 + x1*x5*x6 + x2*x3*x7 - x0*x5*x7 - x1*x3*x8 + x0*x4*x8
```
```python
>>> from sage.all import *

R = PolynomialRing(QQ, Integer(9), 'x')
A = matrix(R, Integer(3), Integer(3), R.gens()); A

[x0  x1  x2]
[x3  x4  x5]
[x6  x7  x8]

>>> det(A)
-x2*x4*x6 + x1*x5*x6 + x2*x3*x7 - x0*x5*x7 - x1*x3*x8 + x0*x4*x8

sage: M = Matrix([[1,2,3], [4,5,6], [7,8,9]], immutable=True)

Traceback (most recent call last):
  ... 
ValueError: matrix is immutable; please change a copy instead
(i.e., use copy(M) to change a copy of M).

>>> from sage.all import *

M = Matrix([[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5), Integer(6)], [Integer(7),Integer(8),Integer(9)]], immutable=True)

Traceback (most recent call last):
  ... 
ValueError: matrix is immutable; please change a copy instead
(i.e., use copy(M) to change a copy of M).

Using `row_keys` and `column_keys`:

sage: M = matrix([[1,2,3], [4,5,6]], column_keys=['a','b','c'], row_keys=['u','v']); M

Generic morphism:
  From: Free module generated by {'a', 'b', 'c'} over Integer Ring
  To:   Free module generated by {'u', 'v'} over Integer Ring

sage: print(M._unicode_art_matrix())
    a  b  c
u|1 2 3|
v|4 5 6|

>>> from sage.all import *

M = matrix([[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5), Integer(6)]], column_keys=['a','b','c'], row_keys=['u','v']); M

Generic morphism:
  From: Free module generated by {'a', 'b', 'c'} over Integer Ring
  To:   Free module generated by {'u', 'v'} over Integer Ring

>>> print(M._unicode_art_matrix())
    a  b  c
u|1 2 3|
v|4 5 6|

It is allowed to specify dimensions redundantly:

sage: M = matrix(2, 3, [[1,2,3], [4,5,6]], column_keys=['a','b','c'], row_keys=['u','v']); M

Generic morphism:
  From: Free module generated by {'a', 'b', 'c'} over Integer Ring
  To:   Free module generated by {'u', 'v'} over Integer Ring
```
AUTHORS:

Create a matrix.

This implements the `matrix` constructor:

```python
sage: matrix([[1,2],[3,4]])
[1 2]
[3 4]
```

It also contains methods to create special types of matrices, see `matrix.tab` for more options. For example:

```python
sage: matrix.identity(2)
[1 0]
[0 1]

sage: matrix.identity(Integer(2))
[1 0]
[0 1]
```

INPUT:

The `matrix()` command takes the entries of a matrix, optionally preceded by a ring and the dimensions of the matrix, and returns a matrix.

The entries of a matrix can be specified as a flat list of elements, a list of lists (i.e., a list of rows), a list of Sage vectors, a callable object, or a dictionary having positions as keys and matrix entries as values (see the examples). If you pass in a callable object, then you must specify the number of rows and columns. You can create a matrix of zeros by passing an empty list or the integer zero for the entries. To construct a multiple of the identity (cf), you can specify square dimensions and pass in `c`. Calling `matrix()` with a Sage object may return something that makes sense. Calling `matrix()` with a NumPy array will convert the array to a matrix.

All arguments (even the positional ones) are optional.

Positional and keyword arguments:
• **base_ring** – parent of the entries of the matrix (despite the name, this is not a priori required to be a ring). By default, determine this from the given entries, falling back to \( \mathbb{Z} \) if no entries are given.

• **nrows** – the number of rows in the matrix, or a finite or enumerated family of arbitrary objects that index the rows of the matrix

• **ncols** – the number of columns in the matrix, or a finite or enumerated family of arbitrary objects that index the columns of the matrix

• **entries** – see examples below.

If any of **nrows**, **ncols**, **row_keys**, **column_keys** is given as keyword argument, then none of these may be given as positional arguments.

**Keyword-only arguments:**

• **sparse** – (boolean) create a sparse matrix. This defaults to True when the entries are given as a dictionary, otherwise defaults to False.

• **row_keys** – a finite or enumerated family of arbitrary objects that index the rows of the matrix

• **column_keys** – a finite or enumerated family of arbitrary objects that index the columns of the matrix

• **space** – matrix space which will be the parent of the output matrix. This determines **base_ring**, **nrows**, **row_keys**, **ncols**, **column_keys**, and **sparse**.

• **immutable** – (boolean) make the matrix immutable. By default, the output matrix is mutable.

**OUTPUT:** a matrix or, more generally, a homomorphism between free modules

**EXAMPLES:**

sage: M = Matrix([[1,2,3], [4,5,6], [7,8,9]], immutable=True)
sage: M[0] = [9,9,9]
Traceback (most recent call last):
  ...  ValueError: matrix is immutable; please change a copy instead
(i.e., use copy(M) to change a copy of M).

>>> from sage.all import *
>>> M = Matrix([[Integer(1),Integer(2),Integer(3)],
              [Integer(4),Integer(5),Integer(6)],
              [Integer(7),Integer(8),Integer(9)]], immutable=True)
>>> M[Integer(0)] = [Integer(9),Integer(9),Integer(9)]
Traceback (most recent call last):
  ...  ValueError: matrix is immutable; please change a copy instead
(i.e., use copy(M) to change a copy of M).

Using row_keys and column_keys:

sage: M = matrix([[1,2,3], [4,5,6]],
               column_keys=['a','b','c'], row_keys=['u','v']); M
Generic morphism:
  From: Free module generated by {'a', 'b', 'c'} over Integer Ring
  To:   Free module generated by {'u', 'v'} over Integer Ring
sage: print(M._unicode_art_matrix())
a b c
u | 1 2 3
  v |4 5 6

>>> from sage.all import *
>>> M = matrix([[Integer(1),Integer(2),Integer(3)],
              [Integer(4),Integer(5),Integer(6)]],
              column_keys=['a','b','c'], row_keys=['u','v']); M
Generic morphism:
  From: Free module generated by {'a', 'b', 'c'} over Integer Ring
  To:   Free module generated by {'u', 'v'} over Integer Ring

It is allowed to specify dimensions redundantly:

sage: M = matrix(2, 3, [[1,2,3], [4,5,6]],
               column_keys=['a','b','c'], row_keys=['u','v']); M
Generic morphism:
  From: Free module generated by {'a', 'b', 'c'} over Integer Ring
  To:   Free module generated by {'u', 'v'} over Integer Ring

Chapter 2. General matrix Constructor and display options
>>> from sage.all import *
>>> M = matrix(Integer(2), Integer(3), [[Integer(1),Integer(2),Integer(3)],
\[-\]\[Integer(4),Integer(5),Integer(6)]],
\...
column_keys=['a','b','c'], row_keys=['u','v']); M
Generic morphism:
From: Free module generated by {a, b, c} over Integer Ring
To: Free module generated by {u, v} over Integer Ring

- Jeroen Demeyer (2018-02-20): completely rewritten using MatrixArgs, see Issue #24742

sage.matrix.constructor.options(*get_value, **set_value)

Global options for matrices.

OPTIONS:
- format_numeric – (default: :{(prec)}) string used for formatting floating point numbers of an
  (optional) precision prec; only supported for entry types implementing __format__
- max_cols – (default: 49) maximum number of columns to display
- max_rows – (default: 19) maximum number of rows to display
- precision – (default: None) number of digits to display for floating point entries; if None, the exact
  representation is used instead. This option is also set by the IPython magic %precision.

EXAMPLES:

sage: matrix.options.max_cols = 6
sage: matrix.options.max_rows = 3
sage: matrix(ZZ, 3, 6)
\[
[0 0 0 0 0 0]
[0 0 0 0 0 0]
[0 0 0 0 0 0]
\]
sage: matrix(ZZ, 3, 7)
3 x 7 dense matrix over Integer Ring...
sage: matrix(ZZ, 4, 6)
4 x 6 dense matrix over Integer Ring...
sage: matrix.options._reset()

>>> from sage.all import *
>>> matrix.options.max_cols = Integer(6)
>>> matrix.options.max_rows = Integer(3)
>>> matrix(ZZ, Integer(3), Integer(6))
\[
[0 0 0 0 0 0]
[0 0 0 0 0 0]
[0 0 0 0 0 0]
\]
>>> matrix(ZZ, Integer(3), Integer(7))
3 x 7 dense matrix over Integer Ring...
>>> matrix(ZZ, Integer(4), Integer(6))
4 x 6 dense matrix over Integer Ring...
>>> matrix.options._reset()
The precision can also be set via the IPython magic:

```
sage: from sage.repl.interpreter import get_test_shell
sage: shell = get_test_shell()
sage: shell.run_cell('%precision 5')
%.5f
sage: matrix.options.precision
5
e

sage: A = matrix(RR, [[200/3]]); A
[[66.667]]
```

The number format can be specified as well:

```
sage: matrix.options.format_numeric = '{:.{prec}e}''
sage: A
[6.66667e+1]
sage: matrix.options.format_numeric = '{:.{prec}f}''
sage: A
[66.66667]
sage: matrix.options.format_numeric = '{:.{prec}g}''
sage: A
[+66.667]
sage: matrix.options._reset()
```

```
>>> from sage.all import *
>>> from sage.repl.interpreter import get_test_shell
>>> shell = get_test_shell()
>>> shell.run_cell('%precision 5')
%.5f
>>> matrix.options.precision
5
>>> A = matrix(RR, [[Integer(200)/Integer(3)]]); A
[66.667]
```

See GlobalOptions for more features of these options.
CONSTRUCTORS FOR SPECIAL MATRICES

This module gathers several constructors for special, commonly used or interesting matrices. These can be reached through `matrix.<tab>`.

For example, here is a circulant matrix of order five:

```
sage: matrix.circulant(SR.var('a b c d e'))  # needs sage.symbolic
[a b c d e]
[e a b c d]
[d e a b c]
[c d e a b]
[b c d e a]
```

```
>>> from sage.all import *

>>> matrix.circulant(SR.var('a b c d e'))  # needs sage.symbolic
[a b c d e]
[e a b c d]
[d e a b c]
[c d e a b]
[b c d e a]
```

The following constructions are available:
The Combinatorics module provides further matrix constructors, such as Hadamard matrices and Latin squares. See:

- `sage.combinat.matrices.hadamard_matrix`
- `sage.combinat.matrices.latin`

```python
sage.matrix.special.block_diagonal_matrix(*sub_matrices, **kwds)
```

This function is available as block_diagonal_matrix(…) and matrix.block_diagonal(…).

Create a block matrix whose diagonal block entries are given by sub_matrices, with zero elsewhere.

See also `block_matrix()`.

**EXAMPLES:**

```python
sage: A = matrix(ZZ, 2, [1,2,3,4])
sage: block_diagonal_matrix(A, A)
[1 2|0 0]
[3 4|0 0]
[---+---]
[0 0|1 2]
[0 0|3 4]
```

```python
>>> from sage.all import *

>>> A = matrix(ZZ, Integer(2), [Integer(1),Integer(2),Integer(3),Integer(4)])

>>> block_diagonal_matrix(A, A)

[1 2|0 0]
[3 4|0 0]
[---+---]
[0 0|1 2]
[0 0|3 4]
```
The sub-matrices need not be square:

```
sage: B = matrix(QQ, 2, 3, range(6))
sage: block_diagonal_matrix(~A, B)
[ -2 1| 0 0 0]
[ 3/2 -1/2| 0 0 0]
[------------------------]
[ 0 0| 0 1 2]
[ 0 0| 3 4 5]
```

```
>>> from sage.all import *

>>> B = matrix(QQ, Integer(2), Integer(3), range(Integer(6)))

>>> block_diagonal_matrix(~A, B)
[ -2 1| 0 0 0]
[ 3/2 -1/2| 0 0 0]
[------------------------]
[ 0 0| 0 1 2]
[ 0 0| 3 4 5]
```

`sage.matrix.special.block_matrix(*args, **kwds)`

This function is available as `block_matrix(…)` and `matrix.block(…)`.

Return a larger matrix made by concatenating submatrices (rows first, then columns). For example, the matrix

```
[ A B ]
[ C D ]
```

is made up of submatrices A, B, C, and D.

**INPUT:**

The `block_matrix` command takes a list of submatrices to add as blocks, optionally preceded by a ring and the number of block rows and block columns, and returns a matrix.

The submatrices can be specified as a list of matrices (using `nrows` and `ncols` to determine their layout), or a list of lists of matrices, where each list forms a row.

- `ring` – the base ring
- `nrows` – the number of block rows
- `ncols` – the number of block cols
- `sub_matrices` – matrices (see below for syntax)
- `subdivide` – boolean, whether or not to add subdivision information to the matrix
- `sparse` – boolean, whether to make the resulting matrix sparse

**EXAMPLES:**

```
sage: A = matrix(QQ, 2, 2, [3,9,6,10])
sage: block_matrix([ [A, -A], [-A, 100*A] ])
[  3   9| -3  -9]
[  6  10| -6  -10]
[------------------------]
[ -5/12 3/8| 300   900]
[  1/4 -1/8| 600  1000]
```
If the number of submatrices in each row is the same, you can specify the submatrices as a single list too:

```
sage: block_matrix(2, 2, [ A, A, A, A ])
[ 3 9| 3 9]
[ 6 10| 6 10]
[-------]
[ 3 9| 3 9]
[ 6 10| 6 10]
```

One can use constant entries:

```
sage: block_matrix([ [1, A], [0, 1] ])
[ 1 0| 3 9]
[ 0 1| 6 10]
[-------]
[ 0 0| 1 0]
[ 0 0| 0 1]
```

A zero entry may represent any square or non-square zero matrix:

```
sage: B = matrix(QQ, 1, 1, [ 1 ])
sage: C = matrix(QQ, 2, 2, [ 2, 3, 4, 5 ])
sage: block_matrix([ [B, 0], [0, C] ])
[1|0 0]
[---]
[0|2 3]
[0|4 5]
```

(continues on next page)
One can specify the number of rows or columns as keywords too:

```python
sage: block_matrix([A, -A, ~A, 100*A], ncols=4)
[ 3  9 -3 -9 -5/12 3/8 300  900]
[ 6 10 -6 -10  1/4 -1/8  600 1000]
sage: block_matrix([A, -A, ~A, 100*A], nrows=1)
[ 3  9 -3 -9 -5/12 3/8 300  900]
[ 6 10 -6 -10  1/4 -1/8  600 1000]
```

It handles base rings nicely too:

```python
sage: R.<x> = ZZ['x']
sage: block_matrix([1/2, A, 0, x-1], parent=R)
[ 1/2  0 | 3  9]
[ 0  1/2 | 6 10]
```

Subdivisions are optional. If they are disabled, the columns need not line up:

```python
>>> block_matrix(Integer(2), Integer(2), [Integer(1)/Integer(2), A, Integer(0), x-1]).parent()
Full MatrixSpace of 4 by 4 dense matrices over Univariate Polynomial Ring in x over Rational Field
```
```python
sage: B = matrix(QQ, 2, 3, range(6))
sage: block_matrix([ [-A, B], [B, -A] ], subdivide=False)
[-5/12 3/8 0 1 2]  
[ 1/4 -1/8 3 4 5]  
[ 0 1 2 -5/12 3/8]  
[ 3 4 5 1/4 -1/8]
```

Without subdivisions it also deduces dimensions for scalars if possible:

```python
sage: C = matrix(ZZ, 1, 2, range(2))
sage: block_matrix([ [ C, 0 ], [ 3, 4 ], [ 5, 6, C ] ], subdivide=False)
[0 1 0 0]  
[3 0 4 0]  
[0 3 0 4]  
[5 6 0 1]
```

If all submatrices are sparse (unless there are none at all), the result will be a sparse matrix. Otherwise it will be dense by default. The `sparse` keyword can be used to override this:

```python
sage: A = Matrix(ZZ, 2, 2, [0, 1, 0, 0], sparse=True)
sage: block_matrix([ [ A ], [ A ]]).parent()
Full MatrixSpace of 4 by 2 sparse matrices over Integer Ring
sage: block_matrix([ [ A ], [ A ]], sparse=False).parent()
Full MatrixSpace of 4 by 2 dense matrices over Integer Ring
```

Consecutive zero submatrices are consolidated.

```python
sage: B = matrix(2, range(4))
sage: C = matrix(2, 8, range(16))
sage: block_matrix(2, [[B,0,0,B], [C]], subdivide=False)
[ 0 1 0 0 0 0 0 1]  
(continues on next page)
```
Ambiguity is not tolerated.

```
sage: B = matrix(2, range(4))
sage: C = matrix(2, 8, range(16))
sage: block_matrix(2, [[B,0,B,0],[C]], subdivide=False)
Traceback (most recent call last):
...  
ValueError: insufficient information to determine submatrix widths
```

Giving only a flat list of submatrices does not work:

```
sage: A = matrix(2, 3, range(6))
sage: B = matrix(3, 3, range(9))
sage: block_matrix([A, A, B, B])
Traceback (most recent call last):
...  
ValueError: must specify either nrows or ncols
```

```
>>> from sage.all import *
>>> B = matrix(Integer(2), range(Integer(4)))
>>> C = matrix(Integer(2), Integer(8), range(Integer(16)))
>>> block_matrix(Integer(2), [[B,Integer(0),Integer(0),B],[C]], subdivide=False)
Traceback (most recent call last):
...  
ValueError: insufficient information to determine submatrix widths
```

```
>>> from sage.all import *
>>> B = matrix(Integer(2), range(Integer(4)))
>>> C = matrix(Integer(2), Integer(8), range(Integer(16)))
>>> block_matrix(Integer(2), [[B,Integer(0),Integer(0),B],[C]], subdivide=False)
Traceback (most recent call last):
...  
ValueError: insufficient information to determine submatrix widths
```

```
sage.matrix.special.circulant (v, sparse=None)
```

This function is available as circulant(...) and matrix.circulant(...).

Return the circulant matrix specified by its 1st row $v$

A circulant $n \times n$ matrix specified by the 1st row $v = (v_0...v_{n-1})$ is the matrix $(c_{ij})_{0 \leq i,j \leq n-1}$, where $c_{ij} = v_{j-i \mod b}$.

INPUT:
• v – a list or a vector of values

• sparse – None by default; if `sparse` is set to True, the output will be sparse. Respectively, setting it to False produces dense output. If `sparse` is not set, and if `v` is a vector, the output sparsity is determined by the sparsity of `v`; else, the output will be dense.

EXAMPLES:

```python
sage: v = [1, 2, 3, 4, 8]
sage: matrix.circulant(v)
[1 2 3 4 8]
[8 1 2 3 4]
[4 8 1 2 3]
[3 4 8 1 2]
[2 3 4 8 1]
sage: m = matrix.circulant(vector(GF(3), [0, 1, -1], sparse=True)); m
[0 1 2]
[2 0 1]
[1 2 0]
sage: m.is_sparse()
True
```

```python
>>> from sage.all import *

>>> v = [Integer(1), Integer(2), Integer(3), Integer(4), Integer(8)]

>>> matrix.circulant(v)
[1 2 3 4 8]
[8 1 2 3 4]
[4 8 1 2 3]
[3 4 8 1 2]
[2 3 4 8 1]

>>> m = matrix.circulant(vector(GF(Integer(3)), [Integer(0), Integer(1), -Integer(1)], sparse=True)); m
[0 1 2]
[2 0 1]
[1 2 0]

>>> m.is_sparse()
True
```

`sage.matrix.special.column_matrix(*args, **kwds)`

This function is available as `column_matrix(...)` and `matrix.column(...)`. Construct a matrix, and then swap rows for columns and columns for rows.

**Note:** Linear algebra in Sage favors rows over columns. So, generally, when creating a matrix, input vectors and lists are treated as rows. This function is a convenience that turns around this convention when creating a matrix. If you are not familiar with the usual `matrix()` constructor, you might want to consider it first.

**INPUT:**

Inputs are almost exactly the same as for the `matrix()` constructor, which are documented there. But see examples below for how dimensions are handled.

**OUTPUT:**

Output is exactly the transpose of what the `matrix()` constructor would return. In other words, the `matrix` constructor builds a matrix and then this function exchanges rows for columns, and columns for rows.

**EXAMPLES:**
The most compelling use of this function is when you have a collection of lists or vectors that you would like to become the columns of a matrix. In almost any other situation, the `matrix` constructor can probably do the job just as easily, or easier.

```sage
sage: col_1 = [1,2,3]
sage: col_2 = [4,5,6]
sage: column_matrix([col_1, col_2])
[1 4]
[2 5]
[3 6]
```

```sage
sage: v1 = vector(QQ, [10, 20])
sage: v2 = vector(QQ, [30, 40])
sage: column_matrix(QQ, [v1, v2])
[10 30]
[20 40]
```

```python
>>> from sage.all import *

>>> col_1 = [Integer(1),Integer(2),Integer(3)]
>>> col_2 = [Integer(4),Integer(5),Integer(6)]
>>> column_matrix([col_1, col_2])
[1 4]
[2 5]
[3 6]
```

```sage
>>> v1 = vector(QQ, [Integer(10), Integer(20)])
>>> v2 = vector(QQ, [Integer(30), Integer(40)])
>>> column_matrix(QQ, [v1, v2])
[10 30]
[20 40]
```

If you only specify one dimension along with a flat list of entries, then it will be the number of columns in the result (which is different from the behavior of the `matrix` constructor).

```sage
sage: column_matrix(ZZ, 8, range(24))
[ 0  3  6  9 12 15 18 21]
[ 1  4  7 10 13 16 19 22]
[ 2  5  8 11 14 17 20 23]
```

```python
>>> from sage.all import *

>>> column_matrix(ZZ, Integer(8), range(Integer(24)))
[ 0  3  6  9 12 15 18 21]
[ 1  4  7 10 13 16 19 22]
[ 2  5  8 11 14 17 20 23]
```

And when you specify two dimensions, then they should be number of columns first, then the number of rows, which is the reverse of how they would be specified for the `matrix` constructor.

```sage
sage: column_matrix(QQ, 5, 3, range(15))
[ 0  3  6  9 12]
[ 1  4  7 10 13]
[ 2  5  8 11 14]
```

```python
>>> from sage.all import *

>>> column_matrix(QQ, Integer(5), Integer(3), range(Integer(15)))
[ 0  3  6  9 12]
```

(continues on next page)
And a few unproductive, but illustrative, examples.

```python
sage: A = matrix(ZZ, 3, 4, range(12))
sage: B = column_matrix(ZZ, 3, 4, range(12))
sage: A == B.transpose()
True
sage: A = matrix(QQ, 7, 12, range(84))
sage: A == column_matrix(A.columns())
True

`sage.matrix.special.companion_matrix(poly, format='right')`

This function is available as `companion_matrix(...)` and `matrix.companion(...)`. Create a companion matrix from a monic polynomial.

**INPUT:**

- `poly` – a univariate polynomial, or an iterable containing the coefficients of a polynomial, with low-degree coefficients first. The polynomial (or the polynomial implied by the coefficients) must be monic. In other words, the leading coefficient must be one. A symbolic expression that might also be a polynomial is not proper input, see examples below.

- `format` – (default: ‘right’); specifies one of four variations of a companion matrix. Allowable values are ‘right’, ‘left’, ‘top’ and ‘bottom’, which indicates which border of the matrix contains the negatives of the coefficients.

**OUTPUT:**

A square matrix with a size equal to the degree of the polynomial. The returned matrix has ones above, or below the diagonal, and the negatives of the coefficients along the indicated border of the matrix (excepting the leading
one coefficient). See the first examples below for precise illustrations.

EXAMPLES:

Each of the four possibilities. Notice that the coefficients are specified and their negatives become the entries of the matrix. The leading one must be given, but is not used. The permutation matrix $P$ is the identity matrix, with the columns reversed. The last three statements test the general relationships between the four variants.

```
sage: poly = [-2, -3, -4, -5, -6, 1]
sage: R = companion_matrix(poly, format='right'); R
[0 0 0 0 2]
[1 0 0 0 3]
[0 1 0 0 4]
[0 0 1 0 5]
[0 0 0 1 6]
sage: L = companion_matrix(poly, format='left'); L
[6 1 0 0 0]
[5 0 1 0 0]
[4 0 0 1 0]
[3 0 0 0 1]
[2 0 0 0 0]
sage: B = companion_matrix(poly, format='bottom'); B
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[2 3 4 5 6]
sage: T = companion_matrix(poly, format='top'); T
[6 5 4 3 2]
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]

sage: perm = Permutation([5, 4, 3, 2, 1])
sage: P = perm.to_matrix()
sage: L == P*R*P
True
sage: B == R.transpose()
True
sage: T == P*R.transpose()*P
True
```

```
>>> from sage.all import *

poly = [-Integer(2), -Integer(3), -Integer(4), -Integer(5), -Integer(6), ...
         -Integer(1)]
>>> R = companion_matrix(poly, format='right'); R
[0 0 0 0 2]
[1 0 0 0 3]
[0 1 0 0 4]
[0 0 1 0 5]
[0 0 0 1 6]
>>> L = companion_matrix(poly, format='left'); L
[6 1 0 0 0]
[5 0 1 0 0]
[4 0 0 1 0]
[3 0 0 0 1]
[2 0 0 0 0]
```

(continues on next page)
A polynomial may be used as input, however a symbolic expression, even if it looks like a polynomial, is not regarded as such when used as input to this routine. Obtaining the list of coefficients from a symbolic polynomial is one route to the companion matrix.

```python
sage: x = polygen(QQ, 'x')
sage: p = x^3 - 4*x^2 + 8*x - 12
sage: companion_matrix(p)
[ 0 0 12]
[ 1 0 -8]
[ 0 1 4]
sage: # needs sage.symbolic
sage: y = var('y')
sage: q = y^3 - 2*y + 1
sage: companion_matrix(q)
Traceback (most recent call last):
  ...TypeError: input must be a polynomial (not a symbolic expression, see docstring), or other iterable, not y^3 - 2*y + 1
sage: coeff_list = [q(y=0)] + [q.coefficient(y^k) for k in range(1, q.degree(y) + 1)]
sage: coeff_list
[1, -2, 0, 1]
sage: companion_matrix(coeff_list)
[ 0 0 -1]
[ 1 0 2]
[ 0 1 0]
```
The minimal polynomial of a companion matrix is equal to the polynomial used to create it. Used in a block diagonal construction, they can be used to create matrices with any desired minimal polynomial, or characteristic polynomial.

\[
\begin{bmatrix}
  0 & 0 & -1 \\
  1 & 0 & 2 \\
  0 & 1 & 0 \\
\end{bmatrix}
\]

The minimal polynomial of a companion matrix is equal to the polynomial used to create it. Used in a block diagonal construction, they can be used to create matrices with any desired minimal polynomial, or characteristic polynomial.

\[
\begin{bmatrix}
  0 & 0 & -1 \\
  1 & 0 & 2 \\
  0 & 1 & 0 \\
\end{bmatrix}
\]

AUTHOR:
• Rob Beezer (2011-05-19)

sage.matrix.special.diagonal_matrix(arg0=None, arg1=None, arg2=None, sparse=True)

This function is available as diagonal_matrix(...) and matrix.diagonal(...).

Return a square matrix with specified diagonal entries, and zeros elsewhere.

FORMATS:
1. diagonal_matrix(entries)
2. diagonal_matrix(nrows, entries)
3. diagonal_matrix(ring, entries)
4. diagonal_matrix(ring, nrows, entries)

INPUT:
• entries – the values to place along the diagonal of the returned matrix. This may be a flat list, a flat tuple, a vector or free module element, or a one-dimensional NumPy array.
• nrows – the size of the returned matrix, which will have an equal number of columns
• ring – the ring containing the entries of the diagonal entries. This may not be specified in combination with a NumPy array.
• sparse – (default: True); whether or not the result has a sparse implementation.

OUTPUT:
A square matrix over the given ring with a size given by nrows. If the ring is not given it is inferred from the given entries. The values on the diagonal of the returned matrix come from entries. If the number of entries is not enough to fill the whole diagonal, it is padded with zeros.

EXAMPLES:
We first demonstrate each of the input formats with various different ways to specify the entries.

Format 1: a flat list of entries.

sage: A = diagonal_matrix([2, 1.3, 5]); A
[ 2.000000000000000 0.000000000000000 0.000000000000000]
[0.000000000000000 1.000000000000000 0.000000000000000]

(continues on next page)
Format 2: size specified, a tuple with initial entries. Note that a short list of entries is effectively padded with zeros.

```
sage: A = diagonal_matrix(3, (4, 5)); A
[4 0 0]
[0 5 0]
[0 0 0]
sage: A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
```

Format 3: ring specified, a vector of entries.

```
sage: A = diagonal_matrix(QQ, vector(ZZ, [1,2,3])); A
[1 0 0]
[0 2 0]
[0 0 3]
sage: A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Rational Field
```

Format 4: ring, size and list of entries.

```
sage: A = diagonal_matrix(FiniteField(3), 3, [2, 16]); A
[2 0 0]
[0 1 0]
[0 0 0]
sage: A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Finite Field of size 3
```
Matrices and Spaces of Matrices, Release 10.4

```python
>>> from sage.all import *
>>> A = diagonal_matrix(FiniteField(Integer(3)), Integer(3), [Integer(2),
   Integer(16)]); A
[2 0 0]
[0 1 0]
[0 0 0]
>>> A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Finite Field of size 3

NumPy arrays may be used as input.

```sage```
# needs numpy
import numpy
entries = numpy.array([1.2, 5.6]); entries
array([1.2, 5.6])
A = diagonal_matrix(3, entries); A
[1.2 0.0 0.0]
[0.0 5.6 0.0]
[0.0 0.0 0.0]
A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Real Double Field
```

```sage```
# needs numpy
j = complex(0,1)
entries = numpy.array([2.0+j, 8.1, 3.4+2.6*j]); entries
array([2. +1.j , 8.1+0.j , 3.4+2.6j])
A = diagonal_matrix(entries); A
[2.0 + 1.0*I 0.0 0.0]
[0.0 8.1 0.0]
[0.0 0.0 3.4 + 2.6*I]
A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Complex Double Field
```

```sage```
# needs numpy
entries = numpy.array([4, 5, 6])
A = diagonal_matrix(entries); A
[4 0 0]
[0 5 0]
[0 0 6]
A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
```

```sage```
# needs numpy
entries = numpy.array([4.1, 5.2, 6.3])
A = diagonal_matrix(ZZ, entries); A
Traceback (most recent call last):
  ...TypeError: unable to convert 4.1 to an element of Integer Ring
```

```sage```
# needs numpy
import numpy
entries = numpy.array([RealNumber('1.2'), RealNumber('5.6')]); entries
array((1.2, 5.6))
A = diagonal_matrix(Integer(3), entries); A
[1.2 0.0 0.0]
```

```python```
>>> from sage.all import *
>>> # needs numpy
>>> import numpy
>>> entries = numpy.array([RealNumber('1.2'), RealNumber('5.6')]); entries
array((1.2, 5.6))
>>> A = diagonal_matrix(Integer(3), entries); A
[1.2 0.0 0.0]
```
[0.0 5.6 0.0]
[0.0 0.0 0.0]
>>> A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Real Double Field

>>> # needs numpy
>>> j = complex(Integer(0),Integer(1))
>>> entries = numpy.array([RealNumber('2.0')+j, RealNumber('8.1'), RealNumber('3.4')
˓→+RealNumber('2.6')*j]); entries
array([2. +1.j , 8.1+0.j , 3.4+2.6j])
>>> A = diagonal_matrix(entries); A
[2.0 + 1.0*I 0.0 0.0]
[ 0.0 8.1 0.0]
[ 0.0 0.0 3.4 + 2.6*I]
>>> A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Complex Double Field

>>> # needs numpy
>>> entries = numpy.array([Integer(4), Integer(5), Integer(6)])
>>> A = diagonal_matrix(entries); A
[4 0 0]
[0 5 0]
[0 0 6]
>>> A.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring

>>> entries = numpy.array([RealNumber('4.1'), RealNumber('5.2'), RealNumber('6.3')
˓→])
>>> A = diagonal_matrix(ZZ, entries); A
# needs numpy
# needs numpy
Traceback (most recent call last):
... TypeError: unable to convert 4.1 to an element of Integer Ring

By default returned matrices have a sparse implementation. This can be changed when using any of the formats.

sage: A = diagonal_matrix([1,2,3], sparse=False)
sage: A.parent()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

>>> from sage.all import *
>>> A = diagonal_matrix([Integer(1),Integer(2),Integer(3)], sparse=False)
>>> A.parent()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

An empty list and no ring specified defaults to the integers.

sage: A = diagonal_matrix([])
sage: A.parent()
Full MatrixSpace of 0 by 0 sparse matrices over Integer Ring

>>> from sage.all import *
>>> A = diagonal_matrix([])
>>> A.parent()
Full MatrixSpace of 0 by 0 sparse matrices over Integer Ring

Giving the entries improperly may first complain about not being iterable:
Matrices and Spaces of Matrices, Release 10.4

```
sage: diagonal_matrix(QQ, 5, 10)
Traceback (most recent call last):
... retal
TypeError: 'sage.rings.integer.Integer' object is not iterable
```

Giving too many entries will raise an error.

```
sage: diagonal_matrix(QQ, 3, [1,2,3,4])
Traceback (most recent call last):
... retal
ValueError: number of diagonal matrix entries (4) exceeds the requested matrix size (3)
```

A negative size sometimes causes the error that there are too many elements.

```
sage: diagonal_matrix(-2, [2])
Traceback (most recent call last):
... retal
ValueError: number of diagonal matrix entries (1) exceeds the requested matrix size (-2)
```

Types for the entries need to be iterable (tuple, list, vector, NumPy array, etc):

```
sage: diagonal_matrix(x^2) # needs sage.symbolic
Traceback (most recent call last):
... retal
TypeError: 'sage.symbolic.expression.Expression' object is not iterable
```

```
>>> from sage.all import *

>>> diagonal_matrix(QQ, Integer(5), Integer(10))
Traceback (most recent call last):
... retal
TypeError: 'sage.rings.integer.Integer' object is not iterable
```

```
>>> from sage.all import *

>>> diagonal_matrix(QQ, Integer(3), [Integer(1),Integer(2),Integer(3),Integer(4)])
Traceback (most recent call last):
... retal
ValueError: number of diagonal matrix entries (4) exceeds the requested matrix size (3)
```

```
>>> from sage.all import *

>>> diagonal_matrix(-2, [2])
Traceback (most recent call last):
... retal
ValueError: number of diagonal matrix entries (1) exceeds the requested matrix size (-2)
```

```
>>> from sage.all import *

>>> diagonal_matrix(-Integer(2), [Integer(2)])
Traceback (most recent call last):
... retal
ValueError: number of diagonal matrix entries (1) exceeds the requested matrix size (-2)
```

```
sage: diagonal_matrix(x^2) # needs sage.symbolic
Traceback (most recent call last):
... retal
TypeError: 'sage.symbolic.expression.Expression' object is not iterable
```

```
>>> from sage.all import *

>>> diagonal_matrix(x**Integer(2)) ... # needs sage.symbolic
Traceback (most recent call last):
... retal
TypeError: 'sage.symbolic.expression.Expression' object is not iterable
```

AUTHOR:
sage.matrix.special.elementary_matrix(arg0, arg1=None, **kwds)

This function is available as elementary_matrix(...) and matrix.elementary(...).

Creates a square matrix that corresponds to a row operation or a column operation.

FORMATS:

In each case, \( R \) is the base ring, and is optional. \( n \) is the size of the square matrix created. Any call may include the \( \text{sparse} \) keyword to determine the representation used. The default is \( \text{False} \) which leads to a dense representation. We describe the matrices by their associated row operation, see the output description for more.

- \( \text{elementary_matrix}(R, n, \text{row1}=i, \text{row2}=j) \)
  The matrix which swaps rows \( i \) and \( j \).

- \( \text{elementary_matrix}(R, n, \text{row1}=i, \text{scale}=s) \)
  The matrix which multiplies row \( i \) by \( s \).

- \( \text{elementary_matrix}(R, n, \text{row1}=i, \text{row2}=j, \text{scale}=s) \)
  The matrix which multiplies row \( j \) by \( s \) and adds it to row \( i \).

Elementary matrices representing column operations are created in an entirely analogous way, replacing \( \text{row1} \) by \( \text{col1} \) and replacing \( \text{row2} \) by \( \text{col2} \).

Specifying the ring for entries of the matrix is optional. If it is not given, and a scale parameter is provided, then a ring containing the value of \( \text{scale} \) will be used. Otherwise, the ring defaults to the integers.

OUTPUT:

An elementary matrix is a square matrix that is very close to being an identity matrix. If \( E \) is an elementary matrix and \( A \) is any matrix with the same number of rows, then \( E \times A \) is the result of applying a row operation to \( A \). This is how the three types created by this function are described. Similarly, an elementary matrix can be associated with a column operation, so if \( E \) has the same number of columns as \( A \), then \( A \times E \) is the result of performing a column operation on \( A \).

An elementary matrix representing a row operation is created if \( \text{row1} \) is specified, while an elementary matrix representing a column operation is created if \( \text{col1} \) is specified.

EXAMPLES:

Over the integers, creating row operations. Recall that row and column numbering begins at zero.

```python
sage: A = matrix(ZZ, 4, 10, range(40)); A
[ 0 1 2 3 4 5 6 7 8 9]

[ 4 5 56 7]
[ 8 9 100 11]
[12 13 144 15]
[16 17 188 19]
```
An elementary matrix is always nonsingular. Then repeated row operations can be represented by products of elementary matrices, and this product is again nonsingular. If row operations are to preserve fundamental properties of a matrix (like rank), we do not allow scaling a row by zero. Similarly, the corresponding elementary matrix is not constructed. Also, we do not allow adding a multiple of a row to itself, since this could also lead to a new zero row.

```
sage: A = matrix(QQ, 4, 10, range(40)); A
[ 0  1  2  3  4  5  6  7  8  9]
[10 11 12 13 14 15 16 17 18 19]
[20 21 22 23 24 25 26 27 28 29]
[30 31 32 33 34 35 36 37 38 39]
sage: E1 = elementary_matrix(QQ, 4, row1=0, row2=1)
```

(continues on next page)
If the ring is not specified, and a scale parameter is given, the base ring for the matrix is chosen to contain the scale parameter. Otherwise, if no ring is given, the default is the integers.
sage: E = elementary_matrix(4, row1=1, scale=4/3)
sage: E.parent()
Full MatrixSpace of 4 by 4 dense matrices over Rational Field

sage: # needs sage.symbolic
sage: E = elementary_matrix(4, row1=1, scale=I)
sage: E.parent()
Full MatrixSpace of 4 by 4 dense matrices over
Number Field in I with defining polynomial x^2 + 1 with I = 1*I

sage: # needs sage.rings.complex_double sage.symbolic
sage: E = elementary_matrix(4, row1=1, scale=CDF(I))
sage: E.parent()
Full MatrixSpace of 4 by 4 dense matrices over Complex Double Field

sage: # needs sage.rings.number_field sage.symbolic
sage: E = elementary_matrix(4, row1=1, scale=QQbar(I))
sage: E.parent()
Full MatrixSpace of 4 by 4 dense matrices over Algebraic Field

>>> from sage.all import *
>>> E = elementary_matrix(Integer(4), row1=Integer(1), row2=Integer(3))
>>> E.parent()
Full MatrixSpace of 4 by 4 dense matrices over Integer Ring

>>> E = elementary_matrix(Integer(4), row1=Integer(1), scale=Integer(4)/
-Integer(3))
>>> E.parent()
Full MatrixSpace of 4 by 4 dense matrices over Rational Field

>>> # needs sage.symbolic
>>> E = elementary_matrix(Integer(4), row1=Integer(1), scale=I)
>>> E.parent()
Full MatrixSpace of 4 by 4 dense matrices over
Number Field in I with defining polynomial x^2 + 1 with I = 1*I

>>> # needs sage.rings.complex_double sage.symbolic
>>> E = elementary_matrix(Integer(4), row1=Integer(1), scale=CDF(I))
>>> E.parent()
Full MatrixSpace of 4 by 4 dense matrices over Complex Double Field

>>> # needs sage.rings.number_field sage.symbolic
>>> E = elementary_matrix(Integer(4), row1=Integer(1), scale=QQbar(I))
>>> E.parent()
Full MatrixSpace of 4 by 4 dense matrices over Algebraic Field

Returned matrices have a dense implementation by default, but a sparse implementation may be requested.

sage: E = elementary_matrix(4, row1=0, row2=1)
sage: E.is_dense()
True

sage: E = elementary_matrix(4, row1=0, row2=1, sparse=True)
sage: E.is_sparse()
True
And the ridiculously small cases. The zero-row matrix cannot be built since then there are no rows to manipulate.

```python
>>> E = elementary_matrix(Integer(4), row1=Integer(0), row2=Integer(1))
>>> E.is_dense()
True

>>> E = elementary_matrix(Integer(4), row1=Integer(0), row2=Integer(1),
˓→sparse=True)
>>> E.is_sparse()
True
```
We can also pass the elements of the last row, starting at the second column:

```sage```
matrix.hankel(SR.var('a, b, c, d, e'), SR.var('f, g, h, i'))
```

A third order Hankel matrix in the integers:

```sage```
matrix.hankel([1, 2, 3])
```

The second argument allows to customize the last row:

```sage```
matrix.hankel([1..3], [7..10])
```

(continues on next page)
sage.matrix.special.hilbert(dim, ring=Rational Field)
This function is available as hilbert(...) and matrix.hilbert(...).

Return a Hilbert matrix of the given dimension.

The \( n \) dimensional Hilbert matrix is a square matrix with entries being unit fractions,
\[
H_{ij} = \frac{1}{i+j-1}, \quad i, j = 1, \ldots, n.
\]

For more information see the Wikipedia article Hilbert_matrix.

INPUT:

- \( \text{dim} \) – integer, the dimension of the Hilbert matrix
- \( \text{ring} \) – base ring (default: \( \mathbb{Q} \)) of the resulting matrix

EXAMPLES:

```python
sage: matrix.hilbert(5)
[ 1 1/2 1/3 1/4 1/5]
[1/2 1/3 1/4 1/5 1/6]
[1/3 1/4 1/5 1/6 1/7]
[1/4 1/5 1/6 1/7 1/8]
[1/5 1/6 1/7 1/8 1/9]```

```python
>>> from sage.all import *
>>> matrix.hilbert(Integer(5))
[ 1 1/2 1/3 1/4 1/5]
[1/2 1/3 1/4 1/5 1/6]
[1/3 1/4 1/5 1/6 1/7]
[1/4 1/5 1/6 1/7 1/8]
[1/5 1/6 1/7 1/8 1/9]```

sage.matrix.special.identity_matrix(ring, n=0, sparse=False)
This function is available as identity_matrix(...) and matrix.identity(...).

Return the \( n \times n \) identity matrix over the given ring.

The default ring is the integers.

EXAMPLES:

```python
sage: M = identity_matrix(QQ, 2); M
[1 0]
[0 1]
sage: M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: M = identity_matrix(2); M
[1 0]
[0 1]
sage: M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring
sage: M.is_mutable()
```
sage: M = identity_matrix(3, sparse=True); M
[1 0 0]
[0 1 0]
[0 0 1]
sage: M.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
sage: M.is_mutable()
True

>>> from sage.all import *
>>> M = identity_matrix(QQ, Integer(2)); M
[1 0]
[0 1]
>>> M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
>>> M = identity_matrix(Integer(2)); M
[1 0]
[0 1]
>>> M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring
>>> M.is_mutable()
True
>>> M = identity_matrix(Integer(3), sparse=True); M
[1 0 0]
[0 1/3*sqrt(3) 2/3*sqrt(3)]
[0 -2/3*sqrt(3) 1/3*sqrt(3)]

sage.matrix.special.ith_to_zero_rotation_matrix(v, i, ring=None)

This function is available as ith_to_zero_rotation_matrix(...) and matrix.ith_to_zero_rotation(...).

Return a rotation matrix that sends the i-th coordinates of the vector v to zero by doing a rotation with the (i-1)-th coordinate.

INPUT:

• v – vector
• i – integer
• ring – ring (default: None) of the resulting matrix

OUTPUT:

A matrix

EXAMPLES:

sage: from sage.matrix.constructor import ith_to_zero_rotation_matrix
sage: v = vector((1,2,3))
sage: ith_to_zero_rotation_matrix(v, 2)
#...
[ 1 0 0]
[ 0 2/13*sqrt(13) 3/13*sqrt(13)]
[ 0 -3/13*sqrt(13) 2/13*sqrt(13)]
sage: ith_to_zero_rotation_matrix(v, 2) * v  # needs sage.symbolic
(1, sqrt(13), 0)

>>> from sage.all import *
>>> from sage.matrix.constructor import ith_to_zero_rotation_matrix
>>> v = vector((Integer(1),Integer(2),Integer(3)))
>>> ith_to_zero_rotation_matrix(v, Integer(2))  # needs sage.symbolic
[ 1 0 0]
[ 0 2/13*sqrt(13) 3/13*sqrt(13)]
[ 0 -3/13*sqrt(13) 2/13*sqrt(13)]
>>> ith_to_zero_rotation_matrix(v, Integer(2)) * v  # needs sage.symbolic
(1, sqrt(13), 0)

sage: ith_to_zero_rotation_matrix(v, 0)  # needs sage.symbolic
[ 3/10*sqrt(10) 0 -1/10*sqrt(10)]

AUTHORS:
Sébastien Labbé (April 2010)

`sage.matrix.special.jordan_block(eigenvalue, size, sparse=False)`
This function is available as jordan_block(...) and matrix.jordan_block(...).

Return the Jordan block for the given eigenvalue with given size.

**INPUT:**
- `eigenvalue` — eigenvalue for the diagonal entries of the block
- `size` — size of the square matrix
- `sparse` — (default: False); if True, return a sparse matrix

**EXAMPLES:**

```python
sage: jordan_block(5, 3)
[5 1 0]
[0 5 1]
[0 0 5]
```

```python
>>> from sage.all import *
```

```python
>>> jordan_block(Integer(5), Integer(3))
[5 1 0]
[0 5 1]
[0 0 5]
```

`sage.matrix.special.lehmer(ring, n=0)`
This function is available as lehmer(...) and matrix.lehmer(...).

Return the $n \times n$ Lehmer matrix.

The default ring is the rationals.

Element $(i, j)$ in the Lehmer matrix is $\min(i, j)/\max(i, j)$.

See Wikipedia article Lehmer_matrix.

**EXAMPLES:**

```python
sage: matrix.lehmer(3)
[1 1/2 1/3]
[1/2 1 2/3]
[1/3 2/3 1]
```

```python
>>> from sage.all import *
```

```python
>>> matrix.lehmer(Integer(3))
[1 1/2 1/3]
[1/2 1 2/3]
[1/3 2/3 1]
```
**sage.matrix.special.matrix_method**(func=None, name=None)

Allows a function to be tab-completed on the global matrix constructor object.

**INPUT:**

- **func** – a single argument. The function that is being decorated.
- ****kwds – a single optional keyword argument name=<string>. The name of the corresponding method in the global matrix constructor object. If not given, it is derived from the function name.

**EXAMPLES:**

```python
sage: from sage.matrix.constructor import matrix_method
sage: def foo_matrix(n):
    return matrix.diagonal(range(n))

sage: matrix_method(foo_matrix)
<function foo_matrix at ...>

sage: matrix.foo(5)
[0 0 0 0 0]
[0 1 0 0 0]
[0 0 2 0 0]
[0 0 0 3 0]
[0 0 0 0 4]

sage: matrix_method(foo_matrix, name=bar)
<function foo_matrix at ...>

sage: matrix.bar(3)
[0 0 0]
[0 1 0]
[0 0 2]
```

**sage.matrix.special.ones_matrix**(ring, nrows=None, ncols=None, sparse=False)

This function is available as ones_matrix(...) and matrix.ones(...).

Return a matrix with all entries equal to 1.

**CALL FORMATS:**

In each case, the optional keyword sparse can be used.

1. ones_matrix(ring, nrows, ncols)
2. ones_matrix(ring, nrows)
3. ones_matrix(nrows, ncols)
4. ones_matrix(nrows)

INPUT:

- **ring** – (default: ZZ); base ring for the matrix.
- **nrows** – number of rows in the matrix.
- **ncols** – number of columns in the matrix. If omitted, defaults to the number of rows, producing a square matrix.
- **sparse** – (default: False); if True creates a sparse representation.

OUTPUT:

A matrix of size **nrows** by **ncols** over the **ring** with every entry equal to 1. While the result is far from sparse, you may wish to choose a sparse representation when mixing this matrix with other sparse matrices.

EXAMPLES:

A call specifying the ring and the size.

```
sage: M = ones_matrix(QQ, 2, 5); M
[1 1 1 1 1]
[1 1 1 1 1]
sage: M.parent()
Full MatrixSpace of 2 by 5 dense matrices over Rational Field
```

Without specifying the number of columns, the result is square.

```
sage: M = ones_matrix(RR, 2); M
[1.00000000000000 1.00000000000000]
[1.00000000000000 1.00000000000000]
sage: M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Real Field with 53 bits of precision
```

The ring defaults to the integers if not given.

```
sage: M = ones_matrix(2, 3); M
[1 1 1]
[1 1 1]
sage: M.parent()
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring
```
A lone integer input produces a square matrix over the integers.

```
sage: M = ones_matrix(3); M
[1 1 1]
[1 1 1]
[1 1 1]
sage: M.parent()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
```

The result can have a sparse implementation.

```
sage: M = ones_matrix(3, 1, sparse=True); M
[1]
[1]
[1]
sage: M.parent()
Full MatrixSpace of 3 by 1 sparse matrices over Integer Ring
```

Giving just a ring will yield an error.

```
sage: ones_matrix(CC)
Traceback (most recent call last):
  ...
ValueError: constructing an all ones matrix requires at least one dimension
```

This function is available as random_diagonalizable_matrix(...) and matrix.random_diagonalizable(...).
Create a random matrix that diagonalizes nicely.
To be used as a teaching tool. Return matrices have only real eigenvalues.

**INPUT:**

If eigenvalues and dimensions are not specified in a list, they will be assigned randomly.

- `parent` – the desired size of the square matrix.
- `eigenvalues` – the list of desired eigenvalues (default=None).
- `dimensions` – the list of dimensions corresponding to each eigenspace (default=None).

**OUTPUT:**

A square, diagonalizable, matrix with only integer entries. The eigenspaces of this matrix, if computed by hand, give basis vectors with only integer entries.

**Note:** It is easiest to use this function via a call to the `random_matrix()` function with the `algorithm='diagonalizable'` keyword. We provide one example accessing this function directly, while the remainder will use this more general function.

**EXAMPLES:**

A diagonalizable matrix, size 5.

```
sage: from sage.matrix.constructor import random_diagonalizable_matrix
sage: matrix_space = sage.matrix.matrix_space.MatrixSpace(QQ, 5)
sage: A = random_diagonalizable_matrix(matrix_space)
sage: # needs sage.rings.number_field
sage: eigenvalues = A.eigenvalues()
sage: S = A.right_eigenmatrix()[1]
sage: eigenvalues2 = (S.inverse()*A*S).diagonal()
sage: sorted(eigenvalues) == sorted(eigenvalues2)
True
```

A diagonalizable matrix with eigenvalues and dimensions designated, with a check that if eigenvectors were calculated by hand entries would all be integers.

```
sage: eigenvalues = [ZZ.random_element() for _ in range(3)]
sage: B = random_matrix(QQ, 6, algorithm='diagonalizable',
....:                   eigenvalues=eigenvalues, dimensions=[2,3,1])
sage: all(x in ZZ for x in (B-(-12*identity_matrix(6))).rref().list())
True
sage: all(x in ZZ for x in (B-(4*identity_matrix(6))).rref().list())
```

(continues on next page)
Todo: Modify the routine to allow for complex eigenvalues.

Billy Wonderly (2010-07)

sage.matrix.special.random_echelonizable_matrix(parent, rank, upper_bound=None, max_tries=100)

This function is available as random_echelonizable_matrix(...) and matrix.random_echelonizable(...).
Generate a matrix of a desired size and rank, over a desired ring, whose reduced row-echelon form has only integral values.

INPUT:

- **parent** – A matrix space specifying the base ring, dimensions and representation (dense/sparse) for the result. The base ring must be exact.
- **rank** – Rank of result, i.e. the number of non-zero rows in the reduced row echelon form.
- **upper_bound** – If designated, size control of the matrix entries is desired. Set upper_bound to 1 more than the maximum value entries can achieve. If None, no size control occurs. But see the warning below. (default: None)
- **max_tries** – If designated, number of tries used to generate each new random row; only matters when upper_bound!=None. Used to prevent endless looping. (default: 100)
OUTPUT:
A matrix not in reduced row-echelon form with the desired dimensions and properties.

Warning: When upper_bound is set, it is possible for this constructor to fail with a ValueError. This may happen when the upper_bound, rank and/or matrix dimensions are all so small that it becomes infeasible or unlikely to create the requested matrix. If you must have this routine return successfully, do not set upper_bound.

Note: It is easiest to use this function via a call to the random_matrix() function with the algorithm='echelonizable' keyword. We provide one example accessing this function directly, while the remainder will use this more general function.

EXAMPLES:
Generated matrices have the desired dimensions, rank and entry size. The matrix in reduced row-echelon form has only integer entries.

```python
sage: from sage.matrix.constructor import random_echelonizable_matrix
sage: matrix_space = sage.matrix.matrix_space.MatrixSpace(QQ, 5, 6)
sage: A = random_echelonizable_matrix(matrix_space, rank=4, upper_bound=40)
sage: A.rank()
4
sage: max(map(abs,A.list())) < 40
True
sage: A.rref() == A.rref().change_ring(ZZ)
True
```

An example with default settings (i.e. no entry size control).

```python
sage: C = random_matrix(QQ, 6, 7, algorithm='echelonizable', rank=5)
sage: C.rank()
5
sage: C.rref() == C.rref().change_ring(ZZ)
True
```

(continues on next page)
A matrix without size control may have very large entry sizes.

```python
sage: D = random_matrix(ZZ, 7, 8, algorithm='echelonizable', rank=6); D
# random
[ 1 2 8 -35 -178 -239 -284 778]
[ 4 9 37 -163 -827 -1111 -1324 3624]
[ 5 6 21 -88 -454 -607 -708 1951]
[ 4 -5 -22 97 491 656 779 -2140]
[ 4 4 13 -55 -283 -377 -436 1206]
[ 4 11 43 -194 -982 -1319 -1576 4310]
[ 1 -2 -13 59 294 394 481 -1312]
```

Matrices can be generated over any exact ring.

```python
sage: # needs sage.rings.finite_rings
sage: F.<a> = GF(2^3)
```

```python
sage: B = random_matrix(F, 4, 5, algorithm='echelonizable', rank=4,
....:       upper_bound=None)

sage: B.rank()
4
sage: B.base_ring() is F
True
```

Square matrices over ZZ or QQ with full rank are always unimodular.

```python
sage: E = random_matrix(QQ, 7, 7, algorithm='echelonizable', rank=7)
sage: det(E)
1
```

```python
sage: E = random_matrix(ZZ, 7, 7, algorithm='echelonizable', rank=7)
sage: det(E)
1
```
```python
>>> from sage.all import *
>>> E = random_matrix(QQ, Integer(7), Integer(7), algorithm='echelonizable',
                     rank=Integer(7))
>>> det(E)
1
>>> E = random_matrix(ZZ, Integer(7), Integer(7), algorithm='echelonizable',
                     rank=Integer(7))
>>> det(E)
1
```

**AUTHOR:**
Billy Wonderly (2010-07)

`sage.matrix.special.random_matrix` *(ring, nrows, ncols=None, algorithm='randomize', implementation=None, *args, **kwds)*

This function is available as `random_matrix(...)` and `matrix.random(...)`. Return a random matrix with entries in a specified ring, and possibly with additional properties.

**INPUT:**

- `ring` – base ring for entries of the matrix
- `nrows` – `Integer`; number of rows
- `ncols` – (default: `None`); number of columns; if `None` defaults to `nrows`
- `algorithm` – (default: `randomize`); determines what properties the matrix will have. See examples below for possible additional arguments.
  - `randomize` – create a matrix of random elements from the base ring, possibly controlling the density of non-zero entries.
  - `echelon_form` – creates a matrix in echelon form
  - `echelonizable` – creates a matrix that has a predictable echelon form
  - `subspaces` – creates a matrix whose four subspaces, when explored, have reasonably sized, integral valued, entries.
  - `unimodular` – creates a matrix of determinant 1.
  - `diagonalizable` – creates a diagonalizable matrix whose eigenvectors, if computed by hand, will have only integer entries.
- `implementation` – (None or string or a matrix class) a possible implementation. See the documentation of the constructor of `MatrixSpace`.
- `*args, **kwds` – arguments and keywords to describe additional properties. See more detailed documentation below.

**Warning:** Matrices generated are not uniformly distributed. For unimodular matrices over finite field this function does not even generate all of them: for example `Matrix.random(GF(3), 2, algorithm='unimodular')` never generates `[[2,0],[0,2]]`. This function is made for teaching purposes.
Warning: An upper bound on the absolute value of the entries may be set when the algorithm is echelonizable or unimodular. In these cases it is possible for this constructor to fail with a ValueError. If you must have this routine return successfully, do not set upper_bound. This behavior can be partially controlled by a max_tries keyword.

Note: When constructing matrices with random entries and no additional properties (i.e. when algorithm='randomize'), most of the randomness is controlled by the random_element method for elements of the base ring of the matrix, so the documentation of that method may be relevant or useful.

EXAMPLES:

Random integer matrices. With no arguments, the majority of the entries are zero, -1, and 1, and rarely “large.”

```python
sage: from collections import defaultdict
sage: total_count = 0
sage: dic = defaultdict(Integer)
sage: def add_samples(*args, **kwds):
   ....:     global dic, total_count
   ....:     for _ in range(100):
   ....:         A = random_matrix(*args, **kwds)
   ....:         for a in A.list():
   ....:             dic[a] += 1
   ....:         total_count += 1.0
sage: expected = lambda n : 2 / (5*abs(n)*(abs(n) + 1)) if n != 0 else 1/5
sage: expected(0)
1/5
sage: expected(0) == expected(1) == expected(-1)
True
sage: expected(100)
1/25250
sage: add_samples(ZZ, 5, 5)
```

(continues on next page)
1/25250

```python
>>> add_samples(ZZ, Integer(5), Integer(5))
>>> while not all(abs(dic[a]/total_count - expected(a)) < RealNumber('0.001') for a in dic):
    add_samples(ZZ, Integer(5), Integer(5))
```

The `distribution` keyword set to `uniform` will limit values between -2 and 2.

```python
sage: expected = lambda n : 1/5 if n in range(-2, 3) else 0
sage: total_count = 0
sage: dic = defaultdict(Integer)
sage: add_samples(ZZ, 5, 5, distribution='uniform')
sage: while not all(abs(dic[a]/total_count - expected(a)) < 0.001 for a in dic):
    add_samples(ZZ, 5, 5, distribution='uniform')
```

```python
>>> from sage.all import *

>>> expected = lambda n : Integer(1)/Integer(5) if n in range(-Integer(2), Integer(3)) else Integer(0)
>>> total_count = Integer(0)
>>> dic = defaultdict(Integer)
>>> add_samples(ZZ, Integer(5), Integer(5), distribution='uniform')
>>> while not all(abs(dic[a]/total_count - expected(a)) < RealNumber('0.001') for a in dic):
    ...    add_samples(ZZ, Integer(5), Integer(5), distribution='uniform')
```

The `x` and `y` keywords can be used to distribute entries uniformly. When both are used `x` is the minimum and `y` is one greater than the maximum.

```python
sage: expected = lambda n : 1/30 if n in range(70, 100) else 0
sage: total_count = 0
sage: dic = defaultdict(Integer)
```

```python
sage: add_samples(ZZ, 4, 8, x=70, y=100)
sage: while not all(abs(dic[a]/total_count - expected(a)) < 0.001 for a in dic):
    add_samples(ZZ, 4, 8, x=70, y=100)
```

```python
sage: expected = lambda n : 1/10 if n in range(-5, 5) else 0
sage: total_count = 0
sage: dic = defaultdict(Integer)
```

```python
sage: add_samples(ZZ, 3, 7, x=-5, y=5)
sage: while not all(abs(dic[a]/total_count - expected(a)) < 0.001 for a in dic):
    ...    add_samples(ZZ, 3, 7, x=-5, y=5)
```

```python
>>> from sage.all import *

>>> expected = lambda n : Integer(1)/Integer(30) if n in range(Integer(70), Integer(100)) else Integer(0)
>>> total_count = Integer(0)
>>> dic = defaultdict(Integer)
```

```python
>>> add_samples(ZZ, Integer(4), Integer(8), x=Integer(70), y=Integer(100))
>>> while not all(abs(dic[a]/total_count - expected(a)) < RealNumber('0.001') for a in dic):
    ...    add_samples(ZZ, Integer(4), Integer(8), x=Integer(70), y=Integer(100))
```

```python
>>> expected = lambda n : Integer(1)/Integer(10) if n in range(-Integer(5), Integer(5)) else Integer(0)
>>> total_count = Integer(0)
>>> dic = defaultdict(Integer)
```

(continues on next page)
If only $x$ is given, then it is used as the upper bound of a range starting at 0.

To control the number of nonzero entries, use the `density` keyword at a value strictly below the default of 1.0.

The `density` keyword is used to compute the number of entries per row that will be nonzero, but the same entry may be selected more than once. So the value provided will be an upper bound for the density of the created matrix. Note that for a square matrix it is only necessary to set a single dimension.
sage: expected_density = (1 - (99/100)^75)
sage: float(expected_density)
0.529...
sage: while abs(density_sum/total_count - expected_density) > 0.001:
....:   add_sample(ZZ, 100, x=20, y=30, density=0.75)

>>> from sage.all import *
>>> def add_sample(*args, **kwds):
...     global density_sum, total_count
...     total_count += RealNumber('1.0')
...     A = random_matrix(*args, **kwds)
...     density_sum += float(A.density())

>>> # needs sage.libs.linbox (otherwise timeout)
>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> add_sample(ZZ, Integer(5), x=Integer(10), y=Integer(10), density=RealNumber('0.75'))
>>> expected_density = (Integer(1) - (Integer(4)/Integer(5))^Integer(3))
>>> float(expected_density)
0.488
>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001'):
...     add_sample(ZZ, Integer(5), x=Integer(10), y=Integer(10), density=RealNumber('0.75'))

>>> # needs sage.libs.linbox (otherwise timeout)
>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> add_sample(ZZ, Integer(5), x=Integer(20), y=Integer(30), density=RealNumber('0.75'))
>>> density_sum/total_count - expected_density) > RealNumber('0.001'):
...     add_sample(ZZ, Integer(5), x=Integer(20), y=Integer(30), density=RealNumber('0.75'))

>>> # needs sage.libs.linbox (otherwise timeout)
>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> add_sample(ZZ, Integer(100), x=Integer(20), y=Integer(30), density=RealNumber('0.75'))
>>> expected_density = (Integer(1) - (Integer(99)/Integer(100))^Integer(75))
>>> float(expected_density)
0.529...
>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001'):
...     add_sample(ZZ, Integer(100), x=Integer(20), y=Integer(30), density=RealNumber('0.75'))

For a matrix with low density it may be advisable to insist on a sparse representation, as this representation is not selected automatically.

sage: A = random_matrix(ZZ, 5, 5)
sage: A.is_sparse()
False
sage: A = random_matrix(ZZ, 5, 5, sparse=True)
sage: A.is_sparse()
True
Matrices and Spaces of Matrices, Release 10.4

>>> from sage.all import *

>>> A = random_matrix(ZZ, Integer(5), Integer(5))
>>> A.is_sparse()
False
>>> A = random_matrix(ZZ, Integer(5), Integer(5), sparse=True)
>>> A.is_sparse()
True

For algorithm testing you might want to control the number of bits, say 10,000 entries, each limited to 16 bits.

sage: # needs sage.libs.linbox (otherwise timeout)
sage: A = random_matrix(ZZ, 100, 100, x=2**16); A
100 x 100 dense matrix over Integer Ring (use the '.str()' method to see the...
    entries)

>>> from sage.all import *

>>> # needs sage.libs.linbox (otherwise timeout)

>>> A = random_matrix(ZZ, Integer(100), Integer(100), x=Integer(2)**Integer(16));

One can prescribe a specific matrix implementation:

sage: K.<a> = FiniteField(2^8) # needs sage.rings.finite_rings

sage: type(random_matrix(K, 2, 5))
<class 'sage.matrix.matrix_gf2e_dense.Matrix_gf2e_dense'>

sage: type(random_matrix(K, 2, 5, implementation="generic"))
<class 'sage.matrix.matrix_generic_dense.Matrix_generic_dense'>

Random rational matrices. Now num_bound and den_bound control the generation of random elements, by specifying limits on the absolute value of numerators and denominators (respectively). Entries will be positive and negative (map the absolute value function through the entries to get all positive values). If either the numerator or denominator bound (or both) is not used, then the values default to 2:

sage: A = random_matrix(QQ, 2, 8, num_bound=20, den_bound=4)
sage: A.dimensions()
(2, 8)
sage: type(A)
<class 'sage.matrix.matrix_rational_dense.Matrix_rational_dense'>

(continues on next page)
True

```python
sage: A = random_matrix(QQ, 4, density=0.5, sparse=True)
sage: type(A)
<class 'sage.matrix.matrix_rational_sparse.Matrix_rational_sparse'>
sage: A.density() <= 0.5
True

sage: A = random_matrix(QQ, 3, 10, num_bound = 99, den_bound = 99)
sage: positives = list(map(abs, A.list()))
sage: A1 = matrix(QQ, 3, 10, positives)
sage: all(abs(A.list()[i]) == A1.list()[i] for i in range(30))
True

sage: all(a.numerator() in range(100) and
.....    a.denominator() in range(1, 100)
.....    for a in A1.list())
True

sage: A = random_matrix(QQ, 4, 10, den_bound = 10)
```

```python
sage: all(a.numerator() in range(-2, 3) and
.....    a.denominator() in range(1, 11)
.....    for a in A.list())
True

sage: A = random_matrix(QQ, 4, 10)
```

```python
sage: all(a.numerator() in range(-2, 3) and
.....    a.denominator() in range(1, 3)
.....    for a in A.list())
True
```

```python
>>> from sage.all import *
>>> A = random_matrix(QQ, Integer(2), Integer(8), num_bound=Integer(20), den_bound=Integer(4))
>>> A.dimensions()

... a.denominator() in range(Integer(1), Integer(11)) for a in A.list())
True

>>> A = random_matrix(QQ, Integer(4), Integer(10))
>>> all(a.numerator() in range(-Integer(2), Integer(3)) and...
... a.denominator() in range(Integer(1), Integer(3)) for a in A.list())
True

Random matrices over other rings. Several classes of matrices have specialized randomize() methods. You can locate these with the Sage command:

search_def('randomize')

The default implementation of randomize() relies on the random_element() method for the base ring. The density and sparse keywords behave as described above. Since we have a different randomisation when using the optional meataxe package, we have to make sure that we use the default implementation in this test:

sage: K.<a> = FiniteField(3^2)  # needs sage.rings.finite_rings
sage: A = random_matrix(K, 2, 5, implementation='generic')  # needs sage.rings.finite_rings
sage: type(A)
<class 'sage.matrix.matrix_generic_dense.Matrix_generic_dense'>

sage: A.base_ring() is K  # needs sage.rings.finite_rings
True
sage: TestSuite(A).run()

sage: A = random_matrix(RR, 3, 4, density=0.66)

sage: type(A)
<class 'sage.matrix.matrix_generic_dense.Matrix_generic_dense'>

sage: A.base_ring() is RR
True
sage: TestSuite(A).run()

sage: A = random_matrix(ComplexField(32), 3, density=0.8, sparse=True)

sage: A.is_sparse()
True

sage: type(A)
<class 'sage.matrix.matrix_generic_sparse.Matrix_generic_sparse'>

sage: A.base_ring() is ComplexField(32)
True
sage: TestSuite(A).run()

from sage.all import *

K = FiniteField(Integer(3)**Integer(2), names=('a',)); (a,) = K._first_.ngens()  # needs sage.rings.finite_rings
A = random_matrix(K, Integer(2), Integer(5), implementation='generic')  # needs sage.rings.finite_rings

(continues on next page)
Random matrices in echelon form. The algorithm='echelon_form' keyword, along with a requested number of non-zero rows (num_pivots) will return a random matrix in echelon form. When the base ring is QQ the result has integer entries. Other exact rings may be also specified.

```
sage: A = random_matrix(QQ, 4, 8, algorithm='echelon_form', num_pivots=3)
sage: A.base_ring()
Rational Field
sage: (A.nrows(), A.ncols())
(4, 8)
sage: A in sage.matrix.matrix_space.MatrixSpace(ZZ, 4, 8)
True
sage: A.rank()
3
sage: A == A.rref()
True
```

```
>>> from sage.all import *

>>> A = random_matrix(QQ, Integer(4), Integer(8), algorithm='echelon_form', num_pivots=Integer(3))

>>> A.base_ring()
Rational Field

>>> (A.nrows(), A.ncols())
(4, 8)

>>> A in sage.matrix.matrix_space.MatrixSpace(ZZ, Integer(4), Integer(8))
True

>>> A.rank()
3

>>> A == A.rref()
True
```

For more, see the documentation of the `random_rref_matrix()` function. In the notebook or at the Sage command-line, first execute the following to make this further documentation available:
Random matrices with predictable echelon forms. The algorithm='echelonizable' keyword, along with a requested rank (rank) and optional size control (upper_bound) will return a random matrix in echelon form. When the base ring is \( \mathbb{Z} \) or \( \mathbb{Q} \) the result has integer entries, whose magnitudes can be limited by the value of upper_bound, and the echelon form of the matrix also has integer entries. Other exact rings may be also specified, but there is no notion of controlling the size. Square matrices of full rank generated by this function always have determinant one, and can be constructed with the unimodular keyword.

```python
from sage.matrix.constructor import random_rref_matrix

A = random_matrix(QQ, 4, 8, algorithm='echelonizable', rank=3, upper_bound=60)
A.base_ring()
Rational Field
(A.nrows(), A.ncols())
(4, 8)
A in sage.matrix.matrix_space.MatrixSpace(ZZ, 4, 8)
True
A.rank()
3
all(abs(x)<60 for x in A.list())
True
A.rref() in sage.matrix.matrix_space.MatrixSpace(ZZ, 4, 8)
True
```

For more, see the documentation of the random_echelonizable_matrix() function. In the notebook or at the Sage command-line, first execute the following to make this further documentation available:

```python
from sage.all import *
A = random_matrix(QQ, Integer(4), Integer(8), algorithm='echelonizable',
....:
eigenvalues=[2,3,-1], dimensions=[1,2,2]); A
A.base_ring()
Rational Field
(A.nrows(), A.ncols())
(4, 8)
A in sage.matrix.matrix_space.MatrixSpace(ZZ, Integer(4), Integer(8))
True
A.rank()
3
all(abs(x)<Integer(60) for x in A.list())
True
A.rref() in sage.matrix.matrix_space.MatrixSpace(ZZ, Integer(4), Integer(8))
True
```

Random diagonalizable matrices. The algorithm='diagonalizable' keyword, along with a requested matrix size (size) and optional lists of eigenvalues (eigenvalues) and the corresponding eigenspace dimensions (dimensions) will return a random diagonalizable matrix. When the eigenvalues and dimensions are not specified the result will have randomly generated values for both that fit with the designated size.

```python
A = random_matrix(QQ, 5, algorithm='diagonalizable', # random
....:
eigenvalues=[2,3,-1], dimensions=[1,2,2]); A
all(x in ZZ for x in (A - (2*identity_matrix(5))).rref().list())
True
all(x in ZZ for x in (A - 3*identity_matrix(5)).rref().list())
True
```

(continues on next page)
For more, see the documentation of the \texttt{random_diagonalizable_matrix()} function. In the notebook
or at the Sage command-line, first execute the following to make this further documentation available:

\begin{verbatim}
from sage.matrix.constructor import random_diagonalizable_matrix
\end{verbatim}

Random matrices with predictable subspaces. The \texttt{algorithm='subspaces'} keyword, along with an optional
rank (\texttt{rank}) will return a matrix whose natural basis vectors for its four fundamental subspaces, if computed as
described in the documentation of the \texttt{random_subspaces_matrix()} contain only integer entries. If \texttt{rank},
is not set, the rank of the matrix will be generated randomly.

\begin{verbatim}
sage: B = random_matrix(QQ, 5, 6, algorithm='subspaces', rank=3); B  # random
sage: B-expanded = B.augment(identity_matrix(5)).rref()
sage: (B.nrows(), B.ncols())
(5, 6)
sage: all(x in ZZ for x in B-expanded.list())
True
sage: C = B-expanded.submatrix(0, 0, B.nrows() - B.nullity(), B.ncols())
\end{verbatim}

True
```

For more, see the documentation of the `random_unimodular_matrix()` function. In the notebook or at the Sage command-line, first execute the following to make this further documentation available:

```python
from sage.matrix.constructor import random_unimodular_matrix
```

**AUTHOR:**

- William Stein (2007-02-06)
- Rob Beezer (2010-08-25) Documentation, code to allow additional types of output

```python
sage.matrix.special.random_rref_matrix(parent, num_pivots)
```

This function is available as `random_rref_matrix(...)` and `matrix.random_rref(...)`. Generate a matrix in reduced row-echelon form with a specified number of non-zero rows.

**INPUT:**

- `parent` – A matrix space specifying the base ring, dimensions and representation (dense/sparse) for the result. The base ring must be exact.
- `num_pivots` – The number of non-zero rows in the result, i.e. the rank.

**OUTPUT:**

A matrix in reduced row echelon form with `num_pivots` non-zero rows. If the base ring is \(\mathbb{Z}\) or \(\mathbb{Q}\) then the entries are all integers.

**Note:** It is easiest to use this function via a call to the `random_matrix()` function with the `algorithm='echelon_form'` keyword. We provide one example accessing this function directly, while the remainder will use this more general function.

**EXAMPLES:**

Matrices generated are in reduced row-echelon form with specified rank. If the base ring is \(\mathbb{Q}\) the result has only integer entries.

```python
sage: from sage.matrix.constructor import random_rref_matrix
sage: matrix_space = sage.matrix.matrix_space.MatrixSpace(QQ, 5, 6)
sage: A = random_rref_matrix(matrix_space, num_pivots=4); A
# random
[[ 1  0  0 -6  0 -3]
[ 0  1  0  2  0  3]
[ 0  0  1 -4  0 -2]
[ 0  0  0  1  3]
[ 0  0  0  0  0]]
sage: A.base_ring()
Rational Field
sage: (A.nrows(), A.ncols())
(5, 6)
sage: A in sage.matrix.matrix_space.MatrixSpace(ZZ, 5, 6)
True
sage: A.rank()
9
```

(continues on next page)
Matrices can be generated over other exact rings.

```python
sage: B = random_matrix(FiniteField(7), 4, 4, # random
                     algorithm='echelon_form', num_pivots=3); B

[[1 0 0 0]
 [0 1 0 6]
 [0 0 1 1]
 [0 0 0 0]]
sage: B.rank() == 3
True
sage: B.base_ring()
Finite Field of size 7
sage: B == B.rref()
True
```

```python
>>> from sage.all import *

>>> B = random_matrix(FiniteField(Integer(7)), Integer(4), Integer(4), # random
                     algorithm='echelon_form', num_pivots=Integer(3)); B

[[1 0 0 0]
 [0 1 0 6]
 [0 0 1 1]
 [0 0 0 0]]
>>> B.rank() == Integer(3)
True
>>> B.base_ring()
Finite Field of size 7
>>> B == B.rref()
True
```

AUTHOR:
Billy Wonderly (2010-07)
sage.matrix.special.random_subspaces_matrix(parent, rank=None)

This function is available as random_subspaces_matrix(...) and matrix.random_subspaces(...).

Create a matrix of the designated size and rank whose right and left null spaces, column space, and row space have desirable properties that simplify the subspaces.

**INPUT:**

- parent – A matrix space specifying the base ring, dimensions, and representation (dense/sparse) for the result. The base ring must be exact.
- rank – The desired rank of the return matrix (default: None).

**OUTPUT:**

A matrix whose natural basis vectors for its four subspaces, when computed, have reasonably sized, integral valued, entries.

**Note:** It is easiest to use this function via a call to the random_matrix() function with the algorithm='subspaces' keyword. We provide one example accessing this function directly, while the remainder will use this more general function.

**EXAMPLES:**

A 6x8 matrix with designated rank of 3. The four subspaces are determined using one simple routine in which we augment the original matrix with the equal row dimension identity matrix. The resulting matrix is then put in reduced row-echelon form and the subspaces can then be determined by analyzing subdivisions of this matrix. See the four subspaces routine in [Bee] for more.

```python
sage: from sage.matrix.constructor import random_subspaces_matrix
sage: matrix_space = sage.matrix.matrix_space.MatrixSpace(QQ, 6, 8)
sage: B = random_subspaces_matrix(matrix_space, rank=3)
sage: B.rank()
3
sage: B.nullity()
3
sage: {B.nrows(), B.ncols()}
(6, 8)
sage: all(x in ZZ for x in B.list())
True
sage: B_expanded = B.augment(identity_matrix(6)).rref()
sage: all(x in ZZ for x in B_expanded.list())
True
```

```python
>>> from sage.all import *
>>> from sage.matrix.constructor import random_subspaces_matrix
>>> matrix_space = sage.matrix.matrix_space.MatrixSpace(QQ, Integer(6),
    -Integer(8))
>>> B = random_subspaces_matrix(matrix_space, rank=Integer(3))
>>> B.rank()
3
>>> B.nullity()
3
>>> {B.nrows(), B.ncols()}
(6, 8)
>>> all(x in ZZ for x in B.list())
True
>>> B_expanded = B.augment(identity_matrix(Integer(6))).rref()
```
Check that we fixed Issue #10543 (echelon forms should be immutable):

```sage
B_expanded.isImmutable()
```

We want to modify `B_expanded`, so replace it with a copy:

```sage
B_expanded = copy(B_expanded)
B_expanded.subdivide(B.nrows() - B.nullity(), B.ncols())
C = B_expanded.subdivision(0, 0)
L = B_expanded.subdivision(1, 1)
B.right_kernel() == C.right_kernel()
B.row_space() == C.row_space()
B.column_space() == L.right_kernel()
B.left_kernel() == L.row_space()
```

A matrix to show that the null space of the L matrix is the column space of the starting matrix.

```sage
A = random_matrix(QQ, 5, 7, algorithm='subspaces', rank=None)
(A.nrows(), A.ncols())
(5, 7)
all(x in ZZ for x in A.list())
True
A_expanded = A.augment(identity_matrix(5)).rref()
all(x in ZZ for x in A_expanded.list())
True
C = A_expanded.submatrix(0, 0, A.nrows() - A.nullity(), A.ncols())
L = A_expanded.submatrix(A.nrows() - A.nullity(), A.ncols())
A.right_kernel() == C.right_kernel()
A.row_space() == C.row_space()
```
True
sage: A.column_space() == L.right_kernel()
True
sage: A.left_kernel() == L.row_space()
True

>>> from sage.all import *
>>> A = random_matrix(QQ, Integer(5), Integer(7), algorithm='subspaces',
-> rank=None)
>>> (A.nrows(), A.ncols())
(5, 7)
>>> all(x in ZZ for x in A.list())
True
>>> A_expanded = A.augment(identity_matrix(Integer(5))).rref()
>>> all(x in ZZ for x in A_expanded.list())
True
>>> C = A_expanded.submatrix(Integer(0), Integer(0), A.nrows() - A.nullity(), A.
-> ncols())
>>> L = A_expanded.submatrix(A.nrows() - A.nullity(), A.ncols())
>>> A.right_kernel() == C.right_kernel()
True
>>> A.row_space() == C.row_space()
True
>>> A.column_space() == L.right_kernel()
True
>>> A.left_kernel() == L.row_space()
True

sage.matrix.special.random_unimodular_matrix (parent, upper_bound=None, max_tries=100)
This function is available as random_unimodular_matrix(...) and matrix.random_unimodular(...).
Generate a random unimodular (determinant 1) matrix of a desired size over a desired ring.

INPUT:

- **parent** – A matrix space specifying the base ring, dimensions and representation (dense/sparse) for the result. The base ring must be exact.

- **upper_bound** – For large matrices over QQ or ZZ, upper_bound is the largest value matrix entries can achieve. But see the warning below.

- **max_tries** – If designated, number of tries used to generate each new random row; only matters when upper_bound!=None. Used to prevent endless looping. (default: 100)

A matrix not in reduced row-echelon form with the desired dimensions and properties.

OUTPUT:
An invertible matrix with the desired properties and determinant 1.

**Warning:** When upper_bound is set, it is possible for this constructor to fail with a ValueError. This may happen when the upper_bound, rank and/or matrix dimensions are all so small that it becomes infeasible or unlikely to create the requested matrix. If you must have this routine return successfully, do not set upper_bound.
Note: It is easiest to use this function via a call to the \texttt{random_matrix()} function with the \texttt{algorithm='unimodular'} keyword. We provide one example accessing this function directly, while the remainder will use this more general function.

EXAMPLES:

A matrix size 5 over \(\mathbb{Q}\).

\begin{verbatim}
sage: from sage.matrix.constructor import random_unimodular_matrix
sage: matrix_space = sage.matrix.matrix_space.MatrixSpace(QQ, 5)
sage: A = random_unimodular_matrix(matrix_space)
sage: det(A)
1
\end{verbatim}

A matrix size 6 with entries no larger than 50.

\begin{verbatim}
sage: B = random_matrix(ZZ, 7, algorithm='unimodular', upper_bound=50)
sage: det(B)
1
sage: all(abs(b) < 50 for b in B.list())
True
\end{verbatim}

A matrix over the number Field in \(y\) with defining polynomial \(y^2 - 2y - 2\).

\begin{verbatim}
sage: # needs sage.rings.number_field
sage: y = polygen(ZZ, 'y')
sage: K = NumberField(y^2 - 2*y - 2, 'y')
sage: C = random_matrix(K, 3, algorithm='unimodular')
sage: det(C)
1
sage: C.base_ring() is K
True
\end{verbatim}
AUTHOR:
Billy Wonderly (2010-07)
sage.matrix.special.toeplitz(c, r, ring=None)
This function is available as toeplitz(...) and matrix.toeplitz(...).
Return a Toeplitz matrix of given first column and first row.
In a Toeplitz matrix, each descending diagonal from left to right is constant, such that:
\[ T_{i,j} = T_{i+1,j+1} \]
For more information see the Wikipedia article Toeplitz_matrix.
INPUT:
• c – vector, first column of the Toeplitz matrix
• r – vector, first row of the Toeplitz matrix, counting from the second column
• ring – base ring (default: None) of the resulting matrix
EXAMPLES:
A rectangular Toeplitz matrix:

```
sage: matrix.toeplitz([1..4], [5..6])
[1 5 6]
[2 1 5]
[3 2 1]
[4 3 2]
```
```
from sage.all import *
```
```
matrix.toeplitz((ellipsis_range(Integer(1),Ellipsis,Integer(4))), (ellipsis_
˓→range(Integer(5),Ellipsis,Integer(6))))
[1 5 6]
[2 1 5]
[3 2 1]
[4 3 2]
```
The following \( N \times N \) Toeplitz matrix arises in the discretization of boundary value problems:

```
sage: N = 4
sage: matrix.toeplitz([-2, 1] + [0]*(N-2), [1] + [0]*(N-2))
[-2  1  0  0]
[ 1 -2  1  0]
[ 0  1 -2  1]
[ 0  0  1 -2]
```
```
from sage.all import *
```
```
N = Integer(4)
```
```
matrix.toeplitz([-Integer(2), Integer(1)] + [Integer(0)]*(N-Integer(2)),␣
˓→[Integer(1)] + [Integer(0)]*(N-Integer(2)))
[-2  1  0  0]
[ 1 -2  1  0]
```
(continues on next page)
sage.matrix.special.vandermonde\((v, \text{ring}=\text{None})\)

This function is available as vandermonde(...) and matrix.vandermonde(...).

Return a Vandermonde matrix of the given vector.

The \(n\) dimensional Vandermonde matrix is a square matrix with columns being the powers of a given vector \(v\),

\[
V_{ij} = v_i^{j-1}, \quad i, j = 1, \ldots, n.
\]

For more information see the Wikipedia article Vandermonde_matrix.

INPUT:

- \(v\) – vector, the second column of the Vandermonde matrix
- \(\text{ring}\) – base ring (default: None) of the resulting matrix

EXAMPLES:

A Vandermonde matrix of order three over the symbolic ring:

```bash
sage: matrix.vandermonde(SR.var(['x0', 'x1', 'x2']))
# needs sage.symbolic
[ 1 x0 x0^2]
[ 1 x1 x1^2]
[ 1 x2 x2^2]
```

```bash
>>> from sage.all import *
>>> matrix.vandermonde(SR.var(['x0', 'x1', 'x2']))
# needs sage.symbolic
[ 1 x0 x0^2]
[ 1 x1 x1^2]
[ 1 x2 x2^2]
```

sage.matrix.special.vector_on_axis_rotation_matrix\((v, i, \text{ring}=\text{None})\)

This function is available as vector_on_axis_rotation_matrix(...) and matrix.vector_on_axis_rotation(...).

Return a rotation matrix \(M\) such that \(\det(M) = 1\) sending the vector \(v\) on the \(i\)-th axis so that all other coordinates of \(Mv\) are zero.

**Note:** Such a matrix is not uniquely determined. This function returns one such matrix.

INPUT:

- \(v\) – vector
- \(i\) – integer
- \(\text{ring}\) – ring (default: None) of the resulting matrix

OUTPUT:

A matrix

EXAMPLES:
Matrices and Spaces of Matrices, Release 10.4

```python
sage: from sage.matrix.constructor import vector_on_axis_rotation_matrix
sage: v = vector((1,2,3))
sage: vector_on_axis_rotation_matrix(v, 2) * v
# needs sage.symbolic

sage.matrix.special.zero_matrix(ring, nrows=None, ncols=None, sparse=False)

This function is available as zero_matrix(...) and matrix.zero(...).

Return the nrows × ncols zero matrix over the given ring.

The default ring is the integers.

EXAMPLES:

sage: M = zero_matrix(QQ, 2); M
[0 0]
[0 0]
sage: M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field

sage: M = zero_matrix(2, 3); M
[0 0 0]
[0 0 0]
sage: M.parent()
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring

sage: M.is_mutable()
True

sage: M = zero_matrix(3, 1, sparse=True); M
[0]
[0]
[0]
sage: M.parent()
Full MatrixSpace of 3 by 1 sparse matrices over Integer Ring

sage: M.is_mutable()
True

sage: matrix.zero(5)
[0 0 0 0 0]
```python
>>> from sage.all import *

>>> M = zero_matrix(QQ, Integer(2)); M
[0 0]
[0 0]

>>> M.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field

>>> M = zero_matrix(Integer(2), Integer(3)); M
[0 0 0]
[0 0 0]

>>> M.parent()
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring

>>> M.is_mutable()
True

>>> M = zero_matrix(Integer(3), Integer(1), sparse=True); M
[0]
[0]

HELPERS FOR CREATING MATRICES

class sage.matrix.args.MatrixArgs
    Bases: object

    Collect arguments for constructing a matrix.

    This class is meant to pass around arguments, for example from the global matrix() constructor to the matrix space or to the element class constructor.

    A typical use case is first creating a MatrixArgs instance, possibly adjusting the attributes. This instance can then be passed around and a matrix can be constructed from it using the matrix() method. Also, a flat list can be constructed using list() or a sparse dict using dict(). It is safe to construct multiple objects (of the same or a different kind) from the same MatrixArgs instance.

    MatrixArgs also supports iteration using the iter() method. This is a more low-level interface.

    When MatrixArgs produces output, it is first finalized. This means that all missing attributes are derived or guessed. After finalization, you should no longer change the attributes or it will end up in an inconsistent state. You can also finalize explicitly by calling the finalized() method.

    A MatrixArgs can contain invalid input. This is not checked when constructing the MatrixArgs instance, but it is checked either when finalizing or when constructing an object from it.

    **Warning:** Instances of this class should only be temporary, they are not meant to be stored long-term.

    **EXAMPLES:**

    ```python
    sage: from sage.matrix.args import MatrixArgs
    sage: ma = MatrixArgs(2, 2, (x for x in range(4))); ma
    <MatrixArgs for None; typ=UNKNOWN; entries=<generator ...>>
    sage: ma.finalized()
    <MatrixArgs for Full MatrixSpace of 2 by 2 dense matrices over Integer Ring; typ=SEQ_FLAT; entries=[0, 1, 2, 3]>
    ```

    ```python
    >>> from sage.all import *
    >>> from sage.matrix.args import MatrixArgs
    >>> ma = MatrixArgs(Integer(2), Integer(2), (x for x in range(Integer(4)))); ma
    <MatrixArgs for None; typ=UNKNOWN; entries=<generator ...>>
    >>> ma.finalized()
    <MatrixArgs for Full MatrixSpace of 2 by 2 dense matrices over Integer Ring; typ=SEQ_FLAT; entries=[0, 1, 2, 3]>
    ```

    Many types of input are possible:
sage: ma = MatrixArgs(2, 2, entries=None); ma.finalized()
<MatrixArgs for Full MatrixSpace of 2 by 2 dense matrices over Integer Ring; typ=ZERO; entries=None>

```

Test invalid input:

```python
sage: MatrixArgs(ZZ, 2, 2, entries="abcd").finalized()
```

```python
Traceback (most recent call last):
```
base

column_keys

dict \((\text{convert}=\text{True})\)

Return the entries of the matrix as a \texttt{dict}.

The keys of this \texttt{dict} are the non-zero positions \((i, j)\). The corresponding value is the entry at that position. Zero values are skipped.

If \texttt{convert} is \texttt{True}, the entries are converted to the base ring. Otherwise, the entries are returned as given.

\textbf{EXAMPLES:}

\begin{verbatim}
from sage.all import *

>>> MatrixArgs(ZZ, Integer(2), Integer(2), entries="abcd").finalized()
Traceback (most recent call last):
... TypeError: unable to convert 'abcd' to a matrix

>>> MatrixArgs(ZZ, Integer(2), Integer(2), entries=MatrixArgs()).finalized()
Traceback (most recent call last):
... TypeError: unable to convert <MatrixArgs for None; typ=UNKNOWN; entries=None> to a matrix

from sage.matrix.args import MatrixArgs

>>> L = list(range(6))
>>> MatrixArgs(2, 3, L).dict()
{(0, 1): 1, (0, 2): 2, (1, 0): 3, (1, 1): 4, (1, 2): 5}

>>> from sage.matrix.args import MatrixArgs

>>> L = list(range(Integer(6)))
>>> MatrixArgs(Integer(2), Integer(3), L).dict()
{(0, 1): 1, (0, 2): 2, (1, 0): 3, (1, 1): 4, (1, 2): 5}

>>> ma = MatrixArgs(GF(2), 2, 3, L)
>>> ma.dict(convert=False)
{(0, 1): 1, (0, 2): 2, (1, 0): 3, (1, 1): 4, (1, 2): 5}
>>> ma.dict()
{(0, 1): 1, (1, 0): 1, (1, 2): 1}

>>> ma = MatrixArgs(GF(Integer(2)), Integer(2), Integer(3), L)
>>> ma.dict(convert=False)
{(0, 1): 1, (0, 2): 2, (1, 0): 3, (1, 1): 4, (1, 2): 5}
>>> ma.dict()
{(0, 1): 1, (1, 0): 1, (1, 2): 1}
\end{verbatim}
**element** *(immutable=False)*

Return the matrix or morphism.

**INPUT:**

- **immutable** – boolean; if True, the result will be immutable.

**OUTPUT:** an element of self.space

**Note:** This may change self.entries, making it unsafe to access the self.entries attribute after calling this method.

**EXAMPLES:**

```python
sage: from sage.matrix.args import MatrixArgs
sage: M = matrix(2, 3, range(6), sparse=True)
sage: ma = MatrixArgs(M); ma.finalized()
<MatrixArgs for Full MatrixSpace of 2 by 3 sparse matrices over Integer Ring; typ=MATRIX; entries=[0 1 2] [3 4 5]>
sage: M2 = ma.element(immutable=True); M2.parent()

entries

finalized()

Determine all missing values.

Depending on the input, this might be a non-trivial operation. In some cases, this will do most of the work of constructing the matrix. That is actually not a problem since we eventually want to construct the matrix anyway. However, care is taken to avoid double work or needless checking or copying.

OUTPUT: self

EXAMPLES:

>>> from sage.matrix.args import MatrixArgs
>>> MatrixArgs(pi).finalized()
# needs sage.symbolic
Traceback (most recent call last):

ValueError: sequence too short (expected length 6, got 1)
```

### iter (convert=True, sparse=False)

Iteration over the entries in the matrix

**INPUT:**

- `convert` – If True, the entries are converted to the base right. If False, the entries are returned as given.
- `sparse` – See OUTPUT below.

**OUTPUT:** iterator

- If `sparse` is False: yield all entries of the matrix in the following order:

---

### Chapter 4. Helpers for creating matrices
If `sparse` is True: yield instances of `SparseEntry`. The indices \((i, j)\) are guaranteed to lie within the matrix. Zero entries in the input are not skipped.

**Warning:** If an iterator is given as input to `MatrixArgs`, it may be exhausted breaking any further usage. Otherwise, it is safe to iterate multiple times.

**EXAMPLES:**

```python
sage: from sage.matrix.args import SparseEntry, MatrixArgs
sage: ma = MatrixArgs(ZZ, 2, 3, iter(range(6)))
```

```python
sage: list(ma.iter())
[0, 1, 2, 3, 4, 5]
```

```python
sage: ma = MatrixArgs(ZZ, 3, 3, [SparseEntry(0, 0, 0)])
```

```python
sage: list(ma.iter())
Traceback (most recent call last):
... TypeError: dense iteration is not supported for sparse input
```

```python
>>> from sage.all import *
>>> from sage.matrix.args import SparseEntry, MatrixArgs
>>> ma = MatrixArgs(ZZ, Integer(2), Integer(3), iter(range(Integer(6))))
```

```python
>>> list(ma.iter())
[0, 1, 2, 3, 4, 5]
```

```python
>>> ma = MatrixArgs(ZZ, Integer(3), Integer(3), [SparseEntry(Integer(0), Integer(0))])
```

```python
>>> list(ma.iter())
Traceback (most recent call last):
... TypeError: dense iteration is not supported for sparse input
```

Sparse examples:

```python
sage: ma = MatrixArgs(3, 3, pi) # needs sage.symbolic
```

```python
sage: list(ma.iter(sparse=True)) # needs sage.symbolic
[SparseEntry(0, 0, pi), SparseEntry(1, 1, pi), SparseEntry(2, 2, pi)]
```

```python
sage: ma = MatrixArgs(2, 3)
```

```python

>>> ma.finalized()
Traceback (most recent call last):
... IndexError: invalid row index 1

kwds

list (convert=True)

Return the entries of the matrix as a flat list of scalars.

If possible and convert=False, this returns a direct reference to self.entries without copying.

INPUT:

• convert – If True, the entries are converted to the base ring. Otherwise, the entries are returned as given.

Note: This changes self.entries to the returned list. This means that it is unsafe to access the self.entries attribute after calling this method.

EXAMPLES:
sage: from sage.matrix.args import MatrixArgs
sage: L = list(range(6))
[0, 1, 2, 3, 4, 5]

>>> from sage.all import *

>>> from sage.matrix.args import MatrixArgs

>>> L = list(range(Integer(6)))

>>> MatrixArgs(Integer(2), Integer(3), L).list()
[0, 1, 2, 3, 4, 5]

sage: ma = MatrixArgs(RDF, 2, 3, L)

sage: ma.list(convert=False)
[0, 1, 2, 3, 4, 5]

sage: ma.list()
[0.0, 1.0, 2.0, 3.0, 4.0, 5.0]

>>> from sage.all import *

>>> ma = MatrixArgs(RDF, Integer(2), Integer(3), L)

>>> ma.list(convert=False)
[0, 1, 2, 3, 4, 5]

>>> ma.list()
[0.0, 1.0, 2.0, 3.0, 4.0, 5.0]

If we remove our reference to the input L and convert=False, no copy is made:

sage: idL = id(L)
sage: ma = MatrixArgs(2, 3, L)
sage: del L
sage: L = ma.list(convert=False)
sage: id(L) == idL
True

>>> from sage.all import *

>>> idL = id(L)

>>> ma = MatrixArgs(Integer(2), Integer(3), L)

>>> del L

>>> L = ma.list(convert=False)

>>> id(L) == idL
True

matrix (convert=True)

Return the entries of the matrix as a Sage Matrix.

If possible, this returns a direct reference to self.entries without copying.

INPUT:

• convert – if True, the matrix is guaranteed to have the correct parent matrix space. If False, the input matrix may be returned even if it lies in the wrong space.

Note: This changes self.entries to the returned matrix. This means that it is unsafe to access the self.entries attribute after calling this method.

EXAMPLES:
```python
sage: from sage.matrix.args import MatrixArgs
sage: M = matrix(2, 3, range(6), sparse=True)

>>> from sage.all import *
>>> from sage.matrix.args import MatrixArgs
>>> M = matrix(Integer(2), Integer(3), range(Integer(6)), sparse=True)

sage: ma = MatrixArgs(M); ma.finalized()
<MatrixArgs for Full MatrixSpace of 2 by 3 sparse matrices over Integer Ring; typ=MATRIX; entries=[0 1 2]
[3 4 5]>
sage: ma.matrix()
[0 1 2]
[3 4 5]

>>> from sage.all import *
>>> ma = MatrixArgs(M); ma.finalized()
<MatrixArgs for Full MatrixSpace of 2 by 3 sparse matrices over Integer Ring; typ=MATRIX; entries=[0 1 2]
[3 4 5]>

>>> ma.matrix()
[0 1 2]
[3 4 5]

sage: ma = MatrixArgs(M, sparse=False); ma.finalized()
<MatrixArgs for Full MatrixSpace of 2 by 3 dense matrices over Integer Ring; typ=MATRIX; entries=[0 1 2]
[3 4 5]>

sage: ma.matrix()
[0 1 2]
[3 4 5]

>>> from sage.all import *
>>> ma = MatrixArgs(M, sparse=False); ma.finalized()
<MatrixArgs for Full MatrixSpace of 2 by 3 dense matrices over Integer Ring; typ=MATRIX; entries=[0 1 2]
[3 4 5]>

>>> ma.matrix()
[0 1 2]
[3 4 5]

sage: ma = MatrixArgs(RDF, M); ma.finalized()
<MatrixArgs for Full MatrixSpace of 2 by 3 sparse matrices over Real Double Field; typ=MATRIX; entries=[0 1 2]
[3 4 5]>

sage: ma.matrix(convert=False)
[0.0 1.0 2.0]
[3.0 4.0 5.0]

>>> from sage.all import *
>>> ma = MatrixArgs(RDF, M); ma.finalized()
<MatrixArgs for Full MatrixSpace of 2 by 3 sparse matrices over Real Double Field; typ=MATRIX; entries=[0 1 2]
[3 4 5]>
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

over Real Double Field; typ=MATRIX; entries=[0 1 2]
[3 4 5]>

```python
>>> ma.matrix(convert=False)
[0 1 2]
[3 4 5]
>>> ma.matrix()
[0.0 1.0 2.0]
[3.0 4.0 5.0]
```

If we remove our reference to the input $M$, no copy is made:

```python
sage: idM = id(M)
sage: ma = MatrixArgs(M)
sage: del M
sage: M = ma.matrix()
sage: id(M) == idM
True
```

Immutable matrices are never copied:

```python
sage: M.set_immutable()
sage: matrix(M) is M
True
```

```python
>>> from sage.all import *
>>> idM = id(M)
>>> ma = MatrixArgs(M)
>>> del M
>>> M = ma.matrix()
>>> id(M) == idM
True
```

```python
ncols
nrows
row_keys

set_column_keys (column_keys)
Set the column keys with consistency checking.
If the value was previously set, it must remain the same.

EXAMPLES:
```
```
sage: ma.set_column_keys('abcd')
0
sage: ma.finalized()
<MatrixArgs for
  Set of Morphisms
    from Free module generated by {a, b, c, d} over Integer Ring
    to Ambient free module of rank 2 over the principal ideal domain
    Integer Ring
    in Category of finite dimensional modules with basis over
      (Dedekind domains and euclidean domains
      and noetherian rings and infinite enumerated sets
      and metric spaces);
    typ=ZERO; entries=None>

>>> from sage.all import *
>>> from sage.matrix.args import MatrixArgs
>>> ma = MatrixArgs(Integer(2), Integer(4))
>>> ma.set_column_keys('xyz')
Traceback (most recent call last):
...  ValueError: inconsistent column keys: should be of cardinality 4 but got xyz
>>> ma.set_column_keys('abcd')
0
>>> ma.finalized()
<MatrixArgs for
  Set of Morphisms
    from Free module generated by {a, b, c, d} over Integer Ring
    to Ambient free module of rank 2 over the principal ideal domain
    Integer Ring
    in Category of finite dimensional modules with basis over
      (Dedekind domains and euclidean domains
      and noetherian rings and infinite enumerated sets
      and metric spaces);
    typ=ZERO; entries=None>

set_row_keys(row_keys)

Set the row keys with consistency checking.

If the value was previously set, it must remain the same.

EXAMPLES:

sage: from sage.matrix.args import MatrixArgs
sage: ma = MatrixArgs(2, 4)
sage: ma.set_row_keys('xyz')
Traceback (most recent call last):
...  ValueError: inconsistent row keys: should be of cardinality 2 but got xyz
sage: ma.set_row_keys(['u', 'v'])
0
sage: ma.finalized()
<MatrixArgs for
  Set of Morphisms
    from Ambient free module of rank 4 over the principal ideal domain
    Integer Ring
    to Free module generated by {'u', 'v'} over Integer Ring
    in Category of finite dimensional modules with basis over
      (Dedekind domains and euclidean domains
      and noetherian rings and infinite enumerated sets
      and metric spaces);
    typ=ZERO; entries=None>
set_space (space)

Set inputs from a given matrix space.

INPUT:

- space — a MatrixSpace or a homset of modules with basis

EXAMPLES:

```python
from sage.matrix.args import MatrixArgs
ma = MatrixArgs(Integer(2), Integer(4))
ma.set_row_keys('xyz')
Traceback (most recent call last):
  ... ValueError: inconsistent row keys: should be of cardinality 2 but got xyz
ma.set_row_keys(['u', 'v'])
0
ma.finalized()
<MatrixArgs for Set of Morphisms from Ambient free module of rank 4 over the principal ideal domain Integer Ring to Free module generated by ('u', 'v') over Integer Ring in Category of finite dimensional modules with basis over (Dedekind domains and euclidean domains and noetherian rings and infinite enumerated sets and metric spaces); typ=ZERO; entries=None>
```

```python
set_space(S)
Setinputsfromagivenmatrixspace.
```

```python
sage: from sage.matrix.args import MatrixArgs
sage: ma = MatrixArgs(Integer(2), Integer(4))
```

```python
sage: S = MatrixSpace(QQ, 3, 2, sparse=True)
sage: _. = ma.set_space(S)
sage: ma.finalized()
<MatrixArgs for Full MatrixSpace of 3 by 2 sparse matrices over Rational Field; typ=ZERO; entries=None>
```

```python
sage: M = ma.matrix(); M
[0 0]
[0 0]
[0 0]
```

```python
sage: M.parent() is S
True
```

```python
>>> from sage.all import *
```

```python
>>> from sage.matrix.args import MatrixArgs
```

```python
>>> ma = MatrixArgs(Integer(3), Integer(2), sparse=True)
```

```python
>>> _. = ma.set_space(S)
```

```python
>>> ma.finalized()
<MatrixArgs for Full MatrixSpace of 3 by 2 sparse matrices over Rational Field; typ=ZERO; entries=None>
```
From a homset:

```python
sage: C = CombinatorialFreeModule(ZZ, ['a', 'b', 'c'])
sage: R = CombinatorialFreeModule(ZZ, ['u', 'v'])
sage: S = Hom(C, R); S
Set of Morphisms
  from Free module generated by {'a', 'b', 'c'} over Integer Ring
to Free module generated by {'u', 'v'} over Integer Ring
  in Category of finite dimensional modules with basis over Integer Ring
sage: ma = MatrixArgs()
sage: _ = ma.set_space(S)
sage: ma.finalized()
<MatrixArgs for Set of Morphisms
  from Free module generated by {'a', 'b', 'c'} over Integer Ring
to Free module generated by {'u', 'v'} over Integer Ring
  in Category of finite dimensional modules with basis over Integer Ring;
typ=ZERO; entries=None>
```
class sage.matrix.args.SparseEntry

Bases: object

Specialized class for dealing with sparse input in MatrixArgs. An instance of SparseEntry represents one position in a matrix to be constructed. To construct a sparse matrix, one would typically make a list of such.

Previous versions of Sage used a dict as data structure for sparse input, but that is not so suitable because the keys are not guaranteed to be of the correct format. There is also the performance cost of creating tuples of Python integers.

Users of this class are expected to know what they are doing, so the indices are not checked when constructing a matrix.

INPUT:

- \( i, j \) – row and column index
- entry – value to be put at position \((i, j)\)

EXAMPLES:

```python
d>>> from sage.matrix.args import SparseEntry
d>>> SparseEntry(123, 456, "abc")
SparseEntry(123, 456, 'abc')
d>>> SparseEntry(1/3, 2/3, x)
# needs sage.symbolic
Traceback (most recent call last):
... TypeError: unable to convert rational 1/3 to an integer
```

```python
d>>> from sage.all import *  
d>>> SparseEntry(Integer(123), Integer(456), "abc")
SparseEntry(Integer(123), Integer(456), 'abc')
d>>> SparseEntry(Integer(1)/Integer(3), Integer(2)/Integer(3), x)  
# needs sage.symbolic
Traceback (most recent call last):

```
MATRICES OVER AN ARBITRARY RING

AUTHORS:
- William Stein
- Martin Albrecht: conversion to Pyrex
- Jaap Spies: various functions
- Gary Zablackis: fixed a sign bug in generic determinant.
- William Stein and Robert Bradshaw - complete restructuring.
- Rob Beezer - refactor kernel functions.

Elements of matrix spaces are of class Matrix (or a class derived from Matrix). They can be either sparse or dense, and can be defined over any base ring.

EXAMPLES:
We create the $2 \times 3$ matrix
\[
\begin{pmatrix}
1 & 2 & 3 \\
4 & 5 & 6
\end{pmatrix}
\]
as an element of a matrix space over $\mathbb{Q}$:

```
sage: M = MatrixSpace(QQ, 2, 3)
sage: A = M([1, 2, 3, 4, 5, 6]); A
[1 2 3]
[4 5 6]
sage: A.parent()
Full MatrixSpace of 2 by 3 dense matrices over Rational Field
```

Alternatively, we could create $A$ more directly as follows (which would completely avoid having to create the matrix space):

```
sage: A = matrix(QQ, 2, [1, 2, 3, 4, 5, 6]); A
[1 2 3]
[4 5 6]
```
We next change the top-right entry of $A$. Note that matrix indexing is 0-based in Sage, so the top right entry is $(0, 2)$, which should be thought of as “row number 0, column number 2”.

```python
sage: A[0,2] = 389
sage: A
[[1, 2, 389],
 [4, 5, 6]]
```

Also notice how matrices print. All columns have the same width and entries in a given column are right justified. Next we compute the reduced row echelon form of $A$.

```python
sage: A.rref()
[[1, 0, -1933/3],
 [0, 1, 1550/3]]
```

## 5.1 Indexing

Sage has quite flexible ways of extracting elements or submatrices from a matrix:

```python
sage: m=[(1, -2, -1, -1, 9), (1, 8, 6, 2, 2), (1, 1, -1, 1, 4), (-1, 2, -2, -1, 4)] ; M = matrix(m)
sage: M
[[1, -2, -1, -1, 9],
 [1, 8, 6, 2, 2],
 [1, 1, -1, 1, 4],
 [-1, 2, -2, -1, 4]]
```

```python
sage: m=[(Integer(1), -Integer(2), -Integer(1), -Integer(1), Integer(9)), (Integer(1), Integer(8), Integer(6), Integer(2), Integer(2)), (Integer(1), Integer(1), -Integer(1), Integer(1), Integer(4)), (-Integer(1), Integer(2), -Integer(2), -Integer(1), Integer(4))] ; M = matrix(m)
sage: M
[[1, -2, -1, -1, 9],
 [1, 8, 6, 2, 2],
 [1, 1, -1, 1, 4],
 [-1, 2, -2, -1, 4]]
```
Get the 2 x 2 submatrix of M, starting at row index and column index 1:

```
sage: M[1:3,1:3]
[ 8 6]
[ 1 -1]
```

```
>>> from sage.all import *

>>> M[Integer(1):Integer(3),Integer(1):Integer(3)]
[ 8 6]
[ 1 -1]
```

Get the 2 x 3 submatrix of M starting at row index and column index 1:

```
sage: M[1:3,[1..3]]
[ 8 6 2]
[ 1 -1 1]
```

```
>>> from sage.all import *

>>> M[Integer(1):Integer(3),(ellipsis_range(Integer(1),Ellipsis,Integer(3)))]
[ 8 6 2]
[ 1 -1 1]
```

Get the second column of M:

```
sage: M[:,1]
[-2]
[ 8]
[ 1]
[ 2]
```

```
>>> from sage.all import *

>>> M[:,Integer(1)]
[-2]
[ 8]
[ 1]
[ 2]
```

Get the first row of M:

```
sage: M[0,:]
[ 1 -2 -1 -1 9]
```

```
>>> from sage.all import *

>>> M[Integer(0),:]
[ 1 -2 -1 -1 9]
```

Get the last row of M (negative numbers count from the end):

```
sage: M[-1,:]
[-1 2 -2 -1 4]
```

```
>>> from sage.all import *

>>> M[-Integer(1),:]
[-1 2 -2 -1 4]
```

More examples:

5.1. Indexing
A series of three numbers, separated by colons, like $n:m:s$, means numbers from $n$ up to (but not including) $m$, in steps of $s$. So $0:5:2$ means the sequence $[0, 2, 4]$: 
We can also change submatrices using these indexing features:
matrices and spaces of matrices, release 10.4

sage: M = matrix([(1, -2, -1, -1, 9), (1, 8, 6, 2, 2), (1, 1, -1, 1, 4), (-1, 2, -2, -1, 4)]); M
[ 1 -2 -1 -1 9]
[ 1 8 6 2 2]
[ 1 1 -1 1 4]
[-1 2 -2 -1 4]

>>> from sage.all import *

>>> M = matrix([(Integer(1), -Integer(2), -Integer(1), -Integer(1), Integer(9)),
               (Integer(1), Integer(8), Integer(6), Integer(2), Integer(2)),
               (Integer(1), -Integer(1), Integer(1), Integer(1), Integer(4)),
               (-Integer(1), Integer(2), -Integer(2), -Integer(1), Integer(4))]); M
[ 1 -2 -1 -1 9]
[ 1 8 6 2 2]
[ 1 1 -1 1 4]
[-1 2 -2 -1 4]

set the 2 x 2 submatrix of M, starting at row index and column index 1:
sage: M[1:3,1:3] = [[1,0],[0,1]]; M
[ 1 -2 -1 -1 9]
[ 1 1 0 2 2]
[ 1 0 1 1 4]
[-1 2 -2 -1 4]

>>> from sage.all import *

>>> M[Integer(1):Integer(3),Integer(1):Integer(3)] = [[Integer(1),Integer(0)],
               [Integer(0),Integer(1)]]; M
[ 1 -2 -1 -1 9]
[ 1 1 0 2 2]
[ 1 0 1 1 4]
[-1 2 -2 -1 4]

set the 2 x 3 submatrix of M starting at row index and column index 1:
sage: M[1:3,[1..3]] = M[2:4,0:3]; M
[ 1 -2 -1 -1 9]
[ 1 1 0 1 2]
[ 1 -1 2 -2 4]
[-1 2 -2 -1 4]

>>> from sage.all import *

>>> M[Integer(1):Integer(3),ellipsis_range(Integer(1),Ellipsis,Integer(3)) =
               M[Integer(2):Integer(4),Integer(0):Integer(3)]; M
[ 1 -2 -1 -1 9]
[ 1 1 0 1 2]
[ 1 -1 2 -2 4]
[-1 2 -2 -1 4]

set part of the first column of M:
sage: M[1:,0] = [[2],[3],[4]]; M
[ 1 -2 -1 -1 9]
[ 2 1 0 1 2]
[ 3 -1 2 -2 4]
[ 4 2 -2 -1 4]

134 Chapter 5. Matrices over an arbitrary ring
Or do a similar thing with a vector:

```
sage: M[1:,0]=vector([-2,-3,-4]); M
[ 1 -2 -1 -1  9]
[-2  1  0  1  2]
[-3 -1  2 -2  4]
[-4  2 -2 -1  4]
```

Or a constant:

```
sage: M[1:,0]=30; M
[ 1 -2 -1 -1  9]
[30  1  0  1  2]
[30 -1  2 -2  4]
[30  2 -2 -1  4]
```

Set the first row of M:

```
sage: M[0, :]=[[20,21,22,23,24]]; M
[20 21 22 23 24]
[30  1  0  1  2]
[30 -1  2 -2  4]
[30  2 -2 -1  4]
sage: M[0, :]=vector([0,1,2,3,4]); M
[ 0  1  2  3  4]
[30  1  0  1  2]
[30 -1  2 -2  4]
[30  2 -2 -1  4]
sage: M[0, :]=-3; M
[-3 -3 -3 -3 -3]
[30  1  0  1  2]
[30 -1  2 -2  4]
[30  2 -2 -1  4]
```

```
sage: A = matrix(ZZ,3,4, [3, 2, -5, 0, 1, -1, 1, -4, 1, 0, 1, -3]); A
(continues on next page)
```
We can use the step feature of slices to set every other column:

```
sage: A[:,0:3:2] = 5; A
[ 5 2 5 0]
[ 5 -1 5 -4]
[ 5 0 5 -3]
```

```
sage: A[1:,0:4:2] = [[100,200],[300,400]]; A
[ 5 2 5 0]
[100 -1 200 -4]
[300 0 400 -3]
```

We can also count backwards to flip the matrix upside down:
sage: A[::-1,::] = A; A
[300 0 400 -3]
[100 -1 200 -4]
[ 5 2 5 0]

sage: A[1:,3::-1] = [[2, 3, 0, 1], [9, 8, 7, 6]]; A
[300 0 400 -3]
[ 1 0 3 2]
[ 6 7 8 9]

sage: A[1::2] = A[1::2]; A
[300 0 400 -3]
[ 1 3 3 1]
[ 6 8 8 6]

sage: A[::-1,3:1:-1] = [[4, 3], [1, 2], [-1, -2]]; A
[300 0 -2 -1]
[ 1 3 2 1]
[ 6 8 3 4]

We save and load a matrix:

sage: A = matrix(Integers(8), 3, range(9))
sage: loads(dumps(A)) == A
True

>>> from sage.all import *
>>> A = matrix(Integers(8), 3, range(9))
>>> loads(dumps(A)) == A
True

MUTABILITY: Matrices are either immutable or not. When initially created, matrices are typically mutable, so one can

5.1. Indexing
change their entries. Once a matrix $A$ is made immutable using `A.set_immutable()` the entries of $A$ cannot be changed, and $A$ can never be made mutable again. However, properties of $A$ such as its rank, characteristic polynomial, etc., are all cached so computations involving $A$ may be more efficient. Once $A$ is made immutable it cannot be changed back. However, one can obtain a mutable copy of $A$ using `copy(A)`.

**EXAMPLES:**

```python
sage: A = matrix(RR, 2, [1, 10, 3.5, 2])
sage: A.set_immutable()
sage: copy(A) is A
False
```

```python
>>> from sage.all import *

>>> A = matrix(RR, Integer(2), [Integer(1), Integer(10), RealNumber('3.5'), Integer(2)])

>>> A.set_immutable()

>>> copy(A) is A
False
```

The echelon form method always returns immutable matrices with known rank.

**EXAMPLES:**

```python
sage: A = matrix(Integers(8), 3, range(9))
sage: A.determinant()
0
sage: A[0,0] = 5
sage: A.determinant()
1
sage: A.set_immutable()

sage: A[0,0] = 5
Traceback (most recent call last):
  ... ValueError: matrix is immutable; please change a copy instead (i.e., use copy(M) to change a copy of M).
```

```python
>>> from sage.all import *

>>> A = matrix(Integers(Integer(8)), Integer(3), range(Integer(9)))

>>> A.determinant()
0

>>> A[Integer(0), Integer(0)] = Integer(5)

>>> A.determinant()
1

>>> A.set_immutable()

>>> A[Integer(0), Integer(0)] = Integer(5)
Traceback (most recent call last):
  ... ValueError: matrix is immutable; please change a copy instead (i.e., use copy(M) to change a copy of M).
```
5.1.1 Implementation and Design

Class Diagram (an x means that class is currently supported):

```
x Matrix
x Matrix_sparse
  x Matrix_generic_sparse
  x Matrix_rational_sparse
  x Matrix_cyclo_sparse
  x Matrix_modn_sparse
  x Matrix_CC_sparse
  x Matrix_RR_sparse
  x Matrix_RDF_sparse
  x Matrix_CDF_sparse

x Matrix_dense
x Matrix_generic_dense
x Matrix_integer_dense
x Matrix_rational_dense
  x Matrix_cyclo_dense  -- idea: restrict scalars to QQ, compute charpoly there, → factor
  x Matrix_modn_dense
  x Matrix_CC_dense
  x Matrix_RR_dense
x Matrix_real_double_dense
x Matrix_complex_double_dense
x Matrix_complex_ball_dense
```

The corresponding files in the sage/matrix library code directory are named

```
[matrix] [base ring] [dense or sparse].
```

New matrices types can only be implemented in Cython.

*********** LEVEL 1 ***********

NON-OPTIONAL

For each base field it is *absolutely* essential to completely implement the following functionality for that base ring:

* __cinit__  -- should use check_allocarray from cysignals.memory (only needed if allocate memory)
* __init__   -- this signature: 'def __init__(self, parent, entries, copy,... → coerce)'
  * __dealloc__ -- use sig_free (only needed if allocate memory)
  * set_unsafe(self, size_t i, size_t j, x) -- doesn't do bounds or any other checks;
    → assumes x is in self._base_ring
  * get_unsafe(self, size_t i, size_t j) -- doesn't do checks
  * __richcmp__  -- always the same (I don't know why its needed -- bug in PYREX).

Note that the __init__ function must construct the all zero matrix if `''entries ==...
→ None'``.

*********** LEVEL 2 ***********

IMPORTANT (and *highly* recommended):

(continues on next page)
After getting the special class with all level 1 functionality to work, implement all of the following (they should not change functionality, except speed (always faster!) in any way):

* def _pickle(self):
  return data, version
* def _unpickle(self, data, int version):
  reconstruct matrix from given data and version; may assume _parent, _nrows, _ncols are set.
  Use version numbers >= 0 so if you change the pickle strategy then old objects still unpickle.
* cdef _list -- list of underlying elements (need not be a copy)
* cdef _dict -- sparse dictionary of underlying elements
* cdef _add_ -- add two matrices with identical parents
* _matrix_times_matrix_c_impl -- multiply two matrices with compatible dimensions and identical base rings (both sparse or both dense)
* cpdef _richcmp_ -- compare two matrices with identical parents
* cdef _lmul_c_impl -- multiply this matrix on the right by a scalar, i.e., self * scalar
* cdef _rmul_c_impl -- multiply this matrix on the left by a scalar, i.e., scalar * self
* __copy__
* __neg__

The list and dict returned by _list and _dict will *not* be changed by any internal algorithms and are not accessible to the user.

*********** LEVEL 3 **********
OPTIONAL:

* cdef _sub_
* __invert__
* _multiply_classical
* __deepcopy__

Further special support:
* Matrix windows -- to support Strassen multiplication for a given base ring.
* Other functions, e.g., transpose, for which knowing the specific representation can be helpful.

.. note::

- For caching, use self.fetch and self.cache.

- Any method that can change the matrix should call `check_mutability()` first. There are also many fast cdef’d bounds checking methods.

- Kernels of matrices
  Implement only a left_kernel() or right_kernel() method, whichever requires the least overhead (usually meaning little or no transposing). Let the methods in the matrix2 class handle left, right, generic kernel distinctions.
BASE CLASS FOR MATRICES, PART 0

Note: For design documentation see matrix/docs.py.

EXAMPLES:

```python
sage: matrix(2, [1,2,3,4])
[1 2]
[3 4]
```

```python
>>> from sage.all import *
>>>
>>> matrix(Integer(2), [Integer(1),Integer(2),Integer(3),Integer(4)])
[1 2]
[3 4]
```

class sage.matrix.matrix0.Matrix

Bases: Matrix

A generic matrix.

The Matrix class is the base class for all matrix classes. To create a Matrix, first create a MatrixSpace, then coerce a list of elements into the MatrixSpace. See the documentation of MatrixSpace for more details.

EXAMPLES:

We illustrate matrices and matrix spaces. Note that no actual matrix that you make should have class Matrix; the class should always be derived from Matrix.

```python
sage: M = MatrixSpace(CDF,2,3); M
Full MatrixSpace of 2 by 3 dense matrices over Complex Double Field
sage: a = M([1,2,3, 4,5,6]); a
[1.0 2.0 3.0]
[4.0 5.0 6.0]
sage: type(a)
<class 'sage.matrix.matrix_complex_double_dense.Matrix_complex_double_dense'>
sage: parent(a)
Full MatrixSpace of 2 by 3 dense matrices over Complex Double Field
```

```python
>>> from sage.all import *
>>>
>>> M = MatrixSpace(CDF,Integer(2),Integer(3)); M
Full MatrixSpace of 2 by 3 dense matrices over Complex Double Field
>>>
>>> a = M([Integer(1),Integer(2),Integer(3), Integer(4),Integer(5),Integer(6)]);
˓→a
[1.0 2.0 3.0]
```

(continues on next page)
[4.0 5.0 6.0]

```python
>>> type(a)
<class 'sage.matrix.matrix_complex_double_dense.Matrix_complex_double_dense'>
>>> parent(a)
Full MatrixSpace of 2 by 3 dense matrices over Complex Double Field
```

```
sage: matrix(CDF, 2, 3, [1, 2, 3, 4, 5, 6])
[1.0 2.0 3.0]
[4.0 5.0 6.0]
sage: Mat(CDF, 2, 3)(range(1, 7))
[1.0 2.0 3.0]
[4.0 5.0 6.0]
```

```
>>> from sage.all import *

>>> matrix(CDF, Integer(2), Integer(3), [Integer(1), Integer(2), Integer(3),
\                       Integer(4), Integer(5), Integer(6)])
[1.0 2.0 3.0]
[4.0 5.0 6.0]
```

```
>>> from sage.all import *

>>> Q.<i,j,k> = QuaternionAlgebra(QQ, -1,-1)
>>> matrix(Q,2,1,[1,2])
[1]
[2]
```

```
>>> from sage.all import *

>>> Q = QuaternionAlgebra(QQ, -Integer(1),-Integer(1), names=('i', 'j', 'k',));
\   (i, j, k,) = Q._first_ngens(3)
>>> matrix(Q,Integer(2),Integer(1),[Integer(1),Integer(2)])
[1]
[2]
```

**act_on_polynomial(f)**

Return the polynomial f(self*x).

**INPUT:**

- `self` — an `n x n` matrix
- `f` — a polynomial in `n` variables `x=(x1,...,xn)`

**OUTPUT:** The polynomial `f(self*x)`.

**EXAMPLES:**

```
sage: R.<x,y> = QQ[]
sage: x, y = R.gens()
sage: f = x**2 - y**2
sage: M = MatrixSpace(QQ, 2)
sage: A = M([[1,2,3,4]])
sage: A.act_on_polynomial(f)
-8*x^2 - 20*x*y - 12*y^2
```

```
act_on_polynomial(f)
Return the polynomial f(self*x).

INPUT:

- self — an n x n matrix
- f — a polynomial in n variables x=(x1,...,xn)

OUTPUT: The polynomial f(self*x).

EXAMPLES:

```
sage: R.<x,y> = QQ[]
sage: x, y = R.gens()
sage: f = x**2 - y**2
sage: M = MatrixSpace(QQ, 2)
sage: A = M([[1,2,3,4]])
sage: A.act_on_polynomial(f)
-8*x^2 - 20*x*y - 12*y^2
```

```
142 Chapter 6. Base class for matrices, part 0
```
add_multiple_of_column \( (i, j, s, \text{start}_\text{row}=0) \)
Add \( s \) times column \( j \) to column \( i \).

EXAMPLES: We add \(-1\) times the third column to the second column of an integer matrix, remembering to start numbering cols at zero:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: a.add_multiple_of_column(1,2,-1)
sage: a
[ 0 -1 2]
[ 3 -1 5]
```

To add a rational multiple, we first need to change the base ring:

```
sage: a = a.change_ring(QQ)
sage: a.add_multiple_of_column(1,0,1/3)
sage: a
[ 0 -1 2]
[ 3 0 5]
```

If not, we get an error message:

```
sage: a.add_multiple_of_column(1, 0, SR.I())  # needs sage.symbolic
Traceback (most recent call last):
...
TypeError: Multiplying column by Symbolic Ring element cannot be done over Rational Field, use change_ring or with_added_multiple_of_column instead.
```
add_multiple_of_row \( i, j, s, \text{start\_col}=0 \)

Add \( s \) times row \( j \) to row \( i \).

**EXAMPLES:** We add -3 times the first row to the second row of an integer matrix, remembering to start numbering rows at zero:

\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5
\end{bmatrix}
\]

```python
>>> a = matrix(ZZ, 2, 3, range(6)); a
```

```plaintext
[0 1 2]
[3 4 5]
```

```python
>>> a.add_multiple_of_row(1, 0, -3)
```

```plaintext
[0 1 2]
[3 1 -1]
```

To add a rational multiple, we first need to change the base ring:

```python
>>> a = a.change_ring(QQ)
```

```plaintext
[0 1 2]
[3 4/3 -1/3]
```

If not, we get an error message:

```python
>>> a.add_multiple_of_row(1, 0, SR.I())  # needs sage.symbolic
```

Traceback (most recent call last):
...
```

**TypeError:** Multiplying row by Symbolic Ring element cannot be done over Rational Field, use change_ring or with_added_multiple_of_row instead.
add_to_entry\((i, j, elt)\)
Add\(elt\) to the entry at position \((i, j)\).

EXAMPLES:

\[
sage: m = \text{matrix}(\text{QQ}[\text{\texttt{x,y}}], 2, 2)
sage: m.add_to_entry(0, 1, 2)
sage: m
\begin{pmatrix}
0 & 2 \\
0 & 0
\end{pmatrix}
\]

anticommutator\((\text{other})\)
Return the anticommutator \((A, B)\).
The anticommutator of two \(n \times n\) matrices \(A\) and \(B\) is defined as \(\{A, B\} := AB + BA\) (sometimes this is written as \([A, B]_+\)).

EXAMPLES:

\[
sage: A = \text{Matrix}(\text{ZZ}, 2, 2, \text{range}(4))
sage: B = \text{Matrix}(\text{ZZ}, 2, 2, [0, 1, 0, 0])
sage: A.anticommutator(B)
\begin{pmatrix}
2 & 3 \\
0 & 2
\end{pmatrix}
sage: A.anticommutator(B) == B.anticommutator(A)
True
sage: A.commutator(B) + B.anticommutator(A) == 2*A*B
True
\]

base_ring()
Return the base ring of the matrix.

EXAMPLES:

```python
sage: m = matrix(QQ, 2, [1,2,3,4])
sage: m.base_ring()
Rational Field
```

```python
>>> from sage.all import *
>>> m = matrix(QQ, Integer(2), [Integer(1),Integer(2),Integer(3),Integer(4)])
>>> m.base_ring()
Rational Field
```

### `change_ring` *(ring)*

Return the matrix obtained by coercing the entries of this matrix into the given ring.

Always returns a copy (unless self is immutable, in which case returns self).

EXAMPLES:

```python
sage: A = Matrix(QQ, 2, 2, [1/2, 1/3, 1/3, 1/4])
sage: A.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: A.change_ring(GF(25,'a'))  # needs sage.rings.finite_rings
[3 2]
[2 4]
sage: A.change_ring(GF(25,'a')).parent()  # needs sage.rings.finite_rings
Full MatrixSpace of 2 by 2 dense matrices over Finite Field in a of size 5^2
sage: A.change_ring(ZZ)  # needs sage.rings.finite_rings
Traceback (most recent call last):
... TypeError: matrix has denominators so can't change to ZZ
```

```python
>>> from sage.all import *
>>> A = Matrix(QQ, Integer(2), Integer(2), [Integer(1)/Integer(2), Integer(1)/Integer(3), Integer(1)/Integer(3), Integer(1)/Integer(4)])
>>> A.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
>>> A.change_ring(GF(Integer(25),'a'))  # needs sage.rings.finite_rings
[3 2]
[2 4]
>>> A.change_ring(GF(Integer(25),'a')).parent()  # needs sage.rings.finite_rings
Full MatrixSpace of 2 by 2 dense matrices over Finite Field in a of size 5^2
>>> A.change_ring(ZZ)  # needs sage.rings.finite_rings
Traceback (most recent call last):
... TypeError: matrix has denominators so can't change to ZZ
```

Changing rings preserves subdivisions:
sage: A.subdivide([1], []); A
[1/2 1/3]
[--------]
[1/3 1/4]
sage: A.change_ring(GF(25, 'a'))
# needs sage.rings.finite_rings
[3 2]
[---]
[2 4]

>>> from sage.all import *

>>> A.subdivide([Integer(1)], []); A
[1/2 1/3]
[--------]
[1/3 1/4]

>>> A.change_ring(GF(Integer(25), 'a'))
# needs sage.rings.finite_rings
[3 2]
[---]
[2 4]

\textbf{commutator}(\textit{other})

Return the commutator self*other - other*self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = Matrix(ZZ, 2, 2, range(4))
sage: B = Matrix(ZZ, 2, 2, [0, 1, 0, 0])
sage: A.commutator(B)
[-2 -3]
[ 0 2]
sage: A.commutator(B) == -B.commutator(A)
True

>>> from sage.all import *

>>> A = Matrix(ZZ, Integer(2), Integer(2), range(Integer(4)))

>>> B = Matrix(ZZ, Integer(2), Integer(2), [Integer(0), Integer(1),
                                           Integer(0), Integer(0)])

>>> A.commutator(B)
[-2 -3]
[ 0 2]

>>> A.commutator(B) == -B.commutator(A)
True
\end{verbatim}

\textbf{dense_coefficient_list}(\textit{order} = None)

Return a list of all coefficients of self.

By default, this is the same as \textit{list}().

\textbf{INPUT:}

\begin{itemize}
  \item \textit{order} -- (optional) an ordering of the basis indexing set
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = matrix([[1, 2, 3], [4, 5, 6]])
sage: A.dense_coefficient_list()
[1, 2, 3, 4, 5, 6]
\end{verbatim}
sage: A.dense_coefficient_list([(1,2), (1,0), (0,1), (0,2), (0,0), (1,1)])
[6, 4, 2, 3, 1, 5]

>>> from sage.all import *
>>>
A = matrix([[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5), Integer(6)]])
>>>
A.dense_coefficient_list()
[1, 2, 3, 4, 5, 6]

Dictionary of the elements of self with keys pairs (i,j) and values the nonzero entries of self.

INPUT:

• copy – (default: True) make a copy of the dict corresponding to self

If copy=True, then is safe to change the returned dictionary. Otherwise, this can cause undesired behavior by mutating the dict.

EXAMPLES:

sage: R.<x,y> = QQ[]
sage: a = matrix(R,2,[x,y,0, 0,0,2*x+y]); a
[ x y 0]
[ 0 0 2*x + y]
sage: d = a.dict(); d
{(0, 0): x, (0, 1): y, (1, 2): 2*x + y}

>>> from sage.all import *
>>>
R = QQ['x', 'y']; (x, y,) = R._first_ngens(2)
>>>
a = matrix(R,Integer(2),[x,y,Integer(0), Integer(0),Integer(0), Integer(2)*x+y]); a
[ x y 0]
[ 0 0 2*x + y]
>>>
d = a.dict(); d
{(0, 0): x, (0, 1): y, (1, 2): 2*x + y}

Notice that changing the returned list does not change a (the list is a copy):

sage: d[0,0] = 25
sage: a
[ x y 0]
[ 0 0 2*x + y]

>>> from sage.all import *
>>> d[Integer(0),Integer(0)] = Integer(25)
>>> a
[ x y 0]
[ 0 0 2*x + y]

dimensions()

Return the dimensions of this matrix as the tuple (nrows, ncols).
EXAMPLES:

```
sage: M = matrix([[1,2,3],[4,5,6]])
sage: N = M.transpose()
sage: M.dimensions()
(2, 3)
sage: N.dimensions()
(3, 2)
```

```
>>> from sage.all import *

>>> M = matrix([[Integer(1),Integer(2),Integer(3)],
              [Integer(4),Integer(5),Integer(6)]])

>>> N = M.transpose()

>>> M.dimensions()
(2, 3)

>>> N.dimensions()
(3, 2)
```

AUTHORS:

- Benjamin Lundell (2012-02-09): examples

inverse_of_unit (algorithm=None)

Return the inverse of this matrix in the same matrix space.

The matrix must be invertible on the base ring. Otherwise, an ArithmeticError is raised.

The computation goes through the matrix of cofactors and avoids division. In particular the base ring does not need to have a fraction field.

INPUT:

- algorithm – (default: None) either None or "df" (for division free)

EXAMPLES:

```
sage: R.<a,b,c,d> = ZZ[]
sage: RR = R.quotient(a*d - b*c - 1)
sage: a,b,c,d = RR.gens()  # needs sage.libs.singular

sage: m = matrix(2, [a,b, c,d])

sage: n = m.inverse_of_unit()  # needs sage.libs.singular

sage: m * n  # needs sage.libs.singular
[1 0]
[0 1]
```

```
sage: matrix(RR, 2, 1, [a,b]).inverse_of_unit()  # needs sage.libs.singular
Traceback (most recent call last):
  ...
ArithmeticError: self must be a square matrix
```

```
sage: matrix(RR, 1, 1, [2]).inverse_of_unit()  # needs sage.libs.singular
Traceback (most recent call last):
  ...
ArithmeticError: non-invertible matrix
```

(continues on next page)
sage: R = ZZ.cartesian_product(ZZ)
sage: m = matrix(R, 2, [R((2,1)), R((1,1)), R((1,1)), R((1,2))])
sage: m * m.inverse_of_unit()
[(1, 1) (0, 0)]
[(0, 0) (1, 1)]

```python
>>> from sage.all import *
>>> R = ZZ['a, b, c, d']; (a, b, c, d,) = R._first_ngens(4)
>>> RR = R.quotient(a*d - b*c - Integer(1))
>>> a,b,c,d = RR.gens()

# needs sage.libs.singular
>>> m = matrix(Integer(2), [a,b, c,d])
>>> n = m.inverse_of_unit()
# needs sage.libs.singular
>>> m * n
# needs sage.libs.singular
[1 0]
[0 1]
```

Tests for Issue #28570:

```python
sage: P = posets.TamariLattice(7)  # needs sage.graphs
sage: M = P._hasse_diagram._leq_matrix  # needs sage.graphs
sage: M.inverse_of_unit()  # this was very slow, now 1s
# needs sage.graphs
429 x 429 sparse matrix over Integer Ring...
sage: m = matrix(Zmod(2**2), 1, 1, [1], sparse=True)
sage: mi = ~m; mi
[1]
sage: mi.parent()
Full MatrixSpace of 1 by 1 sparse matrices over Ring of integers modulo 4
```
# needs sage.graphs

```python
>>> M = P._hasse_diagram._leq_matrix  # needs sage.graphs
>>> M.inverse_of_unit()  # this was very slow, now 1s
429 x 429 sparse matrix over Integer Ring...
```

```python
>>> m = matrix(Zmod(Integer(2)**Integer(2)), Integer(1), Integer(1),
             [Integer(1)], sparse=True)
```

```python
>>> mi = ~m; mi
[1]
```

```python
>>> mi.parent()
Full MatrixSpace of 1 by 1 sparse matrices over Ring of integers modulo 4
```

### is_alternating()

Return `True` if `self` is an alternating matrix.

Here, “alternating matrix” means a square matrix $A$ satisfying $A^T = -A$ and such that the diagonal entries of $A$ are 0. Notice that the condition that the diagonal entries be 0 is not redundant for matrices over arbitrary ground rings (but it is redundant when 2 is invertible in the ground ring). A square matrix $A$ only required to satisfy $A^T = -A$ is said to be “skew-symmetric”, and this property is checked by the `is_skew_symmetric()` method.

#### EXAMPLES:

```python
>>> from sage.all import *
>>> n = matrix(Zmod(Integer(4)), [Integer(0), Integer(1),
                                    -Integer(1), Integer(2)])
```

```python
>>> n.is_alternating()
False
```

In contrast to the property of being skew-symmetric, the property of being alternating does not tolerate nonzero entries on the diagonal even if they are their own negatives:

```python
>>> n = matrix(Zmod(4), [[0, 1], [-1, 2]])
```

```python
>>> n.is_alternating()
False
```

### is_dense()

Return `True` if this is a dense matrix.

In Sage, being dense is a property of the underlying representation, not the number of nonzero entries.
EXAMPLES:

```python
sage: matrix(QQ, 2, 2, range(4)).is_dense()
True
sage: matrix(QQ, 2, 2, range(4), sparse=True).is_dense()
False
```

```python
>>> from sage.all import *

>>> matrix(QQ, Integer(2), Integer(2), range(Integer(4))).is_dense()
True
```

```python
is_hermitian()

Return True if the matrix is equal to its conjugate-transpose.

OUTPUT:

True if the matrix is square and equal to the transpose with every entry conjugated, and False otherwise.

Note that if conjugation has no effect on elements of the base ring (such as for integers), then the is_symmetric() method is equivalent and faster.

This routine is for matrices over exact rings and so may not work properly for matrices over RR or CC. For matrices with approximate entries, the rings of double-precision floating-point numbers, RDF and CDF, are a better choice since the `sage.matrix.matrix_double_dense.Matrix_double_dense.is_hermitian()` method has a tolerance parameter. This provides control over allowing for minor discrepancies between entries when checking equality.

The result is cached.

EXAMPLES:

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQbar, [[ 1 + I, 1 - 6*I, -1 - I],
....: [-3 - I, -4*I, -2],
....: [-1 + I, -2 - 8*I, 2 + I]])

sage: A.is_hermitian()
False

sage: B = A * A.conjugate_transpose()

sage: B.is_hermitian()
True
```

```python
>>> from sage.all import *

>>> # needs sage.rings.number_field

>>> A = matrix(QQbar, [[ Integer(1) + I, 1 - 6*I, -1 - I],
....: [-3 - I, -4*I, -2],
....: [-1 + I, -2 - 8*I, 2 + I]])

>>> A.is_hermitian()
False

>>> B = A * A.conjugate_transpose()

>>> B.is_hermitian()
True
```

Sage has several fields besides the entire complex numbers where conjugation is non-trivial.
A matrix that is nearly Hermitian, but for a non-real diagonal entry.

A rectangular matrix is never Hermitian.
Decomposition

```
needs sage.rings.number_field
False

>>> from sage.all import *
>>> A = matrix(QQbar, Integer(3), Integer(4))  # needs sage.rings.number_field
>>> A.is_hermitian()  # needs sage.rings.number_field
False

A square, empty matrix is trivially Hermitian.

sage: A = matrix(QQ, 0, 0)
sage: A.is_hermitian()
True

>>> from sage.all import *
>>> A = matrix(QQ, Integer(0), Integer(0))
>>> A.is_hermitian()
True

is_immutable()

Return True if this matrix is immutable.

See the documentation for self.set_immutable for more details about mutability.

EXAMPLES:

sage: A = Matrix(QQ['t','s'], 2, 2, range(4))
sage: A.is_immutable()
False
sage: A.set_immutable()

sage: A.is_immutable()
True

>>> from sage.all import *
>>> A = Matrix(QQ['t','s'], Integer(2), Integer(2), range(Integer(4)))
>>> A.is_immutable()
False
>>> A.set_immutable()

>>> A.is_immutable()
True

is_invertible()

Return True if this matrix is invertible.

EXAMPLES: The following matrix is invertible over $\mathbb{Q}$ but not over $\mathbb{Z}$.

sage: A = MatrixSpace(ZZ, 2)(range(4))
sage: A.is_invertible()
False
sage: A.matrix_over_field().is_invertible()
True
The inverse function is a constructor for matrices over the fraction field, so it can work even if A is not invertible.

The next matrix is invertible over \(\mathbb{Z}\).

The following nontrivial matrix is invertible over \(\mathbb{Z}[x]\).
**ismutable()**

Return True if this matrix is mutable.

See the documentation for self.set_immutable for more details about mutability.

**EXAMPLES:**

```python
sage: A = Matrix(QQ['t','s'], 2, 2, range(4))
sage: A.is_mutable()
True
sage: A.set_immutable()
sage: A.is_mutable()
False
```

```python
>>> from sage.all import *

>>> A = Matrix(QQ['t','s'], Integer(2), Integer(2), range(Integer(4)))

>>> A.is_mutable()
True

>>> A.set_immutable()

>>> A.is_mutable()
False
```

**issingular()**

Return True if self is singular.

**OUTPUT:**

A square matrix is singular if it has a zero determinant and this method will return True in exactly this case. When the entries of the matrix come from a field, this is equivalent to having a nontrivial kernel, or lacking an inverse, or having linearly dependent rows, or having linearly dependent columns.

For square matrices over a field the methods is_invertible() and is_singular() are logical opposites. However, it is an error to apply is_singular() to a matrix that is not square, while is_invertible() will always return False for a matrix that is not square.

**EXAMPLES:**

A singular matrix over the field QQ.

```python
sage: A = matrix(QQ, 4, [-1,2,-3,6, 0,-1,-1,0, -1,1,-5,7, -1,6,5,2])
sage: A.is_singular()
True

sage: A.right_kernel().dimension()
1
```

```python
>>> from sage.all import *

>>> A = matrix(QQ, Integer(4), [-Integer(1),Integer(2),-Integer(3),Integer(6), -Integer(0),-Integer(1),-Integer(1),Integer(0), -Integer(1),Integer(1),- Integer(5),Integer(7), -Integer(1),Integer(6),Integer(5),Integer(2)])

>>> A.is_singular()
True

>>> A.right_kernel().dimension()
1
```

A matrix that is not singular, i.e. nonsingular, over a field.

```python
sage: B = matrix(QQ, 4, [1,-3,-1,-5, 2,-5,-2,-7, -2,5,3,4, -1,4,2,6])
sage: B.is_singular()
False
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```
sage: B.left_kernel().dimension()
0
```

```
>>> from sage.all import *

>>> B = matrix(QQ, Integer(4), [Integer(1),-Integer(3),-Integer(1),-
    Integer(5), Integer(2),-Integer(5),-Integer(2),-Integer(7), -Integer(2),
    Integer(5),Integer(3),Integer(4), -Integer(1),Integer(4),Integer(2),
    -Integer(6)])

>>> B.is_singular()
False

>>> B.left_kernel().dimension()
0
```

For **rectangular** matrices, invertibility is always `False`, but asking about singularity will give an error.

```
sage: C = matrix(QQ, 5, range(30))
sage: C.is_invertible()
False

sage: C.is_singular()
Traceback (most recent call last):
...
ValueError: self must be a square matrix
```

```
>>> from sage.all import *

>>> C = matrix(QQ, Integer(5), range(Integer(30)))

>>> C.is_invertible()
False

>>> C.is_singular()
Traceback (most recent call last):
...
ValueError: self must be a square matrix
```

When the base ring is not a field, then a matrix may be both not invertible and not singular.

```
sage: D = matrix(ZZ, 4, [2,0,-4,8, 2,1,-2,7, 2,5,7,0, 0,1,4,-6])
sage: D.is_invertible()
False

sage: D.is_singular()
False

sage: d = D.determinant(); d
2

sage: d.is_unit()
False
```

```
>>> from sage.all import *

>>> D = matrix(ZZ, Integer(4), [Integer(2),Integer(0),-Integer(4),Integer(8),-
    Integer(2),Integer(1),-Integer(2),Integer(7), Integer(2),Integer(5),
    Integer(7),Integer(0), Integer(0),Integer(1),Integer(4),-Integer(6)])

>>> D.is_invertible()
False

>>> D.is_singular()
False

>>> d = D.determinant(); d
2

>>> d.is_unit()
False
```
is_skew_hermitian()

Return True if the matrix is equal to the negative of its conjugate transpose.

OUTPUT:
True if the matrix is square and equal to the negative of its conjugate transpose, and False otherwise.

Note that if conjugation has no effect on elements of the base ring (such as for integers), then the is_skew_symmetric() method is equivalent and faster.

This routine is for matrices over exact rings and so may not work properly for matrices over RR or CC. For matrices with approximate entries, the rings of double-precision floating-point numbers, RDF and CDF, are a better choice since the sage.matrix.matrix_double_dense.Matrix_double_dense.is_skew_hermitian() method has a tolerance parameter. This provides control over allowing for minor discrepancies between entries when checking equality.

The result is cached.

EXAMPLES:

```
sage: A = matrix(QQbar, [[0, -1], [1, 0]])  # needs sage.rings.number_field
sage: A.is_skew_hermitian()  # needs sage.rings.number_field
True

>>> from sage.all import *
>>> A = matrix(QQbar, [[Integer(0), -Integer(1)], [Integer(1), Integer(0)]])
>>> A.is_skew_hermitian()  # needs sage.rings.number_field
True
```

A matrix that is nearly skew-Hermitian, but for a non-real diagonal entry.

```
sage: # needs sage.rings.number_field
sage: A = matrix(QQbar, [[ -I, -1, 1-I], [ 1, 1, -1], [-1-I, 1, -I]])
```

```
sage: A.is_skew_hermitian()
False
sage: A[1, 1] = -I
sage: A.is_skew_hermitian()
True
```

Rectangular matrices are never skew-Hermitian.
sage: A = matrix(QQbar, 3, 4)  # needs sage.rings.number_field
sage: A.is_skew_hermitian()  # needs sage.rings.number_field
False

>>> from sage.all import *

>>> A = matrix(QQbar, Integer(3), Integer(4))  # needs sage.rings.number_field

>>> A.is_skew_hermitian()  # needs sage.rings.number_field
False

A square, empty matrix is trivially Hermitian.

sage: A = matrix(QQ, 0, 0)
sage: A.is_skew_hermitian()
True

>>> from sage.all import *

>>> A = matrix(QQ, Integer(0), Integer(0))

>>> A.is_skew_hermitian()
True

is_skew_symmetric()

Return True if self is a skew-symmetric matrix.

Here, “skew-symmetric matrix” means a square matrix $A$ satisfying $A^T = -A$. It does not require that the diagonal entries of $A$ are 0 (although this automatically follows from $A^T = -A$ when 2 is invertible in the ground ring over which the matrix is considered). Skew-symmetric matrices $A$ whose diagonal entries are 0 are said to be “alternating”, and this property is checked by the is_alternating() method.

EXAMPLES:

sage: m = matrix(QQ, [[0,2], [-2,0]])
sage: m.is_skew_symmetric()
True

sage: m = matrix(QQ, [[1,2], [2,1]])
sage: m.is_skew_symmetric()
False

>>> from sage.all import *

>>> m = matrix(QQ, [[Integer(0),Integer(2)], [-Integer(2),Integer(0)]])

>>> m.is_skew_symmetric()
True

>>> m = matrix(QQ, [[Integer(1),Integer(2)], [Integer(2),Integer(1)]])

>>> m.is_skew_symmetric()
False

Skew-symmetric is not the same as alternating when 2 is a zero-divisor in the ground ring:

sage: n = matrix(Zmod(4), [[0, 1], [-1, 2]])
sage: n.is_skew_symmetric()
True
**Matrices and Spaces of Matrices, Release 10.4**

```python
>>> from sage.all import *
>>> n = matrix(Zmod(Integer(4)), [[Integer(0), Integer(1)], [-Integer(1), Integer(2)]]);
n.is_skew_symmetric()
True
```

but yet the diagonal cannot be completely arbitrary in this case:

```python
sage: n = matrix(Zmod(4), [[0, 1], [-1, 3]])
sage: n.is_skew_symmetric()
False
```

```python
>>> from sage.all import *
>>> n = matrix(Zmod(Integer(4)), [[Integer(0), Integer(1)], [-Integer(1), Integer(3)]]);
n.is_skew_symmetric()
False
```

**is_skew_symmetrizable** *(return_diag=False, positive=True)*

This function takes a square matrix over an ordered integral domain and checks if it is skew-symmetrizable. A matrix $B$ is skew-symmetrizable iff there exists an invertible diagonal matrix $D$ such that $DB$ is skew-symmetric.

**Warning:** Expects self to be a matrix over an ordered integral domain.

**INPUT:**

- `return_diag` – bool (default: False) if True and self is skew-symmetrizable the diagonal entries of the matrix $D$ are returned.
- `positive` – bool (default: True) if True, the condition that $D$ has positive entries is added.

**OUTPUT:**

- True – if self is skew-symmetrizable and return_diag is False
- the diagonal entries of a matrix $D$ such that $DB$ is skew-symmetric – iff self is skew-symmetrizable and return_diag is True
- False – iff self is not skew-symmetrizable

**EXAMPLES:**

```python
sage: matrix([[0,6],[3,0]]).is_skew_symmetrizable(positive=False)
True
sage: matrix([[0,6],[3,0]]).is_skew_symmetrizable(positive=True)
False
```

```python
sage: M = matrix(4, [0,1,0,0, -1,0,-1,0, 0,2,0,1, 0,0,-1,0]); M
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 2 0 1]
[ 0 0 -1 0]

sage: M.is_skew_symmetrizable(return_diag=True)
[1, 1, 1/2, 1/2]
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

False

>>> M = matrix(Integer(4), [Integer(0),Integer(1),Integer(0),Integer(0),-Integer(1),Integer(0),-Integer(1),Integer(0), Integer(0),Integer(2),0,1,0,0,-Integer(1),Integer(0),-Integer(1),Integer(0), Integer(0),Integer(2),0,1,0,0,-Integer(1),Integer(0),-Integer(1),Integer(0)]); M
[ 0 1 0 0]
[-1 0 -1 0]
[ 0 2 0 1]
[ 0 0 -1 0]

>>> M.is_skew_symmetrizable(return_diag=True)
[1, 1, 1/2, 1/2]

>>> M2 = diagonal_matrix([Integer(1),Integer(1),Integer(1)/Integer(2),Integer(1)/Integer(2)]) * M; M2
[ 0 1 0 0]
[ -1 0 -1 0]
[ 0 1 0 1/2]
[ 0 0 -1/2 0]

>>> M2.is_skew_symmetric()
True
\end{verbatim}

REFERENCES:

• [FZ2001]

\textbf{is_sparse()}

Return True if this is a sparse matrix.

In Sage, being sparse is a property of the underlying representation, not the number of nonzero entries.

EXAMPLES:

\begin{verbatim}
sage: matrix(QQ, 2, 2, range(4)).is_sparse()
False
sage: matrix(QQ, 2, 2, range(4), sparse=True).is_sparse()
True

>>> from sage.all import *
>>>
>>> matrix(QQ, Integer(2), Integer(2), range(Integer(4))).is_sparse()
False
\end{verbatim}

(continues on next page)
is_square()  
Return True precisely if this matrix is square, i.e., has the same number of rows and columns.

EXAMPLES:

```
sage: matrix(QQ, 2, 2, range(4)).is_square()
True
sage: matrix(QQ, 2, 3, range(6)).is_square()
False
```

is_symmetric()  
Return True if this is a symmetric matrix.

A symmetric matrix is necessarily square.

EXAMPLES:

```
sage: m = Matrix(QQ, 2, range(0,4))
sage: m.is_symmetric()
False
sage: m = Matrix(QQ, 2, (1,1,1,1,1,1))
sage: m.is_symmetric()
False
sage: m = Matrix(QQ, 1, (2,))
sage: m.is_symmetric()
True
```

is_symmetrizable(return_diag=False, positive=True)  
This function takes a square matrix over an ordered integral domain and checks if it is symmetrizable. A matrix $B$ is symmetrizable iff there exists an invertible diagonal matrix $D$ such that $DB$ is symmetric.
### Warning

Expects `self` to be a matrix over an ordered integral domain.

**INPUT:**

- `return_diag` – bool (default: False) if True and `self` is symmetrizable the diagonal entries of the matrix $D$ are returned.
- `positive` – bool (default: True) if True, the condition that $D$ has positive entries is added.

**OUTPUT:**

- `True` – if `self` is symmetrizable and `return_diag` is False
- the diagonal entries of a matrix $D$ such that $DB$ is symmetric – iff `self` is symmetrizable and `return_diag` is True
- `False` – iff `self` is not symmetrizable

**EXAMPLES:**

```python
sage: matrix([[0, 6], [3, 0]]).is_symmetrizable(positive=False)
True
sage: matrix([[0, 6], [3, 0]]).is_symmetrizable(positive=True)
True
sage: matrix([[0, 6], [0, 0]]).is_symmetrizable(return_diag=True)
False
sage: matrix([2]).is_symmetrizable(positive=True)
True
sage: matrix([[1, 2], [3, 4]]).is_symmetrizable(return_diag=true)
[1, 2/3]
```

```python
>>> from sage.all import *
>>> matrix([[Integer(0), Integer(6)], [Integer(3), Integer(0)]]).is_symmetrizable(positive=False)
True
>>> matrix([[Integer(0), Integer(6)], [Integer(3), Integer(0)]]).is_symmetrizable(positive=True)
True
>>> matrix([[Integer(0), Integer(6)], [Integer(0), Integer(0)]]).is_symmetrizable(return_diag=True)
False
>>> matrix([[Integer(2)]]).is_symmetrizable(positive=True)
True
>>> matrix([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]).is_symmetrizable(return_diag=true)
[1, 2/3]
```

**REFERENCES:**

- [FZ2001]
**is_unit()**

Return True if this matrix is invertible.

**EXAMPLES:** The following matrix is invertible over \( \mathbb{Q} \) but not over \( \mathbb{Z} \).

```sage
sage: A = MatrixSpace(ZZ, 2)(range(4))
sage: A.is_invertible()
False
sage: A.matrix_over_field().is_invertible()
True

>>> from sage.all import *

A = MatrixSpace(ZZ, Integer(2))(range(Integer(4)))
>>> A.is_invertible()
False
>>> A.matrix_over_field().is_invertible()
True
```

The inverse function is a constructor for matrices over the fraction field, so it can work even if \( A \) is not invertible.

```sage
sage: ~A  # inverse of A
[-3/2 1/2]
[ 1 0]

>>> from sage.all import *

~A  # inverse of A
[-3/2 1/2]
[ 1 0]
```

The next matrix is invertible over \( \mathbb{Z} \).

```sage
sage: A = MatrixSpace(IntegerRing(), 2)([1,10,0,-1])
sage: A.is_invertible()
True
sage: ~A  # compute the inverse
[ 1 10]
[ 0 -1]

>>> from sage.all import *

~A  # compute the inverse
[ 1 10]
[ 0 -1]
```

The following nontrivial matrix is invertible over \( \mathbb{Z}[x] \).

```sage
sage: R.<x> = PolynomialRing(IntegerRing())
sage: A = MatrixSpace(R, 2)([1,x,0,-1])
sage: A.is_invertible()
True
sage: ~A  # compute the inverse
[ 1 x]
[ 0 -1]
```
```python
>>> from sage.all import *

R = PolynomialRing(IntegerRing(), names=('x',)); (x,) = R._first_ngens(1)
A = MatrixSpace(R, Integer(2))([Integer(1), x, Integer(0), -Integer(1)])
A.is_invertible()
True
~A
[ 1 x]
[ 0 -1]
```

**items()**

Return an iterable of ((i,j), value) elements.

This may (but is not guaranteed to) suppress zero values.

**EXAMPLES:**

```python
sage: a = matrix(QQ['x,y'], 2, range(6), sparse=True); a
[ 0  1  2]
[ 3  4  5]
sage: list(a.items())
[((0, 1), 1), ((0, 2), 2), ((1, 0), 3), ((1, 1), 4), ((1, 2), 5)]
```

```python
>>> from sage.all import *

a = matrix(QQ['x,y'], Integer(2), range(Integer(6)), sparse=True); a
[ 0  1  2]
[ 3  4  5]
>>> list(a.items())
[((0, 1), 1), ((0, 2), 2), ((1, 0), 3), ((1, 1), 4), ((1, 2), 5)]
```

**iterates(v, n, rows=True)**

Let $A$ be this matrix and $v$ be a free module element. If rows is True, return a matrix whose rows are the entries of the following vectors:

$$v, vA, vA^2, \ldots, vA^{n-1}.$$  

If rows is False, return a matrix whose columns are the entries of the following vectors:

$$v, Av, A^2v, \ldots, A^{n-1}v.$$  

**INPUT:**

- $v$ – free module element
- $n$ – nonnegative integer

**EXAMPLES:**

```python
sage: A = matrix(ZZ, 2, [1,1,3,5]); A
[1 1]
[3 5]
sage: v = vector([1,0])
sage: A.iterates(v, 0)
[]
sage: A.iterates(v, 5)
[ 1  0]
[ 1  1]
[ 4  6]
[ 22 34]
[124 192]
```
Another example:

```
sage: a = matrix(ZZ, 3, range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: v = vector([1,0,0])
sage: a.iterates(v, 4)
[ 1 0 0]
[ 0 1 2]
[ 15 18 21]
[180 234 288]
sage: a.iterates(v, 4, rows=False)
[ 1 0 15 180]
[ 0 3 42 558]
[ 0 6 69 936]
```

```
>>> from sage.all import *
>>> a = matrix(ZZ, Integer(3), range(Integer(9))); a
[0 1 2]
[3 4 5]
[6 7 8]
>>> v = vector([Integer(1),Integer(0),Integer(0)])
>>> a.iterates(v, Integer(4))
[ 1 0 0]
[ 0 1 2]
[ 15 18 21]
[180 234 288]
>>> a.iterates(v, Integer(4), rows=False)
[ 1 0 15 180]
[ 0 3 42 558]
[ 0 6 69 936]
```

```
linear_combination_of_columns(v)

Return the linear combination of the columns of self given by the coefficients in the list v.

INPUT:

- v – a list of scalars. The length can be less than the number of columns of self but not greater.

OUTPUT:

The vector (or free module element) that is a linear combination of the columns of self. If the list of scalars has fewer entries than the number of columns, additional zeros are appended to the list until it has as many
entries as the number of columns.

**EXAMPLES:**

```python
sage: a = matrix(ZZ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: a.linear_combination_of_columns([1,1,1])
(3, 12)
sage: a.linear_combination_of_columns([0,0,0])
(0, 0)
sage: a.linear_combination_of_columns([1/2,2/3,3/4])
(13/6, 95/12)
```

The list `v` can be anything that is iterable. Perhaps most naturally, a vector may be used.

```python
sage: v = vector(ZZ, [1,2,3])
sage: a.linear_combination_of_columns(v)
(8, 26)
```

We check that a matrix with no columns behaves properly.

```python
sage: matrix(QQ, 2, 0).linear_combination_of_columns([])
(0, 0)
```

The object returned is a vector, or a free module element.

```python
sage: B = matrix(ZZ, 4, 3, range(12))
sage: w = B.linear_combination_of_columns([-1,2,-3])
sage: w
(-4, -10, -16, -22)
sage: w.parent()
```

(continues on next page)
Ambient free module of rank 4 over the principal ideal domain Integer Ring

```sage
x = B.linear_combination_of_columns([1/2, 1/3, 1/4])
x
(5/6, 49/12, 22/3, 127/12)
x.parent()  # Vector space of dimension 4 over Rational Field
```

```sage
from sage.all import *
B = matrix(ZZ, Integer(4), Integer(3), range(Integer(12)))
w = B.linear_combination_of_columns([-Integer(1), Integer(2), -Integer(3)])
w
(-4, -10, -16, -22)
w.parent()  # Ambient free module of rank 4 over the principal ideal domain Integer Ring
```

```sage
x = B.linear_combination_of_columns([Integer(1)/Integer(2), Integer(1)/Integer(3), Integer(1)/Integer(4)])
x
(5/6, 49/12, 22/3, 127/12)
x.parent()  # Vector space of dimension 4 over Rational Field
```

The length of \( v \) can be less than the number of columns, but not greater.

```sage
A = matrix(QQ, 3, 5, range(15))
A.linear_combination_of_columns([1, -2, 3, -4])
(-8, -18, -28)
A.linear_combination_of_columns([1, 2, 3, 4, 5, 6])
Traceback (most recent call last):
... ValueError: length of v must be at most the number of columns of self
```

```sage
from sage.all import *
A = matrix(QQ, Integer(3), Integer(5), range(Integer(15)))
A.linear_combination_of_columns([Integer(1), -Integer(2), Integer(3), -Integer(4)])
(-8, -18, -28)
A.linear_combination_of_columns([Integer(1), Integer(2), Integer(3), -Integer(4), Integer(5), Integer(6)])
Traceback (most recent call last):
... ValueError: length of v must be at most the number of columns of self
```

**linear_combination_of_rows**  
Return the linear combination of the rows of \( \text{self} \) given by the coefficients in the list \( v \).

**INPUT:**

- \( v \) – a list of scalars. The length can be less than the number of rows of \( \text{self} \) but not greater.

**OUTPUT:**

The vector (or free module element) that is a linear combination of the rows of \( \text{self} \). If the list of scalars has fewer entries than the number of rows, additional zeros are appended to the list until it has as many entries as the number of rows.

**EXAMPLES:**
The list \( v \) can be anything that is iterable. Perhaps most naturally, a vector may be used.

The object returned is a vector, or a free module element.

We check that a matrix with no rows behaves properly.

The object returned is a vector, or a free module element.
from sage.all import *

B = matrix(ZZ, Integer(4), Integer(3), range(Integer(12)))
w = B.linear_combination_of_rows([-Integer(1), Integer(2), -Integer(3), -Integer(4)])
w
(24, 26, 28)
w.parent()
Ambient free module of rank 3 over the principal ideal domain Integer Ring

x = B.linear_combination_of_rows([Integer(1)/Integer(2), Integer(1)/Integer(3), Integer(1)/Integer(4), Integer(1)/Integer(5)])
x
(43/10, 67/12, 103/15)
x.parent()
Vector space of dimension 3 over Rational Field

The length of v can be less than the number of rows, but not greater.

A = matrix(QQ, Integer(3), Integer(4), range(Integer(12)))
A.linear_combination_of_rows([Integer(2), Integer(3)])
(12, 17, 22, 27)
A.linear_combination_of_rows([Integer(1), Integer(2), Integer(3), -Integer(4)])
Traceback (most recent call last):
... ValueError: length of v must be at most the number of rows of self

list()
List of the elements of self ordered by elements in each row. It is safe to change the returned list.

Warning:  This function returns a list of the entries in the matrix self. It does not return a list of the rows of self, so it is different than the output of list(self), which returns [self[0], self[1], ...].

EXAMPLES:
sage: R.<x,y> = QQ[]
sage: a = matrix(R, 2, [x,y,x*y, y,x,2*x+y]); a
[ x y x*y]
[ y x 2*x + y]
sage: v = a.list(); v
[x, y, x*y, y, x, 2*x + y]
```python
>>> from sage.all import *
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> a = matrix(R,Integer(2),[x,y,x*y, y,x,Integer(2)*x+y]); a
[ x y x*y]
[ y x 2*x + y]
>>> v = a.list(); v
[x, y, x*y, y, x, 2*x + y]
```

Note that `list(a)` is different than `a.list()`:

```python
sage: a.list()
[x, y, x*y, y, x, 2*x + y]
sage: list(a)
[(x, y, x*y), (y, x, 2*x + y)]
```

Notice that changing the returned list does not change `a` (the list is a copy):

```python
sage: v[0] = 25
sage: a
[ x y x*y]
[ y x 2*x + y]
```

`mod(p)`

Return matrix mod \( p \), over the reduced ring.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> M = matrix(ZZ, Integer(2), Integer(2), [Integer(5), Integer(9), Integer(13), Integer(15)]);
>>> M.mod(Integer(7))
[5 2]
[6 1]
sage: parent(M.mod(Integer(7)))
Full MatrixSpace of 2 by 2 dense matrices over Ring of integers modulo 7
```

`monomial_coefficients` *(copy=True)*

Dictionary of the elements of `self` with keys pairs \((i, j)\) and values the nonzero entries of `self`. 

```python
>>> from sage.all import *
>>> M = matrix(ZZ, Integer(2), Integer(2), [Integer(5), Integer(9), Integer(13), Integer(15)]);
>>> M.mod(Integer(7))
[5 2]
[6 1]
```
INPUT:

- `copy` (default: `True`) make a copy of the `dict` corresponding to `self`

If `copy=True`, then it is safe to change the returned dictionary. Otherwise, this can cause undesired behavior by mutating the `dict`.

EXAMPLES:

```python
sage: R.<x,y> = QQ[]
sage: a = matrix(R,2,[x,y,0, 0,0,2*x+y]); a
[ x y 0]
[ 0 0 2*x + y]
sage: d = a.dict(); d
{(0, 0): x, (0, 1): y, (1, 2): 2*x + y}
```

```python
>>> from sage.all import *

>>> R = QQ['x', 'y']; (x, y,) = R._first_ngens(2)

>>> a = matrix(R,Integer(2),[x,y,Integer(0), Integer(0),Integer(0),Integer(2)*x+y]); a
[ x y 0]
[ 0 0 2*x + y]

>>> d = a.dict(); d
{(0, 0): x, (0, 1): y, (1, 2): 2*x + y}
```

Notice that changing the returned list does not change `a` (the list is a copy):

```python
sage: d[0,0] = 25
sage: a
[ x y 0]
[ 0 0 2*x + y]
```

```python
>>> from sage.all import *

>>> d[Integer(0),Integer(0)] = Integer(25)

>>> a
[ x y 0]
[ 0 0 2*x + y]
```

```
multiplicative_order()
```

Return the multiplicative order of this matrix, which must therefore be invertible.

Only implemented over finite fields and over \( \mathbb{Z} \).

EXAMPLES:

Over finite fields:

```python
sage: A = matrix(GF(59), 3, [10,56,39,53,56,33,58,24,55])
sage: A.multiplicative_order() # needs sage.libs.pari
580
sage: (A^580).is_one()
True
```

```python
sage: B = matrix(GF(10007^3, 'b'), 0) # needs sage.rings.finite_rings
sage: B.multiplicative_order() # needs sage.rings.finite_rings
1
```
sage: # needs sage.rings.finite_rings
sage: M = MatrixSpace(GF(11^2, 'e'), 5)
sage: E = M.random_element()
sage: while E.det() == 0:
    ....:     E = M.random_element()
sage: (E**E.multiplicative_order()).is_one()
True

>>> from sage.all import *
>>> A = matrix(GF(Integer(59)), Integer(3), [Integer(10),Integer(56),
    →Integer(39),Integer(53),Integer(56),Integer(53),Integer(53),Integer(58),Integer(24),
    →Integer(55)])
>>> A.multiplicative_order()  #...
→needs sage.libs.pari
580
>>> (A**Integer(580)).is_one()
True

>>> B = matrix(GF(Integer(10007)**Integer(3), 'b'), Integer(0))  #
→needs sage.rings.finite_rings
>>> B.multiplicative_order()  #
→needs sage.rings.finite_rings
1

>>> # needs sage.rings.finite_rings
>>> M = MatrixSpace(GF(Integer(11)**Integer(2), 'e'), Integer(5))
>>> E = M.random_element()
>>> while E.det() == Integer(0):
    ....:     E = M.random_element()
>>> (E**E.multiplicative_order()).is_one()
True

Over \mathbb{Z}:

sage: m = matrix(ZZ, 2, 2, [-1,1,-1,0])
sage: m.multiplicative_order()  #...
→needs sage.libs.pari
3

mutate(k)

Mutates self at row and column index k.

**Warning:** Only makes sense if self is skew-symmetrizable.

INPUT:

• k – integer at which row/column self is mutated.

EXAMPLES:

Mutation of the B-matrix of the quiver of type \(A_3\):

```
sage: M = matrix(ZZ, 3, [0,1,0,-1,0,-1,0,1,0]); M
[ 0 1 0]
[-1 0 -1]
[ 0 1 0]

sage: M.mutate(0); M
[ 0 -1 0]
[ 1 0 -1]
[ 0 1 0]

sage: M.mutate(1); M
[ 0 1 -1]
[-1 0 1]
[ 1 -1 0]

sage: M = matrix(ZZ, 6, [0,1,0,-1,0,1,0,0,0,1,0,0,1,0,0,0,0,0,0,1]); M
[ 0 1 0]
[-1 0 -1]
[ 0 1 0]
[ 1 0 0]

  • [FZ2001]

cols()
Return the number of columns of this matrix.

EXAMPLES:
```
sage: M = MatrixSpace(QQ, 2, 3)
sage: A = M([1,2,3, 4,5,6])
sage: A
[1 2 3]
[4 5 6]
sage: A.ncols()
sage: A.nrows()
3
2
```
>>> from sage.all import *
>>> M = MatrixSpace(QQ, Integer(2), Integer(3))
>>> A = M([Integer(1),Integer(2),Integer(3), Integer(4),Integer(5),
→Integer(6)])
>>> A
[1 2 3]
[4 5 6]
>>> A.ncols()
3
>>> A.nrows()
2

AUTHORS:

• Naqi Jaffery (2006-01-24): examples

nonpivots()

Return the list of i such that the i-th column of self is NOT a pivot column of the reduced row echelon form of self.

OUTPUT: sorted tuple of (Python) integers

EXAMPLES:

sage: a = matrix(QQ, 3, 3, range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.echelon_form()
[ 1 0 -1]
[ 0 1 2]
[ 0 0 0]
sage: a.nonpivots()
(2,)

nonzero_positions(copy=True, column_order=False)

Return the sorted list of pairs (i, j) such that self[i, j] != 0.

INPUT:

• copy – (default: True) it is safe to change the resulting list (unless you give the option copy=False)

• column_order – (default: False) If True, returns the list of pairs (i, j) such that self[i, j] != 0, but sorted by columns, i.e., column j=0 entries occur first, then column j=1 entries, etc.

EXAMPLES:
nonzero_positions_in_column(i)

Return a sorted list of the integers \( j \) such that \( \text{self}[j,i] \) is nonzero, i.e., such that the \( j \)-th position of the \( i \)-th column is nonzero.

INPUT:

- \( i \) – an integer

OUTPUT: list

EXAMPLES:

```python
sage: a = matrix(QQ, 3,2, [1,2,0,2,0,0]); a
[1 2]
[0 2]
[0 0]
sage: a.nonzero_positions_in_column(0)

[0 2]
[0 0]
sage: a.nonzero_positions_in_column(0)
[(0, 0), (0, 1), (1, 0)]
```
nonzero_positions_in_row(i)

Return the integers $j$ such that $\text{self}[i,j]$ is nonzero, i.e., such that the $j$-th position of the $i$-th row is nonzero.

INPUT:

• $i$ – an integer

OUTPUT: list

EXAMPLES:

```sage
da = matrix(QQ, 3, 2, [1,2,0,2,0,0]); da
[1 2]
[0 2]
[0 0]
da = nonzero_positions_in_row(0)
[0, 1]
da = nonzero_positions_in_row(1)
[1]
da = nonzero_positions_in_row(2)
[]
```
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

>>> a.nonzero_positions_in_row(Integer(0))
[0, 1]
>>> a.nonzero_positions_in_row(Integer(1))
[1]
>>> a.nonzero_positions_in_row(Integer(2))
[]

\textbf{nrows}() \newline
Return the number of rows of this matrix.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: M = MatrixSpace(QQ, 6, 7)
sage: A = M([1,2,3,4,5,6,7, 22,3/4,34,11,7,5,3, 99,65,1/2,2/3,3/5,4/5,5/6, 9, ˓
  → 8/9, 9/8,7/6,7/6,7,76,4, 0,9,8,7,6,5,4, 123,99,91,28,6,1024,1])
sage: A

\textbf{AUTHORS:}

- Naqi Jaffrey (2006-01-24): examples

\textbf{permute_columns} \textit{(permutation)}

Permutes the columns of \texttt{self} by applying the permutation group element \texttt{permutation}.
As permutation group elements act on integers \(\{1, \ldots, n\}\), columns are considered numbered from 1 for this operation.

**INPUT:**

- permutation – a PermutationGroupElement.

**EXAMPLES:** We create a matrix:

```python
sage: M = matrix(ZZ, [[1, 0, 0, 0, 0], [0, 2, 0, 0, 0], [0, 0, 3, 0, 0], [0, 0, 0, 4, 0], [0, 0, 0, 0, 5]])
sage: M
[ 1  0  0  0  0]
[ 0  2  0  0  0]
[ 0  0  3  0  0]
[ 0  0  0  4  0]
[ 0  0  0  0  5]
```

Next of all, create a permutation group element and act on \(M\) with it:

```python
sage: # needs sage.groups
g = PermutationGroup([('1,2,3,4,5'), '(1,2,3,4,5)'])
sage: sigma, tau = g.gens()
sage: sigma
(1,2,3,4,5)
sage: M.permute_columns(sigma)
sage: M
[ 0  0  1  0  0]
[ 2  0  0  0  0]
[ 0  3  0  0  0]
[ 0  0  0  4  0]
[ 0  0  0  5  0]
```
**permute_rows** *(permutation)*

Permute the rows of `self` by applying the permutation group element `permutation`.

As permutation group elements act on integers \(\{1, \ldots, n\}\), rows are considered numbered from 1 for this operation.

**INPUT:**

- `permutation` — a `PermutationGroupElement`

**EXAMPLES:** We create a matrix:

```python
sage: M = matrix(ZZ, [[1,0,0,0,0],[0,2,0,0,0],[0,0,3,0,0],[0,0,0,4,0],[0,0,0,0,5]])
sage: M
[1 0 0 0 0]
[0 2 0 0 0]
[0 0 3 0 0]
[0 0 0 4 0]
[0 0 0 0 5]
```

Next of all, create a permutation group element and act on `M`:

```python
sage: G = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: sigma, tau = G.gens()
sage: sigma
(1,2,3)(4,5)
sage: M.permute_rows(sigma)
sage: M
[0 2 0 0 0]
[0 0 3 0 0]
[1 0 0 0 0]
[0 0 0 5]
[0 0 0 4 0]
```

(continues on next page)
permute_rows_and_columns (row_permutation, column_permutation)

Permute the rows and columns of self by applying the permutation group elements row_permutation and column_permutation respectively.

As permutation group elements act on integers \(\{1, \ldots, n\}\), rows and columns are considered numbered from 1 for this operation.

INPUT:

- row_permutation — a PermutationGroupElement
- column_permutation — a PermutationGroupElement

OUTPUT:

- A matrix.

EXAMPLES: We create a matrix:

```python
sage: M = matrix(ZZ, [[1,0,0,0,0],[0,2,0,0,0],[0,0,3,0,0],[0,0,0,4,0],[0,0,0,0,5]])
sage: M
[1 0 0 0 0]
[0 2 0 0 0]
[0 0 3 0 0]
[0 0 0 4 0]
[0 0 0 0 5]
```

Next of all, create a permutation group element and act on M:

```python
# needs sage.groups
sage: G = PermutationGroup([(1,2,3)(4,5), (1,2,3,4,5)])
sage: sigma, tau = G.gens()
sage: sigma
(1,2,3)(4,5)
sage: M.permute_rows_and_columns(sigma,tau)
sage: M
[2 0 0 0 0]
[0 3 0 0 0]
[0 0 0 1 0]
```

(continues on next page)
\[ \begin{bmatrix} 0 & 0 & 5 & 0 \\ 0 & 0 & 4 & 0 \end{bmatrix} \]

```python
>>> from sage.all import *

# needs sage.groups

G = PermutationGroup([('1,2,3)(4,5)', '(1,2,3,4,5)'))

sigma, tau = G gens()

sigma

(1,2,3)(4,5)

M.permute_rows_and_columns(sigma, tau)

M

\[ \begin{bmatrix} 2 & 0 & 0 & 0 & 0 \\ 0 & 3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 5 & 0 & 0 \end{bmatrix} \]
```

**pivots()**

Return the pivot column positions of this matrix.

OUTPUT: a tuple of Python integers: the position of the first nonzero entry in each row of the echelon form.

This returns a tuple so it is immutable; see Issue #10752.

**EXAMPLES:**

```python
sage: A = matrix(QQ, 2, 2, range(4))
sage: A.pivots()
(0, 1)
```

```python
>>> from sage.all import *

A = matrix(QQ, Integer(2), Integer(2), range(Integer(4)))

A.pivots()

(0, 1)
```

**rank()**

Return the rank of this matrix.

**EXAMPLES:**

```python
sage: m = matrix(GF(7), 5, range(25))
sage: m.rank()
2
```

```python
>>> from sage.all import *

m = matrix(GF(Integer(7)), Integer(5), range(Integer(25)))

m.rank()

2
```

Rank is not implemented over the integers modulo a composite yet.: 

```python
sage: m = matrix(Integers(4), 2, [2,2,2,2])
sage: m.rank()
Traceback (most recent call last):
...
NotImplementedError: Echelon form not implemented over 'Ring of integers
modulo 4'.
```
```python
>>> from sage.all import *

```n
```python
>>> m = matrix(Integers(Integer(4)), Integer(2), [Integer(2),Integer(2),
   \rightarrow Integer(2),Integer(2)])
>>> m.rank()
Traceback (most recent call last):
...
NotImplementedError: Echelon form not implemented over 'Ring of integers...
  \rightarrow modulo 4'.
```n

**rescale_col**(\(i, s, \text{start\_row} = 0\))

Replace \(i\)-th col of self by \(s\) times \(i\)-th col of self.

**INPUT:**

- \(i\) – \(i\)-th column
- \(s\) – scalar
- \(\text{start\_row}\) – only rescale entries at this row and lower

**EXAMPLES:** We rescale the last column of a matrix over the rational numbers:

```python
sage: a = matrix(QQ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: a.rescale_col(2, 1/2); a
[ 0 1 1]
[ 3 4 5/2]
```

```python
R.<x> = QQ[]
>>> from sage.all import *

```n
```python
>>> a = matrix(QQ, Integer(2), Integer(3), range(Integer(6)));
>>> a.rescale_col(Integer(2), Integer(1)/Integer(2)); a
[ 0 1 1]
[ 3 4 5/2]
```

```python
Wescalethelastcolumnofamatrixoverapolynomialring:

```n
```python
sage: a = matrix(R, 2, 3, [1,x,x^2,x^3,x^4,x^5]); a
[ 1 x x^2]
[x^3 x^4 x^5]
sage: a.rescale_col(2, 1/2); a
[ 1 x 1/2*x^2]
[x^3 x^4 1/2*x^5]
```

```python
>>> from sage.all import *

```n
```python
>>> a = matrix(R, Integer(2), Integer(3), [Integer(1),x,x**Integer(2),
   \rightarrow x**Integer(3),x**Integer(4),x**Integer(5))]; a
[ 1 x x^2]
[x^3 x^4 x^5]
```

```python
>>> a.rescale_col(Integer(2), Integer(1)/Integer(2)); a
[ 1 x 1/2*x^2]
[x^3 x^4 1/2*x^5]
```

We try and fail to rescale a matrix over the integers by a non-integer:
sage: a = matrix(ZZ, 2, 3, [0, 1, 2, 3, 4, 4]); a
[0 1 2]
[3 4 4]
sage: a.rescale_col(2, 1/2)
Traceback (most recent call last):
... TypeError: Rescaling column by Rational Field element cannot be done over Integer Ring, use change_ring or with_rescaled_col instead.

>>> from sage.all import *
>>> a = matrix(ZZ, Integer(2), Integer(3), [Integer(0), Integer(1), Integer(2), Integer(3), Integer(4), Integer(4)]); a
[0 1 2]
[3 4 4]
>>> a.rescale_col(Integer(2), Integer(1)/Integer(2))
Traceback (most recent call last):
... TypeError: Rescaling column by Rational Field element cannot be done over Integer Ring, use change_ring or with_rescaled_col instead.

To rescale the matrix by 1/2, you must change the base ring to the rationals:

sage: a = a.change_ring(QQ); a
[0 1 2]
[3 4 4]
sage: a.rescale_col(2,1/2); a
[0 1 1]
[3 4 2]

rescale_row(i, s, start_col=0)
Replace i-th row of self by s times i-th row of self.

INPUT:
- i – ith row
- s – scalar
- start_col – only rescale entries at this column and to the right

EXAMPLES: We rescale the second row of a matrix over the rational numbers:

sage: a = matrix(QQ, 3, range(6)); a
[0 1]
[2 3]
[4 5]
sage: a.rescale_row(1, 1/2); a
[ 0 1]
[ 1 3/2]
[ 4 5]
We rescale the second row of a matrix over a polynomial ring:

```
sage: R.<x> = QQ[]
sage: a = matrix(R, 3, [1,x,x^2,x^3,x^4,x^5]); a
[  1  x]
[ x^2  x^3]
[ x^4  x^5]
sage: a.rescale_row(1, 1/2); a
[ 1  x]
[1/2*x^2 1/2*x^3]
[ x^4  x^5]
```

We try and fail to rescale a matrix over the integers by a non-integer:

```
sage: a = matrix(ZZ, 2, 3, [0,1,2, 3,4,4]); a
[0 1 2]
[3 4 4]
sage: a.rescale_row(1, 1/2)
Traceback (most recent call last):
  ...
TypeError: Rescaling row by Rational Field element cannot be done over Integer Ring, use change_ring or with_rescaled_row instead.
```

To rescale the matrix by $1/2$, you must change the base ring to the rationals:
sage: a = a.change_ring(QQ); a
[0 1 2]
[3 4 4]
sage: a.rescale_col(1, 1/2); a
[ 0 1/2 2]
[ 3 2 4]

reverse_rows_and_columns()
Reverse the row order and column order of this matrix.

This method transforms a matrix $m_{i,j}$ with $0 \leq i < \text{nrows}$ and $0 \leq j < \text{ncols}$ into $m_{\text{nrows}-i-1,\text{ncols}-j-1}$.

EXAMPLES:
sage: m = matrix(ZZ, 2, 2, range(4))
sage: m.reverse_rows_and_columns()
sage: m
[3 2]
[1 0]
sage: m = matrix(ZZ, 2, 3, range(6), sparse=True)
sage: m.reverse_rows_and_columns()
sage: m
[5 4 3]
[2 1 0]
sage: m = matrix(ZZ, 3, 2, range(6), sparse=True)
sage: m.reverse_rows_and_columns()
sage: m
[5 4]
[3 2]
[1 0]
sage: m.reverse_rows_and_columns()
sage: m
[0 1]
[2 3]
[4 5]
sage: m = matrix(QQ, 3, 2, [1/i for i in range(1,7)])
sage: m.reverse_rows_and_columns()
sage: m
[1/6 1/5]
[1/4 1/3]
[1/2 1]
sage: R.<x,y> = ZZ['x,y']
sage: m = matrix(R, 3, 3, lambda i,j: x**i*y**j, sparse=True)
sage: m.reverse_rows_and_columns()
sage: m
[x^2*y^2 x^2*y x^2]
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

\[
\begin{bmatrix}
x y^2 & x y & x \\
y^2 & y & 1
\end{bmatrix}
\]

```python
>>> from sage.all import *

>>> m = matrix(ZZ, Integer(2), Integer(2), range(Integer(4)))
>>> m.reverse_rows_and_columns()

>>> m
[3 2]
[1 0]

>>> m = matrix(ZZ, Integer(2), Integer(3), range(Integer(6)), sparse=True)
>>> m.reverse_rows_and_columns()

>>> m
[5 4 3]
[2 1 0]

>>> m = matrix(ZZ, Integer(3), Integer(2), range(Integer(6)), sparse=True)
>>> m.reverse_rows_and_columns()

>>> m
[5 4]
[3 2]
[1 0]

>>> m = matrix(QQ, Integer(3), Integer(2), [Integer(1)/i for i in range(Integer(1),Integer(7))])
>>> m.reverse_rows_and_columns()

>>> m
[1/6 1/5]
[1/4 1/3]
[1/2 1]

>>> R = ZZ['x,y']; (x, y,) = R._first_ngens(2)
>>> m = matrix(R, Integer(3), Integer(3), lambda i,j: x**i*y**j, sparse=True)
>>> m.reverse_rows_and_columns()

>>> m
[ x^2 y^2 x^2 y x^2]
[ x^2 y x y]
[ y^2 y 1]
```

If the matrix is immutable, the method raises an error:

```python
sage: m = matrix(ZZ, 2, [1, 3, -2, 4])
sage: m.set_immutable()
sage: m.reverse_rows_and_columns()
Traceback (most recent call last):
...
ValueError: matrix is immutable; please change a copy instead (i.e., use copy(M) to change a copy of M).
```

```python
>>> from sage.all import *

>>> m = matrix(ZZ, Integer(2), [Integer(1), Integer(3), -Integer(2),...
-Integer(4)])
(continues on next page)
```

189
m.set_immutable()
m.reverse_rows_and_columns()
Traceback (most recent call last):
...
ValueError: matrix is immutable; please change a copy instead (i.e., use copy(M) to change a copy of M).

\texttt{set\_col\_to\_multiple\_of\_col}(i, j, s)

Set column \(i\) equal to \(s\) times column \(j\).

EXAMPLES: We change the second column to \(-3\) times the first column.

\begin{verbatim}
sage: a = matrix(ZZ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: a.set_col_to_multiple_of_col(1, 0, -3)
sage: a
[ 0 0 2]
[ 3 -9 5]
\end{verbatim}

If we try to multiply a column by a rational number, we get an error message:

\begin{verbatim}
sage: a.set_col_to_multiple_of_col(1, 0, 1/2)
Traceback (most recent call last):
...
TypeError: Multiplying column by Rational Field element cannot be done over...
Integer Ring, use change_ring or with_col_set_to_multiple_of_col instead.
\end{verbatim}

\texttt{set\_immutable()}

Call this function to set the matrix as immutable.

Matrices are always mutable by default, i.e., you can change their entries using \(A[i, j] = x\). However, mutable matrices aren’t hashable, so can’t be used as keys in dictionaries, etc. Also, often when implementing a class, you might compute a matrix associated to it, e.g., the matrix of a Hecke operator. If you return this matrix to the user you’re really returning a reference and the user could then change an entry; this could be confusing. Thus you should set such a matrix immutable.

EXAMPLES:
sage: A = Matrix(QQ, 2, 2, range(4))
sage: A.is_mutable()
True
sage: A[0,0] = 10
sage: A
[10  1]
[ 2  3]

>>> from sage.all import *

>>> A = Matrix(QQ, Integer(2), Integer(2), range(Integer(4)))

>>> A.is_mutable()
True

>>> A[Integer(0),Integer(0)] = Integer(10)

>>> A
[10  1]
[ 2  3]

Mutable matrices are not hashable, so can’t be used as keys for dictionaries:

sage: hash(A)
Traceback (most recent call last):
  ...TypeError: mutable matrices are unhashable

sage: v = (A:1)
Traceback (most recent call last):
  ...TypeError: mutable matrices are unhashable

If we make A immutable it suddenly is hashable.

sage: A.set_immutable()
sage: A.is_mutable()
False
sage: A[0,0] = 10
Traceback (most recent call last):
  ...ValueError: matrix is immutable; please change a copy instead
  (i.e., use copy(M) to change a copy of M).

sage: hash(A) #random
12

sage: v = {A:1}; v
({[10  1]
 [ 2  3]: 1})

>>> from sage.all import *

>>> A.set_immutable()
(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> A.is_mutable()
False
>>> A[Integer(0),Integer(0)] = Integer(10)
Traceback (most recent call last):
  ...  #random
>>> v = {A:Integer(1)}; v
{[10 1]
 [ 2 3]: 1}
```

**set_row_to_multiple_of_row(i, j, s)**

Set row i equal to s times row j.

**EXAMPLES:** We change the second row to -3 times the first row:

```python
sage: a = matrix(ZZ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: a.set_row_to_multiple_of_row(1, 0, -3)
sage: a
[ 0 1 2]
[ 0 -3 -6]
```

If we try to multiply a row by a rational number, we get an error message:

```python
sage: a.set_row_to_multiple_of_row(1, 0, 1/2)
Traceback (most recent call last):
  ...  #random
>>> from sage.all import *
>>> a = matrix(ZZ, Integer(2), Integer(3), range(Integer(6))); a
[0 1 2]
[3 4 5]
>>> a.set_row_to_multiple_of_row(Integer(1), Integer(0), -Integer(3))
>>> a
[ 0 1 2]
[ 0 -3 -6]
```

```python
>>> from sage.all import *
>>> a.set_row_to_multiple_of_row(1, 0, 1/2)
Traceback (most recent call last):
  ...  #random
>>> from sage.all import *
>>> a.set_row_to_multiple_of_row(Integer(1), Integer(0), Integer(1)/
Integer(2))
Traceback (most recent call last):
  ...  #random
```

**str**(rep_mapping=None, zero=None, plus_one=None, minus_one=None, unicode=False, shape=None, character_art=False, left_border=None, right_border=None, top_border=None, bottom_border=None)

Return a nice string representation of the matrix.

**INPUT:**
• **rep_mapping** – a dictionary or callable used to override the usual representation of elements.

  If **rep_mapping** is a dictionary then keys should be elements of the base ring and values the desired string representation. Values sent in via the other keyword arguments will override values in the dictionary. Use of a dictionary can potentially take a very long time due to the need to hash entries of the matrix. Matrices with entries from QQbar are one example.

  If **rep_mapping** is callable then it will be called with elements of the matrix and must return a string. Simply call `repr()` on elements which should have the default representation.

• **zero** – string (default: None); if not None use the value of zero as the representation of the zero element.

• **plus_one** – string (default: None); if not None use the value of plus_one as the representation of the one element.

• **minus_one** – string (default: None); if not None use the value of minus_one as the representation of the negative of the one element.

• **unicode** – boolean (default: False). Whether to use Unicode symbols instead of ASCII symbols for brackets and subdivision lines.

• **shape** – one of "square" or "round" (default: None). Switches between round and square brackets. The default depends on the setting of the **unicode** keyword argument. For Unicode symbols, the default is round brackets in accordance with the TeX rendering, while the ASCII rendering defaults to square brackets.

• **character_art** – boolean (default: False); if True, the result will be of type AsciiArt or UnicodeArt which support line breaking of wide matrices that exceed the window width

• **left_border**, **right_border** – sequence (default: None); if not None, call `str()` on the elements and use the results as labels for the rows of the matrix. The labels appear outside of the parentheses.

• **top_border**, **bottom_border** – sequence (default: None); if not None, call `str()` on the elements and use the results as labels for the columns of the matrix. The labels appear outside of the parentheses.

**EXAMPLES:**

```
sage: R = PolynomialRing(QQ,6,'z')
sage: a = matrix(2,3, R.gens())
sage: a._repr_()
'[z0 z1 z2]\n[z3 z4 z5]'

sage: M = matrix([[1,0],[2,-1]])
sage: M.str()
'[ 1 0]\n[ 2 -1]

sage: M.str(plus_one=+,minus_one=-,zero=.)
[+ .]
[2 -]

sage: M.str({1:"not this one",2:"II"},minus_one="*",plus_one="I")
[I 0]\n[II *]

sage: def print_entry(x):
    ...:     if x>0:
    ...:         return '+'
    ...:     elif x<0:
    ...:         return '-'
    ...:     else:
    ...:         return '.'

sage: M.str(print_entry)
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

\[
\begin{pmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9
\end{pmatrix}
\]

\[
\begin{pmatrix}
\text{I} & 0 \\
\text{II} & \ast
\end{pmatrix}
\]
If `character_art` is set, the lines of large matrices are wrapped in a readable way:

```plaintext
sage: set_random_seed(0)
sage: matrix.random(RDF, 3, 5).str(unicode=True, character_art=True)
⎛ -0.27440062056807446 0.5031965950979831 -0.001975438590219314
| -0.05461130074681608 -0.033673314214051286 -0.9401270875197381
| 0.199062566106645512 0.3242250183948632 0.6026443545751128
| 0.9467802263760512 0.5056889961514748
| -0.35104242112828943 0.5084492941557279
| -0.9541798283979341 -0.8948790563276592
```

The number of floating point digits to display is controlled by `matrix.options.precision` and can also be set by the IPython magic `%precision`. This does not affect the internal precision of the represented data, but only the textual display of matrices:

```plaintext
sage: matrix.options.precision = 4
sage: A = matrix(RR, [[1/3, 200/3], [-3, 1e6]]); A
[ 0.3333 66.67]
[ -3.000 1.000E+6]
sage: unicode_art(A)
⎛ 0.3333 66.67⎞
⎝ -3.000 1.000E+6⎠
sage: matrix.options.precision = None
sage: A
[ 0.333333333333 66.666666666667]
[ -3.000000000000 1.000000000000e6]
```

```plaintext
>>> from sage.all import *
```
Matrices with borders:

```python
sage: M = matrix([[1,2,3], [4,5,6], [7,8,9]])
sage: M.subdivide(None, 2)

sage: print(M.str(unicode=True, top_border=['ab', 'cde', 'f'], bottom_border=['*', '', ''], left_border=[1, 10, 100], right_border=['', '<', '']))
```

```
ab cde f
1  1  2  3
10 4  5  6 <
100 7  8  9 *
```

```python
>>> from sage.all import *

>>> M = matrix([[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5), Integer(6)], [Integer(7),Integer(8),Integer(9)]]

>>> M.subdivide(None, Integer(2))

>>> print(M.str(unicode=True, top_border=['ab', 'cde', 'f'], bottom_border=['*', '', ''], left_border=[Integer(1), Integer(10), Integer(100)], right_border=['', '<', '']))
```

```
ab cde f
1  1  2  3
10 4  5  6 <
100 7  8  9 *
```

swap_columns ($c1, c2$)

Swap columns $c1$ and $c2$ of self.

EXAMPLES: We create a rational matrix:

```python
sage: M = MatrixSpace(QQ,3,3)
sage: A = M([1,9,-7,4/5,4,3,6,4,3])
sage: A
[ 1  9  7]
[4/5  4  3]
[ 6  4  3]
```

```python
>>> from sage.all import *

>>> M = MatrixSpace(QQ,Integer(3),Integer(3))

>>> A = M([Integer(1),Integer(9),-Integer(7),Integer(4)/Integer(5),Integer(4), Integer(3),Integer(6),Integer(4),Integer(3)])

>>> A
[ 1  9  7]
```

(continues on next page)
Since the first column is numbered zero, this swaps the second and third columns:

\[
\begin{bmatrix}
4/5 & 4 & 3 \\
6 & 4 & 3
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & -7 & 9 \\
4/5 & 3 & 4 \\
6 & 3 & 4
\end{bmatrix}
\]

```python
sage: A.swap_columns(1, 2); A
\[
\begin{bmatrix}
1 & -7 & 9 \\
4/5 & 3 & 4 \\
6 & 3 & 4
\end{bmatrix}
\]
```

```python
>>> from sage.all import *

>>> A.swap_columns(Integer(1), Integer(2)); A
\[
\begin{bmatrix}
1 & -7 & 9 \\
4/5 & 3 & 4 \\
6 & 3 & 4
\end{bmatrix}
\]
```

**swap_rows(r1, r2)**

Swap rows r1 and r2 of self.

**EXAMPLES:** We create a rational matrix:

```python
sage: M = MatrixSpace(QQ, 3, 3)
sage: A = M([1, 9, -7, 4/5, 4, 3, 6, 4, 3])
sage: A
\[
\begin{bmatrix}
1 & 9 & -7 \\
4/5 & 4 & 3 \\
6 & 4 & 3
\end{bmatrix}
\]
```

```python
>>> from sage.all import *

>>> M = MatrixSpace(QQ, Integer(3), Integer(3))

>>> A = M([Integer(1), Integer(9), -Integer(7), Integer(4)/Integer(5), -Integer(4), Integer(3), Integer(6), Integer(4), Integer(3)])

>>> A
\[
\begin{bmatrix}
1 & 9 & -7 \\
4/5 & 4 & 3 \\
6 & 4 & 3
\end{bmatrix}
\]
```

Since the first row is numbered zero, this swaps the first and third rows:

```python
sage: A.swap_rows(0, 2); A
\[
\begin{bmatrix}
6 & 4 & 3 \\
4/5 & 4 & 3 \\
1 & 9 & -7
\end{bmatrix}
\]
```

```python
>>> from sage.all import *

>>> A.swap_rows(Integer(0), Integer(2)); A
\[
\begin{bmatrix}
6 & 4 & 3 \\
4/5 & 4 & 3 \\
1 & 9 & -7
\end{bmatrix}
\]
```

**with_added_multiple_of_column(i, j, s, start_row=0)**

Add s times column j to column i, returning new matrix.

**EXAMPLES:** We add -1 times the third column to the second column of an integer matrix, remembering to start numbering cols at zero:
Matrices and Spaces of Matrices, Release 10.4

```
sage: a = matrix(ZZ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_added_multiple_of_column(1, 2, -1); b
[ 0 -1  2]
[ 3 -1  5]

>>> from sage.all import *

>>>

The original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_added_multiple_of_column(0, 1, 1/3); a
[ 1/3  1  2]
[13/3  4  5]
```

```
>>> from sage.all import *

>>>

>>>
```

with_added_multiple_of_row(i, j, s, start_col=0)

Add s times row j to row i, returning new matrix.

EXAMPLES: We add -3 times the first row to the second row of an integer matrix, remembering to start numbering rows at zero:

```
sage: a = matrix(ZZ,2,3,range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_added_multiple_of_row(1,0,-3); b
[ 0  1  2]
[ 3 -1 -1]

>>> from sage.all import *

>>>
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```
>>> b = a.with_added_multiple_of_row(Integer(1), Integer(0), -Integer(3)); b
[0 1 2]
[3 1 -1]
```

The original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

```
>>> from sage.all import *

>>> a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_added_multiple_of_row(0, 1, 1/3); a
[1 7/3 11/3]
[3 4 5]
```

```
>>> from sage.all import *

>>> a = a.with_added_multiple_of_row(Integer(0), Integer(1), Integer(1)/Integer(3)); a
[1 7/3 11/3]
[3 4 5]
```

**with_col_set_to_multiple_of_col(i, j, s)**

Set column $i$ equal to $s$ times column $j$, returning a new matrix.

**EXAMPLES:** We change the second column to -3 times the first column.

```
sage: a = matrix(ZZ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_col_set_to_multiple_of_col(1, 0, -3); b
[0 0 2]
[3 -9 5]
```

```
>>> from sage.all import *

>>> a = matrix(ZZ, Integer(2), Integer(3), range(Integer(6))); a
[0 1 2]
[3 4 5]
```

```
>>> b = a.with_col_set_to_multiple_of_col(Integer(1), Integer(0), -Integer(3)); b
[0 0 2]
[3 -9 5]
```

Note that the original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```
Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_col_set_to_multiple_of_col(1, 0, 1/2); a
[ 0 0 2]
[ 3 3/2 5]
```

```
>>> from sage.all import *
>>> a = a.with_col_set_to_multiple_of_col(Integer(1), Integer(0), Integer(1)/Integer(2)); a
[ 0 0 2]
[ 3 3/2 5]
```

with_permuted_columns (permutation)

Return the matrix obtained from permuting the columns of self by applying the permutation group element permutation.

As permutation group elements act on integers \{1, \ldots, n\}, columns are considered numbered from 1 for this operation.

INPUT:

• permutation, a PermutationGroupElement

OUTPUT:

• A matrix.

EXAMPLES: We create some matrix:

```
sage: M = matrix(ZZ, [[1,0,0,0,0],[0,2,0,0,0],[0,0,3,0,0],[0,0,0,4,0],[0,0,0,0,5]])
sage: M
[1 0 0 0 0]
[0 2 0 0 0]
[0 0 3 0 0]
[0 0 0 4 0]
[0 0 0 0 5]
```

```
>>> from sage.all import *
>>> M = matrix(ZZ, [[Integer(1),Integer(0),Integer(0),Integer(0),Integer(0)],[Integer(0),Integer(2),Integer(0),Integer(0),Integer(0)],[Integer(0),Integer(0),Integer(3),Integer(0),Integer(0)],[Integer(0),Integer(0),Integer(0),Integer(4),Integer(0)],[Integer(0),Integer(0),Integer(0),Integer(5)]]))
>>> M
[1 0 0 0 0]
[0 2 0 0 0]
[0 0 3 0 0]
[0 0 0 4 0]
[0 0 0 0 5]
```

Next of all, create a permutation group element and act on \(M\):
**with_permuted_rows** *(permutation)*

Return the matrix obtained from permuting the rows of `self` by applying the permutation group element `permutation`.

As permutation group elements act on integers \( \{1, \ldots, n\} \), rows are considered numbered from 1 for this operation.

**INPUT:**

- `permutation` – a `PermutationGroupElement`

**OUTPUT:**

- A matrix.

**EXAMPLES:** We create a matrix:

```
sage: M = matrix(ZZ, [[1,0,0,0,0],[0,2,0,0,0],[0,0,3,0,0],[0,0,0,4,0],[0,0,0,0,5]])
sage: M
[1 0 0 0 0]
[0 2 0 0 0]
[0 0 3 0 0]
[0 0 0 4 0]
[0 0 0 0 5]
```
Next of all, create a permutation group element and act on $M$:

```
sage: # needs sage.groups
g = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])
sage: sigma, tau = g.gens()
sage: sigma
(1,2,3)(4,5)
sage: M.with_permuted_rows(sigma)
[0 2 0 0 0]
[0 0 3 0 0]
[1 0 0 0 0]
[0 0 0 5]
[0 0 0 4 0]
```

```
>>> from sage.all import *

>>> # needs sage.groups

>>> g = PermutationGroup(['(1,2,3)(4,5)', '(1,2,3,4,5)'])

>>> sigma, tau = g.gens()

>>> sigma
(1,2,3)(4,5)

>>> M.with_permuted_rows(sigma)
[0 2 0 0 0]
[0 0 3 0 0]
[1 0 0 0 0]
[0 0 0 5]
[0 0 0 4 0]
```

\texttt{with\_permuted\_rows\_and\_columns}(row\_permutation, column\_permutation)

Return the matrix obtained from permuting the rows and columns of \texttt{self} by applying the permutation group elements \texttt{row\_permutation} and \texttt{column\_permutation}.

As permutation group elements act on integers \(\{1, \ldots, n\}\), rows and columns are considered numbered from 1 for this operation.

INPUT:

- \texttt{row\_permutation} – a PermutationGroupElement
- \texttt{column\_permutation} – a PermutationGroupElement

OUTPUT:

- A matrix.

EXAMPLES: We create a matrix:
Next of all, create a permutation group element and act on \( M \):

```
sage: # needs sage.groups
g = PermutationGroup([('1,2,3),(4,5)', '(1,2,3,4,5)'])
sage: sigma, tau = g.gens()
sage: sigma
(1,2,3)(4,5)
sage: M.with_permuted_rows_and_columns(sigma, tau)
```

```
2 0 0 0 0
0 3 0 0 0
0 0 0 1 0
0 0 5 0
0 4 0
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>>
g = PermutationGroup([('1,2,3),(4,5)', '(1,2,3,4,5)'])
>>>
sigma, tau = g.gens()
>>>
sigma
(1,2,3)(4,5)
>>>
M.with_permuted_rows_and_columns(sigma, tau)
```

```
2 0 0 0 0
0 3 0 0 0
0 0 0 1 0
0 0 5 0
0 4 0
```

with_rescaled_col \((i, s, \text{start\_row}=0)\)

Replaces \(i\)-th col of self by \(s\) times \(i\)-th col of self, returning new matrix.

EXAMPLES: We rescale the last column of a matrix over the integers:

```
sage: a = matrix(ZZ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_rescaled_col(2, -2); b
[ 0  1 -4]
[ 3  4 -10]
```
The original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_rescaled_col(1, 1/3); a
[ 0 1/3 2]
[ 3 4/3 5]
```

```
sage: a = a.with_rescaled_col(Integer(1), Integer(1)/Integer(3)); a
[ 0 1/3 2]
[ 3 4/3 5]
```

```
with_rescaled_row(i, s, start_col=0)
```

Replaces i-th row of self by s times i-th row of self, returning new matrix.

**EXAMPLES:** We rescale the second row of a matrix over the integers:

```
sage: a = matrix(ZZ, 3, 2, range(6)); a
[0 1]
[2 3]
[4 5]
sage: b = a.with_rescaled_row(1, -2); b
[0 1]
[-4 -6]
[4 5]
```

```
>>> from sage.all import *

>>> a = matrix(ZZ, Integer(3), Integer(2), range(Integer(6))); a
[0 1]
[2 3]
[4 5]
```

```
>>> b = a.with_rescaled_row(Integer(1), -Integer(2)); b
[0 1]
[-4 -6]
[4 5]
```

The original matrix is unchanged:
Adding a rational multiple is okay, and reassigning a variable is okay:

```
sage: a = a.with_rescaled_row(2, 1/3); a
[ 0  1]
[ 2  3]
[4/3 5/3]
```

```
sage: a = a.with_rescaled_row(Integer(2), Integer(1)/Integer(3)); a
[ 0  1]
[ 2  3]
[4/3 5/3]
```

```
with_row_set_to_multiple_of_row(i, j, s)
Set row i equal to s times row j, returning a new matrix.

EXAMPLES: We change the second row to -3 times the first row:
```
sage: a = matrix(ZZ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: b = a.with_row_set_to_multiple_of_row(1, 0, -3); b
[ 0  1  2]
[ 0 -3 -6]
```

```
>>> from sage.all import *
>>> a = matrix(ZZ, Integer(2), Integer(3), range(Integer(6))); a
[0 1 2]
[3 4 5]
>>> b = a.with_row_set_to_multiple_of_row(Integer(1), Integer(0), -Integer(3)); b
[ 0  1  2]
[ 0 -3 -6]
```

Note that the original matrix is unchanged:

```
sage: a
[0 1 2]
[3 4 5]
```

```
>>> from sage.all import *
>>> a
[0 1 2]
[3 4 5]
```

Adding a rational multiple is okay, and reassigning a variable is okay:
with_swapped_columns(c1, c2)

Swaps columns $c_1$ and $c_2$ of self and return a new matrix.

**INPUT:**

- $c_1, c_2$ – integers specifying columns of self to interchange

**OUTPUT:**

A new matrix, identical to self except that columns $c_1$ and $c_2$ are swapped.

**EXAMPLES:**

Remember that columns are numbered starting from zero.

```sage
sage: A = matrix(QQ, 4, range(20))
sage: A.with_swapped_columns(1, 2)
[ 0 2 1 3 4]
[ 5 7 6 8 9]
[10 12 11 13 14]
[15 17 16 18 19]
```

Trying to swap a column with itself will succeed, but still return a new matrix.

```sage
sage: A = matrix(QQ, 4, range(20))
sage: B = A.with_swapped_columns(2, 2)
sage: A == B
True
sage: A is B
False
```

The column specifications are checked.
with_swapped_rows$(r1, r2)$

Swap rows $r1$ and $r2$ of self and return a new matrix.

**INPUT:**

- $r1, r2$ – integers specifying rows of self to interchange

**OUTPUT:**

A new matrix, identical to self except that rows $r1$ and $r2$ are swapped.

**EXAMPLES:**

Remember that rows are numbered starting from zero.

\[
\begin{bmatrix}
0 & 1 & 2 & 3 & 4 \\
10 & 11 & 12 & 13 & 14 \\
5 & 6 & 7 & 8 & 9 \\
15 & 16 & 17 & 18 & 19
\end{bmatrix}
\]
True

```
sage: A = B
False
```

```
from sage.all import *

from sage.matrix.matrix0 import set_max_cols

set_max_cols(50)

doctest:...: DeprecationWarning: 'set_max_cols' is replaced by 'matrix.options.'

>>> from sage.matrix.matrix0 import set_max_cols

set_max_cols(50)

doctest:...: DeprecationWarning: 'set_max_cols' is replaced by 'matrix.options.'

See https://github.com/sagemath/sage/issues/30552 for details.
```

```
sage.matrix.matrix0.set_max_rows(n)
```

The row specifications are checked.

```
sage: A = matrix(4, range(20))

sage: A.with_swapped_rows(-1, 2)
Traceback (most recent call last):
...
IndexError: matrix row index out of range
```

```
sage: A.with_swapped_rows(2, 5)
Traceback (most recent call last):
...
IndexError: matrix row index out of range
```

Therowspecificationsarechecked.
Sets the global variable max_rows (which is used in deciding how to output a matrix).

**EXAMPLES:**

```
sage: from sage.matrix.matrix0 import set_max_rows
sage: set_max_rows(20)
doctest:...: DeprecationWarning: 'set_max_rows' is replaced by 'matrix.options.
˓→max_rows'
See https://github.com/sagemath/sage/issues/30552 for details.
```

```
>>> from sage.all import *
>>> from sage.matrix.matrix0 import set_max_rows
>>> set_max_rows(Integer(20))
doctest:...: DeprecationWarning: 'set_max_rows' is replaced by 'matrix.options.
˓→max_rows'
See https://github.com/sagemath/sage/issues/30552 for details.
```

```
sage.matrix.matrix0.unpickle(cls, parent, immutability, cache, data, version)
```

Unpickle a matrix. This is only used internally by Sage. Users should never call this function directly.

**EXAMPLES:** We illustrating saving and loading several different types of matrices.

**OVER \(\mathbb{Z}\):**

```
sage: A = matrix(ZZ, 2, range(4))
sage: loads(dumps(A))  # indirect doctest
[0 1]
[2 3]
```

```
>>> from sage.all import *
>>> A = matrix(ZZ, Integer(2), range(Integer(4)))
>>> loads(dumps(A))  # indirect doctest
[0 1]
[2 3]
```

Sparse **OVER \(\mathbb{Q}\):**

Dense over \(\mathbb{Q}[x, y]\):

Dense over finite field.
BASE CLASS FOR MATRICES, PART 1

For design documentation see `sage.matrix.docs`.

```python
class sage.matrix.matrix1.Matrix
    Bases: Matrix
    
augment(right, subdivide=False)
    Returns a new matrix formed by appending the matrix (or vector) right on the right side of self.
    
    INPUT:
    
    • right – a matrix, vector or free module element, whose dimensions are compatible with self.
    • subdivide – (default: False); request the resulting matrix to have a new subdivision, separating self from right.
    
    OUTPUT:

    A new matrix formed by appending right onto the right side of self. If right is a vector (or free module element) then in this context it is appropriate to consider it as a column vector. (The code first converts a vector to a 1-column matrix.)

    If subdivide is True then any column subdivisions for the two matrices are preserved, and a new subdivision is added between self and right. If the row divisions are identical, then they are preserved, otherwise they are discarded. When subdivide is False there is no subdivision information in the result.

    Warning: If subdivide is True then unequal row subdivisions will be discarded, since it would be ambiguous how to interpret them. If the subdivision behavior is not what you need, you can manage subdivisions yourself with methods like `get_subdivisions()` and `subdivide()`. You might also find `block_matrix()` or `block_diagonal_matrix()` useful and simpler in some instances.
```

EXAMPLES:

Augmenting with a matrix.

```python
sage: A = matrix(QQ, 3, range(12))
sage: B = matrix(QQ, 3, range(9))
sage: A.augment(B)
```

```python
[ 0 1 2 3 0 1 2]
[ 4 5 6 7 3 4 5]
[ 8 9 10 11 6 7 8]
```

```python
>>> from sage.all import *
>>> A = matrix(QQ, Integer(3), range(Integer(12)))
(continues on next page)```
Matrices and Spaces of Matrices, Release 10.4

>>> B = matrix(QQ, Integer(3), range(Integer(9)))
>>> A.augment(B)
[ 0 1 2 3 0 1 2]
[ 4 5 6 7 3 4 5]
[ 8 9 10 11 6 7 8]

Augmenting with a vector.

sage: A = matrix(QQ, 2, [0, 2, 4, 6, 8, 10])
sage: v = vector(QQ, 2, [100, 200])
sage: A.augment(v)
[ 0 2 4 100]
[ 6 8 10 200]

Errors are raised if the sizes are incompatible.

sage: A = matrix(RR, [[1, 2],[3, 4]])
sage: B = matrix(RR, [[10, 20], [30, 40], [50, 60]])
sage: A.augment(B)
Traceback (most recent call last):
  ...TypeError: number of rows must be the same, 2 != 3
sage: v = vector(RR, [100, 200, 300])
sage: A.augment(v)
Traceback (most recent call last):
  ...TypeError: number of rows must be the same, 2 != 3

Setting subdivide to True will, in its simplest form, add a subdivision between self and right.

sage: A = matrix(QQ, 3, range(12))
sage: B = matrix(QQ, 3, range(15))
(continues on next page)
From previous page

```
sage: A.augment(B, subdivide=True)

\[
\begin{array}{cccc|cccc}
0 & 1 & 2 & 3 & 0 & 1 & 2 & 3 & 4 \\
4 & 5 & 6 & 7 & 5 & 6 & 7 & 8 & 9 \\
8 & 9 & 10 & 11 & 10 & 11 & 12 & 13 & 14
\end{array}
\]
```

Column subdivisions are preserved by augmentation, and enriched, if subdivisions are requested. (So multiple augmentations can be recorded.)

```
sage: A = matrix(QQ, 3, range(6))
sage: A.subdivide(None, [1])
sage: B = matrix(QQ, 3, range(9))
sage: B.subdivide(None, [2])
sage: A.augment(B, subdivide=True)

\[
\begin{array}{c|c|c|c}
0 & 1 & 0 & 1 & 2 \\
---+-----
2 & 3 & 3 & 4 & 5 \\
4 & 5 & 6 & 7 & 8 \\
---+-----
\end{array}
\]
```

Row subdivisions can be preserved, but only if they are identical. Otherwise, this information is discarded and must be managed separately.

```
sage: A = matrix(QQ, 3, range(6))
sage: A.subdivide([1,3], None)
sage: B = matrix(QQ, 3, range(9))
sage: B.subdivide([1,3], None)
sage: A.augment(B, subdivide=True)

\[
\begin{array}{c}
0 & 1 & 2 \\
\hline
2 & 3 & 4 & 5 \\
4 & 5 & 6 & 7 & 8 \\
\hline
\end{array}
\]
```

```
The result retains the base ring of `self` by coercing the elements of `right` into the base ring of `self`.

```python
sage: A = matrix(QQ, 2, [1,2])
sage: B = matrix(RR, 2, [sin(1.1), sin(2.2)])
sage: C = A.augment(B); C
[ 1 1.83017397205358938]
[ 2 1.06580492131825561]
sage: C.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

Sometimes it is not possible to coerce into the base ring of `self`. A solution is to change the base ring of `self` to a more expansive ring. Here we mix the rationals with a ring of polynomials with rational coefficients.

```python
sage: A = matrix(QQ, 2, [1,2])
sage: B = matrix(RR, 2, [sin(1.1), sin(2.2)])
sage: C = A.augment(B); C
[ 1 1.83017397205358938]
[ 2 1.06580492131825561]
sage: C.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```
sage: R.<y> = PolynomialRing(QQ)
sage: A = matrix(QQ, 1, [1,2])
sage: B = matrix(R, 1, [y, y^2])

sage: C = B.augment(A); C
[ y y^2 1 2]
sage: C.parent()
Full MatrixSpace of 1 by 4 dense matrices over Univariate Polynomial Ring in y over Rational Field

sage: D = A.augment(B)
Traceback (most recent call last):
  ...TypeError: y is not a constant polynomial

sage: E = A.change_ring(R)
sage: F = E.augment(B); F
[ 1 2 y y^2]
sage: F.parent()
Full MatrixSpace of 1 by 4 dense matrices over Univariate Polynomial Ring in y over Rational Field

>>> from sage.all import *

>>> R = PolynomialRing(QQ, names=('y',)); (y,) = R._first_ngens(1)
>>> A = matrix(QQ, Integer(1), [Integer(1),Integer(2)])
>>> B = matrix(R, Integer(1), [y, y**Integer(2)])

>>> C = B.augment(A); C
[ y y^2 1 2]
>>> C.parent()
Full MatrixSpace of 1 by 4 dense matrices over Univariate Polynomial Ring in y over Rational Field

>>> D = A.augment(B)
Traceback (most recent call last):
  ...TypeError: y is not a constant polynomial

>>> E = A.change_ring(R)
>>> F = E.augment(B); F
[ 1 2 y y^2]
>>> F.parent()
Full MatrixSpace of 1 by 4 dense matrices over Univariate Polynomial Ring in y over Rational Field

AUTHORS:

- Naqi Jaffery (2006-01-24): examples
- Rob Beezer (2010-12-07): vector argument, docstring, subdivisions

block_sum (other)

Return the block matrix that has self and other on the diagonal:

```
[ self  0 ]
[  0 other ]
```

EXAMPLES:
```python
sage: A = matrix(QQ[['t']], 2, range(1, 5))
sage: A.block_sum(100*A)
[ 1 2 0 0]
[ 3 4 0 0]
[ 0 0 100 200]
[ 0 0 300 400]
```

```python
>>> from sage.all import *
```---

```
>>> A = matrix(QQ[['t']], Integer(2), range(Integer(1), Integer(5)))
>>> A.block_sum(Integer(100)*A)
[ 1 2 0 0]
[ 3 4 0 0]
[ 0 0 100 200]
[ 0 0 300 400]
```

\[ \text{column}(i, \text{from\_list}=False) \]

Return the \( i \)'th column of this matrix as a vector.

This column is a dense vector if and only if the matrix is a dense matrix.

**INPUT:**

- \( i \) – integer
- \text{from\_list} = \text{bool} (default: False); if true, returns the \( i \)'th element of \text{self.columns}() (see \text{columns}()), which may be faster, but requires building a list of all columns the first time it is called after an entry of the matrix is changed.

**EXAMPLES:**

```python
sage: a = matrix(2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: a.column(1)
(1, 4)
```

```python
>>> from sage.all import *
```---

```
>>> a = matrix(Integer(2), Integer(3), range(Integer(6))); a
[0 1 2]
[3 4 5]
>>> a.column(Integer(1))
(1, 4)
```

If the column is negative, it wraps around, just like with list indexing, e.g., -1 gives the right-most column:

```python
sage: a.column(-1)
(2, 5)
```

```python
>>> from sage.all import *
```---

```
>>> a.column(-Integer(1))
(2, 5)
```

\[ \text{column\_ambient\_module}(\text{base\_ring}=None, \text{sparse}=None) \]

Return the free module that contains the columns of the matrix.

**EXAMPLES:**
columns (copy=True)

Return a list of the columns of self.

INPUT:

- copy – (default: True) if True, return a copy of the list of columns which is safe to change.

If self is a sparse matrix, columns are returned as sparse vectors, otherwise returned vectors are dense.

EXAMPLES:
needs sage.symbolic

sage: parent(m.columns()[0])  
# needs sage.symbolic
Sparse vector space of dimension 3 over Real Field with 53 bits of precision

sage: A = matrix(QQ, 2, range(4), sparse=True)
sage: v = A.columns()[0]
sage: v.is_sparse()  
True

delete_columns(dcols, check=True)

Return the matrix constructed from deleting the columns with indices in the dcols list.

INPUT:

- dcols – list of indices of columns to be deleted from self.
- check – checks whether any index in dcols is out of range. Defaults to True.

See also:

The methods delete_rows() and matrix_from_columns() are related.

EXAMPLES:

sage: A = Matrix(3, 4, range(12)); A
[ 0 1 2 3]
[ 4 5 6 7]
[ 8 9 10 11]
sage: A.delete_columns([0,2])
[ 1 3]  
(continues on next page)
```python
>>> from sage.all import *

>>> A = Matrix(Integer(3), Integer(4), range(Integer(12))); A
[ 0 1 2 3]
[ 4 5 6 7]
[ 8 9 10 11]

>>> A.delete_columns([Integer(0), Integer(2)])
[ 1 3]
[ 5 7]
[ 9 11]

dcols can be a tuple. But only the underlying set of indices matters.

sage: A.delete_columns((2, 0, 2))
[ 1 3]
[ 5 7]
[ 9 11]

>>> from sage.all import *

>>> A.delete_columns((Integer(2), Integer(0), Integer(2)))
[ 1 3]
[ 5 7]
[ 9 11]

The default is to check whether any index in dcols is out of range.

sage: A.delete_columns([-1, 2, 4])
Traceback (most recent call last):
  ...
IndexError: [-1, 4] contains invalid indices
sage: A.delete_columns([-1, 2, 4], check=False)
[ 0 1 3]
[ 4 5 7]
[ 8 9 11]

>>> from sage.all import *

>>> A.delete_columns([-Integer(1), Integer(2), Integer(4)])
Traceback (most recent call last):
  ...
IndexError: [-1, 4] contains invalid indices
>>> A.delete_columns([-Integer(1), Integer(2), Integer(4)], check=False)
[ 0 1 3]
[ 4 5 7]
[ 8 9 11]
```

AUTHORS:

- Wai Yan Pong (2012-03-05)

**delete_rows (drows, check=True)**

Return the matrix constructed from deleting the rows with indices in the drows list.

**INPUT:**

- drows – list of indices of rows to be deleted from self.
• check – (boolean, default: True); whether to check if any index in drows is out of range.

See also:
The methods delete_columns() and matrix_from_rows() are related.

EXAMPLES:

```sage
sage: A = Matrix(4, 3, range(12)); A
[ 0 1 2]
[ 3 4 5]
[ 6 7 8]
[ 9 10 11]
sage: A.delete_rows([0,2])
[ 3 4 5]
[ 9 10 11]
```

drows can be a tuple. But only the underlying set of indices matters.

```sage
sage: A.delete_rows((2,0,2))
[ 3 4 5]
[ 9 10 11]
```

The default is to check whether the any index in drows is out of range.

```sage
sage: A.delete_rows([-1,2,4])
Traceback (most recent call last):
  ...
IndexError: [-1, 4] contains invalid indices
sage: A.delete_rows([-1,2,4], check=False)
[ 0 1 2]
[ 3 4 5]
[ 9 10 11]
```

```sage
>>> from sage.all import *

>>> A = Matrix(Integer(4), Integer(3), range(Integer(12))); A
[ 0 1 2]
[ 3 4 5]
[ 6 7 8]
[ 9 10 11]

>>> A.delete_rows([Integer(0),Integer(2)])
[ 3 4 5]
[ 9 10 11]
```

```sage
>>> from sage.all import *

>>> A.delete_rows((Integer(2),Integer(0),Integer(2)))
[ 3 4 5]
[ 9 10 11]
```

```sage
sage: A.delete_rows((2,0,2))
[ 3 4 5]
[ 9 10 11]
```

```
>>> from sage.all import *

>>> A.delete_rows((Integer(2),Integer(0),Integer(2)))
[ 3 4 5]
[ 9 10 11]
```

```sage
>>> from sage.all import *

>>> A.delete_rows([-Integer(1),Integer(2),Integer(4)])
Traceback (most recent call last):
  ...
IndexError: [-1, 4] contains invalid indices

>>> A.delete_rows([-Integer(1),Integer(2),Integer(4)], check=False)
[ 0 1 2]
[ 3 4 5]
[ 9 10 11]
```
dense_columns (copy=True)
Return list of the dense columns of self.

INPUT:
- copy – (default: True) if True, return a copy so you can modify it safely

EXAMPLES:
An example over the integers:

```
sage: a = matrix(3, 3, range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.dense_columns()
[(0, 3, 6), (1, 4, 7), (2, 5, 8)]
```

```
>>> from sage.all import *
>>> a = matrix(Integer(3), Integer(3), range(Integer(9))); a
[0 1 2]
[3 4 5]
[6 7 8]
>>> a.dense_columns()
[(0, 3, 6), (1, 4, 7), (2, 5, 8)]
```

We do an example over a polynomial ring:

```
sage: R.<x> = QQ[]
sage: a = matrix(R, 2, [x,x^2, 2/3*x,1+x^5]); a
[ x  x^2]
[ 2/3*x  x^5 + 1]
sage: a.dense_columns()
[(x, 2/3*x), (x^2, x^5 + 1)]
sage: a = matrix(R, 2, [x,x^2, 2/3*x,1+x^5], sparse=True)
sage: c = a.dense_columns(); c
[(x, 2/3*x), (x^2, x^5 + 1)]
sage: parent(c[1])
Ambient free module of rank 2 over the principal ideal domain
Univariate Polynomial Ring in x over Rational Field
```

```
>>> from sage.all import *
>>> a = matrix(R, Integer(2), [x,x**Integer(2), Integer(2)/Integer(3)*x, →Integer(1)+x**Integer(5)]); a
[ x  x^2]
[ 2/3*x  x^5 + 1]
>>> a.dense_columns()
[(x, 2/3*x), (x^2, x^5 + 1)]
>>> a = matrix(R, Integer(2), [x,x**Integer(2), Integer(2)/Integer(3)*x, →Integer(1)+x**Integer(5)], sparse=True)
>>> c = a.dense_columns(); c
[(x, 2/3*x), (x^2, x^5 + 1)]
>>> parent(c[Integer(1)])
Ambient free module of rank 2 over the principal ideal domain
Univariate Polynomial Ring in x over Rational Field
```

dense_matrix()
If this matrix is sparse, return a dense matrix with the same entries. If this matrix is dense, return this matrix
(not a copy).

**Note:** The definition of “dense” and “sparse” in Sage have nothing to do with the number of nonzero entries. Sparse and dense are properties of the underlying representation of the matrix.

**EXAMPLES:**

```
sage: A = MatrixSpace(QQ, 2, sparse=True)([1, 2, 0, 1])
sage: A.is_sparse()
True
sage: B = A.dense_matrix()
sage: B.is_sparse()
False
sage: A == B
True
sage: B.dense_matrix() is B
True
sage: A*B
[1 4]
[0 1]
sage: A.parent()
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
sage: B.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

In Sage, the product of a sparse and a dense matrix is always dense:

```
>>> from sage.all import *
>>> A = MatrixSpace(QQ, Integer(2), sparse=True)([Integer(1), Integer(2),
-    Integer(0), Integer(1)])
>>> A.is_sparse()
True
>>> B = A.dense_matrix()
>>> B.is_sparse()
False
>>> A == B
True
>>> B.dense_matrix() is B
True
>>> A*B
[1 4]
[0 1]
>>> A.parent()
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
>>> B.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

```
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> (B\times A).parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
```

dense_rows (copy=True)

Return list of the dense rows of self.

INPUT:

- copy – (default: True) if True, return a copy so you can modify it safely (note that the individual vectors in the copy should not be modified since they are mutable!)

EXAMPLES:

```python
sage: m = matrix(3, range(9)); m
[0 1 2]
[3 4 5]
[6 7 8]
sage: v = m.dense_rows(); v
[(0, 1, 2), (3, 4, 5), (6, 7, 8)]
sage: v is m.dense_rows()
False
sage: m.dense_rows(copy=False) is m.dense_rows(copy=False)
True
sage: m[0,0] = 10
sage: m.dense_rows()
[(10, 1, 2), (3, 4, 5), (6, 7, 8)]
```

lift ()

Return lift of self to the covering ring of the base ring R, which is by definition the ring returned by calling cover_ring() on R, or just R itself if the cover_ring method is not defined.

EXAMPLES:

```python
>>> from sage.all import *
>>> m = matrix(Integer(3), range(Integer(9))); m
[0 1 2]
[3 4 5]
[6 7 8]
>>> v = m.dense_rows(); v
[(0, 1, 2), (3, 4, 5), (6, 7, 8)]
>>> v is m.dense_rows()
False
>>> m.dense_rows(copy=False) is m.dense_rows(copy=False)
True
>>> m[Integer(0),Integer(0)] = Integer(10)
>>> m.dense_rows()
[((10, 1, 2), (3, 4, 5), (6, 7, 8)]
```

223
>>> from sage.all import *

>>> M = Matrix(Integers(Integer(7)), Integer(2), Integer(2), [Integer(5),
Integer(9), Integer(13), Integer(15)]); M
\[
\begin{bmatrix}
5 & 9 \\
6 & 1
\end{bmatrix}
\]

>>> M.lift()
\[
\begin{bmatrix}
5 & 9 \\
6 & 1
\end{bmatrix}
\]

>>> parent(M.lift())
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring

The field QQ doesn't have a cover_ring method:

```
sage: hasattr(QQ, 'cover_ring')
False
```

```
>>> from sage.all import *

>>> hasattr(QQ, 'cover_ring')
False
```

So lifting a matrix over QQ gives back the same exact matrix.

```
sage: B = matrix(QQ, 2, [1..4])
sage: B.lift()
\[
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}
\]

sage: B.lift() is B
True
```

```
>>> from sage.all import *

>>> B = matrix(QQ, Integer(2), (ellipsis_range(Integer(1),Ellipsis,
Integer(4))))

>>> B.lift()
\[
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}
\]

>>> B.lift() is B
True
```

**lift_centered()**

Apply the lift_centered method to every entry of self.

**OUTPUT:**

If self is a matrix over the Integers mod $n$, this method returns the unique matrix $m$ such that $m$ is congruent to self mod $n$ and for every entry $m[i,j]$ we have $-n/2 < m[i,j] \leq n/2$. If the coefficient ring does not have a cover_ring method, return self.

**EXAMPLES:**

```
sage: M = Matrix(Integers(8), 2, 4, range(8)); M
\[
\begin{bmatrix}
0 & 1 & 2 & 3 \\
4 & 5 & 6 & 7
\end{bmatrix}
\]

sage: L = M.lift_centered(); L
\[
\begin{bmatrix}
0 & 1 & 2 & 3 \\
4 & -3 & -2 & -1
\end{bmatrix}
\]

sage: parent(L)
Full MatrixSpace of 2 by 4 dense matrices over Integer Ring
```
Matrices and Spaces of Matrices, Release 10.4

>>> from sage.all import *

>>> M = Matrix(Integers(Integer(8)), Integer(2), Integer(4),
... range(Integer(8))); M
[0 1 2 3]
[4 5 6 7]

>>> L = M.lift_centered(); L
[ 0 1 2 3]
[ 4 -3 -2 -1]

>>> parent(L)
Full MatrixSpace of 2 by 4 dense matrices over Integer Ring

The returned matrix is congruent to M modulo 8:

sage: L.mod(Integer(8))
[0 1 2 3]
[4 5 6 7]

The field QQ doesn’t have a cover_ring method:

sage: hasattr(QQ, 'cover_ring')
False

sage: hasattr(QQ, 'cover_ring')
False

So lifting a matrix over QQ gives back the same exact matrix.

sage: B = matrix(QQ, 2, [1..4])
sage: B
[1 2]
[3 4]

sage: B.lift_centered() is B
True

sage: B = matrix(QQ, Integer(2), (ellipsis_range(Integer(1), Ellipsis,
... Integer(4)))); B
[1 2]
[3 4]

sage: B.lift_centered() is B
True

matrix_from_columns (columns)

Return the matrix constructed from self using columns with indices in the columns list.

EXAMPLES:
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 0
\end{bmatrix}
\]

\textit{sage}: \texttt{A.matrix_from_columns([2,1])}
\[
\begin{bmatrix}
2 & 1 \\
5 & 4 \\
0 & 7
\end{bmatrix}
\]

\texttt{>>> from sage.all import *}
\texttt{>>> M = MatrixSpace(Integers(Integer(8)), Integer(3), Integer(3))}
\texttt{>>> A = M(range(Integer(9))); A}
\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 0
\end{bmatrix}
\]

\texttt{>>> A.matrix_from_columns([Integer(2),Integer(1)])}
\[
\begin{bmatrix}
6 & 7 & 0 \\
3 & 4 & 5
\end{bmatrix}
\]

\textbf{matrix\_from\_rows(rows)}

Return the matrix constructed from self using rows with indices in the rows list.

\textbf{EXAMPLES:}

\texttt{sage}: \texttt{M = MatrixSpace(Integers(8), 3, 3)}
\texttt{sage}: \texttt{A = M(range(9)); A}
\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 0
\end{bmatrix}
\]

\texttt{sage}: \texttt{A.matrix\_from\_rows([2,1])}
\[
\begin{bmatrix}
6 & 7 & 0 \\
3 & 4 & 5
\end{bmatrix}
\]

\texttt{>>> from sage.all import *}
\texttt{>>> M = MatrixSpace(Integers(Integer(8)), Integer(3), Integer(3))}
\texttt{>>> A = M(range(Integer(9))); A}
\[
\begin{bmatrix}

[4 5]
[7 0]

Note that row and column indices can be reordered or repeated:

sage: A.matrix_from_rows_and_columns([2, 1], [2, 1])

[0 7]
[5 4]

For example here we take from row 1 columns 2 then 0 twice, and do this 3 times:

sage: A.matrix_from_rows_and_columns([1, 1, 1], [2, 0, 0])

[5 3 3]

• Didier Deshommes: some Pyrex speedups implemented

matrix_over_field()

Return copy of this matrix, but with entries viewed as elements of the fraction field of the base ring (assuming it is defined).

EXAMPLES:

sage: A = MatrixSpace(IntegerRing(), 2)([1, 2, 3, 4])
sage: B = A.matrix_over_field()
sage: B
[1 2]
[3 4]
sage: B.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field

>>> from sage.all import *

>>> A = MatrixSpace(IntegerRing(),Integer(2))([[Integer(1),Integer(2)],
    [Integer(3),Integer(4)]])

>>> B = A.matrix_over_field()

>>> B
[1 2]
[3 4]

Full MatrixSpace of 2 by 2 dense matrices over Rational Field

matrix_space(nrows=None, ncols=None, sparse=None)

Return the ambient matrix space of self.

INPUT:

• nrows, ncols – (optional) number of rows and columns in returned matrix space.
• sparse – whether the returned matrix space uses sparse or dense matrices.

EXAMPLES:

sage: m = matrix(3, [1..9])

sage: m.matrix_space()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

sage: m.matrix_space(ncols=2)
Full MatrixSpace of 3 by 2 dense matrices over Integer Ring

sage: m.matrix_space(1)
Full MatrixSpace of 1 by 3 dense matrices over Integer Ring

sage: m.matrix_space(1, 2, True)
Full MatrixSpace of 1 by 2 sparse matrices over Integer Ring

sage: M = MatrixSpace(QQ, 3, implementation=generic)

sage: m = M.an_element()

sage: m.matrix_space()
Full MatrixSpace of 3 by 3 dense matrices over Rational Field

sage: m.matrix_space(nrows=2, ncols=12)
Full MatrixSpace of 2 by 12 dense matrices over Rational Field

sage: m.matrix_space(nrows=2, sparse=True)
Full MatrixSpace of 2 by 3 sparse matrices over Rational Field

>>> from sage.all import *

>>> m = matrix(Integer(3), (ellipsis_range(Integer(1),Ellipsis,Integer(9))))

>>> m.matrix_space()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

>>> m.matrix_space(ncols=Integer(2))
Full MatrixSpace of 3 by 2 dense matrices over Integer Ring

>>> m.matrix_space(Integer(1))
Full MatrixSpace of 1 by 3 dense matrices over Integer Ring

>>> m.matrix_space(Integer(1), Integer(2), True)
Full MatrixSpace of 1 by 2 sparse matrices over Integer Ring
Full MatrixSpace of 1 by 2 sparse matrices over Integer Ring

```python
>>> M = MatrixSpace(QQ, Integer(3), implementation='generic')
>>> m = M.an_element()
>>> m.matrix_space()
Full MatrixSpace of 3 by 3 dense matrices over Rational Field
    (using Matrix_generic_dense)
>>> m.matrix_space(nrows=Integer(2), ncols=Integer(12))
Full MatrixSpace of 2 by 12 dense matrices over Rational Field
    (using Matrix_generic_dense)
>>> m.matrix_space(nrows=Integer(2), sparse=True)
Full MatrixSpace of 2 by 3 sparse matrices over Rational Field
```

`new_matrix(nrows=None, ncols=None, entries=None, coerce=True, copy=True, sparse=None)`

Create a matrix in the parent of this matrix with the given number of rows, columns, etc. The default parameters are the same as for self.

**INPUT:**

These three variables get sent to `matrix_space()`:

- `nrows, ncols` – number of rows and columns in returned matrix. If not specified, defaults to `None` and will give a matrix of the same size as self.

- `sparse` – whether returned matrix is sparse or not. Defaults to same value as self.

The remaining three variables (`coerce, entries, and copy`) are used by `sage.matrix.matrix_space.MatrixSpace()` to construct the new matrix.

**Warning:** This function called with no arguments returns the zero matrix of the same dimension and sparseness of self.

**EXAMPLES:**

```python
sage: A = matrix(ZZ,2,2,[1,2,3,4]); A
[1 2]
[3 4]
sage: A.new_matrix()
[0 0]
[0 0]
sage: A.new_matrix(1,1)
[0]
sage: A.new_matrix(3,3).parent()
Full MatrixSpace of 3 by 3 dense matrices over Integer Ring
```

```python
>>> from sage.all import *
>>> A = matrix(ZZ,Integer(2),Integer(2),[Integer(1),Integer(2),Integer(3), Integer(4)]); A
[1 2]
[3 4]
>>> A.new_matrix()
[0 0]
[0 0]
>>> A.new_matrix(Integer(1),Integer(1))
[0]
```
A.new_matrix(Integer(3),Integer(3)).parent()

Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

sage: A = matrix(RR,2,3,[1.1,2.2,3.3,4.4,5.5,6.6]); A

[1.10000000000000 2.20000000000000 3.30000000000000]
[4.40000000000000 5.50000000000000 6.60000000000000]

sage: A.new_matrix()

[0.000000000000000 0.000000000000000 0.000000000000000]
[0.000000000000000 0.000000000000000 0.000000000000000]

sage: A.new_matrix().parent()

Full MatrixSpace of 2 by 3 dense matrices over Real Field with 53 bits of precision

from sage.all import *

A = matrix(RR,Integer(2),Integer(3),[RealNumber(1.1),RealNumber(2.2),
RealNumber(3.3),RealNumber(4.4),RealNumber(5.5),RealNumber(6.6)]); A

[1.10000000000000 2.20000000000000 3.30000000000000]
[4.40000000000000 5.50000000000000 6.60000000000000]

A.new_matrix()

[0.000000000000000 0.000000000000000 0.000000000000000]

from sage.all import *

M = MatrixSpace(ZZ, Integer(2), Integer(3), implementation=generic)

m = M.an_element()

Full MatrixSpace of 2 by 3 dense matrices over Integer Ring

m.new_matrix().parent()

Full MatrixSpace of 2 by 3 dense matrices over Integer Ring

m.new_matrix(Integer(3),Integer(3)).parent()

Full MatrixSpace of 3 by 3 dense matrices over Integer Ring

m.new_matrix(Integer(3),Integer(3), sparse=True).parent()

Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring

numpy (dtype=None)

Return the Numpy matrix associated to this matrix.

INPUT:

• dtype – The desired data-type for the array. If not given, then the type will be determined as the minimum type required to hold the objects in the sequence.

EXAMPLES:
sage: # needs numpy
sage: a = matrix(3, range(12))
sage: a.numpy()
array([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
sage: a.numpy('f')
array([[ 0.,  1.,  2.,  3.],
        [ 4.,  5.,  6.,  7.],
        [ 8.,  9., 10., 11.]], dtype=float32)
sage: a.numpy('d')
array([[ 0.,  1.,  2.,  3.],
        [ 4.,  5.,  6.,  7.],
        [ 8.,  9., 10., 11.])
sage: a.numpy('B')
array([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]], dtype=uint8)

>>> from sage.all import *
>>> # needs numpy
>>> a = matrix(Integer(3), range(Integer(12)))
>>> a.numpy()
array([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> a.numpy('f')
array([[ 0.,  1.,  2.,  3.],
        [ 4.,  5.,  6.,  7.],
        [ 8.,  9., 10., 11.]], dtype=float32)
>>> a.numpy('d')
array([[ 0.,  1.,  2.,  3.],
        [ 4.,  5.,  6.,  7.],
        [ 8.,  9., 10., 11.])
>>> a.numpy('B')
array([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]], dtype=uint8)

Type numpy.typecodes for a list of the possible typecodes:
Alternatively, numpy automatically calls this function (via the magic __array__() method) to convert Sage matrices to numpy arrays:

```python
sage: import numpy
sage: b = numpy.array(a); b
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11]])
```

```python
sage: b.dtype
dtype(int32) # 32-bit
dtype(int64) # 64-bit
```

```python
sage: b.shape
(3, 4)
```

```python
>>> from sage.all import *
>>>
>>> b = numpy.array(a); b
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11]])
```

```python
>>> b.dtype
dtype(int32) # 32-bit
dtype(int64) # 64-bit
```

```python
>>> b.shape
(3, 4)
```

```python
row(i, from_list=False)
```

Return the i\textsuperscript{th} row of this matrix as a vector.

This row is a dense vector if and only if the matrix is a dense matrix.

**INPUT:**

- i – integer
- from_list – bool (default: False); if true, returns the i\textsuperscript{th} element of self.rows() (see `rows()`), which may be faster, but requires building a list of all rows the first time it is called after an entry of the matrix is changed.

**EXAMPLES:**

```python
sage: a = matrix(2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: a.row(0)
(0, 1, 2)
sage: a.row(1)
(3, 4, 5)
sage: a.row(-1) # last row
(3, 4, 5)
```
>>> from sage.all import *

>>> a = matrix(Integer(2), Integer(3), range(Integer(6))); a
[0 1 2]
[3 4 5]

>>> a.row(Integer(0))
(0, 1, 2)

>>> a.row(Integer(1))
(3, 4, 5)

>>> a.row(-Integer(1))  # last row
(3, 4, 5)

row_ambient_module (base_ring=None, sparse=None)

Return the free module that contains the rows of the matrix.

EXAMPLES:

```
sage: M = matrix(Zmod(5), 2, 3)
sage: M.row_ambient_module()
Vector space of dimension 3 over Ring of integers modulo 5
sage: M.row(1).parent() == M.row_ambient_module()
True
sage: M = Matrix(ZZ, 3, 4)
sage: M.row_ambient_module()
Ambient free module of rank 4 over the principal ideal domain Integer Ring
sage: M.row_ambient_module(QQ)
Vector space of dimension 4 over Rational Field
sage: M = Matrix(QQ, 4, 5)
sage: M.row_ambient_module()
Vector space of dimension 5 over Rational Field
sage: M.row_ambient_module(ZZ)
Ambient free module of rank 5 over the principal ideal domain Integer Ring
```

>>> from sage.all import *

```
>>> M = matrix(Zmod(Integer(5)), Integer(2), Integer(3))
>>> M.row_ambient_module()
Vector space of dimension 3 over Ring of integers modulo 5
>>> M.row(Integer(1)).parent() == M.row_ambient_module()
True
>>> M = Matrix(ZZ, Integer(3), Integer(4))
>>> M.row_ambient_module()
Ambient free module of rank 4 over the principal ideal domain Integer Ring
>>> M.row_ambient_module(QQ)
Vector space of dimension 4 over Rational Field
>>> M = Matrix(QQ, Integer(4), Integer(5))
>>> M.row_ambient_module()
Vector space of dimension 5 over Rational Field
>>> M.row_ambient_module(ZZ)
Ambient free module of rank 5 over the principal ideal domain Integer Ring
```

rows (copy=True)

Return a list of the rows of self.

INPUT:
• copy – (default: True) if True, return a copy of the list of rows which is safe to change.

If self is a sparse matrix, rows are returned as sparse vectors, otherwise returned vectors are dense.

EXAMPLES:

```sage
sage: matrix(3, [1..9]).rows()
[(1, 2, 3), (4, 5, 6), (7, 8, 9)]
sage: matrix(RR, 2, [sqrt(2), pi, exp(1), 0]).rows() # needs sage.symbolic
[(1.41421356237310, 3.14159265358979), (2.71828182845905, 0.000000000000000)]
sage: matrix(RR, 0, 2, []).rows()
[]
sage: m = matrix(RR, 3, 3, {(1,2): pi, (2, 2): -1, (0,1): sqrt(2)}) # needs sage.symbolic
sage: parent(m.rows()[0]) # needs sage.symbolic
Sparse vector space of dimension 3 over Real Field with 53 bits of precision
```

Sparse matrices produce sparse rows.

```sage
sage: A = matrix(QQ, 2, range(4), sparse=True)
sage: v = A.rows()[0]
sage: v.is_sparse()
True
```

```sage
from sage.all import *

A = matrix(QQ, Integer(2), range(Integer(4)), sparse=True)
>>> v = A.rows()[Integer(0)]
>>> v.is_sparse()
True
```

```sage
set_column (col, v)
Sets the entries of column col to the entries of v.
```

**INPUT:**

• col – index of column to be set.

• v – a list or vector of the new entries.
OUTPUT:
Changes the matrix in-place, so there is no output.

EXAMPLES:
New entries may be contained in a vector:

```
sage: A = matrix(QQ, 5, range(25))
sage: u = vector(QQ, [0, -1, -2, -3, -4])
sage: A.set_column(2, u)
sage: A
[ 0 1 0 3 4]
[ 5 6 -1 8 9]
[10 11 -2 13 14]
[15 16 -3 18 19]
[20 21 -4 23 24]
```

New entries may be in any sort of list:

```
sage: A = matrix([[1, 2], [3, 4]]); A
[1 2]
[3 4]
sage: A.set_column(0, [0, 0]); A
[0 2]
[0 4]
sage: A.set_column(1, (0, 0)); A
[0 0]
[0 0]
```

```
>>> from sage.all import *

>>> A = matrix(QQ, Integer(5), range(Integer(25)))
>>> u = vector(QQ, [Integer(0), -Integer(1), -Integer(2), -Integer(3), -Integer(4)])
>>> A.set_column(Integer(2), u)

>>> A
[ 0 1 0 3 4]
[ 5 6 -1 8 9]
[10 11 -2 13 14]
[15 16 -3 18 19]
[20 21 -4 23 24]
```

```
set_row(row, v)
```
Sets the entries of row row to the entries of v.

INPUT:

- `row` – index of row to be set.
• \( v \) – a list or vector of the new entries.

OUTPUT:

Changes the matrix in-place, so there is no output.

EXAMPLES:

New entries may be contained in a vector:

```python
sage: A = matrix(QQ, 5, range(25))
sage: u = vector(QQ, [0, -1, -2, -3, -4])
sage: A.set_row(2, u)
sage: A
[ 0 1 2 3 4]
[ 5 6 7 8 9]
[ 0 -1 -2 -3 -4]
[15 16 17 18 19]
[20 21 22 23 24]
```

```python
>>> from sage.all import *

>>> A = matrix(QQ, Integer(5), range(Integer(25)))

>>> u = vector(QQ, [Integer(0), -Integer(1), -Integer(2), -Integer(3), -Integer(4)])

>>> A.set_row(Integer(2), u)

>>> A
[ 0 1 2 3 4]
[ 5 6 7 8 9]
[ 0 -1 -2 -3 -4]
[15 16 17 18 19]
[20 21 22 23 24]
```

New entries may be in any sort of list:

```python
sage: A = matrix([[1, 2], [3, 4]]); A
[[1 2]
 [3 4]

sage: A.set_row(0, [0, 0]); A
[0 0]
[3 4]

sage: A.set_row(1, (0, 0)); A
[0 0]
[0 0]
```

```python
>>> from sage.all import *

>>> A = matrix([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]);

>>> A.set_row(Integer(0), [Integer(0), Integer(0)]); A

>>> A.set_row(Integer(1), (Integer(0), Integer(0))); A
```

```

\textbf{sparse_columns} (\texttt{copy=True})

Return a list of the columns of self as sparse vectors (or free module elements).

INPUT:
• copy – (default: True) if True, return a copy so you can modify it safely

EXAMPLES:

```sage
sage: a = matrix(2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: v = a.sparse_columns(); v
[(0, 3), (1, 4), (2, 5)]
sage: v[1].is_sparse()
True
```

```python
>>> from sage.all import *
>>> a = matrix(Integer(2), Integer(3), range(Integer(6))); a
[0 1 2]
[3 4 5]
>>> v = a.sparse_columns(); v
[(0, 3), (1, 4), (2, 5)]
>>> v[Integer(1)].is_sparse()
True
```

**sparse_matrix()**

If this matrix is dense, return a sparse matrix with the same entries. If this matrix is sparse, return this matrix (not a copy).

**Note:** The definition of “dense” and “sparse” in Sage have nothing to do with the number of nonzero entries. Sparse and dense are properties of the underlying representation of the matrix.

EXAMPLES:

```sage
sage: A = MatrixSpace(QQ,2, sparse=False)([[1,2,0,1]])
sage: A.is_sparse()
False
sage: B = A.sparse_matrix()
sage: B.is_sparse()
True
sage: A == B
True
sage: B.sparse_matrix() is B
True
sage: A*B
[1 4]
[0 1]
sage: A.parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: B.parent()
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
sage: (A*B).parent()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: (B*A).parent()
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field
```

```python
>>> from sage.all import *
>>> A = MatrixSpace(QQ,Integer(2), sparse=False)([[Integer(1),Integer(2),
˓→Integer(0),Integer(1)])
```

(continues on next page)
A.is_sparse()  
False  

B = A.sparse_matrix()  
B.is_sparse()  
True  

A == B  
True  

B.sparse_matrix() is B  
True  

A*B  
[[1 4]  
[0 1]]  

A.parent()  
Full MatrixSpace of 2 by 2 dense matrices over Rational Field  

B.parent()  
Full MatrixSpace of 2 by 2 sparse matrices over Rational Field  

(A*B).parent()  
Full MatrixSpace of 2 by 2 dense matrices over Rational Field  

(B*A).parent()  
Full MatrixSpace of 2 by 2 dense matrices over Rational Field  

**sparse_rows** *(copy=True)*  
Return a list of the rows of self as sparse vectors (or free module elements).  

**INPUT:**  
- **copy** – (default: **True**) if True, return a copy so you can modify it safely  

**EXAMPLES:**  

```python  
sage: m = Mat(ZZ, 3, 3, sparse=True)(range(9)); m  
[[0 1 2]  
[3 4 5]  
[6 7 8]]  
sage: v = m.sparse_rows(); v  
[[0, 1, 2], [3, 4, 5], [6, 7, 8]]  
sage: m.sparse_rows(copy=False) is m.sparse_rows(copy=False)  
True  
sage: v[1].is_sparse()  
True  
sage: m[0,0] = 10  
sage: m.sparse_rows()  
[(10, 1, 2), (3, 4, 5), (6, 7, 8)]  
```  

```python  
>>> from sage.all import *  
```  

```python  
sage: m = Mat(ZZ, Integer(3), Integer(3), sparse=True)(range(Integer(9))); m  
[[0 1 2]  
[3 4 5]  
[6 7 8]]  
sage: v = m.sparse_rows(); v  
[[0, 1, 2], [3, 4, 5], [6, 7, 8]]  
sage: m.sparse_rows(copy=False) is m.sparse_rows(copy=False)  
True  
sage: v[Integer(1)].is_sparse()  
True  
sage: m[Integer(0),Integer(0)] = Integer(10)  
```
stack \((\text{bottom, } \text{subdivide}=\text{False})\)

Return a new matrix formed by appending the matrix (or vector) \(\text{bottom}\) below \(\text{self}\):

\[
\begin{bmatrix}
\text{self} \\
\text{bottom}
\end{bmatrix}
\]

INPUT:

- \(\text{bottom}\) – a matrix, vector or free module element, whose dimensions are compatible with \(\text{self}\).
- \(\text{subdivide}\) – (default: \(\text{False}\)); request the resulting matrix to have a new subdivision, separating \(\text{self}\) from \(\text{bottom}\).

OUTPUT:

A new matrix formed by appending \(\text{bottom}\) beneath \(\text{self}\). If \(\text{bottom}\) is a vector (or free module element) then in this context it is appropriate to consider it as a row vector. (The code first converts a vector to a 1-row matrix.)

If \(\text{subdivide}\) is \(\text{True}\) then any row subdivisions for the two matrices are preserved, and a new subdivision is added between \(\text{self}\) and \(\text{bottom}\). If the column divisions are identical, then they are preserved, otherwise they are discarded. When \(\text{subdivide}\) is \(\text{False}\) there is no subdivision information in the result.

**Warning:** If \(\text{subdivide}\) is \(\text{True}\) then unequal column subdivisions will be discarded, since it would be ambiguous how to interpret them. If the subdivision behavior is not what you need, you can manage subdivisions yourself with methods like \(\text{subdivisions()}\) and \(\text{subdivide()}\). You might also find \(\text{block_matrix()}\) or \(\text{block_diagonal_matrix()}\) useful and simpler in some instances.

**EXAMPLES:**

Stacking with a matrix.

\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 8
\end{bmatrix}
\]

\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 8
\end{bmatrix}
\]

\[
\begin{bmatrix}
9 & 10 & 11 \\
0 & 1 & 2 \\
3 & 4 & 5
\end{bmatrix}
\]

\[
\begin{bmatrix}
6 & 7 & 8
\end{bmatrix}
\]

\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 8
\end{bmatrix}
\]

\[
\begin{bmatrix}
9 & 10 & 11 \\
0 & 1 & 2
\end{bmatrix}
\]

\[
\begin{bmatrix}
6 & 7 & 8
\end{bmatrix}
\]
Stacking with a vector.

```python
sage: A = matrix(QQ, 3, 2, [0, 2, 4, 6, 8, 10])
sage: v = vector(QQ, 2, [100, 200])
sage: A.stack(v)
```

```
[ 0  2]
[ 4  6]
[ 8 10]
[100 200]
```

Errors are raised if the sizes are incompatible.

```python
sage: A = matrix(RR, [[1, 2],[3, 4]])
sage: B = matrix(RR, [[10, 20, 30], [40, 50, 60]])
sage: A.stack(B)
Traceback (most recent call last):
... 
TypeError: number of columns must be the same, not 2 and 3
```

```python
sage: v = vector(RR, [100, 200, 300])
sage: A.stack(v)
Traceback (most recent call last):
... 
TypeError: number of columns must be the same, not 2 and 3
```

```python
>>> from sage.all import *

>>> A = matrix(RR, [[Integer(1), Integer(2)], [Integer(3), Integer(4)]])
>>> B = matrix(RR, [[Integer(10), Integer(20), Integer(30)], [Integer(40), Integer(50), Integer(60)]])
>>> A.stack(B)
Traceback (most recent call last):
... 
TypeError: number of columns must be the same, not 2 and 3
```

```python
>>> v = vector(RR, [Integer(100), Integer(200), Integer(300)])
>>> A.stack(v)
Traceback (most recent call last):
... 
TypeError: number of columns must be the same, not 2 and 3
```

Setting `subdivide` to `True` will, in its simplest form, add a subdivision between `self` and `bottom`. 

240 Chapter 7. Base class for matrices, part 1
Row subdivisions are preserved by stacking, and enriched, if subdivisions are requested. (So multiple stackings can be recorded.)

Column subdivisions can be preserved, but only if they are identical. Otherwise, this information is discarded and must be managed separately.
```
sage: A = matrix(QQ, 2, 5, range(10))
sage: A.subdivide(None, [2,4])
sage: B = matrix(QQ, 3, 5, range(15))
sage: B.subdivide(None, [2,4])
sage: A.stack(B, subdivide=True)
[ 0 1 2 3 4]
[ 5 6 7 8 9]
[-----+-----+--]
[ 0 1 2 3 4]
[ 5 6 7 8 9]
[10 11 12 13 14]
sage: A.subdivide(None, [1,2])
sage: A.stack(B, subdivide=True)
[ 0 1 2 3 4]
[ 5 6 7 8 9]
[------------]
[ 0 1 2 3 4]
[ 5 6 7 8 9]
[10 11 12 13 14]
```
Matrices and Spaces of Matrices, Release 10.4

[ 1.00000000000000  2.00000000000000]
sage: D.parent()
Full MatrixSpace of 2 by 2 dense matrices
over Real Field with 53 bits of precision

```python
>>> from sage.all import *

>>> A = matrix(QQ, Integer(1), Integer(2), [Integer(1), Integer(2)])
>>> B = matrix(RR, Integer(1), Integer(2), [sin(RealNumber(1.1)), sin(RealNumber(2.2))])
>>> C = A.stack(B); C

[ 1.00000000000000  2.00000000000000]
[0.891207360061435  0.808496403819590]
```

```python
>>> D = B.stack(A); D

[0.891207360061435  0.808496403819590]
[ 1.00000000000000  2.00000000000000]
```

```python
sage: R.<y> = PolynomialRing(ZZ)
sage: A = matrix(QQ, 1, 2, [1, 2/3])
sage: B = matrix(R, 1, 2, [y, y^2])
```

```python
sage: C = A.stack(B); C

[ 1 2/3]
[y y^2]
```

```python
sage: C.parent()
Full MatrixSpace of 2 by 2 dense matrices
over Univariate Polynomial Ring in y over Rational Field
```

```python
>>> from sage.all import *
>>> R = PolynomialRing(ZZ, names=('y',)); (y,) = R._first_ngens(1)
>>> A = matrix(QQ, Integer(1), Integer(2), [Integer(1), Integer(2)/Integer(3)])
>>> B = matrix(R, Integer(1), Integer(2), [y, y**Integer(2)])
```

```python
>>> C = A.stack(B); C

[ 1 2/3]
[y y^2]
```

```python
>>> C.parent()
Full MatrixSpace of 2 by 2 dense matrices
over Univariate Polynomial Ring in y over Rational Field
```

Stacking a dense matrix atop a sparse one returns a sparse matrix:

```python
sage: M = Matrix(ZZ, 2, 3, range(6), sparse=False)
sage: N = diagonal_matrix([10, 11, 12], sparse=True)
sage: P = M.stack(N); P

[ 0 1 2]
[ 3 4 5]
[10 0 0]
[ 0 11 0]
```

(continues on next page)
One can stack matrices over different rings (Issue #16399).

```python
sage: M = Matrix(ZZ, 2, 3, range(6))
sage: N = Matrix(QQ, 1, 3, [10, 11, 12])
sage: M.stack(N)
[ 0 1 2]
[ 3 4 5]
[10 11 12]
sage: N.stack(M)
[10 11 12]
[ 0 1 2]
[ 3 4 5]
```

```python
>>> from sage.all import *

>>> M = Matrix(ZZ, Integer(2), Integer(3), range(Integer(6)), sparse=False)
>>> N = diagonal_matrix([Integer(10), Integer(11), Integer(12)], sparse=True)
>>> P = M.stack(N); P
[10 0 0]
[ 0 11 0]
[ 0 0 12]
[ 0 1 2]
[ 3 4 5]
>>> P.is_sparse()
True
```
AUTHORS:

- Rob Beezer (2011-03-19): rewritten to mirror code for `augment()`
- Jeroen Demeyer (2015-01-06): refactor, see Issue #16399. Put all boilerplate in one place (here) and put the actual type-dependent implementation in `_stack_impl`.

**submatrix**(row=0, col=0, nrows=-1, ncols=-1)

Return the matrix constructed from self using the specified range of rows and columns.

**INPUT:**

- row, col – index of the starting row and column. Indices start at zero.
- nrows, ncols – (optional) number of rows and columns to take. If not provided, take all rows below and all columns to the right of the starting entry.

**See also:**

The functions `matrix_from_rows()`, `matrix_from_columns()`, and `matrix_from_rows_and_columns()` allow one to select arbitrary subsets of rows and/or columns.

**EXAMPLES:**

Take the 3 × 3 submatrix starting from entry (1,1) in a 4 × 4 matrix:

```
sage: m = matrix(4, [1..16])
sage: m.submatrix(1, 1)
[ 6  7  8]
[10 11 12]
[14 15 16]
```

```
>>> from sage.all import *
>>> m = matrix(Integer(4), (ellipsis_range(Integer(1),Ellipsis,Integer(16))))
>>> m.submatrix(Integer(1), Integer(1))
[ 6  7  8]
[10 11 12]
[14 15 16]
```

Same thing, except take only two rows:

```
sage: m.submatrix(1, 1, 2)
[ 6  7  8]
[10 11 12]
```

```
>>> from sage.all import *
>>> m.submatrix(Integer(1), Integer(1), Integer(2))
[ 6  7  8]
[10 11 12]
```

And now take only one column:

```
sage: m.submatrix(1, 1, 2, 1)
[ 6]
[10]
```
```python
>>> from sage.all import *
>>> m.submatrix(Integer(1), Integer(1), Integer(2), Integer(1))
[ 6]
[10]
```

You can take zero rows or columns if you want:

```python
sage: m.submatrix(1, 1, 0)
[]
sage: parent(m.submatrix(1, 1, 0))
Full MatrixSpace of 0 by 3 dense matrices over Integer Ring
```

```python
>>> from sage.all import *
>>> m.submatrix(Integer(1), Integer(1), Integer(0))
[]
>>> parent(m.submatrix(Integer(1), Integer(1), Integer(0)))
Full MatrixSpace of 0 by 3 dense matrices over Integer Ring
```

**zero_pattern_matrix** *(ring=\text{None})*

Return a matrix that contains one for corresponding zero entries.

All other entries are zero.

**INPUT:**

- `ring` - (optional); base ring of the output; default is \text{ZZ}

**OUTPUT:**

A new dense matrix with same dimensions as \text{self} and with base ring \text{ring}.

**EXAMPLES:**

```python
sage: M = Matrix(ZZ, 2, [1,2,-2,0])
sage: M.zero_pattern_matrix()
[0 0]
[0 1]
sage: M = Matrix(QQ, 2, [1,2/3,-2,0])
sage: M.zero_pattern_matrix()
[0 0]
[0 1]
```

```python
>>> from sage.all import *
>>> M = Matrix(ZZ, Integer(2), [Integer(1),Integer(2),-Integer(2),Integer(0)])
>>> M.zero_pattern_matrix()
[0 0]
[0 1]
```

```python
>>> M = Matrix(QQ, Integer(2), [Integer(1),Integer(2)/Integer(3),-Integer(2),-Integer(0)])
>>> M.zero_pattern_matrix()
[0 0]
[0 1]
```

Default base ring for the output is \text{ZZ}:

```python
sage: M.zero_pattern_matrix().base_ring()
Integer Ring
```
Specify a different base ring for the output:

```
sage: M.zero_pattern_matrix(GF(2)).base_ring()
Finite Field of size 2
```

Examples for different base rings for `self`:

```
sage: M = Matrix(Zmod(8), 3, 2, [2, 3, 9, 8, 1, 0]); M
[2 3]
[1 0]
[1 0]
sage: M.zero_pattern_matrix()
[0 0]
[0 1]
[0 1]
```

```
sage: W.<a> = CyclotomicField(100) # needs sage.rings.number_field
sage: M = Matrix(Zmod(Integer(8)), 2, 3, [a, a/2, 0, a^2, a^[100]-1, a^[2] - a]); M # needs sage.rings.number_field
[ a 1/2*a 0]
[ a^2 0 a^[2] - a]
sage: M.zero_pattern_matrix() # needs sage.rings.number_field
[0 0 1]
[0 1 0]
```

(continues on next page)
sage: # needs sage.rings.finite_rings
sage: K.<a> = GF(2^4)
sage: l = [a^2 + 1, a^3 + 1, 0, 0, a, a^3 + a + 1, a + 1, ...
.....: a + 1, a^2, a^3 + a + 1, a^3 + a, a^3 + a]
sage: M = Matrix(K, 3, 4, l); M
[ a^2 + 1 a^3 + 1 0 0]
[ a a^3 + a + 1 a + 1 a + 1]
[ a^2 a^3 + a + 1 a^3 + a a^3 + a]
sage: M.zero_pattern_matrix()
[0 0 1 1]
[0 0 0 0]
[0 0 0 0]

>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> K = GF(Integer(2)**Integer(4), names=('a',)); (a,) = K._first_ngens(1)
>>> l = [a**Integer(2) + Integer(1), a**Integer(3) + Integer(1), Integer(0),...
.....: a**Integer(3) + a + Integer(1), a + Integer(1),...
.....: a + Integer(1), a**Integer(2), a**Integer(3) + a + Integer(1),...
.....: a**Integer(3) + a, a**Integer(3) + a]
>>> M = Matrix(K, Integer(3), Integer(4), l); M
[ a^2 + 1 a^3 + 1 0 0]
[ a a^3 + a + 1 a + 1 a + 1]
[ a^2 a^3 + a + 1 a^3 + a a^3 + a]
>>> M.zero_pattern_matrix()
[0 0 1 1]
[0 0 0 0]
[0 0 0 0]

sage: # needs sage.rings.finite_rings
sage: K.<a> = GF(25)
sage: M = Matrix(K, 2, 3, [0, 2, 3, 5, a, a^2])
sage: M
[ 0 2 3]
[ 0 a a + 3]
sage: M.zero_pattern_matrix()
[1 0 0]
[1 0 0]
Note: This method can be optimized by improving `get_is_zero_unsafe()` for derived matrix classes.
BASE CLASS FOR MATRICES, PART 2

For design documentation see matrix/docs.py.

AUTHORS:

• William Stein: initial version

• Jaap Spies (2006-02-24): added prod_of_row_sums, permanent, permanental_minor, rook_vector methods

• Robert Bradshaw (2007-06-14): added subdivide method

• Jaap Spies (2007-11-14): implemented _binomial, _choose auxiliary functions

• David Loeffler (2008-12-05): added smith_form method

• David Loeffler (2009-06-01): added _echelon_form_PID method

• Sebastian Pancratz (2009-06-25): implemented adjoint and charpoly methods; fixed adjoint reflecting the change that _adjoint is now implemented in Matrix; used the division-free algorithm for charpoly

• Rob Beezer (2009-07-13): added elementwise_product method

• Miguel Marco (2010-06-19): modified eigenvalues and eigenvectors functions to allow the option extend=False

• Thierry Monteil (2010-10-05): bugfix for Issue #10063, so that the determinant is computed even for rings for which the is_field method is not implemented.

• Rob Beezer (2010-12-13): added conjugate_transpose method

• Rob Beezer (2011-02-05): refactored all of the matrix kernel routines; added extended_echelon_form, right_kernel_matrix, QR, _gram_schmidt_noscale, is_similar methods

• Moritz Minzlaff (2011-03-17): corrected _echelon_form_PID method for matrices of one row, fixed in Issue #9053

• Rob Beezer (2011-06-09): added is_normal, is_diagonalizable, LU, cyclic_subspace, zigzag_form, rational_form methods

• Rob Beezer (2012-05-27): added indefinite_factorization, is_positive_definite, cholesky methods

• Darij Grinberg (2013-10-01): added first (slow) pfaffian implementation

• Mario Pernici (2014-07-01): modified rook_vector method

• Rob Beezer (2015-05-25): modified is_similar method
Matrices and Spaces of Matrices, Release 10.4

- Samuel Lelièvre (2020-09-18): improved method `LLL_gram` based on a patch by William Stein posted at Issue #5178, moving the method from its initial location in `sage.matrix.integer_matrix_dense`
- Moritz Firsching (2020-10-05): added `quantum_determinant`
- Dima Pasechnik (2022-11-08): fixed `echelonize` for inexact matrices

class sage.matrix.matrix2.Matrix

Bases: Matrix

Base class for matrices, part 2

C

Returns the conjugate matrix.

EXAMPLES:

```python
sage: A = matrix(QQbar, [[ -3, 5 - 3*I, 7 - 4*I],
    # needs sage.rings.number_field
    ....: [7 + 3*I, -1 + 6*I, 3 + 5*I],
    ....: [3 + 3*I, -3 + 6*I, 5 + I]])

sage: A.C
    # needs sage.rings.number_field
[ -3 7 + 3*I 3 + 3*I]
[ 5 - 3*I -1 - 6*I 3 - 5*I]
[ 3 - 3*I -3 - 6*I 5 - 1*I]
```

H

Returns the conjugate-transpose (Hermitian) matrix.

EXAMPLES:

```python
sage: A = matrix(QQbar, [[ -Integer(3), Integer(5) - Integer(3)*I],
    # needs sage.rings.number_field
    ...: [Integer(7) - Integer(4)*I],
    ...: [Integer(7) + Integer(3)*I, -Integer(1) + Integer(6)*I, Integer(3) + Integer(5)*I],
    ...: [Integer(3) + Integer(3)*I, -Integer(3) + Integer(6)*I, Integer(5) + I]])

>>> from sage.all import *

>>> A.C
    # needs sage.rings.number_field
[ -3 7 + 3*I 3 + 3*I]
[ 5 - 3*I -1 - 6*I 3 - 5*I]
[ 3 - 3*I -3 - 6*I 5 - 1*I]
```
LLL\_gram (flag=0)

Return the LLL transformation matrix for this Gram matrix.

That is, the transformation matrix $U$ over \ZZ of determinant 1 that transforms the lattice with this matrix as Gram matrix to a lattice that is LLL-reduced.

Always works when \texttt{self} is positive definite, might work in some semidefinite and indefinite cases.

INPUT:

- \texttt{self} – the Gram matrix of a quadratic form or of a lattice equipped with a bilinear form

- \texttt{flag} – an optional flag passed to \texttt{qflllgram}. According to \texttt{pari:qflllgram}'s documentation the options are:
  - 0 – (default), assume that \texttt{self} has either exact (integral or rational) or real floating point entries. The matrix is rescaled, converted to integers and the behavior is then as in flag=1.
  - 1 – assume that G is integral. Computations involving Gram-Schmidt vectors are approximate, with precision varying as needed.

OUTPUT:

A dense matrix $U$ over the integers with determinant 1 such that $U^T \cdot M \cdot U$ is LLL-reduced.

ALGORITHM:

Calls PARI's \texttt{pari:qflllgram}.

EXAMPLES:

Create a Gram matrix and LLL-reduce it:
For a Gram matrix over RR with a length one first vector and a very short second vector, the LLL-reduced basis is obtained by swapping the two basis vectors (and changing sign to preserve orientation).

```
sage: M = Matrix(RDF, 2, 2, [1, 0, 0, 1e-5])
sage: M.LLL_gram()
needs sage.libs.pari
[ 0 -1]
[ 1 0]
```

The algorithm might work for some semidefinite and indefinite forms:

```
sage: M = Matrix(ZZ, 2, 2, [2, 6, 6, 3]).LLL_gram()
needs sage.libs.pari
[-3 -1]
[ 1 0]
sage: M = Matrix(ZZ, 2, 2, [1, 0, 0, -1]).LLL_gram()
needs sage.libs.pari
[ 0 -1]
[ 1 0]
```

However, it might fail for others, either raising a `ValueError`:

```
sage: M = Matrix(ZZ, 1, 1, [0]).LLL_gram()
needs sage.libs.pari
Traceback (most recent call last):
...
```
ValueError: qflllgram did not return a square matrix, perhaps the matrix is not positive definite

```
sage: Matrix(ZZ, 2, 2, [0, 1, 1, 0]).LLL_gram()  # needs sage.libs.pari
Traceback (most recent call last):
...
ValueError: qflllgram did not return a square matrix, perhaps the matrix is not positive definite
```

```
>>> from sage.all import *

>>> Matrix(ZZ, Integer(1), Integer(1), [Integer(0)]).LLL_gram()  
# needs sage.libs.pari
Traceback (most recent call last):
...
ValueError: qflllgram did not return a square matrix, perhaps the matrix is not positive definite
```

or running forever:

```
sage: Matrix(ZZ, 2, 2, [-5, -1, -1, -5]).LLL_gram()  # not tested, needs sage.libs.pari
Traceback (most recent call last):
...
RuntimeError: infinite loop while calling qflllgram
```

```
>>> from sage.all import *

>>> Matrix(ZZ, Integer(2), Integer(2), [Integer(0), Integer(1), Integer(1), 
-Integer(0)]).LLL_gram()  # needs sage.libs.pari
Traceback (most recent call last):
...
ValueError: qflllgram did not return a square matrix, perhaps the matrix is not positive definite
```

Nonreal input leads to a value error:

```
sage: Matrix(2, 2, [CDF(1, 1), 0, 0, 1]).LLL_gram()  # needs sage.libs.pari
Traceback (most recent call last):
...
ValueError: qflllgram failed, perhaps the matrix is not positive definite
```

```
>>> from sage.all import *

>>> Matrix(Integer(2), Integer(2), [CDF(Integer(1), Integer(1)), Integer(0), Integer(0), Integer(1)]).LLL_gram()  # needs sage.libs.pari
Traceback (most recent call last):
...
ValueError: qflllgram failed, perhaps the matrix is not positive definite
```
**LU** *(pivot=None, format='plu')*

Finds a decomposition into a lower-triangular matrix and an upper-triangular matrix.

**INPUT:**

- **pivot** – pivoting strategy
  - 'auto' (default) – see if the matrix entries are ordered (i.e. if they have an absolute value method), and if so, use a partial pivoting strategy. Otherwise, fall back to the nonzero strategy. This is the best choice for general routines that may call this function for matrix entries of a variety of types.
  - 'partial' – each column is examined for the element with the largest absolute value and the row containing this element is swapped into place.
  - 'nonzero' – the first nonzero element in a column is located and the row with this element is used.

- **format** – contents of output, see more discussion below about output.
  - 'plu' (default) – a triple; matrices P, L and U such that \( A = P \cdot L \cdot U \).
  - 'compact' – a pair; row permutation as a tuple, and the matrices L and U combined into one matrix.

**OUTPUT:**

Suppose that \( A \) is an \( m \times n \) matrix, then an LU decomposition is a lower-triangular \( m \times m \) matrix \( L \) with every diagonal element equal to 1, and an upper-triangular \( m \times n \) matrix, \( U \) such that the product \( LU \), after a permutation of the rows, is then equal to \( A \). For the 'plu' format the permutation is returned as an \( m \times m \) permutation matrix \( P \) such that

\[
A = P \cdot LU
\]

It is more common to place the permutation matrix just to the left of \( A \). If you desire this version, then use the inverse of \( P \) which is computed most efficiently as its transpose.

If the 'partial' pivoting strategy is used, then the non-diagonal entries of \( L \) will be less than or equal to 1 in absolute value. The 'nonzero' pivot strategy may be faster, but the growth of data structures for elements of the decomposition might counteract the advantage.

By necessity, returned matrices have a base ring equal to the fraction field of the base ring of the original matrix.

In the 'compact' format, the first returned value is a tuple that is a permutation of the rows of \( LU \) that yields \( A \). See the doctest for how you might employ this permutation. Then the matrices \( L \) and \( U \) are merged into one matrix – remove the diagonal of ones in \( L \) and the remaining nonzero entries can replace the entries of \( U \) beneath the diagonal.

The results are cached, only in the compact format, separately for each pivot strategy called. Repeated requests for the 'plu' format will require just a small amount of overhead in each call to bust out the compact format to the three matrices. Since only the compact format is cached, the components of the compact format are immutable, while the components of the 'plu' format are regenerated, and hence are mutable.

Notice that while \( U \) is similar to row-echelon form and the rows of \( U \) span the row space of \( A \), the rows of \( U \) are not generally linearly independent. Nor are the pivot columns (or rank) immediately obvious. However for rings without specialized echelon form routines, this method is about twice as fast as the generic echelon form routine since it only acts “below the diagonal”, as would be predicted from a theoretical analysis of the algorithms.

**Note:** This is an exact computation, so limited to exact rings. If you need numerical results, convert the base ring to the field of real double numbers, \( \text{RDF} \) or the field of complex double numbers, \( \text{CDF} \), which will use a faster routine that is careful about numerical subtleties.
ALGORITHM:

EXAMPLES:

Notice the difference in the $L$ matrix as a result of different pivoting strategies. With partial pivoting, every entry of $L$ has absolute value 1 or less.

```
sage: A = matrix(QQ, [[1, -1, 0, 2, 4, 7, -1],
                  ....: [2, -1, 0, 6, 4, 8, -2],
                  ....: [2, 0, 1, 4, 2, 6, 0],
                  ....: [1, 0, -1, 8, -1, -1, -3],
                  ....: [1, 1, 2, -2, -1, 1, 3]])
sage: P, L, U = A.LU(pivot='partial')
sage: P
[0 0 0 0 1]
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 1 0 0]
[0 1 0 0 0]
sage: L
[ 1 0 0 0 0]
[ 1/2 1 0 0 0]
[ 1/2 1/3 1 0 0]
[ 1 2/3 1/5 1 0]
[ 1/2 -1/3 -2/5 0 1]
sage: U
[ 2 -1 0 6 4 8 -2]
[ 0 3/2 2 -5 -3 -3 4]
[ 0 0 -5/3 20/3 -2 -4 -10/3]
[ 0 0 0 0 2/5 4/5 0]
[ 0 0 0 0 1/5 2/5 0]
sage: A == P*L*U
True
sage: P, L, U = A.LU(pivot='nonzero')
sage: P
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]

[ 0 0 0 0 -1 -2 0]
sage: A == P*L*U
True
```

```python
>>> from sage.all import *
>>> A = matrix(QQ, [[Integer(1), -Integer(1), Integer(0), Integer(2), ...
```
An example of the compact format.

```python
sage: B = matrix(QQ, [[1, 3, 5, 5],
               ...: [1, 4, 7, 8],
               ...: [-1, -4, -6, -6],
               ...: [-1, -4, -6, -6])
```

(continues on next page)
We can easily illustrate the relationships between the two formats with a square matrix.

```python
sage: C = matrix(QQ, [[Integer(-2), Integer(3), -Integer(2), -Integer(5)],
                    [ 1,  -2,  1,   3],
                    [-4,   7, -3,  -8],
                    [-3,   8, -1,  -5]])
```

```python
sage: P, L, U = C.LU(format='plu')
sage: perm, M = C.LU(format='compact')
```

```python
>>> from sage.all import *
```

```python
>>> P, L, U = C.LU(format='plu')
```

```python
>>> p = [perm[i]+1 for i in range(len(perm))]
```

```python
>>> P == Permutation(p).to_matrix()
```

```python
True
```
For a nonsingular matrix, and the 'nonzero' pivot strategy there is no need to permute rows, so the permutation matrix will be the identity. Furthermore, it can be shown that then the $L$ and $U$ matrices are uniquely determined by requiring $L$ to have ones on the diagonal.

```
sage: D = matrix(QQ, [[ 1, 0, 2, 0, -2, -1],
                   ....: [ 3, -2, 3, -1, 0, 6],
                   ....: [-4, 2, -3, 1, -1, -8],
                   ....: [-2, 2, -3, 2, 1, 0],
                   ....: [ 0, -1, -1, 0, 2, 5],
                   ....: [-1, 2, -4, -1, 5, -3])

True

The base ring of the matrix may be any field, or a ring which has a fraction field implemented in Sage. The ring needs to be exact (there is a numerical LU decomposition for matrices over `RDF` and `CDF`). Matrices returned are over the original field, or the fraction field of the ring. If the field is not ordered (i.e. the absolute value function is not implemented), then the pivot strategy needs to be ‘nonzero’.

(continues on next page)
With no pivoting strategy given (i.e. `pivot=None`) the routine will try to use partial pivoting, but then fall back to the nonzero strategy. For the nonsingular matrix below, we see evidence of pivoting when viewed over the rationals, and no pivoting over the integers mod 29.

```
sage: entries = [3, 20, 11, 7, 16, 28, 5, 15, 21, 23, 22, 18, 8, 23, 15, 2]
sage: A = matrix(Integers(29), 4, 4, entries)
sage: perm, _ = A.LU(format='compact'); perm
```

(continues on next page)
(0, 1, 2, 3)

sage: B = matrix(QQ, 4, 4, entries)
sage: perm, _ = B.LU(format='compact'); perm
(2, 0, 1, 3)

>>> from sage.all import *

entries = [Integer(3), Integer(20), Integer(11), Integer(7), Integer(16),
            Integer(28), Integer(5), Integer(15), Integer(21), Integer(23), Integer(22),
            Integer(18), Integer(8), Integer(23), Integer(15), Integer(2)]

>>> A = matrix(Integer(29), Integer(4), Integer(4), entries)

>>> perm, _ = A.LU(format='compact'); perm
(0, 1, 2, 3)

>>> B = matrix(QQ, Integer(4), Integer(4), entries)

>>> perm, _ = B.LU(format='compact'); perm
(2, 0, 1, 3)

The $U$ matrix is only guaranteed to be upper-triangular. The rows are not necessarily linearly independent, nor are the pivots columns or rank in evidence.

sage: A = matrix(QQ, [[ 1, -4, 1, 0, -2, 1, 3, 3, 2],

QR (full=True)

Returns a factorization of self as a unitary matrix and an upper-triangular matrix.

INPUT:

• full – (default: True); if True then the returned matrices have dimensions as described below. If False the R matrix has no zero rows and the columns of Q are a basis for the column space of self.

OUTPUT:

If self is an m x n matrix and full=True then this method returns a pair of matrices: Q is an m x m unitary matrix (meaning its inverse is its conjugate-transpose) and R is an m x n upper-triangular matrix with non-negative entries on the diagonal. For a matrix of full rank this factorization is unique (due to the restriction to positive entries on the diagonal).

If full=False then Q has m rows and the columns form an orthonormal basis for the column space of self. So, in particular, the conjugate-transpose of Q times Q will be an identity matrix. The matrix R will still be upper-triangular but will also have full rank, in particular it will lack the zero rows present in a full factorization of a rank-deficient matrix.

The results obtained when full=True are cached, hence Q and R are immutable matrices in this case.

ALGORITHM:

“Modified Gram-Schmidt,” Algorithm 8.1 of [TB1997].

EXAMPLES:

For a nonsingular matrix, the QR decomposition is unique.

```
sage: A = matrix(QQbar, [[-2, 0, -4, -1, -1],
...:   [-2, 1, -6, -3, -1],
...:   [1, 1, 7, 4, 5],
...:   [3, 0, 8, 3, 3],
...:   [-1, 1, -6, -6, 5]])

(continues on next page)
Trivial cases return trivial results of the correct size, and we check $Q$ itself in one case.

 sage: # needs sage.rings.number_field  
 sage: A = zero_matrix(QQbar, 0, 10)  
 sage: Q, R = A.QR()  
 sage: Q.nrows(), Q.ncols()  
 (0, 0)  
 sage: R.nrows(), R.ncols()  
 (0, 10)  
 sage: A = zero_matrix(QQbar, 3, 0)  
 sage: Q, R = A.QR()  
 sage: Q.nrows(), Q.ncols()  
 (3, 3)  
 sage: R.nrows(), R.ncols()  
 (3, 0)  
 sage: Q
 [1 0 0]
 [0 1 0]
 [0 0 1]

 $T$  
 Returns the transpose of a matrix.  

 EXAMPLES:
```
sage: A = matrix(QQ, 5, range(25))
sage: A.T
[ 0 5 10 15 20]
[ 1 6 11 16 21]
[ 2 7 12 17 22]
[ 3 8 13 18 23]
[ 4 9 14 19 24]
```

adjoint(*args, **kwds)

Deprecated: Use `adjugate()` instead. See Issue #10501 for details.

adjoint_classical()

Return the adjugate matrix of `self` (that is, the transpose of the matrix of cofactors).

Let $M$ be an $n \times n$-matrix. The adjugate matrix of $M$ is the $n \times n$-matrix $N$ whose $(i,j)$-th entry is $(-1)^{i+j} \det(M_{j,i})$, where $M_{j,i}$ is the matrix $M$ with its $j$-th row and $i$-th column removed. It is known to satisfy $NM = MN = \det(M)I$.

EXAMPLES:

```
sage: M = Matrix(ZZ, 2, 2, [5,2,3,4]); M
[ 5  2]
[ 3  4]
sage: N = M.adjugate(); N
[ 4 -2]
[-3  5]
sage: M * N
[14  0]
[ 0 14]
sage: N * M
[14  0]
[ 0 14]
sage: M = Matrix(QQ, 2, 2, [5/3,2/56, 33/13,41/10]); M
[ 5/3 1/28]
[33/13 41/10]
sage: N = M.adjugate(); N
[ 41/10 -1/28]
[-33/13 5/3]
sage: M * N
[7363/1092 0]
[ 0 7363/1092]
```

```
An alias is `adjoint_classical()`, which replaces the deprecated `adjoint()` method:

```
sage: M.adjoint()

# needs sage.libs.pari
...
: DeprecationWarning: adjoint is deprecated. Please use adjugate instead.
See https://github.com/sagemath/sage/issues/10501 for details.
[ 41/10 -1/28]
[-33/13 5/3]
sage: M.adjoint_classical()

# needs sage.libs.pari
[ 41/10 -1/28]
[-33/13 5/3]
```

**ALGORITHM:**

Use PARI whenever the method `self._adjugate` is included to do so in an inheriting class. Otherwise, use a generic division-free algorithm that computes the adjugate matrix from the characteristic polynomial.

The result is cached.

`adjugate()`

Return the adjugate matrix of `self` (that is, the transpose of the matrix of cofactors).
Let $M$ be an $n \times n$-matrix. The adjugate matrix of $M$ is the $n \times n$-matrix $N$ whose $(i, j)$-th entry is $(-1)^{i+j} \det(M_{ji})$, where $M_{ji}$ is the matrix $M$ with its $j$-th row and $i$-th column removed. It is known to satisfy $NM = MN = \det(M)I$.

EXAMPLES:

```python
sage: M = Matrix(ZZ,2,2,[5,2,3,4]); M
[5 2]
[3 4]
sage: N = M.adjugate(); N
[ 4 -2]
[-3 5]
sage: M * N
[14 0]
[0 14]
sage: N * M
[14 0]
[0 14]
sage: M = Matrix(QQ, 2, 2, [5/3,2/56, 33/13,41/10]); M
[ 5/3 1/28]
[33/13 41/10]
sage: N = M.adjugate(); N
# needs sage.libs.pari
[41/10 -1/28]
[-33/13 5/3]
sage: M * N
# needs sage.libs.pari
[7363/1092 0]
[0 7363/1092]
```

An alias is `adjoint_classical()`, which replaces the deprecated `adjoint()` method:
ALGORITHM:

Use PARI whenever the method `self._adjugate` is included to do so in an inheriting class. Otherwise, use a generic division-free algorithm that computes the adjugate matrix from the characteristic polynomial.

The result is cached.

`apply_map(phi, R=None, sparse=None)`

Apply the given map phi (an arbitrary Python function or callable object) to this dense matrix. If R is not given, automatically determine the base ring of the resulting matrix.

**INPUT:**

- `sparse` – True to make the output a sparse matrix; default: False
- `phi` – arbitrary Python function or callable object
- `R` – (optional) ring

**OUTPUT:** a matrix over R

**EXAMPLES:**

```
sage: m = matrix(ZZ, 3, 3, range(9))
sage: k.<a> = GF(9)                      #...
    => needs sage.rings.finite_rings
sage: f = lambda x: k(x)                 #...
    => needs sage.rings.finite_rings
sage: n = m.apply_map(f); n               #...
    => needs sage.rings.finite_rings
[0 1 2]
[0 1 2]
[0 1 2]
sage: n.parent()                         #...
    => needs sage.rings.finite_rings
Full MatrixSpace of 3 by 3 dense matrices over Finite Field in a of size 3^2
```
In this example, we explicitly specify the codomain.

```python
sage: s = GF(3)
sage: f = lambda x: s(x)
sage: n = m.apply_map(f, k); n
needs sage.rings.finite_rings
[0 1 2]
[0 1 2]
[0 1 2]
sage: n.parent()
needs sage.rings.finite_rings
Full MatrixSpace of 3 by 3 dense matrices
over Finite Field in a of size 3^2
```

If self is subdivided, the result will be as well:

```python
sage: m = matrix(2, 2, srange(4))
sage: m.subdivide(None, 1); m
[0 1]
[2 3]
sage: m.apply_map(lambda x: x*x)
[0 1]
[4 9]
```

(continues on next page)
If the matrix is sparse, the result will be as well:

```python
sage: m = matrix(ZZ,100,100, sparse=True)
sage: m[18,32] = -6
sage: m[1,83] = 19
sage: n = m.apply_map(abs, R=ZZ)
sage: n.dict()
{(1, 83): 19, (18, 32): 6}
sage: n.is_sparse()
True
```

If the map sends most of the matrix to zero, then it may be useful to get the result as a sparse matrix.

```python
sage: m = matrix(ZZ, 3, 3, range(1, 10))
sage: n = m.apply_map(lambda x: 1//x, sparse=True); n
[1 0 0]
[0 0 0]
[0 0 0]
sage: n.parent()
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
```

**apply_morphism(\(\phi\))**

Apply the morphism \(\phi\) to the coefficients of this dense matrix.

The resulting matrix is over the codomain of \(\phi\).

**INPUT:**

- \(\phi\) – a morphism, so \(\phi\) is callable and \(\phi\).domain() and \(\phi\).codomain() are defined. The codomain must be a ring.

**OUTPUT:** a matrix over the codomain of \(\phi\)

**EXAMPLES:**
We apply a morphism to a matrix over a polynomial ring:

```
sage: R.<x,y> = QQ[]
sage: m = matrix(2, [x,x^2 + y, 2/3*y^2-x, x]); m
[ x  x^2 + y]
[2/3*y^2 - x  x]
sage: phi = R.hom([y,x])
sage: m.apply_morphism(phi)
[ y  y^2 + x]
[2/3*x^2 - y  y]
```

```
>> from sage.all import *
>> m = matrix(ZZ, Integer(3), Integer(3), range(Integer(9)))
>> phi = ZZ.hom(GF(Integer(5)))
>> m.apply_morphism(phi)
[0 1 2]
[3 4 0]
[1 2 3]
```

```
as_bipartite_graph()

Construct a bipartite graph \( \mathcal{B} \) representing the matrix uniquely.

Vertices are labeled 1 to nrows on the left and nrows + 1 to nrows + ncols on the right, representing rows and columns correspondingly. Each row is connected to each column with an edge weighted by the value of the corresponding matrix entry.

This graph is a helper for calculating automorphisms of a matrix under row and column permutations. See automorphisms_of_rows_and_columns().

OUTPUT:
- A bipartite graph.

EXAMPLES:
as_sum_of_permutations()

Returns the current matrix as a sum of permutation matrices

According to the Birkhoff-von Neumann Theorem, any bistochastic matrix can be written as a positive sum of permutation matrices, which also means that the polytope of bistochastic matrices is integer.

As a non-bistochastic matrix can obviously not be written as a sum of permutations, this theorem is an equivalence.

This function, given a bistochastic matrix, returns the corresponding decomposition.

See also:

- bistochastic_as_sum_of_permutations – for more information on this method.
- Birkhoff_polytope()

EXAMPLES:

We create a bistochastic matrix from a convex sum of permutations, then try to deduce the decomposition from the matrix

```python
def as_sum_of_permutations():
    # Returns the current matrix as a sum of permutation matrices
    # According to the Birkhoff-von Neumann Theorem, any bistochastic matrix can
    # be written as a positive sum of permutation matrices, which also means that
    # the polytope of bistochastic matrices is integer.
    # As a non-bistochastic matrix can obviously not be written as a sum of permutations,
    # this theorem is an equivalence.
    # This function, given a bistochastic matrix, returns the corresponding decomposition.
    # See also:
    # - bistochastic_as_sum_of_permutations – for more information on this method.
    # - Birkhoff_polytope()

    EXAMPLES:
    We create a bistochastic matrix from a convex sum of permutations, then try to deduce the decomposition from the matrix

    sage: M = matrix(QQ, [[1/3, 7], [6, 1/4], [8, -5]])
sage: M
    [1/3  7]
    [  6 1/4]
    [  8 -5]

    sage: # needs sage.graphs
    sage: B = M.as_bipartite_graph(); B
    Bipartite graph on 5 vertices
    sage: B.edges(sort=True)
    [(1, 4, 1/3), (1, 5, 7), (2, 4, 6), (2, 5, 1/4), (3, 4, 8), (3, 5, -5)]
    sage: len(B.left) == M.nrows()
    True
    sage: len(B.right) == M.ncols()
    True

    >>> from sage.all import *
    >>> M = matrix(QQ, [[Integer(1)/Integer(3), Integer(7)], [Integer(6), Integer(1)/Integer(4)], [Integer(8), -Integer(5)]])
    >>> M
    [1/3  7]
    [  6 1/4]
    [  8 -5]

    >>> # needs sage.graphs
    >>> B = M.as_bipartite_graph(); B
    Bipartite graph on 5 vertices
    >>> B.edges(sort=True)
    [(1, 4, 1/3), (1, 5, 7), (2, 4, 6), (2, 5, 1/4), (3, 4, 8), (3, 5, -5)]
    >>> len(B.left) == M.nrows()
    True
    >>> len(B.right) == M.ncols()
    True
```
An exception is raised when the matrix is not bistochastic:

```sage
M = Matrix([[2,3],[2,2]])
sage: decomp = bistochastic_as_sum_of_permutations(M) #...
Traceback (most recent call last):
  ...
ValueError: The matrix is not bistochastic
```

**automorphisms_of_rows_and_columns()**

Return the automorphisms of `self` under permutations of rows and columns as a list of pairs of `PermutationGroupElement` objects.

**EXAMPLES:**

```sage
M = Matrix([[2,3],[2,2]])
sage: decomp = bistochastic_as_sum_of_permutations(M) #...
Traceback (most recent call last):
  ...
ValueError: The matrix is not bistochastic
```
sage: # needs sage.graphs sage.groups
sage: M = matrix(ZZ, [[1,0], [1,0], [0,1]]); M
[1 0]
[1 0]
[0 1]
sage: A = M.automorphisms_of_rows_and_columns(); A
[((), ()), ((1,2), ())]
sage: M = matrix(ZZ, [[1,1,1,1], [1,1,1,1]])
sage: A = M.automorphisms_of_rows_and_columns()
sage: len(A)
48

>>> from sage.all import *

>>> # needs sage.graphs sage.groups

>>> M = matrix(ZZ, [[Integer(1), Integer(0)], [Integer(0), Integer(1)]]); M
[1 0]
[0 1]

>>> A = M.automorphisms_of_rows_and_columns(); A
[((), ()), ((1,2), ())]

>>> M = matrix(ZZ, [[Integer(1), Integer(1), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(1), Integer(1)]])

>>> A = M.automorphisms_of_rows_and_columns()

>>> len(A)
48

One can now apply these automorphisms to \( M \) to show that it leaves it invariant:

sage: all(M.with_permuted_rows_and_columns(*i) == M for i in A)  # needs sage.graphs sage.groups
True

>>> from sage.all import *

>>> all(M.with_permuted_rows_and_columns(*i) == M for i in A)  # needs sage.graphs sage.groups
True

Check that Issue #25426 is fixed:

sage: j = matrix([(3, 2, 1, 0, 0),
....: (2, 2, 0, 1, 0),
....: (1, 0, 3, 0, 2),
....: (0, 1, 0, 2, 1),
....: (0, 0, 2, 1, 2)])

sage: j.automorphisms_of_rows_and_columns()  # needs sage.graphs sage.groups
[((), ()), ((1,3)(2,5), (1,3)(2,5))]

>>> from sage.all import *

>>> j = matrix([(Integer(3), Integer(2), Integer(1), Integer(0), Integer(0)),
....: (Integer(2), Integer(2), Integer(0), Integer(1), Integer(0)),
....: (Integer(1), Integer(0), Integer(0), Integer(1), Integer(0)),
....: (Integer(1), Integer(0), Integer(0), Integer(2), Integer(1)),
....: (Integer(0), Integer(0), Integer(2), Integer(1), Integer(2))])

>>> j.automorphisms_of_rows_and_columns()  # needs sage.graphs sage.groups

(continues on next page)
block_ldlt (classical=False)

Compute a block-$LDL^T$ factorization of a Hermitian matrix.

The standard $LDL^T$ factorization of a positive-definite matrix $A$ factors it as $A = LDL^T$ where $L$ is unit-lower-triangular and $D$ is diagonal. If one allows row/column swaps via a permutation matrix $P$, then this factorization can be extended to many positive-semidefinite matrices $A$ via the factorization $P^TA^TP = LDL^T$ that places the zeros at the bottom of $D$ to avoid division by zero. These factorizations extend easily to complex Hermitian matrices when one replaces the transpose by the conjugate-transpose.

However, we can go one step further. If, in addition, we allow $D$ to potentially contain $2 \times 2$ blocks on its diagonal, then every real or complex Hermitian matrix $A$ can be factored as $A = P^L D L^* P$. When the row/column swaps are made intelligently, this process is numerically stable over inexact rings like RDF. Bunch and Kaufman describe such a “pivot” scheme that is suitable for the solution of Hermitian systems, and that is how we choose our row and column swaps.

**INPUT:**

- `classical` — (default: `False`) whether or not to attempt a classical non-block $LDL^T$ factorization with no row/column swaps.

**Warning:** Not all matrices have a classical $LDL^T$ factorization. Set `classical=True` at your own risk, preferably after verifying that your matrix is positive-definite and (over inexact rings) not ill-conditioned.

**OUTPUT:**

If the input matrix is not Hermitian, the output from this function is undefined. Otherwise, we return a triple $(P, L, D)$ such that $A = P^L D L^* P$ and

- $P$ is a permutation matrix,
- $L$ is unit lower-triangular,
- $D$ is a block-diagonal matrix whose blocks are of size one or two.

With `classical=True`, the permutation matrix $P$ is always an identity matrix and the diagonal blocks are always one-by-one. A `ValueError` is raised if the matrix has no classical $LDL^T$ factorization.

**ALGORITHM:**

We essentially follow “Algorithm A” in the paper by Bunch and Kaufman [BK1977] that describes the stable pivoting strategy. The same scheme is described by Higham [Hig2002].

**See also:**

`indefinite_factorization()`

**REFERENCES:**

- [BK1977]
- [Hig2002]

**EXAMPLES:**

This three-by-three real symmetric matrix has one positive, one negative, and one zero eigenvalue – so it is not any flavor of (semi)definite, yet we can still factor it:
sage: A = matrix(QQ, [[0, 1, 0],
....: [1, 1, 2],
....: [0, 2, 0]])
sage: P, L, D = A.block_ldlt()
sage: P
[0 0 1]
[1 0 0]
[0 1 0]
sage: L
[ 1 0 0]
[ 2 1 0]
[ 1 1/2 1]
sage: D
[ 1| 0| 0]
[--+--+--]
[ 0|-4| 0]
[--+--+--]
[ 0| 0| 0]
sage: P.transpose()*A*P == L*D*L.transpose()
True

sage: from sage.all import *
>>> A = matrix(QQ, [[Integer(0), Integer(1), Integer(0)],
... [Integer(1), Integer(1), Integer(2)],
... [Integer(0), Integer(2), Integer(0)]])

>>> P, L, D = A.block_ldlt()

>>> P
[0 0 1]
[1 0 0]
[0 1 0]

>>> L
[ 1 0 0]
[ 2 1 0]
[ 1 1/2 1]

>>> D
[ 1| 0| 0]
[--+--+--]
[ 0|-4| 0]
[--+--+--]
[ 0| 0| 0]

>>> P.transpose()*A*P == L*D*L.transpose()
True

This two-by-two matrix has no classical factorization, but it constitutes its own block-factorization:

sage: A = matrix(QQ, [ [0,1],
....: [1,0] ])
sage: A.block_ldlt(classical=True)
Traceback (most recent call last):
...
ValueError: matrix has no classical LDL^T factorization

sage: A.block_ldlt()
(  
[1 0] [1 0] [0 1]
[0 1], [0 1], [1 0]  )
```python
>>> from sage.all import *
>>> A = matrix(QQ, [ [Integer(0),Integer(1)],
... [Integer(1),Integer(0)] ])
>>> A.block_ldlt(classical=True)
Traceback (most recent call last):
...
ValueError: matrix has no classical LDL^T factorization
>>> A.block_ldlt()
([1 0]
 [0 1], [0 1], [1 0])
```

The same is true of the following complex Hermitian matrix:

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQbar, [ [ 0,I],
....: [-I,0] ])
sage: A.block_ldlt(classical=True)
Traceback (most recent call last):
...
ValueError: matrix has no classical LDL^T factorization
sage: A.block_ldlt()
([1 0]
 [0 1], [0 1], [-I 0])
```

Complete diagonal pivoting could cause problems for the following matrix, since the diagonal entries are small compared to the off-diagonals that must be zeroed; however, the block algorithm refuses to factor it:

```python
sage: A = matrix(RDF, 2, 2, [ [1e-10, 1e-10],
....: [1, 2e-10] ])
sage: _,L,D = A.block_ldlt(classical=True)
sage: L*D*L.T
[1e-10 1.0]
[1.0 0.0]
sage: A.block_ldlt()  # needs scipy
([1.0 0.0]
 [0.0 1.0], [0.0 1.0], [1.0 2e-10])
```
The factorization over an inexact ring is necessarily inexact, but $P^TAP$ will ideally be close to $LDL^*$ in the metric induced by the norm:

```python
>>> from sage.all import *
>>> A = matrix(RDF, 2, 2, [ [RealNumber('1e-10')],
    [ 1 ]])
>>> L,D,L.T
[1e-10 1.0]
[ 1.0 0.0]
>>> A.block_ldlt()
# needs scipy
needs scipy
(1.0 0.0) [1.0 0.0]
(0.0 1.0), [0.0 1.0], [ 1.0 2e-10]
```

This matrix has a singular three-by-three leading principal submatrix, and therefore has no classical factorization:

```python
>>> A = matrix(QQ, [[21, 15, 12, -2],
    [15, 12, 9, 6],
    [12, 9, 7, 3],
    [-2, 6, 3, 8]])
>>> A[0:3,0:3].det() == 0
True
```

```python
>>> A = matrix(QQ, [[21, 15, 12, -2],
    [15, 12, 9, 6],
    [12, 9, 7, 3],
    [-2, 6, 3, 8]])
>>> A[0:3,0:3].det() == 0
True
```

```python
>>> A = matrix(QQ, [[21, 15, 12, -2],
    [15, 12, 9, 6],
    [12, 9, 7, 3],
    [-2, 6, 3, 8]])
>>> A[0:3,0:3].det() == 0
True
```

(continues on next page)
\[
\begin{pmatrix}

\frac{0}{0} & \frac{0}{0} & \frac{0}{0} & \frac{0}{0} \\
\end{pmatrix}
\]

```
from sage.all import *

A = matrix(QQ, 
[[Integer(21), Integer(15), Integer(12), -Integer(2)],
... [Integer(15), Integer(12), Integer(9), Integer(6)],
... [Integer(12), Integer(9), Integer(7), Integer(3)],
... [-Integer(2), Integer(6), Integer(3), Integer(8)]])

A[Integer(0):Integer(3),Integer(0):Integer(3)].det() == Integer(0)
True

A.block_ldlt(classical=True)
Traceback (most recent call last):
...
ValueError: matrix has no classical LDL^T factorization

A.block_ldlt()
```

An indefinite symmetric matrix that happens to have a classical factorization:

```
sage: A = matrix(QQ, [[3, -6, 9, 6, -9],
... [-6, 11, -16, -11, 17],
... [9, -16, 28, 16, -40],
... [6, -11, 16, 9, -19],
... [-9, 17, -40, -19, 68]])
sage: A.block_ldlt(classical=True)[1:]
```

```
[3 | 0 | 0 | 0 | 0]
[3 | 0 | 0 | 0 | 0]
[1 | 0 | 0 | 0 | 0]
[-2 | 1 | 0 | 0 | 0]
[-3 | 1 | -3 | 1 | 1], [0 | 0 | 0 | 0 | -1]
```
An indefinite Hermitian matrix that happens to have a classical factorization:

```python
sage: F.<I> = QuadraticField(-1)
# needs sage.rings.number_field
sage: A = matrix(F, [[ 2, 4 - 2*I, 2 + 2*I],
# needs sage.rings.number_field
....: [4 + 2*I, 8, 10*I],
....: [2 - 2*I, -10*I, -3]])
```

```python
sage: A.block_ldlt(classical=True)[1:] # needs sage.rings.number_field
```

```python
sage: from sage.all import *
```

```python
>>> A = matrix(QQ, 
[ [ Integer(3), -Integer(6), Integer(9), Integer(6), -
Integer(9)],
...
[-Integer(6), Integer(11), -Integer(16), -Integer(11), -
Integer(17)],
...
[ Integer(9), -Integer(16), Integer(28), Integer(16), -
Integer(40)],
...
[-Integer(6), Integer(11), Integer(19), -Integer(9), -
Integer(68)]])```

```python
>>> A.block_ldlt(classical=True)[Integer(1):]
```

(continues on next page)
characteristic_polynomial(*args, **kwds)

Synonym for self.charpoly(…).

EXAMPLES:

```
sage: a = matrix(QQ, 2,2, [1,2,3,4]); a
[1 2]
[3 4]
sage: a.characteristic_polynomial('T')
#... →needs sage.libs.pari
T^2 - 5*T - 2
```

```
>>> from sage.all import *
>>> a = matrix(QQ, Integer(2),Integer(2), [Integer(1),Integer(2),Integer(3),
"("Integer(4))]); a
[1 2]
[3 4]
>>> a.characteristic_polynomial('T')
#... →needs sage.libs.pari
T^2 - 5*T - 2
```

ccharpoly(var='x', algorithm=None)

Returns the characteristic polynomial of self, as a polynomial over the base ring.

ALGORITHM:

If the base ring has a method \texttt{\_\_ matrix\_charpoly}, we use it.

In the generic case of matrices over a ring (commutative and with unity), there is a division-free algorithm, which can be accessed using \texttt{"df"}, with complexity $O(n^4)$. Alternatively, by specifying \texttt{"hessenberg"}, this method computes the Hessenberg form of the matrix and then reads off the characteristic polynomial. Moreover, for matrices over number fields, this method can use PARI’s \texttt{charpoly} implementation instead.

The method’s logic is as follows: If no algorithm is specified, first check if the base ring is a number field (and then use PARI), otherwise check if the base ring is the ring of integers modulo n (in which case compute the characteristic polynomial of a lift of the matrix to the integers, and then coerce back to the base), next check if the base ring is an exact field (and then use the Hessenberg form), or otherwise, use the generic division-free algorithm. If an algorithm is specified explicitly, if \texttt{algorithm} == \texttt{"hessenberg"}, use the Hessenberg form, or otherwise use the generic division-free algorithm.

The result is cached.

INPUT:

* \texttt{var} – a variable name (default: \texttt{\_x\_})

* \texttt{algorithm} – string:
  - \texttt{"df"} – Generic $O(n^4)$ division-free algorithm
  - \texttt{"hessenberg"} – Use the Hessenberg form of the matrix

EXAMPLES:

First a matrix over \mathbb{Z}:
sage: A = MatrixSpace(ZZ, 2)([1, 2, 3, 4])
sage: f = A.charpoly('x')
sage: f
x^2 - 5*x - 2

Univariate Polynomial Ring in x over Integer Ring

sage: f(A)
[0 0]
[0 0]

An example over \( \mathbb{Q} \):

sage: A = MatrixSpace(QQ, 3)(range(9))
sage: A.charpoly('x')
# needs sage.libs.pari
x^3 - 12*x^2 - 18*x

sage: A.trace()
12

sage: A.determinant()
0

We compute the characteristic polynomial of a matrix over the polynomial ring \( \mathbb{Z}[a] \):

sage: R.<a> = PolynomialRing(ZZ)
sage: M = MatrixSpace(R, 2)([a, 1, a, a+1]); M
[ a 1]
[a a + 1]
sage: f = M.charpoly('x'); f
x^2 + (-2*a - 1)*x + a^2

Univariate Polynomial Ring in x
over Univariate Polynomial Ring in a over Integer Ring

sage: M.trace()
2*a + 1

(continues on next page)
We compute the characteristic polynomial of a matrix over the multi-variate polynomial ring \( \mathbb{Z}[x, y] \):

```
sage: R.<x,y> = PolynomialRing(ZZ,2)
sage: A = MatrixSpace(R, 2)([[x, y], [x^2, y^2]])
sage: f = A.charpoly(x); f
x^2 + (-y^2 - x)*x - x^2*y + x*y^2
```

It's a little difficult to distinguish the variables. To fix this, we temporarily view the indeterminate as \( Z \):

```
sage: with localvars(f.parent(), 'Z'): print(f)
Z^2 + (-y^2 - x)*Z - x^2*y + x*y^2
```

We could also compute \( f \) in terms of \( Z \) from the start:

```
sage: A.charpoly('Z')
Z^2 + (-y^2 - x)*Z - x^2*y + x*y^2
```

Here is an example over a number field:

```
sage: # needs sage.rings.number_field
sage: x = QQ['x'].gen()
sage: K.<a> = NumberField(x^2 - 2)
```
sage: m = matrix(K, [[a-1, 2], [a, a+1]])
sage: m.charpoly('Z')
Z^2 - 2*a*Z - 2*a + 1
sage: m.charpoly('a')(m) == 0
True

Over integers modulo \( n \) with composite \( n \):

sage: A = Mat(Integers(6), 3, 3)(range(9))
sage: A.charpoly()
x^3

Here is an example over a general commutative ring, that is to say, as of version 4.0.2, Sage does not even positively determine that \( S \) in the following example is an integral domain. But the computation of the characteristic polynomial succeeds as follows:

sage: # needs sage.libs.singular
sage: R.<a,b> = QQ[]
sage: S.<x,y> = R.quo((b^3))
sage: A = matrix(S, [[x*y^2, 2*x], [2, x^10*y]]); A
\[
\begin{bmatrix}
  x*y^2 & 2*x \\
  2 & x^{10}*y
\end{bmatrix}
\]
sage: A.charpoly(T)
T^2 + (-x^{10}*y - x*y^2)*T - 4*x

Returnsthe Cholesky decomposition of a Hermitian matrix.

INPUT:
A positive-definite matrix. Generally, the base ring for the entries of the matrix needs to be a subfield of the algebraic numbers (\(\text{QQbar}\)). Examples include the rational numbers (\(\text{QQ}\)), some number fields, and real algebraic numbers and the algebraic numbers themselves. Symbolic matrices can also occasionally be factored.

OUTPUT:

For a matrix \(A\) the routine returns a lower triangular matrix \(L\) such that,

\[ A = LL^* \]

where \(L^*\) is the conjugate-transpose. If the matrix is not positive-definite (for example, if it is not Hermitian) then a ValueError results.

If possible, the output matrix will be over the fraction field of the base ring of the input matrix. If that fraction field is missing the requisite square roots but if no imaginaries are encountered, then the algebraic-reals will be used. Otherwise, the algebraic closure of the fraction field (typically \(\text{QQbar}\)) will be used.

ALGORITHM:

First we ensure that the matrix \(A\) is_hermitian(). Afterwards, we attempt to compute a classical block_ldlt() factorization, \(A = LDL^*\), of the matrix. If that fails, then the matrix was not positive-definite and an error is raised. Otherwise we take the entrywise square-root \(\sqrt{D}\) of the diagonal matrix \(D\) (whose entries are the positive eigenvalues of the original matrix) to obtain the Cholesky factorization \(A = \left(L\sqrt{D}\right)\left(L\sqrt{D}\right)^*\). If the necessary square roots cannot be taken in the fraction field of original base ring, then we move to either its algebraic closure or the algebraic reals, depending on whether or not imaginary numbers are required.

EXAMPLES:

This simple example has a result with entries that remain in the field of rational numbers:

```python
sage: A = matrix(QQ, [[ 4, -2, 4, 2],
                   [-2, 10, -2, -7],
                   [ 4, -2, 8, 4],
                   [ 2, -7, 4, 7]])

sage: A.is_symmetric()
True

sage: L = A.cholesky(); L
[ 2 0 0 0]
[-1 3 0 0]
[ 2 0 2 0]
[ 1 -2 1 1]

sage: L.parent()
Full MatrixSpace of 4 by 4 dense matrices over Rational Field

sage: L*L.transpose() == A
True
```

```python
>>> from sage.all import *
>>> A = matrix(QQ, [[ Integer(4), -Integer(2), Integer(4), Integer(2)],
...                   [-Integer(2), Integer(10), -Integer(2), -Integer(7)],
...                   [ Integer(4), -Integer(2), Integer(8), Integer(4)],
...                   [ Integer(2), -Integer(7), Integer(4), Integer(7)]])

>>> A.is_symmetric()
True

>>> L = A.cholesky(); L
[ 2 0 0 0]
[-1 3 0 0]
[ 2 0 2 0]
```

(continues on next page)
This seemingly simple example requires first moving to the rational numbers for field operations, and then square roots necessitate that the result has entries in the field of algebraic numbers:

```python
sage: A = matrix(ZZ, [[ 78, -30, -37, -2],
...[-30, 102, 179, -18],
...[-37, 179, 326, -38],
...[-2, -18, -38, 15]])
```

```python
sage: A.is_symmetric()
```

```python
True
```

```python
sage: L = A.cholesky(); L
```

```python
[ 8.83176086632785? 0 0 ␣
→ 0]
[ -3.396831102433787? 9.51112708681461? 0 ␣
→ 0]
[ -4.189425026335004? 17.32383862241232? 2.886751345948129?
→ 0]
[-0.2264554068289192? -1.973397116652010? -1.649572197684645?
→ 886751345948129?]
```

```python
sage: L.parent()
```

```python
Full MatrixSpace of 4 by 4 dense matrices over Algebraic Real Field
```

```python
sage: L*L.transpose() == A
```

```python
True
```

Some subfields of the complex numbers, such as this number field of complex numbers with rational real and
Matrices and Spaces of Matrices, Release 10.4

imaginary parts, allow for this computation:

```plaintext
sage: # needs sage.rings.number_field
sage: C.<I> = QuadraticField(-1)
sage: A = matrix(C, [[ 23, 17*I + 3, 24*I + 25, 21*I],
                [-17*I + 3, 38, -69*I + 89, 7*I + 15],
                [-24*I + 25, 69*I + 89, 976, 24*I + 6],
                [-21*I, -7*I + 15, -24*I + 6, 28]])
sage: A.is_hermitian()
True
sage: L = A.cholesky(); L
[ 4.79...? 0 0 ]
[ 0.62...? - 3.54...?*I 5.00...? ]
[ 5.21...? - 5.00...?*I 13.58...? + 10.72...?*I ]
[ -4.37...?*I -0.10...? - 0.85...?*I -0.21...? + 0.37...?*I 2.

sage: L.parent()
Full MatrixSpace of 4 by 4 dense matrices over Algebraic Field

sage: (L*L.conjugate_transpose() - A.change_ring(QQbar)).norm() < 10^-10
True
```

The field of algebraic numbers is an ideal setting for this computation:

```plaintext
>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> C = QuadraticField(-Integer(1), names=('I',)); (I,) = C._first_ngens(1)
>>> A = matrix(C, [[ Integer(23), Integer(17)*I + Integer(3),
                -Integer(17)*I + Integer(3), Integer(21)*I],
                [ -Integer(24)*I + Integer(25), Integer(21)*I,
                -Integer(24)*I + Integer(25), Integer(21)*I],
                [ Integer(69)*I + Integer(89), Integer(7)*I + Integer(15),
                -Integer(24)*I + Integer(25), Integer(21)*I],
                [ -Integer(24)*I + Integer(6), Integer(28)])
>>> A.is_hermitian()
True
>>> L = A.cholesky(); L
[ 4.79...? 0 0 ]
[ 0.62...? - 3.54...?*I 5.00...? ]
[ 5.21...? - 5.00...?*I 13.58...? + 10.72...?*I ]
[ -4.37...?*I -0.10...? - 0.85...?*I -0.21...? + 0.37...?*I 2.

>>> L.parent()
Full MatrixSpace of 4 by 4 dense matrices over Algebraic Field
>>> (L*L.conjugate_transpose() - A.change_ring(QQbar)).norm() < Integer(10)**-10
True
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

[2.828427124746190? - 1.414213562373095?*I 1 0]
[4.242640687119285? + 2.828427124746190?*I -2*I + 2 1.732050807568878?]
sage: L.parent()
Full MatrixSpace of 3 by 3 dense matrices over Algebraic Field
sage: L*L.conjugate_transpose() == A
True
```

```python
>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> A = matrix(QQbar, [[ Integer( 2), Integer( 4) + Integer(2)*I, →
Integer(6) - Integer(4)*I],
... [ -Integer(2)*I + Integer(4), Integer(11),→
Integer(10) - Integer(12)*I],
... [ Integer(4)*I + Integer(6), Integer(10) +→
Integer(12)*I, Integer(37)]])
>>> A.is_hermitian()
True
>>> L = A.cholesky()
>>> L
[ 1.414213562373095? 0 0]
[2.828427124746190? - 1.414213562373095?*I 1 0]
[4.242640687119285? + 2.828427124746190?*I -2*I + 2 1.732050807568878?]
>>> L.parent()
Full MatrixSpace of 3 by 3 dense matrices over Algebraic Field
>>> L*L.conjugate_transpose() == A
True
```

Results are cached, hence immutable. Use the copy function if you need to make a change:

```python
sage: A = matrix(QQ, [[ 4, -2, 4, 2],
...: [ -2, 10, -2, -7],
...: [ 4, -2, 8, 4],
...: [ 2, -7, 4, 7]])
```

(continues on next page)
>>> L.is_immutable()
True
>>> from copy import copy
>>> LC = copy(L)
>>> LC[Integer(0),Integer(0)] = Integer(1000)
>>> LC
[ 1000 0 0 0]
[ -1 3 0 0]
[ 2 0 2 0]
[ 1 -2 1 1]

The base ring need not be exact, although you should expect the result to be inexact (correct only in the norm) as well in that case:

```
sage: F = RealField(100)
sage: A = A = matrix(F, [[1.0, 2.0], [2.0, 6.0]])
sage: L = A.cholesky(); L
\[ 1.000... 0.000...\]
\[ 2.000... 1.414...\]
sage: (L*L.transpose() - A).norm() < 1e-10 # needs scipy
True
```

Even symbolic matrices can sometimes be factored:

```
sage: A = matrix(SR, [[pi,0], [0,pi]]) # needs sage.symbolic
sage: A.cholesky()
\[sqrt(pi) 0\]
\[ 0 sqrt(pi)\]
```

There are a variety of situations which will prevent the computation of a Cholesky decomposition.

The base ring may not be able to be viewed as a subset of the complex numbers, implying that “Hermitian” is meaningless:
sage: A = matrix(Integers(6), [[2, 0], [0, 4]])
sage: A.cholesky()
Traceback (most recent call last):
... AttributeError: 'sage.rings.finite_rings.integer_mod.IntegerMod_int'
object has no attribute 'conjugate'

>>> from sage.all import *
>>> A = matrix(Integers(Integer(6)), [[Integer(2), Integer(0)],
\[Integer(0), Integer(4)]])
>>> A.cholesky()
Traceback (most recent call last):
... AttributeError: 'sage.rings.finite_rings.integer_mod.IntegerMod_int'
object has no attribute 'conjugate'

The matrix may not be Hermitian:

```
sage: F.<a> = FiniteField(5^4) # needs sage.rings.finite_rings
sage: A = matrix(F, [[2+a^3, 3], [3, 3]]) # needs sage.rings.finite_rings
sage: A.cholesky() # needs sage.rings.finite_rings
Traceback (most recent call last):
... ValueError: matrix is not Hermitian
```

The matrix may not be positive-definite:

```
sage: # needs sage.rings.number_field
sage: C.<I> = QuadraticField(-1)
sage: B = matrix(C, [[ 2, 4 - 2*I, 2 + 2*I],
...: [4 + 2*I, 8, 10*I],
...: [2 - 2*I, -10*I, -3]])
sage: B.is_positive_definite() False
sage: B.cholesky()
Traceback (most recent call last):
... ValueError: matrix is not positive definite
```

(continues on next page)
```
>>> C = QuadraticField(-Integer(1), names=('I',)); (I,) = C._first_ngens(1)
>>> B = matrix(C, [[ Integer(2), Integer(4) - Integer(2)*I, Integer(2) +
    Integer(2)*I],
    ... [Integer(4) + Integer(2)*I, Integer(8), -
    Integer(10)*I],
    ... [Integer(2) - Integer(2)*I, -Integer(10)*I, -
    Integer(3)]])
>>> B.is_positive_definite()
False
>>> B.cholesky()
Traceback (most recent call last):
  ... ValueError: matrix is not positive definite
```
```
sage: A = matrix(QQ, [[21, 15, 12, -3],
  ....: [15, 12, 9, 12],
  ....: [12, 9, 7, 3],
  ....: [-3, 12, 3, 8]])

sage: A.is_positive_definite()
False
sage: A.cholesky()
Traceback (most recent call last):
  ... ValueError: matrix is not positive definite
```
```
>>> from sage.all import *

>>> A = matrix(QQ, [[Integer(21), Integer(15), Integer(12), -Integer(3)],
  ... [Integer(15), Integer(12), Integer(9), Integer(12)],
  ... [Integer(12), Integer(9), Integer(7), Integer(3)],
  ... [-Integer(3), Integer(12), Integer(3), Integer(8)]])

>>> A.is_positive_definite()
False
>>> A.cholesky()
Traceback (most recent call last):
  ... ValueError: matrix is not positive definite
```
```
column_module()

Return the free module over the base ring spanned by the columns of this matrix.

EXAMPLES:
```
sage: t = matrix(QQ, 3, 3, range(9)); t
[0 1 2]
[3 4 5]
[6 7 8]
sage: t.column_module()
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1 0 -1]
[ 0 1 2]
```
```
```
column_space()

Return the vector space over the base ring spanned by the columns of this matrix.

EXAMPLES:

```python
sage: M = MatrixSpace(QQ, 3, 3)
sage: A = M([1,9,-7, 4/5,4,3, 6,4,3])
sage: A.column_space()
Vector space of degree 3 and dimension 3 over Rational Field
Basis matrix:
[1 0 0]
[0 1 0]
[0 0 1]
```

```python
sage: # needs sage.rings.real_mpfr sage.symbolic
sage: W = MatrixSpace(CC, 2, 2)
sage: B = W([1, 2 + 3*I, 4 + 5*I, 9]); B
[1.00000000000000 2.00000000000000 + 3.00000000000000*I]
[4.00000000000000 + 5.00000000000000*I 9.00000000000000]
sage: B.column_space()
Vector space of degree 2 and dimension 2
over Complex Field with 53 bits of precision
Basis matrix:
[1.00000000000000 0.000000000000000]
[0.000000000000000 1.000000000000000]
```

```python
>>> from sage.all import *

>>> M = MatrixSpace(QQ, Integer(3), Integer(3))

>>> A = M([Integer(1),Integer(9),-Integer(7), Integer(4)/Integer(5),
        Integer(4),Integer(3), Integer(6),Integer(4),Integer(3)])

>>> A.column_space()
Vector space of degree 3 and dimension 3 over Rational Field
Basis matrix:
[1 0 0]
[0 1 0]
[0 0 1]
```

```python
>>> # needs sage.rings.real_mpfr sage.symbolic

>>> W = MatrixSpace(CC, Integer(2), Integer(2))

>>> B = W([Integer(1), Integer(2) + Integer(3)*I, Integer(4) + Integer(5)*I,
        Integer(3), Integer(6),Integer(4),Integer(3)])

>>> B.column_space()
Vector space of degree 2 and dimension 2
over Complex Field with 53 bits of precision
Basis matrix:
[1.00000000000000 0.000000000000000]
[0.000000000000000 1.000000000000000]
```
conjugate()

Return the conjugate of self, i.e. the matrix whose entries are the conjugates of the entries of self.

EXAMPLES:

```
sage: # needs sage.rings.complex_double sage.symbolic
sage: A = matrix(CDF, [[1+I,1],[0,2*I]])
```
```
sage: A.conjugate()
[1.0 - 1.0*I 1.0]
[ 0.0 -2.0*I]
```

```
>>> from sage.all import *
```
```
>>> A = matrix(CDF, [[Integer(1)+I,Integer(1)],[Integer(0),Integer(2)*I]])
```
```
>>> A.conjugate()
[1.0 - 1.0*I 1.0]
[ 0.0 -2.0*I]
```

A matrix over a not-totally-real number field:

```
sage: x = polygen(ZZ, 'x')
sage: K.<j> = NumberField(x^2 + 5) # needs sage.rings.number_field
```
```
sage: M = matrix(K, [[1+j,1],[0,2*j]]) # needs sage.rings.number_field
```
```
sage: M.conjugate() # needs sage.rings.number_field
[-j + 1 1]
[ 0 -2*j]
```

```
>>> from sage.all import *
```
```
>>> M = matrix(K, [[Integer(1)+j,Integer(1)],[Integer(0),Integer(2)*j]]) # needs sage.rings.number_field
```
```
>>> M.conjugate() # needs sage.rings.number_field
[-j + 1 1]
[ 0 -2*j]
```

There is a shortcut for the conjugate:

```
sage: M.C # needs sage.rings.number_field
[-j + 1 1]
[ 0 -2*j]
```

```
>>> from sage.all import *
```
```
>>> M.C # needs sage.rings.number_field
[-j + 1 1]
[ 0 -2*j]
```

There is also a shortcut for the conjugate transpose, or “Hermitian transpose”:
Conjugates work (trivially) for matrices over rings that embed canonically into the real numbers:

```sage
c sage: M = random_matrix(ZZ, 2)
c sage: M == M.conjugate()
True
c sage: M = random_matrix(QQ, 3)
c sage: M == M.conjugate()
True
c sage: M = random_matrix(RR, 2)
c sage: M == M.conjugate()
True
```

```sage
c >>> from sage.all import *
c >>> M.H

-\[ \begin{bmatrix} -j + 1 & 0 \\
 1 & -2*j \end{bmatrix} \]
```

### conjugate_transpose()

Return the transpose of `self` after each entry has been converted to its complex conjugate.

**Note:** This function is sometimes known as the “adjoint” of a matrix, though there is substantial variation and some confusion with the use of that term.

**OUTPUT:**

A matrix formed by taking the complex conjugate of every entry of `self` and then transposing the resulting matrix.

Complex conjugation is implemented for many subfields of the complex numbers. See the examples below, or more at `conjugate()`.

**EXAMPLES:**

```sage
c sage: M = matrix(SR, 2, 2, [[2-I, 2*I], [2*I, 2-I]])
c sage: M.H

-\[ \begin{bmatrix} 2 - I & -2*I \\
 -2*I & 2 - I \end{bmatrix} \]
```

```sage
c sage: M = matrix(SR, 2, 2, [[2-I, 3+4*I], [9-6*I, 5*I]])
c sage: M.base_ring()
```

(continues on next page)
There is also a shortcut for the conjugate transpose, or “Hermitian transpose”:

Matrices over base rings that can be embedded in the real numbers will behave as expected.
Matrices and Spaces of Matrices, Release 10.4

```sage
P = random_matrix(QQ, 3, 4)
P.conjugate_transpose() == P.transpose()
True
```

The conjugate of a matrix is formed by taking conjugates of all the entries. Some specialized subfields of the complex numbers are implemented in Sage and complex conjugation can be applied. (Matrices over quadratic number fields are another class of examples.)

```sage
# needs sage.rings.number_field
C = CyclotomicField(5)
a = C.gen(); a
zeta5
CC(a)
0.309016994374947 + 0.951056516295154*I
M = matrix(C, 1, 2, [a^2, a+a^3])
M.conjugate_transpose()
[ zeta5^3]
[-zeta5^3 - zeta5 - 1]
```

Furthermore, this method can be applied to matrices over quadratic extensions of finite fields:

```sage
F.<a> = GF(9,'a')
# needs sage.rings.finite_rings
N = matrix(F, 2, [0,a,-a,1]); N
# needs sage.rings.finite_rings
[ 0 a]
[2*a 1]
N.conjugate_transpose()
# needs sage.rings.finite_rings
[ 0 a + 2]
[2*a + 1 1]
```

(continues on next page)
Conjugation does not make sense over rings not containing complex numbers or finite fields which are not a quadratic extension:

```python
sage: N = matrix(GF(5), 2, [0,1,2,3])
sage: N.conjugate_transpose()
Traceback (most recent call last):
...  
AttributeError: 'sage.rings.finite_rings.integer_mod.IntegerMod_int' object has no attribute 'conjugate'...
```

```python
from sage.all import *
```

```python
N = matrix(GF(Integer(5)), Integer(2), [Integer(0),Integer(1),Integer(2), Integer(3)])
N.conjugate_transpose()
Traceback (most recent call last):
...  
AttributeError: 'sage.rings.finite_rings.integer_mod.IntegerMod_int' object has no attribute 'conjugate'...
```

cyclic_subspace\((v, var=None, basis='echelon')\)

Create a cyclic subspace for a vector, and optionally, a minimal polynomial for the iterated powers.

These subspaces are also known as Krylov subspaces. They are spanned by the vectors

\(\{v, Av, A^2v, A^3v, \ldots\}\)

**INPUT:**

- `self` – a square matrix with entries from a field.
- `v` – a vector with a degree equal to the size of the matrix and entries compatible with the entries of the matrix.
- `var` – (default: `None`); if specified as a string or a generator of a polynomial ring, then this will be used to construct a polynomial reflecting a relation of linear dependence on the powers \(A^i v\) and this will cause the polynomial to be returned along with the subspace. A generator must create polynomials with coefficients from the same field as the matrix entries.
- `basis` – (default: `echelon`); the basis for the subspace is “echelonized” by default, but the keyword ‘iterates’ will return a subspace with a user basis equal to the largest linearly independent set \(\{v, Av, A^2v, A^3v, \ldots, A^{k-1}v\}\).

**OUTPUT:**

Suppose \(k\) is the smallest power such that \(\{v, Av, A^2v, A^3v, \ldots, A^{k}v\}\) is linearly dependent. Then the subspace returned will have dimension \(k\) and be spanned by the powers 0 through \(k-1\).

If a polynomial is requested through the use of the `var` keyword, then a pair is returned, with the polynomial first and the subspace second. The polynomial is the unique monic polynomial whose coefficients provide a relation of linear dependence on the first \(k\) powers.

For less convenient, but more flexible output, see the helper method “\_cyclic_subspace” in this module.

**EXAMPLES:**
\begin{tabular}{|l|}
\hline
From Sage, the polynomial has coefficients that yield a non-trivial relation of linear dependence on the iterates. Or, equivalently, evaluating the polynomial with the matrix will create a matrix that annihilates the vector. \\
\hline
\end{tabular}

True

decomposition(algorithm='spin', is_diagonalizable=False, dual=False)

Returns the decomposition of the free module on which this matrix A acts from the right (i.e., the action is x goes to x A), along with whether this matrix acts irreducibly on each factor. The factors are guaranteed to be sorted in the same way as the corresponding factors of the characteristic polynomial.

Let A be the matrix acting from the on the vector space V of column vectors. Assume that A is square. This function computes maximal subspaces W_1, \ldots, W_n corresponding to Galois conjugacy classes of eigenvalues of A. More precisely, let f(X) be the characteristic polynomial of A. This function computes the subspace W_i = ker(g_i(A)^n), where g_i(X) is an irreducible factor of f(X) and g_i(X) exactly divides f(X).

If the optional parameter is_diagonalizable is True, then we let W_i = ker(g_i(A)), since then we know that ker(g_i(A)) = ker(g_i(A)^n).

INPUT:

• self – a matrix

• algorithm – ‘spin’ (default): algorithm involves iterating the action of self on a vector. ‘kernel’: naively just compute ker(f_i(A)) for each factor f_i.

• dual – bool (default: False): If True, also returns the corresponding decomposition of V under the action of the transpose of A. The factors are guaranteed to correspond.

• is_diagonalizable – if the matrix is known to be diagonalizable, set this to True, which might speed up the algorithm in some cases.

Note: If the base ring is not a field, the kernel algorithm is used.

OUTPUT:

• Sequence – list of pairs (V,t), where V is a vector spaces and t is a bool, and t is True exactly when the charpoly of self on V is irreducible.

• (optional) list – list of pairs (W,t), where W is a vector space and t is a bool, and t is True exactly when the charpoly of the transpose of self on W is irreducible.

EXAMPLES:

\[
sage: A = matrix(ZZ, 4, [3,4,5,6, 7,3,8,10, 14,5,6,7, 2,2,10,9])
\]

\[
sage: B = matrix(QQ, 6, 6, range(36))
\]

```

decomposition_of_subspace (M, check_restrict=True, **kwds)

Suppose the right action of self on M leaves M invariant. Return the decomposition of M as a list of pairs
(W, is_irred) where is_irred is True if the charpoly of self acting on the factor W is irreducible.

Additional inputs besides M are passed onto the decomposition command.
INPUT:

- \( M \) – A subspace of the free module `self` acts on.
- `check_restrict` – A boolean (default: `True`); Call `restrict` with or without check.
- `kwds` – Keywords that will be forwarded to `decomposition()`.

EXAMPLES:

```
sage: # needs sage.libs.pari
sage: t = matrix(QQ, 3, [3, 0, -2, 0, -2, 0, 0, 0, 0]); t
[ 3  0 -2]
[ 0 -2  0]
[ 0  0  0]
sage: t.fcp('X')  # factored charpoly
(X - 3) * X * (X + 2)
sage: v = kernel(t*(t+2)); v  # an invariant subspace
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[0 1 0]
[0 0 1]
sage: D = t.decomposition_of_subspace(v); D
[(Vector space of degree 3 and dimension 1 over Rational Field
  Basis matrix: [0 0 1],
  True),
  (Vector space of degree 3 and dimension 1 over Rational Field
  Basis matrix: [0 1 0],
  True)]
sage: t.restrict(D[0][0])
[0]
sage: t.restrict(D[1][0])
[-2]
```

```python
>>> from sage.all import *
>>> # needs sage.libs.pari
>>> t = matrix(QQ, Integer(3), [Integer(3), Integer(0), -Integer(2),
  -Integer(2), Integer(0), Integer(0), Integer(0), Integer(0), Integer(0)]); t
[ 3  0 -2]
[ 0 -2  0]
[ 0  0  0]
>>> t.fcp('X')  # factored charpoly
(X - 3) * X * (X + 2)
>>> v = kernel(t*(t+Integer(2))); v  # an invariant subspace
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[0 1 0]
[0 0 1]
>>> D = t.decomposition_of_subspace(v); D
[(Vector space of degree 3 and dimension 1 over Rational Field
  Basis matrix: [0 0 1],
  True),
  (Vector space of degree 3 and dimension 1 over Rational Field
  Basis matrix: [0 1 0],
  True)]
>>> t.restrict(D[Integer(0)][Integer(0)])
[0]
>>> t.restrict(D[Integer(1)][Integer(0)])
```
(continues on next page)
We do a decomposition over \( \mathbb{Z} \):

\[
\text{sage: } a = \text{matrix(}\mathbb{Z} , 6, \begin{bmatrix} 0, & 0, & -2, & 0, & 2, & 0, \\
2, & -4, & -2, & 0, & 2, & 0, \\
0, & 0, & -2, & -2, & 0, & 0, \\
2, & 0, & -2, & -4, & 2, & -2, \\
0, & 2, & 0, & -2, & -2, & 0, \\
0, & 2, & 0, & -2, & 0, & 0 \end{bmatrix})
\]

\[
\text{sage: } a.\text{decomposition_of_subspace}(\mathbb{Z}^6)
\]

\[
\textbf{needs sage/libs/pari}
\]

\[
\begin{align*}
& (\text{Free module of degree 6 and rank 2 over Integer Ring} \\
& \quad \text{Echelon basis matrix:} \\
& \quad \begin{bmatrix} 1 & 0 & 1 & -1 & 1 & -1 \\
& 0 & 1 & 0 & -1 & 2 & -1 \end{bmatrix}, \\
& \quad \text{False}), \\
& (\text{Free module of degree 6 and rank 4 over Integer Ring} \\
& \quad \text{Echelon basis matrix:} \\
& \quad \begin{bmatrix} 1 & 0 & -1 & 0 & 1 & 0 \\
& 0 & 1 & 0 & 0 & 0 & 0 \\
& 0 & 0 & 0 & 1 & 0 & 0 \\
& 0 & 0 & 0 & 0 & 1, \\
& \quad \text{False} )
\end{align*}
\]

\[
\text{denominator}()
\]

Return the least common multiple of the denominators of the elements of self.

If there is no denominator function for the base field, or no LCM function for the denominators, raise a
TypeError.

EXAMPLES:

```python
sage: A = MatrixSpace(QQ, 2)([1/2, 1/3, 1/5, 1/7])
sage: A.denominator()
210
```

```python
>>> from sage.all import *

>>> A = MatrixSpace(QQ, Integer(2))([Integer(1)/Integer(2), Integer(1)/
Integer(3), Integer(1)/Integer(5), Integer(1)/Integer(7)])
>>> A.denominator()
210
```

A trivial example:

```python
sage: A = matrix(QQ, 0,2)
sage: A.denominator()
1
```

```python
>>> from sage.all import *

>>> A = matrix(QQ, Integer(0),Integer(2))
>>> A.denominator()
1
```

Denominators are not defined for real numbers:

```python
sage: A = MatrixSpace(RealField(),2)([1,2,3,4])
sage: A.denominator()
Traceback (most recent call last):
...
TypeError: denominator not defined for elements of the base ring
```

```python
>>> from sage.all import *

>>> A = MatrixSpace(RealField(),Integer(2))([Integer(1),Integer(2),Integer(3),
Integer(4)])
>>> A.denominator()
Traceback (most recent call last):
...
TypeError: denominator not defined for elements of the base ring
```

We can even compute the denominator of matrix over the fraction field of \( \mathbb{Z}[x] \).

```python
sage: K.<x> = Frac(ZZ['x'])
sage: A = MatrixSpace(K,2)([1/x, 2/(x+1), 1, 5/(x^3)])
sage: A.denominator()
x^4 + x^3
```

```python
>>> from sage.all import *

>>> K = Frac(ZZ['x'], names=('x',)); (x,) = K._first_ngens(1)

>>> A = MatrixSpace(K,Integer(2))([Integer(1)/x, Integer(2)/(x+Integer(1)),
 Integer(1), Integer(5)/(x**Integer(3))])

>>> A.denominator()
x^4 + x^3
```

Here's an example involving a cyclotomic field:
### density()

Return the density of the matrix.

By density we understand the ratio of the number of nonzero positions and the self.nrows() * self.ncols(), i.e. the number of possible nonzero positions.

**EXAMPLES:**

First, note that the density parameter does not ensure the density of a matrix, it is only an upper bound.

```sage
density()
```

```sage: A = random_matrix(GF(127), 200, 200, density=0.3)
sage: A.density() <= 0.3
True
```

```sage: from sage.all import *
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(127)), Integer(200), Integer(200),
density=RealNumber('0.3'))
>>> A.density() <= RealNumber('0.3')
True
```

```sage: A = matrix(QQ, 3,3, [0,1,2,3,0,0,6,7,8])
sage: A.density()
2/3
```

```sage: from sage.all import *
>>> from sage.all import *
>>> A = matrix(QQ, Integer(3),Integer(3), [Integer(0),Integer(1),Integer(2),
Integer(3),Integer(0),Integer(0),Integer(6),Integer(7),Integer(8)])
>>> A.density()
2/3
```
```python
sage: a = matrix([[],[],[],[]])
sage: a.density()
0

>>> from sage.all import *
>>> a = matrix([[],[],[],[]])
>>> a.density()
0

derivative(*args)

Derivative with respect to variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

EXAMPLES:

```python
sage: # needs sage.symbolic
sage: v = vector([1,x,x^2])
sage: v.derivative(x)
(0, 1, 2*x)
sage: type(v.derivative(x)) == type(v)
True
sage: v = vector([1,x,x^2], sparse=True)
(0, 1, 2*x)
sage: type(v.derivative(x)) == type(v)
True
sage: v.derivative(x,x)
(0, 0, 2)
```
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

determinant (algorithm=None)

Return the determinant of self.

ALGORITHM:

If the base ring has a method _matrix_determinant(), we call it.

Otherwise, for small matrices (n less than 4), this is computed using the naive formula. In the specific case
of matrices over the integers modulo a non-prime, the determinant of a lift is computed over the integers.
In general, the characteristic polynomial is computed either using the Hessenberg form (specified by "hessenberg") or the generic division-free algorithm (specified by "df"). When the base ring is an exact field, the default choice is "hessenberg", otherwise it is "df". Note that for matrices over most rings, more sophisticated algorithms can be used. (Type A.determinant? to see what is done for a specific matrix A.)

INPUT:

• algorithm – string:
  • "df" – Generic O(n^4) division-free algorithm
  • "hessenberg" – Use the Hessenberg form of the matrix

EXAMPLES:

sage: A = MatrixSpace(Integers(8), 3)([1,7,3, 1,1,1, 3,4,5])
sage: A.det() 6
sage: A.det() is A.det() True
sage: A[0,0] = 10
sage: A.det() 7

>>> from sage.all import *

>>> A = MatrixSpace(Integers(Integer(8)), Integer(3))(Integer(1),Integer(7),
   Integer(3), Integer(1),Integer(1),Integer(1), Integer(3),Integer(4),
   Integer(5))

>>> A.det() 6

>>> A.det() is A.det() True

>>> A[Integer(0),Integer(0)] = Integer(10)

>>> A.det() 7

We compute the determinant of the arbitrary 3x3 matrix:

sage: R = PolynomialRing(QQ, 9, 'x')
sage: A = matrix(R, 3, R.gens())
sage: A
[x0  x1  x2]
[x3  x4  x5]
Matrices and Spaces of Matrices, Release 10.4

[Continued from previous page]

```python
sage: A.determinant()
-x2*x4*x6 + x1*x5*x6 + x2*x3*x7 - x0*x5*x7 - x1*x3*x8 + x0*x4*x8
```

```python
>>> from sage.all import *

>>> R = PolynomialRing(QQ, Integer(9), 'x')

>>> A = matrix(R, Integer(3), R.gens())

>>> A
[x0 x1 x2]
[x3 x4 x5]
[x6 x7 x8]

>>> A.determinant()
-x2*x4*x6 + x1*x5*x6 + x2*x3*x7 - x0*x5*x7 - x1*x3*x8 + x0*x4*x8
```

We create a matrix over $\mathbb{Z}[x, y]$ and compute its determinant.

```python
sage: R.<x,y> = PolynomialRing(IntegerRing(), 2)

sage: A = MatrixSpace(R, 2)([[x, y, x**2, y**2]])

sage: A.determinant()
-x^2*y + x*y^2
```

```python
>>> from sage.all import *

>>> R = PolynomialRing(IntegerRing(), Integer(2), names=(x, y,)); (x, y,)

>>> A = MatrixSpace(R, Integer(2))([[x, y, x**Integer(2), y**Integer(2)]])

>>> A.determinant()
-x^2*y + x*y^2
```

A matrix over a non-domain:

```python
sage: m = matrix(Integers(4), 2, [1,2,2,3])

sage: m.determinant()
3
```

```python
>>> from sage.all import *

>>> m = matrix(Integers(Integer(4)), Integer(2), [Integer(1),Integer(2),

-Integer(2),Integer(3)])

>>> m.determinant()
3
```

`diagonal()`

Return the diagonal entries of `self`.

**OUTPUT:**

A list containing the entries of the matrix that have equal row and column indices, in order of the indices. Behavior is not limited to square matrices.

**EXAMPLES:**

```python
sage: A = matrix([[2, 5], [3, 7]])

sage: A
[2 5]
[3 7]

sage: A.diagonal()
[2, 7]
```
Two rectangular matrices.

```python
sage: B = matrix(3, 7, range(21)); B
[ 0 1 2 3 4 5 6]
[ 7 8 9 10 11 12 13]
[14 15 16 17 18 19 20]
sage: B.diagonal()
[0, 8, 16]
sage: C = matrix(3, 2, range(6)); C
[0 1]
[2 3]
[4 5]
sage: C.diagonal()
[0, 3]
```

Empty matrices behave properly.

```python
sage: E = matrix(0, 5, []); E
[]
sage: E.diagonal()
[]
```

diagonalization (base_field=None)

Return a diagonal matrix similar to self along with the transformation matrix.

INPUT:

- base_field – if given, self is regarded as a matrix over it
OUTPUT: a diagonal matrix $D$ and an invertible matrix $P$ such that $P^{-1}AP = D$, if self is a diagonalizable matrix $A$.

EXAMPLES:

```
sage: # needs sage.libs.pari
sage: A = matrix(QQ, 4, [-4, 6, 3, -3, 5, 3, 3, -6, -4, -3, -3, 6, 3, ...
           →2])
sage: A
[-4  6  3  3]

[3 1]
[0 3]

```
echelon_form(algorithm='default', cutoff=0, **kwds)
```

Return the echelon form of `self`.

**Note:** This row reduction does not use division if the matrix is not over a field (e.g., if the matrix is over the integers). If you want to calculate the echelon form using division, then use `rref()`, which assumes that the matrix entries are in a field (specifically, the field of fractions of the base ring of the matrix).

**INPUT:**

- `algorithm` – string. Which algorithm to use. Choices are
  - 'default': Let Sage choose an algorithm (default).
  - 'classical': Gauss elimination.
  - 'partial_pivoting': Gauss elimination, using partial pivoting (if base ring has absolute value)
  - 'scaled_partial_pivoting': Gauss elimination, using scaled partial pivoting (if base ring has absolute value)
  - 'scaled_partial_pivoting_valuation': Gauss elimination, using scaled partial pivoting (if base ring has valuation)
  - 'strassen': use a Strassen divide and conquer algorithm (if available)

- `cutoff` – integer. Only used if the Strassen algorithm is selected.

- `transformation` – boolean. Whether to also return the transformation matrix. Some matrix backends do not provide this information, in which case this option is ignored.

**OUTPUT:**

The reduced row echelon form of `self`, as an immutable matrix. Note that `self` is not changed by this command. Use `echelonize()` to change `self` in place.

If the optional parameter `transformation=True` is specified, the output consists of a pair `(E, T)` of matrices where `E` is the echelon form of `self` and `T` is the transformation matrix.

**EXAMPLES:**

```
sage: MS = MatrixSpace(GF(19), 2, 3)
sage: C = MS.matrix([1,2,3,4,5,6])
sage: C.rank()
2
sage: C.nullity()
0
sage: C.echelon_form()
[ 1  0 18]
[ 0  1  2]
```
>>> from sage.all import *
>>> MS = MatrixSpace_GF(Integer(19), Integer(2), Integer(3))
>>> C = MS.matrix([[Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(6)]])
>>> C.rank()
2
>>> C.nullity()
0
>>> C.echelon_form()
[ 1 0 18]
[ 0 1  2]

The matrix library used for \( \mathbb{Z}/p\)-matrices does not return the transformation matrix, so the transformation option is ignored:

sage: C.echelon_form(transformation=True)
[ 1 0 18]
[ 0 1  2]

sage: D = matrix(ZZ, 2, 3, [1,2,3,4,5,6])
sage: D.echelon_form(transformation=True)
([1 2 3] [ 1 0]
 [0 3 6], [ 4 -1])
sage: E, T = D.echelon_form(transformation=True)
sage: T*D == E
True

sage: C.echelon_form(transformation=True)
[ 1 0 18]
[ 0 1  2]

sage: D = matrix(ZZ, Integer(2), Integer(3), [1,2,3,4,5,6])
sage: D.echelon_form(transformation=True)
([1 2 3] [ 1 0]
 [0 3 6], [ 4 -1])
sage: E, T = D.echelon_form(transformation=True)
sage: T*D == E
True

echelonize(algorithm='default', cutoff=0, **kwds)

Transform self into a matrix in echelon form over the same base ring as self.

**Note:** This row reduction does not use division if the matrix is not over a field (e.g., if the matrix is over the integers). If you want to calculate the echelon form using division, then use \( \texttt{rref()} \), which assumes that the matrix entries are in a field (specifically, the field of fractions of the base ring of the matrix).

**INPUT:**

- \texttt{algorithm} – string. Which algorithm to use. Choices are
- 'default': Let Sage choose an algorithm (default).
- 'classical': Gauss elimination.
- 'partial_pivoting': Gauss elimination, using partial pivoting (if base ring has absolute value)
- 'scaled_partial_pivoting': Gauss elimination, using scaled partial pivoting (if base ring has absolute value)
- 'scaled_partial_pivoting_valuation': Gauss elimination, using scaled partial pivoting (if base ring has valuation)
- 'strassen': use a Strassen divide and conquer algorithm (if available)

• cutoff – integer. Only used if the Strassen algorithm is selected.
• transformation – boolean. Whether to also return the transformation matrix. Some matrix backends do not provide this information, in which case this option is ignored.

OUTPUT:
The matrix self is put into echelon form. Nothing is returned unless the keyword option transformation=True is specified, in which case the transformation matrix is returned.

EXAMPLES:

```python
sage: a = matrix(QQ, 3,3, range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.echelonize()
sage: a
[ 1 0 -1]
[ 0 1 2]
[ 0 0 0]
```

```python
>>> from sage.all import *

```
Matrices and Spaces of Matrices, Release 10.4

```python
>>> from sage.all import *
>>> a = matrix(QQ, Integer(3), Integer(3), range(Integer(9))); a.set_immutable()
>>> a.echelonize()
Traceback (most recent call last):
...
ValueError: matrix is immutable; please change a copy instead
(i.e., use copy(M) to change a copy of M).
>>> a.echelon_form()
[ 1 0 -1]
[ 0 1 2]
[ 0 0 0]
```

Echelon form over the integers is what is also classically often known as Hermite normal form:

```python
sage: a = matrix(ZZ, 3,3, range(9))
sage: a.echelonize(); a
[ 3 0 -3]
[ 0 1 2]
[ 0 0 0]
```

We compute an echelon form both over a domain and fraction field:

```python
sage: R.<x,y> = QQ[]
sage: a = matrix(R, 2, [x,y, x,y])
sage: a.echelon_form()
# not very useful? -- why two copies of the same row? # needs sage.rings.function_field
[x y]
[x y]
```

```python
>>> from sage.all import *
>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> a = matrix(R, Integer(2), [x,y, x,y])
>>> a.echelon_form()
# not very useful? -- why two copies of the same row? # needs sage.rings.function_field
[x y]
[x y]
```

```python
sage: b = a.change_ring(R.fraction_field())
sage: b.echelon_form()
# potentially useful
[ 1 y/x]
[ 0 0]
```

We check that the echelon form works for matrices over p-adics. See Issue #17272:
```
sage: # needs sage.rings.padics
sage: R = ZpCA(5,5,print_mode='val-unit')
sage: A = matrix(R, 3,3, [250,2369,1147, 106,927,362, 90,398,2483])
sage: A
[5^3 * 2 + O(5^5) 2369 + O(5^5) 1147 + O(5^5)]
[ 106 + O(5^5) 927 + O(5^5) 362 + O(5^5)]
[ 5 * 18 + O(5^5) 398 + O(5^5) 2483 + O(5^5)]
sage: K = R.fraction_field()
sage: A.change_ring(K).augment(identity_matrix(K,3)).echelon_form()
[ 1 + O(5^5) O(5^5) O(5^5) 5 * 212 + O(5^5) 3031 + O(5^5) 2201 + O(5^5)]
[ 0 + O(5^5) 1 + O(5^5) 1348 + O(5^5) 5 * 306 + O(5^5) 2648 + O(5^5)]
[ 0 + O(5^5) 0 + O(5^5) 1987 + O(5^5) 5 * 263 + O(5^5) 154 + O(5^5)]
```

Echelon form is not defined over arbitrary rings:

```
sage: a = matrix(Integers(9), 3,3, range(9))
sage: a.echelon_form()
Traceback (most recent call last):
  ...                      
NotImplementedError: Echelon form not implemented over 'Ring of integers modulo 9'.
```

Involving a sparse matrix:

```
sage: m = matrix(3,[1, 1, 1, 1, 0, 2, 1, 2, 0], sparse=True); m
[1 1 1]
[1 0 2]
```

f = [1 2 0]
sage: m.echelon_form()
[ 1 0 2]
[ 0 1 -1]
[ 0 0 0]
sage: m.echelonize(); m
[ 1 0 2]
[ 0 1 -1]
[ 0 0 0]

The transformation matrix is optionally returned:

sage: m_original = m
sage: transformation_matrix = m.echelonize(transformation=True)
sage: m == transformation_matrix * m_original
True

eigenmatrix_left (other=None)

Return matrices $D$ and $P$, where $D$ is a diagonal matrix of eigenvalues and the rows of $P$ are corresponding eigenvectors (or zero vectors).

INPUT:

• other — a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved

OUTPUT:

If self is a square matrix $A$, then the output is a diagonal matrix $D$ and a matrix $P$ such that

$$PA = DP,$$

where the rows of $P$ are eigenvectors of $A$ and the diagonal entries of $D$ are the corresponding eigenvalues.

If a matrix $B$ is passed as optional argument, the output is a solution to the generalized eigenvalue problem such that

$$PA = DPB.$$
The ordinary eigenvalue problem is equivalent to the generalized one if $B$ is the identity matrix.

The generalized eigenvector decomposition is currently only implemented for matrices over RDF and CDF.

**EXAMPLES:**

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: D, P = A.eigenmatrix_left()
sage: D
[0 0 0]
[0 -1.348469228349535? 0]
[0 0 13.34846922834954?]
sage: P
[1 -2 1]
[1 0.3101020514433644? -0.3797958971132713?]
[1 1.289897948556636? 1.579795897113272?]
sage: P*A == D*P
True
```

Because $P$ is invertible, $A$ is diagonalizable.

```python
sage: A == (~P)*D*P  # needs sage.rings.number_field
True
```

The matrix $P$ may contain zero rows corresponding to eigenvalues for which the algebraic multiplicity is greater than the geometric multiplicity. In these cases, the matrix is not diagonalizable.

```python
sage: A = jordan_block(2, 3); A
[2 1 0]
(continues on next page)```
\[
\begin{bmatrix}
0 & 2 & 1 \\
0 & 0 & 2 \\
\end{bmatrix}
\]

\[
D, P = A.eigenmatrix_left()
\]

\[
D
\begin{bmatrix}
2 & 0 & 0 \\
0 & 2 & 0 \\
0 & 0 & 2 \\
\end{bmatrix}
\]

\[
P
\begin{bmatrix}
0 & 0 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{bmatrix}
\]

\[
P*A == D*P
\]

True

A generalized eigenvector decomposition:

\[
A = matrix(RDF, [[1, -2], [3, 4]])
\]

\[
B = matrix(RDF, [[0, 7], [2, -3]])
\]

\[
D, P = A.eigenmatrix_left(B)
\]

\[
(P * A - D * P * B).norm() < 1e-14
\]

True

The matrix \(B\) in a generalized eigenvalue problem may be singular:

\[
A = matrix(CDF, [[2, 1+I], [4, 2*2*I]])
\]

\[
D, P = A.eigenmatrix_left(B)
\]

\[
D.diagonal() # tol 1e-14
\]
In this case, we can still verify the eigenvector equation for the first eigenvalue and first eigenvector:

```
sage: # needs scipy sage.rings.complex_double sage.symbolic
sage: l = D[0, 0]
sage: v = P[0, :]
sage: (v * A - l * v * B).norm() < 1e-14
True
```

The second eigenvector is contained in the left kernel of $B$:

```
sage: (P[1, :] * B).norm() < 1e-14  # needs scipy sage.rings.complex_double sage.symbolic
True
```

See also:

- `eigenvalues()`, `eigenvectors_left()`, `Matrix_double_dense`
- `eigenvectors_left()`, `eigenmatrix_right()`

**eigenmatrix_right***(other=None)*

Return matrices $D$ and $P$, where $D$ is a diagonal matrix of eigenvalues and the columns of $P$ are corresponding eigenvectors (or zero vectors).

**INPUT:**

- `other` – a square matrix $B$ (default: `None`) in a generalized eigenvalue problem; if `None`, an ordinary eigenvalue problem is solved

**OUTPUT:**

If `self` is a square matrix $A$, then the output is a diagonal matrix $D$ and a matrix $P$ such that

$$AP = PD,$$

where the columns of $P$ are eigenvectors of $A$ and the diagonal entries of $D$ are the corresponding eigenvalues.
If a matrix $B$ is passed as optional argument, the output is a solution to the generalized eigenvalue problem such that

$$AP = BPD.$$ 

The ordinary eigenvalue problem is equivalent to the generalized one if $B$ is the identity matrix.

The generalized eigenvector decomposition is currently only implemented for matrices over RDF and CDF.

**EXAMPLES:**

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: D, P = A.eigenmatrix_right()
sage: D
[0 0 0]
[0 -1.348469228349535? 0]
[0 0 13.34846922834954?]
sage: P
[1 1 1]
[-2 0.1303061543300932? 3.069693845669907?]
[1 -0.7393876913398137? 5.139387691339814?]
sage: A*P == P*D
True
```

Because $P$ is invertible, $A$ is diagonalizable.

```python
sage: A == P*D*(~P) # needs sage.rings.number_field
True
```

The matrix $P$ may contain zero columns corresponding to eigenvalues for which the algebraic multiplicity is greater than the geometric multiplicity. In these cases, the matrix is not diagonalizable.
A generalized eigenvector decomposition:

```
sage: # needs scipy
sage: A = matrix(RDF, [[1, -2], [3, 4]])
sage: B = matrix(RDF, [[0, 7], [2, -3]])
sage: D, P = A.eigenmatrix_right(B)
sage: (A * P - B * P * D).norm() < 1e-14
True
```

The matrix $B$ in a generalized eigenvalue problem may be singular:

```
sage: # needs scipy
sage: A = matrix.identity(RDF, 2)
sage: B = matrix(RDF, [[3, 5], [6, 10]])
```

(continues on next page)
In this case, we can still verify the eigenvector equation for the first eigenvalue and first eigenvector:

```
sage: # needs scipy
sage: l = D[0, 0]
sage: v = P[:, 0]
sage: (A * v - B * v * l).norm() < 1e-14
True
```

The second eigenvector is contained in the right kernel of $B$:

```
sage: (B * P[:, 1]).norm() < 1e-14  # needs scipy
True
```

See also:

- `eigenvalues()`, `eigenvectors_right()`, `Matrix_double_dense.eigenvectors_right()`, `eigenmatrix_left()`.

### eigenspaces_left

(format='all', var='a', algebraic_multiplicity=False)

Compute the left eigenspaces of a matrix.

Note that `eigenspaces_left()` and `left_eigenspaces()` are identical methods. Here “left” refers to the eigenvectors being placed to the left of the matrix.

**INPUT:**

- `self` – a square matrix over an exact field. For inexact matrices consult the numerical or symbolic matrix classes.
- `format` – one of:
  - `'all'` – Attempts to create every eigenspace. This will always be possible for matrices with rational entries.
- 'galois' – For each irreducible factor of the characteristic polynomial, a single eigenspace will be output for a single root/eigenvalue for the irreducible factor.
- None (default) – Uses the 'all' format if the base ring is contained in an algebraically closed field which is implemented. Otherwise, uses the 'galois' format.

• var= string (default: 'a'); variable name used to represent elements of the root field of each irreducible factor of the characteristic polynomial. If var='a', then the root fields will be in terms of a0, a1, a2, ..., where the numbering runs across all the irreducible factors of the characteristic polynomial, even for linear factors.

• algebraic_multiplicity = (boolean, default: False); whether to include the algebraic multiplicity of each eigenvalue in the output. See the discussion below.

OUTPUT:
If algebraic_multiplicity=False, return a list of pairs \((e, V)\) where \(e\) is an eigenvalue of the matrix, and \(V\) is the corresponding left eigenspace. For Galois conjugates of eigenvalues, there may be just one representative eigenspace, depending on the format keyword.

If algebraic_multiplicity=True, return a list of triples \((e, V, n)\) where \(e\) and \(V\) are as above and \(n\) is the algebraic multiplicity of the eigenvalue.

Warning: Uses a somewhat naive algorithm (simply factors the characteristic polynomial and computes kernels directly over the extension field).

EXAMPLES:
We compute the left eigenspaces of a \(3 \times 3\) rational matrix. First, we request 'all' of the eigenvalues, so the results are in the field of algebraic numbers, \(\mathbb{QQbar}\). Then we request just one eigenspace per irreducible factor of the characteristic polynomial with format='galois'.

```sage
A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenspaces_left(format='all'); es

This method is only applicable to exact matrices. The “eigenmatrix” routines for matrices with
double-precision floating-point entries (RDF, CDF) are the best alternative. (Since some platforms return
eigenvectors that are the negatives of those given here, this one example is not tested here.) There are also
“eigenmatrix” routines for matrices with symbolic entries.

A request for 'all' the eigenvalues, when it is not possible, will raise an error. Using the 'galois' format option is more likely to be successful.

```sage
from sage.all import *
>>> # needs sage.rings.finite_rings
>>> F = FiniteField(Integer(11)**Integer(2), names=('b',)); (b,) = F._firstngen();
>>> A = matrix(F, [[b + Integer(1), b + Integer(1)], [Integer(10)*b + 4, 5*b + 4]])
>>> A.eigenspaces_left(format='all')
Traceback (most recent call last):...
NotImplementedError: unable to construct eigenspaces for eigenvalues outside the base field, try the keyword option: format='galois'
>>> A.eigenspaces_left(format='galois')
Traceback (most recent call last):...
NotImplementedError: unable to construct eigenspaces for eigenvalues outside the base field,
```

(continues on next page)
try the keyword option: format='galois'

```python
>>> A.eigenspaces_left(format='galois')  # needs sage.rings.number_field
[ (a0,
  Vector space of degree 2 and dimension 1 over
  Univariate Quotient Polynomial Ring in a0 over
  Finite Field in b of size 11^2
  with modulus x^2 + (5*b + 6)*x + 8*b + 10
  User basis matrix:
  [ 1 6*b*a0 + 3*b + 1]) ]
```

### eigenspaces_right (format='all', var='a', algebraic_multiplicity=False)

Compute the right eigenspaces of a matrix.

Note that `eigenspaces_right()` and `right_eigenspaces()` are identical methods. Here “right” refers to the eigenvectors being placed to the right of the matrix.

**INPUT:**

- **self** – a square matrix over an exact field. For inexact matrices consult the numerical or symbolic matrix classes.
- **format** – default: None
  - 'all' – attempts to create every eigenspace. This will always be possible for matrices with rational entries.
  - 'galois' – for each irreducible factor of the characteristic polynomial, a single eigenspace will be output for a single root/eigenvalue for their reducible factor.
  - None – Uses the ‘all’ format if the base ring is contained in an algebraically closed field which is implemented. Otherwise, uses the ‘galois’ format.
- **var** – (default: 'a'); variable name used to represent elements of the root field of each irreducible factor of the characteristic polynomial. If var='a', then the root fields will be in terms of a0, a1, a2, ...., where the numbering runs across all the irreducible factors of the characteristic polynomial, even for linear factors.
- **algebraic_multiplicity** – (default: False); whether or not to include the algebraic multiplicity of each eigenvalue in the output. See the discussion below.

**OUTPUT:**

If algebraic_multiplicity=False, return a list of pairs (e, V) where e is an eigenvalue of the matrix, and V is the corresponding left eigenspace. For Galois conjugates of eigenvalues, there may be just one representative eigenspace, depending on the format keyword.

If algebraic_multiplicity=True, return a list of triples (e, V, n) where e and V are as above and n is the algebraic multiplicity of the eigenvalue.

**Warning:** Uses a somewhat naive algorithm (simply factors the characteristic polynomial and computes kernels directly over the extension field).

**EXAMPLES:**

Right eigenspaces are computed from the left eigenspaces of the transpose of the matrix. As such, there is a greater collection of illustrative examples at the `eigenspaces_left()`.

We compute the right eigenspaces of a $3 \times 3$ rational matrix.
```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]

  User basis matrix:
      1 1/5*a1 + 2/5 2/5*a1 - 1/5))]

>>> es = A.eigenspaces_right(format='galois',
                            algebraic_multiplicity=True); es
[(0,
  Vector space of degree 3 and dimension 1 over Rational Field
  User basis matrix:
      1 -2 1),
(a1,
  Vector space of degree 3 and dimension 1 over
  Number Field in a1 with defining polynomial x^2 - 12*x - 18
  User basis matrix:
      1 1/5*a1 + 2/5 2/5*a1 - 1/5),
1)]

>>> e, v, n = es[Integer(0)]; v = v.basis()[Integer(0)]
>>> delta = v*e - A*v
>>> abs(abs(delta)) < RealNumber('1e-10')
True

The same computation, but with implicit base change to a field:

```
sage: A = matrix(ZZ, 3, range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.eigenspaces_right(format='galois')  # needs sage.rings.number_field
[(0,
  Vector space of degree 3 and dimension 1 over Rational Field
  User basis matrix:
      1 -2 1),
(a1,
  Vector space of degree 3 and dimension 1 over
  Number Field in a1 with defining polynomial x^2 - 12*x - 18
  User basis matrix:
      1 1/5*a1 + 2/5 2/5*a1 - 1/5))]

>>> from sage.all import *
>>> A = matrix(ZZ, Integer(3), range(Integer(9))); A
```
\begin{verbatim}
>>> A.eigenspaces_right(format='galois')
˓→ needs sage.rings.number_field
[ [0, Vector space of degree 3 and dimension 1 over Rational Field
    User basis matrix:
    [ 1 -2 1]),
  (a1,
   Vector space of degree 3 and dimension 1 over
   Number Field in a1 with defining polynomial x^2 - 12*x - 18
   User basis matrix:
    [ 1 1/5*a1 + 2/5 2/5*a1 - 1/5])

This method is only applicable to exact matrices. The “eigenmatrix” routines for matrices with
double-precision floating-point entries (RDF, CDF) are the best alternative. (Since some platforms return
eigenvectors that are the negatives of those given here, this one example is not tested here.) There are also
“eigenmatrix” routines for matrices with symbolic entries.

---

eigenvalue_multiplicity(s)
Return the multiplicity of s as a generalized eigenvalue of the matrix.

EXAMPLES:

sage: M = Matrix(QQ, [[0,1],[0,0]])
sage: M.eigenvalue_multiplicity(0)
2
sage: M.eigenvalue_multiplicity(1)
0

sage: M = posets.DiamondPoset(5).coxeter_transformation()  # needs sage.graphs sage.libs.flint
sage: [M.eigenvalue_multiplicity(x) for x in [-1, 1]]  # needs sage.graphs sage.libs.flint
[3, 2]

>>> from sage.all import *
>>> M = Matrix(QQ, [[Integer(0),Integer(1)],[Integer(0),Integer(0)]]])
>>> M.eigenvalue_multiplicity(0)
2
>>> M.eigenvalue_multiplicity(Integer(1))
0

(continues on next page)
**eigenvalues** (*extend=True*)

Return a sequence of the eigenvalues of a matrix, with multiplicity. If the eigenvalues are roots of polynomials in QQ, then QQbar elements are returned that represent each separate root.

If the option `extend` is set to `False`, only eigenvalues in the base ring are considered.

**EXAMPLES:**

```
sage: a = matrix(ZZ, 4, range(16)); a
[ 0  1  2  3]
[ 4  5  6  7]
[ 8  9 10 11]
[12 13 14 15]
sage: sorted(a.eigenvalues(), reverse=True)  # needs sage.rings.number_field
[32.46424919657298?, 0, 0, -2.464249196572981?]
```

```
>>> from sage.all import *

>>> a = matrix(ZZ, Integer(4), range(Integer(16))); a
[ 0  1  2  3]
[ 4  5  6  7]
[ 8  9 10 11]
[12 13 14 15]
```

```
>>> sorted(a.eigenvalues(), reverse=True)  # needs sage.rings.number_field
[32.46424919657298?, 0, 0, -2.464249196572981?]
```

```
sage: a = matrix([(1, 9, -1, -1),
....: (-2, 0, -10, 2),
....: (-1, 0, 15, -2),
....: (0, 1, 0, -1)])
sage: a.eigenvalues()  # needs sage.rings.number_field

```
A symmetric matrix $a + a.transpose()$ should have real eigenvalues

```
sage: b = a + a.transpose()
sage: ev = b.eigenvalues(); ev
[-8.35066086057957?, -1.107247901349379?, 5.718651326708515?, 33.73925743522043?]
```

The eigenvalues are elements of QQbar, so they really represent exact roots of polynomials, not just approximations.

```
sage: e = ev[0]; e
-8.35066086057957?
sage: p = e.minpoly(); p
x^4 - 30*x^3 - 171*x^2 + 1460*x + 1784
sage: p(e) == 0
True
```

To perform computations on the eigenvalue as an element of a number field, you can always convert back to a number field element.

```
sage: e.as_number_field_element()
(Number Field in a with defining polynomial y^4 - 2*y^3 - 507*y^2 - 3972*y - 4264, a + 7, Ring morphism:
  From: Number Field in a with defining polynomial y^4 - 2*y^3 - 507*y^2 - 3972*y - 4264
  To:   Algebraic Real Field
  Defn: a |--> -15.35066086057957?)
```
with defining polynomial \( y^4 - 2y^3 - 507y^2 - 3972y - 4264 \),
a + 7,
Ring morphism:
  From: Number Field in a with defining polynomial \( y^4 - 2y^3 - 507y^2 - 3972y - 4264 \)
  \(\rightarrow\) Algebraic Real Field
  Defn: a |--> -15.35066086057957?

Notice the effect of the `extend` option.

```
sage: M = matrix(QQ, [[0,-1,0], [1,0,0], [0,0,2]])
sage: M.eigenvalues()
# needs sage.rings.number_field
[2, -1*I, 1*I]
sage: M.eigenvalues(extend=False)
# needs sage.libs.pari
[2]
```

>> from sage.all import *
>> M = matrix(QQ, [[Integer(0),Integer(1),Integer(0)], [Integer(1), Integer(0),Integer(0)], [Integer(0),Integer(0),Integer(2)]]
>> M.eigenvalues()
# needs sage.rings.number_field
[2, -1*I, 1*I]
>> M.eigenvalues(extend=False)
# needs sage.libs.pari
[2]

The method also works for matrices over finite fields:

```
sage: M = matrix(GF(3), [[0,1,1], [1,2,0], [2,0,1]])
sage: ev = sorted(M.eigenvalues()); ev
# needs sage.rings.finite_rings
[2*z3, 2*z3 + 1, 2*z3 + 2]
```

>> from sage.all import *
>> M = matrix(GF(Integer(3)), [[0,1,1], [1,2,0], [2,0,1]])
>> ev = sorted(M.eigenvalues()); ev
# needs sage.rings.finite_rings
[2*z3, 2*z3 + 1, 2*z3 + 2]

Similarly as in the case of \( \mathbb{Q} \bar{\mathbb{Q}} \), the eigenvalues belong to some algebraic closure but they can be converted to elements of a finite field:

```
sage: e = ev[0]
# needs sage.rings.finite_rings
sage: e.parent()
# needs sage.rings.finite_rings
Algebraic closure of Finite Field of size 3
sage: e.as_finite_field_element()
# needs sage.rings.finite_rings
(Finite Field in z3 of size 3^3, 2*z3,
 Ring morphism:
  From: Finite Field in z3 of size 3^3
```
To: Algebraic closure of Finite Field of size 3
Defn: z3 |--> z3

>>> from sage.all import *

>>> e = ev[Integer(0)]
    # needs sage.rings.finite_rings
>>> e.parent()
    # needs sage.rings.finite_rings
Algebraic closure of Finite Field of size 3
>>> e.as_finite_field_element()
    # needs sage.rings.finite_rings
(Finite Field in z3 of size 3^3, 2*z3,
Ring morphism:
  From: Finite Field in z3 of size 3^3
  To:  Algebraic closure of Finite Field of size 3
  Defn: z3 |--> z3)

\textbf{eigenvectors_left}(\textit{other=None, extend=True})

Compute the left eigenvectors of a matrix.

\textbf{INPUT:}

\begin{itemize}
  \item other – a square matrix \(B\) (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved (currently supported only if the base ring of \textit{self} is \texttt{RDF} or \texttt{CDF})
  \item extend – boolean (default: True)
\end{itemize}

\textbf{OUTPUT:}

For each distinct eigenvalue, returns a list of the form \((e, V, n)\) where \(e\) is the eigenvalue, \(V\) is a list of eigenvectors forming a basis for the corresponding left eigenspace, and \(n\) is the algebraic multiplicity of the eigenvalue.

If the option extend is set to False, then only the eigenvalues that live in the base ring are considered.

\textbf{EXAMPLES:}

We compute the left eigenvectors of a \(3 \times 3\) rational matrix.

\begin{verbatim}
sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
\begin{bmatrix} 0 & 1 & 2 \\ 3 & 4 & 5 \\ 6 & 7 & 8 \end{bmatrix}
sage: es = A.eigenvectors_left(); es
[[0, [ (1, -2, 1) ], 1],
 (-1.348469228349535?, [(1, 0.3101020514433644?, -0.3797958971132713?)], 1),
 (13.34846922834954?, [(1, 1.289897948556636?, 1.579795897113272?)], 1)]
sage: eval, [evec], mult = es[0]
sage: delta = eval*evec - evec*A
sage: abs(abs(delta)) < 1e-10
True
\end{verbatim}

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

>>> es = A.eigenvectors_left(); es
[(0, [(1, -2, 1)], 1),
 (-1.348469228349535?, [(1, 0.3101020514433644?, -0.3797958971132713?)], 1),
 (13.34846922834954?, [(1, 1.289897948556636?, 1.579795897113272?)], 1)]

>>> eval, [evec], mult = es[Integer(0)]

>>> delta = eval*evec - evec*A

>>> abs(abs(delta)) < RealNumber('1e-10')
True

Notice the difference between considering ring extensions or not.

sage: M = matrix(QQ, [[0,-1,0], [1,0,0], [0,0,2]])

sage: M.eigenvectors_left()

# needs sage.rings.number_field

[(2, [(0, 0, 1)], 1),
 (-1*I, [(1, -1*I, 0)], 1),
 (1*I, [(1, 1*I, 0)], 1)]

sage: M.eigenvectors_left(extend=False)

# needs sage.rings.number_field

[(2, [(0, 0, 1)], 1)]

>>> M = matrix(QQ, [[Integer(0),-Integer(1),Integer(0)], [Integer(1), Integer(0),Integer(0)], [Integer(0),Integer(0),Integer(2)]]

>>> M.eigenvectors_left()

# needs sage.rings.number_field

[(2, [(0, 0, 1)], 1),
 (-1*I, [(1, -1*I, 0)], 1),
 (1*I, [(1, 1*I, 0)], 1)]

>>> M.eigenvectors_left(extend=False)

# needs sage.rings.number_field

[(2, [(0, 0, 1)], 1)]

eigenvectors_right (other=None, extend=True)

Compute the right eigenvectors of a matrix.

INPUT:

• other - a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary
eigenvalue problem is solved (currently supported only if the base ring of self is RDF or CDF)

• extend - boolean (default: True)

OUTPUT:

For each distinct eigenvalue, returns a list of the form $(e,V,n)$ where $e$ is the eigenvalue, $V$ is a list of eigenvectors forming a basis for the corresponding right eigenspace, and $n$ is the algebraic multiplicity of the
eigenvalue. If extend = True (the default), this will return eigenspaces over the algebraic closure of the
base field where this is implemented; otherwise it will restrict to eigenvalues in the base field.

EXAMPLES:

We compute the right eigenvectors of a $3 \times 3$ rational matrix.

sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]

True
\end{verbatim}

**elementary_divisors** *(algorithm=None)*

If `self` is a matrix over a principal ideal domain \(R\), return elements \(d_i\) for \(1 \leq i \leq k = \min(r, s)\) where \(r\) and \(s\) are the number of rows and columns of \(self\), such that the cokernel of \(self\) is isomorphic to

\[
R/(d_1) \oplus R/(d_2) \oplus \cdots \oplus R/(d_k)
\]

with \(d_i \mid d_{i+1}\) for all \(i\). These are the diagonal entries of the Smith form of \(self\) (see *smith_form()*).

**INPUT:**

- **algorithm** — ignored

**EXAMPLES:**

\begin{verbatim}
sage: x = polygen(ZZ, 'x')
sage: OE.<w> = EquationOrder(x**Integer(2) - x + Integer(2), names=(w,)); (w,)
# needs sage.rings.number_field
# needs sage.rings.number_field

>> from sage.all import *
>> x = polygen(ZZ, 'x')
>> OE = EquationOrder(x**Integer(2) - x + Integer(2), names=('w',)); (w,)
(continues on next page)
See also:

\texttt{smith_form()}

\textbf{elementwise_product} (right)

Returns the elementwise product of two matrices of the same size (also known as the Hadamard product).

\textbf{INPUT}:

- \texttt{right} – the right operand of the product. A matrix of the same size as \texttt{self} such that multiplication of elements of the base rings of \texttt{self} and \texttt{right} is defined, once Sage’s coercion model is applied. If the matrices have different sizes, or if multiplication of individual entries cannot be achieved, a \texttt{TypeError} will result.

\textbf{OUTPUT}:

A matrix of the same size as \texttt{self} and \texttt{right}. The entry in location \((i, j)\) of the output is the product of the two entries in location \((i, j)\) of \texttt{self} and \texttt{right} (in that order).

The parent of the result is determined by Sage’s coercion model. If the base rings are identical, then the result is dense or sparse according to this property for the left operand. If the base rings must be adjusted for one, or both, matrices then the result will be sparse only if both operands are sparse. No subdivisions are present in the result.

If the type of the result is not to your liking, or the ring could be “tighter,” adjust the operands with \texttt{change_ring()}. Adjust sparse versus dense inputs with the methods \texttt{sparse_matrix()} and \texttt{dense_matrix()}.

\textbf{EXAMPLES}:

```
sage: A = matrix(ZZ, 2, 3, range(6))
sage: B = matrix(QQ, 2, 3, [5, 1/3, 2/7, 11/2, -3/2, 8])
sage: C = A.elementwise_product(B)
sage: C
\begin{bmatrix}
 0 & 1/3 & 4/7 \\
33/2 & -6 & 40
\end{bmatrix}
sage: C.parent()
Full MatrixSpace of 2 by 3 dense matrices over Rational Field
```

```
>>> from sage.all import *
>>> A = matrix(ZZ, Integer(2), Integer(3), range(Integer(6)))
>>> B = matrix(QQ, Integer(2), Integer(3), [Integer(5), Integer(1)/Integer(3),
→ Integer(2)/Integer(7), Integer(11)/Integer(2), -Integer(3)/Integer(2),␣
→ Integer(8)])
>>> C = A.elementwise_product(B)
>>> C
\begin{bmatrix}
 0 & 1/3 & 4/7 \\
33/2 & -6 & 40
\end{bmatrix}
>>> C.parent()
Full MatrixSpace of 2 by 3 dense matrices over Rational Field
```

Notice the base ring of the results in the next two examples.
sage: x = polygen(ZZ, 'x')
sage: D = matrix(ZZ['x'], 2, [1+x^2, 2, 3, 4-x])
sage: E = matrix(QQ, 2, [1, 2, 3, 4])
sage: F = D.elementwise_product(E)
sage: F
[ x^2 + 1  4]
[ 9 -4*x + 16]

over Finite Field of size 3

>>> from sage.all import *

>>> G = matrix(GF(Integer(3)), Integer(2), [Integer(0), Integer(1), Integer(2), Integer(2), Integer(3), Integer(4)])

>>> H = matrix(ZZ, Integer(2), [Integer(1), Integer(2), Integer(3), Integer(4)])

>>> J = G.elementwise_product(H)

>>> J
[0 2]
[0 2]

>>> J.parent()
Full MatrixSpace of 2 by 2 dense matrices
over Finite Field of size 3

Non-commutative rings behave as expected. These are the usual quaternions.

sage: # needs sage.combinat
sage: R.<i,j,k> = QuaternionAlgebra(-1, -1)
sage: A = matrix(R, 2, [1, i, j, k])
sage: B = matrix(R, 2, [i, i, i, i])
sage: A.elementwise_product(B)
[ i -1]
[-k j]

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

sage: B.elementwise_product(A)
[ i -1]
[ k -j]

>>> from sage.all import *
>>> # needs sage.combinat
>>> R = QuaternionAlgebra(-Integer(1), -Integer(1), names=('i', 'j', 'k',));
˓→(i, j, k,) = R._first_ngens(3)
>>> A = matrix(R, Integer(2), [Integer(1),i,j,k])
>>> B = matrix(R, Integer(2), [i,i,i,i])
>>> A.elementwise_product(B)
[ i -1]
[-k j]
>>> B.elementwise_product(A)
[ i -1]
[ k -j]

Input that is not a matrix will raise an error.

sage: A = random_matrix(ZZ, 5, 10, x=20)
sage: A.elementwise_product(vector(ZZ, [1,2,3,4]))
Traceback (most recent call last):
  ...  TypeError: no common canonical parent for objects with parents:
'Full MatrixSpace of 5 by 10 dense matrices over Integer Ring' and
'Ambient free module of rank 4 over the principal ideal domain Integer Ring'

sage: A = matrix(2, 2, range(4))
sage: A.elementwise_product(polygen(parent(A)))
Traceback (most recent call last):
  ...  TypeError: elementwise_product() argument should be a matrix
or coercible to a matrix

>>> from sage.all import *
>>> A = random_matrix(ZZ, 5, 10, x=20)
>>> A.elementwise_product(vector(ZZ, [Integer(1),Integer(2),Integer(3),
˓→Integer(4)]))
Traceback (most recent call last):
  ...  TypeError: no common canonical parent for objects with parents:
'Full MatrixSpace of 5 by 10 dense matrices over Integer Ring' and
'Ambient free module of rank 4 over the principal ideal domain Integer Ring'

>>> A = matrix(Integer(2), Integer(2), range(Integer(4)))
>>> A.elementwise_product(polygen(parent(A)))
Traceback (most recent call last):
  ...  TypeError: elementwise_product() argument should be a matrix
or coercible to a matrix

Matrices of different sizes for operands will raise an error.

sage: A = random_matrix(ZZ, 5, 10, x=20)
sage: B = random_matrix(ZZ, 10, 5, x=40)
sage: A.elementwise_product(B)
Traceback (most recent call last):
...
TypeError: no common canonical parent for objects with parents:
'Full MatrixSpace of 5 by 10 dense matrices over Integer Ring' and
'Full MatrixSpace of 10 by 5 dense matrices over Integer Ring'

>>> from sage.all import *
>>> A = random_matrix(ZZ, Integer(5), Integer(10), x=Integer(20))
>>> B = random_matrix(ZZ, Integer(10), Integer(5), x=Integer(40))
>>> A.elementwise_product(B)
Traceback (most recent call last):
...
TypeError: no common canonical parent for objects with parents:
'Full MatrixSpace of 5 by 10 dense matrices over Integer Ring' and
'Full MatrixSpace of 10 by 5 dense matrices over Integer Ring'

Some pairs of rings do not have a common parent where multiplication makes sense. This will raise an error.

sage: A = matrix(QQ, 3, 2, range(6))
sage: B = matrix(GF(3), 3, [2]*6)
sage: A.elementwise_product(B)
Traceback (most recent call last):
...
TypeError: no common canonical parent for objects with parents:
'Full MatrixSpace of 3 by 2 dense matrices over Rational Field' and
'Full MatrixSpace of 3 by 2 dense matrices over Finite Field of size 3'

We illustrate various combinations of sparse and dense matrices. The usual coercion rules apply:

sage: A = matrix(ZZ, 5, 6, range(30), sparse=False)
sage: B = matrix(ZZ, 5, 6, range(30), sparse=True)
sage: C = matrix(QQ, 5, 6, range(30), sparse=True)
sage: A.elementwise_product(C).is_sparse()
True
sage: B.elementwise_product(C).is_sparse()
True
sage: A.elementwise_product(B).is_dense()
True
sage: B.elementwise_product(A).is_dense()
True
exp()

Calculate the exponential of this matrix X, which is the matrix

\[ e^X = \sum_{k=0}^{\infty} \frac{X^k}{k!}. \]

This function depends on maxima’s matrix exponentiation function, which does not deal well with floating point numbers. If the matrix has floating point numbers, they will be rounded automatically to rational numbers during the computation. If you want approximations to the exponential that are calculated numerically, you may get better results by first converting your matrix to RDF or CDF, as shown in the last example.

EXAMPLES:

```sage
data: # needs sage.symbolic
data: a = matrix([[1,2], [3,4]])
data: a.exp()
data: # needs sage.symbolic
[[-1/22*((sqrt(33) - 11)*e^sqrt(33) - sqrt(33) - 11)*e^(-1/2*sqrt(33) + 5/2), 2/33*(sqrt(33)*e^sqrt(33) - sqrt(33))*e^(-1/2*sqrt(33) + 5/2)],
 [1/11*(sqrt(33)*e^sqrt(33) - sqrt(33))*e^(-1/2*sqrt(33) + 5/2), 1/22*((sqrt(33) + 11)*e^sqrt(33) - sqrt(33) + 11)*e^(-1/2*sqrt(33) + 5/2)]
data: type(a.exp())

\end{pmatrix}
\]
```

```
extended_echelon_form(subdivide=False, **kwds)

Return the echelon form of self augmented with an identity matrix.

INPUT:

- `subdivide` - (boolean, default: False) whether to subdivide the returned matrix. See the description of the (output) below for details.
- `kwds` - additional keywords that can be passed to the method that computes the echelon form.

OUTPUT:

If $A$ is an $m \times n$ matrix, add the $m$ columns of an $m \times m$ identity matrix to the right of self. Then row-reduce this $m \times (n + m)$ matrix. This matrix is returned as an immutable matrix.

If `subdivide` is `True` then the returned matrix has a single division among the columns and a single division among the rows. The column subdivision has $n$ columns to the left and $m$ columns to the right. The row division separates the non-zero rows from the zero rows, when restricted to the first $n$ columns.

For a nonsingular matrix the final $m$ columns of the extended echelon form are the inverse of self. For a matrix of any size, the final $m$ columns provide a matrix that transforms self to echelon form when it multiplies self from the left. When the base ring is a field, the uniqueness of reduced row-echelon form implies that this transformation matrix can be taken as the coefficients giving a canonical set of linear combinations of the rows of self that yield reduced row-echelon form.

When subdivided as described above, and again over a field, the parts of the subdivision in the upper-left corner and lower-right corner satisfy several interesting relationships with the row space, column space, left kernel and right kernel of self. See the examples below.

**Note:** This method returns an echelon form. If the base ring is not a field, no attempt is made to move to the fraction field. See an example below where the base ring is changed manually.

**EXAMPLES:**

The four relationships at the end of this example hold in general.

```python
sage: A = matrix(QQ, [[2, -1, 7, -1, 0, -3],
        ....: [-1, 1, -5, 3, 4, 4],
        ....: [2, -1, 7, 0, 2, -2],
        ....: [2, -1, 7, 0, 2, -2]])

sage: E = A.extended_echelon_form(subdivide=True); E
[ 1 0 2 0 0 -1| 0 -1 0 1 -1]
[ 0 1 -3 0 -2 0| 0 -2 0 2 -3]
[ 0 0 0 1 2 1| 0 2/3 0 -1/3 2/3]
[-----------------------------+------------------------]
[ 0 0 0 0 0 0| 1 2/3 0 -1/3 -1/3]
[ 0 0 0 0 0 0| 0 0 1 0 -1]

sage: J = E.matrix_from_columns(range(6,11)); J
[ 0 -1 0 1 -1]
[ 0 -2 0 2 -3]
[ 0 2/3 0 -1/3 2/3]
[ 1 2/3 0 -1/3 -1/3]
[ 0 0 1 0 -1]

sage: J*A == A.rref()
True
sage: C = E.subdivision(0,0); C
[ 1 0 2 0 0 -1]
```

(continues on next page)
For a nonsingular matrix, the right half of the extended echelon form is the inverse matrix.
The result is in echelon form, so if the base ring is not a field, the leading entry of each row may not be 1. But you can easily change to the fraction field if necessary.
```python
>>> from sage.all import *

>>> A = matrix(ZZ, [[Integer(16), Integer(20), Integer(4), Integer(5), -
Integer(4), Integer(13), Integer(5)], ...
   [Integer(10), Integer(13), Integer(3), -Integer(3), -
Integer(10), Integer(11), Integer(6)], ...
   [Integer(2), -Integer(10), -Integer(4)], ...
   [Integer(10), Integer(13), Integer(3), Integer(3), -
Integer(10), Integer(1), Integer(8)], ...
   [Integer(4), Integer(5), Integer(1), Integer(8), -
Integer(1), Integer(9), Integer(4)], ...
   [Integer(10), Integer(1), -Integer(1)]]

>>> E = A.extended_echelon_form(subdivide=True); E

[ 2 0 -2 2 -9 -3 -4| 0 4 -3 -9 4]
[ 0 1 2 0 1 1| 0 1 2 1 1]
[ 0 0 3 -4 -1 -1| 0 3 1 -3 3]
[----------------+--------------]
[ 0 0 0 0 0 0| 1 6 3 6 5]
[ 0 0 0 0 0 0| 0 7 2 7 6]

>>> J = E.matrix_from_columns(range(Integer(7),Integer(12))); J

[ 0 4 -3 -9 4]
[ 0 1 2 1 1]
[ 0 3 1 -3 3]
[ 1 6 3 6 5]
[ 0 7 2 -7 6]

>>> J*A == A.echelon_form()
True

>>> B = A.change_ring(QQ)

>>> B.extended_echelon_form(subdivide=True)

[ 1 0 -1 0 -19/6 -7/6 -5/3| 0 0 -89/42 -5/2 +1/7]
[ 0 1 1 0 8/3 5/3 5/3| 0 0 34/21 2 -1/7]
[ 0 0 0 1 -4/3 -1/3 -1/3| 0 0 1/21 0 +1/7]
[----------------+-------------------------------]
[ 0 0 0 0 0 0| 1 0 9/7 0 -1/7]
[ 0 0 0 0 0 0| 0 1 2/7 -1 6/7]

Subdivided, or not, the result is immutable, so make a copy if you want to make changes.

```
Matrices and Spaces of Matrices, Release 10.4

[1 0 0 4 6]
[0 1 0 4 2 2]
[0 0 1 5 2 3]

```python
>>> from sage.all import *

A = matrix(FiniteField(Integer(7)), [[Integer(2), Integer(0), Integer(3)],
                                           [Integer(5), Integer(5), Integer(3)],
                                           [Integer(5), Integer(6), Integer(5)]]

E = A.extended_echelon_form()

E.is_mutable()
False

F = A.extended_echelon_form(subdivide=True)

F.is_mutable()
False

G = copy(F)

G.subdivide([], []); G
```

If you want to determine exactly which algorithm is used to compute the echelon form, you can add additional keywords to pass on to the `echelon_form()` routine employed on the augmented matrix. Sending the flag `include_zero_rows` is a bit silly, since the extended echelon form will never have any zero rows.

```python
sage: A = matrix(ZZ, [[1, 2], [5, 0], [5, 9]])

sage: E = A.extended_echelon_form(include_zero_rows=False)

sage: E
```

Return the factorization of the characteristic polynomial of self.

**INPUT:**

- var – (default: ‘x’) name of variable of charpoly

**EXAMPLES:**

```python
sage: M = MatrixSpace(QQ, 3, 3)
sage: A = M([1, 9, 1, -7, 4/5, 4, 3, 6, 4, 3])
sage: A.fcp() #...
```

(continues on next page)
find \( (f, \text{indices}=\text{False}) \)

Find elements in this matrix satisfying the constraints in the function \( f \). The function is evaluated on each element of the matrix.

**INPUT:**

- \( f \) – a function that is evaluated on each element of this matrix.
- \( \text{indices} \) – whether or not to return the indices and elements of this matrix that satisfy the function.

**OUTPUT:** If \( \text{indices} \) is not specified, return a matrix with 1 where \( f \) is satisfied and 0 where it is not. If \( \text{indices} \) is specified, return a dictionary containing the elements of this matrix satisfying \( f \).

**EXAMPLES:**

```python
sage: M = matrix(4,3,[1, -1/2, -1, 1, -1, -1/2, -1, 0, 0, 2, 0, 1])
sage: M.find(lambda entry: entry == 0)
[0 0 0]
[0 0 0]
[0 1 1]
[0 1 0]
```

```python
>>> from sage.all import *

sage: M = MatrixSpace(QQ, Integer(3), Integer(3))
sage: A = M([[Integer(1), Integer(9), -Integer(7), Integer(4)/Integer(5),
              -Integer(7), -Integer(1), -Integer(1)/Integer(2), -Integer(1), -Integer(1)/Integer(2), -Integer(1),
              Integer(0), Integer(0), Integer(2), Integer(0), Integer(1)]])

sage: A.fcp()
```

```python
x^3 - 8*x^2 + 209/5*x - 286
```

```python
>>> from sage.all import *

sage: M = matrix(4,3,[1, -1/2, -1, 1, -1, -1/2, -1, 0, 0, 2, 0, 1])

sage: M.find(lambda u: u < 0)
[0 1 1]
[0 1 1]
[1 0 0]
[0 0 0]
```
fitting_ideal\( (i) \)

Return the \( i \)-th Fitting ideal of the matrix. This is the ideal generated by the \( n - i \) minors, where \( n \) is the
number of columns.

INPUT:
- \(i\) – an integer

OUTPUT:
An ideal on the base ring.

EXAMPLES:

```python
sage: R.<x,y,z> = QQ[]
sage: M = matrix(R, [[2*x-z, 0, y-z^2, 1], [0, z - y, z - x, 0],[z - y, x^2 -> -y, 0, 0]])
sage: M
[ 2*x - z 0 -z^2 + y 1]
[   0  -y + z   -x + z  0]
[    -y + z  x^2 - y  0    0]
sage: (R.ideal(M.minors(i)) == M.fitting_ideal(4-i) for i in range(5))
[True, True, True, True, True]
sage: M.fitting_ideal(0)
Ideal (0) of Multivariate Polynomial Ring in x, y, z over Rational Field
sage: M.fitting_ideal(1)
Ideal (2*x^4 - 3*x^3*z + x^2*z^2 + y^2*z^2 - 2*y*x^2*y - y^3 +...)
Ideal (2*x - z, -z^2 + y, 1, -y + z, -x + z, -y + z, x^2 - y) of Multivariate Polynomial Ring in x, y, z over Rational Field
sage: M.fitting_ideal(3)
Ideal (2*x - z, -z^2 + y, 1, -y + z, -x + z, -y + z, x^2 - y) of Multivariate Polynomial Ring in x, y, z over Rational Field
sage: M.fitting_ideal(4)
Ideal (1) of Multivariate Polynomial Ring in x, y, z over Rational Field
```

```python
>>> from sage.all import *
>>> R = QQ['x, y, z']; (x, y, z,) = R._first_ngens(3)
>>> M = matrix(R, [[Integer(2)*x-z, Integer(0), y-z**Integer(2), Integer(1)],
[Integer(0), z - y, z - x, Integer(0)],[z - y, x**Integer(2) - y, Integer(0), Integer(0)])
>>> M
[ 2*x - z 0 -z^2 + y 1]
[   0  -y + z   -x + z  0]
[    -y + z  x^2 - y  0    0]
>>> (R.ideal(M.minors(i)) == M.fitting_ideal(Integer(4)-i) for i in range(Integer(5))]
[True, True, True, True, True]
>>> M.fitting_ideal(Integer(0))
Ideal (0) of Multivariate Polynomial Ring in x, y, z over Rational Field
>>> M.fitting_ideal(Integer(1))
Ideal (2*x^4 - 3*x^3*z + x^2*z^2 + y^2*z^2 - 2*y*x^2*y - y^3 +...)
Ideal (2*x - z, -z^2 + y, 1, -y + z, -x + z, -y + z, x^2 - y) of Multivariate Polynomial Ring in x, y, z over Rational Field
>>> M.fitting_ideal(Integer(3))
Ideal (2*x - z, -z^2 + y, 1, -y + z, -x + z, -y + z, x^2 - y) of Multivariate Polynomial Ring in x, y, z over Rational Field
>>> M.fitting_ideal(Integer(4))
Ideal (1) of Multivariate Polynomial Ring in x, y, z over Rational Field
```

If the base ring is a field, the Fitting ideals are zero under the corank:
Matrices and Spaces of Matrices, Release 10.4

```python
sage: M = matrix(QQ, [[2,1,3,5],[4,2,6,6],[0,3,2,0]])
sage: M
[2 1 3 5]
[4 2 6 6]
[0 3 2 0]
sage: M.fitting_ideal(0)
Principal ideal (0) of Rational Field
sage: M.fitting_ideal(1)
Principal ideal (1) of Rational Field
sage: M.fitting_ideal(2)
Principal ideal (1) of Rational Field
sage: M.fitting_ideal(3)
Principal ideal (1) of Rational Field
sage: M.fitting_ideal(4)
Principal ideal (1) of Rational Field

>>> from sage.all import *

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>

<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>
```

(continues on next page)
This is also true for univariate polynomials over a field:

```
sage: R.<x> = QQ[]
sage: M = matrix(R,[[x**2-2*x+1, x-1,x**2-1],
   [0,x+1,1]])
sage: M.fitting_ideal(0)
Principal ideal (0) of Univariate Polynomial Ring in x over Rational Field
sage: M.fitting_ideal(1)
Principal ideal (x - 1) of Univariate Polynomial Ring in x over Rational Field
sage: M.fitting_ideal(2)
Principal ideal (1) of Univariate Polynomial Ring in x over Rational Field
```

```
>>> from sage.all import *
>>> R = QQ['x']; (x,) = R._first_ngens(1)
>>> M = matrix(R,[[x**Integer(2)-Integer(2)*x+Integer(1), x-Integer(1),
   x**Integer(2)-Integer(1)],[Integer(0),x+Integer(1),Integer(1)]])
```

get_subdivisions()

Returns the current subdivision of self.

EXAMPLES:

```
sage: M = matrix(5, 5, range(25))
sage: M.subdivisions()
([], [])
sage: M.subdivide(2,3)
```
gram_schmidt (orthonormal=False)

Performs Gram-Schmidt orthogonalization on the rows of the matrix, returning a new matrix and a matrix accomplishing the transformation.

INPUT:

- **self** – a matrix whose rows are to be orthogonalized.
- **orthonormal** – (default: False); if True the returned orthogonal vectors are unit vectors. This keyword is ignored if the matrix is over RDF or CDF and the results are always orthonormal.

OUTPUT:

A pair of matrices, $G$ and $M$ such that if $A$ represents $self$, where the parenthetical properties occur when $orthonormal = True$:

- $A = M^*G$
- The rows of $G$ are an orthogonal (resp. orthonormal) set of vectors.
- $G$ times the conjugate-transpose of $G$ is a diagonal (resp. identity) matrix.
- The row space of $G$ equals the row space of $A$.
- $M$ is a full-rank matrix with zeros above the diagonal.

For exact rings, any zero vectors produced (when the original vectors are linearly dependent) are not output, thus the orthonormal set is linearly independent, and thus a basis for the row space of the original matrix.

Any notion of a Gram-Schmidt procedure requires that the base ring of the matrix has a fraction field implemented. In order to arrive at an orthonormal set, it must be possible to construct square roots of the elements of the base field. In Sage, your best option is the field of algebraic numbers, $\mathbb{Q}\bar{\mathbb{Q}}$, which properly contains the rationals and number fields.
If you have an approximate numerical matrix, then this routine requires that your base field be the real and complex double-precision floating point numbers, RDF and CDF. In this case, the matrix is treated as having full rank, as no attempt is made to recognize linear dependence with approximate calculations.

EXAMPLES:

Inexact Rings, Numerical Matrices:

First, the inexact rings, CDF and RDF.

```python
sage: # needs scipy sage.rings.complex_double sage.symbolic
sage: A = matrix(CDF, [[ 0.6454 + 0.7491*I, -0.8662 + 0.1489*I, 0.7656 - 0.00344*I],
...: [-0.2913 + 0.8057*I, 0.8321 + 0.8170*I, -0.6744 + 0.9248*I],
...: [ 0.2554 + 0.3517*I, -0.4454 - 0.1715*I, 0.8325 - 0.6282*I]])
sage: G, M = A.gram_schmidt()
sage: G.round(6) # random signs
[[-0.422243 - 0.490087*I 0.566698 - 0.097416*I -0.500882 + 0.002251*I]
[-0.057002 - 0.495035*I -0.35059 - 0.625323*I 0.255514 - 0.415284*I]
[ 0.394105 - 0.421778*I -0.392266 - 0.039345*I -0.352905 + 0.62195*I]
sage: M.round(6) # random
[ -1.528503 0.0 0.0]
[ 0.459974 - 0.40061*I -1.741233 0.0]
[-0.934304 + 0.148868*I 0.54833 + 0.073202*I -0.550725]
sage: (A - M*G).zero_at(10**-12)
[0.0 0.0 0.0]
[0.0 0.0 0.0]
[0.0 0.0 0.0]
sage: (G*G.conjugate_transpose()) # random
[0.9999999999999999 0.0 0.0]
[ 0.0 0.9999999999999997 0.0]
[ 0.0 0.0 1.0]
```

```python
>>> from sage.all import *
>>> # needs scipy sage.rings.complex_double sage.symbolic
>>> A = matrix(CDF, [[ RealNumber('0.6454') + RealNumber('0.7491')*I, -
...: RealNumber('0.8662') + RealNumber('0.1489')*I, RealNumber('0.7656') -
...: RealNumber('0.00344')*I],
...: [-RealNumber('0.2913') + RealNumber('0.8057')*I, -
...: RealNumber('0.8321') + RealNumber('0.8170')*I, -RealNumber('0.6744') +
...: RealNumber('0.9248')*I],
...: [ RealNumber('0.2554') + RealNumber('0.3517')*I, -
...: RealNumber('0.4454') - RealNumber('0.1715')*I, RealNumber('0.8325') -
...: RealNumber('0.6282')*I]])
>>> G, M = A.gram_schmidt()
>>> G.round(Integer(6)) # random signs
[[-0.422243 - 0.490087*I 0.566698 - 0.097416*I -0.500882 + 0.002251*I]
[-0.057002 - 0.495035*I -0.35059 - 0.625323*I 0.255514 - 0.415284*I]
[ 0.394105 - 0.421778*I -0.392266 - 0.039345*I -0.352905 + 0.62195*I]
>>> M.round(Integer(6)) # random
[ -1.528503 0.0 0.0]
[ 0.459974 - 0.40061*I -1.741233 0.0]
[-0.934304 + 0.148868*I 0.54833 + 0.073202*I -0.550725]
>>> (A - M*G).zero_at(Integer(10)**-Integer(12))
[0.0 0.0 0.0]
[0.0 0.0 0.0]
[0.0 0.0 0.0]
```
A rectangular matrix. Note that the `orthonormal` keyword is ignored in these cases.

```python
G = G*G.conjugate_transpose()
# random
[[0.9999999999999999 0.0 0.0],
 [0.0 0.9999999999999997 0.0],
 [0.0 0.0 1.0]]
```

Even though a set of vectors may be linearly dependent, no effort is made to decide when a zero vector is really the result of a relation of linear dependence. So in this regard, input matrices are treated as being of full rank. Try one of the base rings that provide exact results if you need exact results.

```python
from sage.all import *
# needs scipy
A = matrix(RDF, [[-0.978325, -0.751994, 0.925305, -0.200512, 0.420458],
                 [-0.474877, -0.983403, 0.089836, 0.132218, 0.672965]])
G, M = A.gram_schmidt(orthonormal=False)
G.round(6)
# random signs
```

Even though a set of vectors may be linearly dependent, no effort is made to decide when a zero vector is really the result of a relation of linear dependence. So in this regard, input matrices are treated as being of full rank. Try one of the base rings that provide exact results if you need exact results.
Exact Rings, Orthonormalization:

To scale a vector to unit length requires taking a square root, which often takes us outside the base ring. For the integers and the rationals, the field of algebraic numbers (QQbar) is big enough to contain what we need, but the price is that the computations are very slow, hence mostly of value for small cases or instruction. Now we need to use the orthonormal keyword.

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQbar, [[6, -8, 1], ....: [4, 1, 3], ....: [6, 3, 3], ....: [7, 1, -5], ....: [7, -3, 5]])
sage: G, M = A.gram_schmidt(orthonormal=True)
```
After Issue #14047, the matrix can also be over the algebraic reals `AA`:

```
sage: # needs sage.rings.number_field
sage: A = matrix(AA, [[6, -8, 1],
[4, 1, 3],
....
[4, 1, 3],

```
MATRICES AND SPACES OF MATRICES, RELEASE 10.4

```

Starting with complex numbers with rational real and imaginary parts. Note the use of the conjugate-transpose when checking the orthonormality.

```python
sage: # needs sage.rings.number_field

A = matrix(QQbar, [[-Integer(2), -Integer(1), Integer(4)*I + Integer(2), -Integer(1)],
                   [-Integer(4)*I, -Integer(2)*I + Integer(17), 0, 9*I + Integer(1)],
                   [1, -2*I - 6, -I + 11, -5*I + Integer(1)]])

G, M = A.gram_schmidt(orthonormal=True)

sage: (M*G - A).norm() < 10^-10
True

sage: id3 = G*G.conjugate().transpose()

sage: (id3 - identity_matrix(3)).norm() < 10^-10
True

sage: G.row_space() == A.row_space()
# long time
True
```

(continues on next page)
A square matrix with small rank. The zero vectors produced as a result of linear dependence get eliminated, so the rows of $G$ are a basis for the row space of $A$. 

```sage
# needs sage.rings.number_field
sage: A = matrix(QQbar, [[2, -6, 3, 8],
                      [1, -3, 2, 5],
                      [0, 0, 2, 4],
                      [2, -6, 3, 8]])
```

```sage
sage: A.change_ring(QQ).rank()
2
```

```sage
sage: G, M = A.gram_schmidt(orthonormal=True)
sage: G

```

```sage
>>> G.row_space() == A.row_space() # long time
True
```
Exact Rings, Orthogonalization:

If we forego scaling orthogonal vectors to unit vectors, we can apply Gram-Schmidt to a much greater variety of rings. Use the `orthonormal=False` keyword (or assume it as the default). Note that now the orthogonality check creates a diagonal matrix whose diagonal entries are the squares of the lengths of the vectors.

First, in the rationals, without involving `QQbar`.

```
sage: A = matrix(QQ, [[-1, 3, 2, 2],
                    [-1, 0, -1, 0],
                    [-1, -2, -3, -1],
                    [ 1, 1, 2, 0]])
sage: A.rank()
3
sage: G, M = A.gram_schmidt()
sage: G
[-1  3  2  2]
[-19/18 1/6 -8/9 1/9]
sage: M
[ 1  0  0]
[-1/18  1  0]
[-13/18  59/35  1]
[ 1/3 -48/35  2]
sage: M*G-A
[0 0 0 0]
[0 0 0 0]
[0 0 0 0]
[0 0 0 0]
sage: G*G.transpose() - identity_matrix(Integer(2)).norm() < Integer(10)**-Integer(10)
True
sage: G.row_space() == A.row_space()
True
```
A complex subfield of the complex numbers.

A slightly edited legacy example.

```
sage: A = matrix(ZZ, [[-1, 2, 5], [-11, 1, 1], [1, -1, -3]]; A
[-1 2 5]
[-11 1 1]
[ 1 -1 -3]
sage: G, mu = A.gram_schmidt()
sage: G
[-1 2 5]
[-52/5 -1/5 -2]
[ 2/187 36/187 -14/187]
sage: mu
[1 0 0]
[3/5 1 0]
[-3/5 -7/187 1]
sage: G.row(0) * G.row(1)
0
sage: G.row(0) * G.row(2)
0
sage: G.row(1) * G.row(2)
0
```

```python
>>> from sage.all import *
>>> A = matrix(ZZ, [[-Integer(1), Integer(2), Integer(5), -Integer(11), Integer(1), Integer(1), Integer(1), -Integer(1), -Integer(3)]; A
[-1 2 5]
[-11 1 1]
[ 1 -1 -3]
```
The relation between $\mu$ and $A$ is as follows.

```python
sage: mu*G == A
True
```

**hadamard_bound()**

Return an int $n$ such that the absolute value of the determinant of this matrix is at most $10^n$.

This is got using both the row norms and the column norms.

This function only makes sense when the base field can be coerced to the real double field RDF or the MPFR Real Field with 53-bits precision.

**EXAMPLES:**

```python
sage: a = matrix(ZZ, 3, [1,2,5,7,-3,4,2,1,123])
sage: a.hadamard_bound()
4
sage: a.det()
-2014
sage: 10^4
10000
```

```python
>>> from sage.all import *
```

```python
>>> a = matrix(ZZ, Integer(3), [Integer(1),Integer(2),Integer(5),Integer(7),-Integer(3),Integer(4),Integer(2),Integer(1),Integer(123)])
>>> a.hadamard_bound()
4
>>> a.det()
-2014
>>> Integer(10)**Integer(4)
10000
```

In this example the Hadamard bound has to be computed (automatically) using MPFR instead of doubles, since doubles overflow:

```python
sage: a = matrix(ZZ, 2, [2^10000, 3^10000, 2^50, 3^19292])
sage: a.hadamard_bound()
12215
sage: len(str(a.det()))
12215
```

```python
>>> from sage.all import *
```
\[ \text{hermite_form}(\text{include_zero_rows} = \text{True}, \text{transformation} = \text{False}) \]

Return the Hermite form of self, if it is defined.

**INPUT:**

- `include_zero_rows` – bool (default: True); if False the zero rows in the output matrix are deleted.
- `transformation` – bool (default: False) a matrix $U$ such that $U \cdot \text{self} = H$.

**OUTPUT:**

- matrix $H$
- (optional) transformation matrix $U$ such that $U \cdot \text{self} = H$, possibly with zero rows deleted...

**EXAMPLES:**

```python
sage: M = FunctionField(GF(7), 'x').maximal_order()
sage: K.<x> = FunctionField(GF(7)); M = K.maximal_order()
sage: A = matrix(M, 2, 3, [x, 1, 2*x, x, 1 + x, 2])
sage: A.hermite_form()
[ x 1 2*x]
[ 0 x 5*x + 2]

sage: A.hermite_form(transformation=True)
\[
\begin{pmatrix}
x & 1 & 2*x \\
0 & x & 5*x + 2 \\
\end{pmatrix}
\]

sage: H, U = A.hermite_form(transformation=True, include_zero_rows=False)
\[
\begin{pmatrix}
x & 1 & 2*x \\
0 & 0 & 0 \\
\end{pmatrix}
\]

sage: U * A == H
True

sage: H, U = A.hermite_form(transformation=True, include_zero_rows=True)
\[
\begin{pmatrix}
x & 1 & 2*x \\
0 & 0 & 5 \\
\end{pmatrix}
\]

sage: U * A == H
True
```
hessenberg_form()

Return Hessenberg form of self.

If the base ring is merely an integral domain (and not a field), the Hessenberg form will (in general) only be defined over the fraction field of the base ring.

EXAMPLES:

```python
sage: A = matrix(ZZ, 4, [2, 1, 1, -2, 2, -1, -1, -1, 1, 2, 3, 4, 5, 6, 7])
sage: h = A.hessenberg_form(); h
[ 2 -7/2 -19/5 -2]
[ 2 1/2 -17/5 -1]
[ 0 25/4 15/2 5/2]
[ 0 0 58/5 3]
sage: parent(h)
Full MatrixSpace of 4 by 4 dense matrices over Rational Field
```

```
Traceback (most recent call last):
  ...TypeError: Hessenbergize only possible for matrices over a field
```
Matrices and Spaces of Matrices, Release 10.4

>>> parent(h)
Full MatrixSpace of 4 by 4 dense matrices over Rational Field
>>> A.hessenbergize()
Traceback (most recent call last):
...
TypeError: Hessenbergize only possible for matrices over a field

**hessenbergize()**

Transform self to Hessenberg form.

The hessenberg form of a matrix $A$ is a matrix that is similar to $A$, so has the same characteristic polynomial as $A$, and is upper triangular except possible for entries right below the diagonal.

**ALGORITHM:** See Henri Cohen’s first book.

**EXAMPLES:**

```python
sage: A = matrix(QQ, 3, [2, 1, 1, -2, 2, 2, -1, -1, -1])
sage: A.hessenbergize(); A
[ 2 3/2 1]
[ -2 3 2]
[ 0 -3 -2]
```

```python
>>> from sage.all import *
```

```python
sage: A = matrix(QQ, Integer(3), [Integer(2), Integer(1), Integer(1), -Integer(2), Integer(2), Integer(2), -Integer(1), -Integer(1), -Integer(1)])
>>> A.hessenbergize(); A
[ 2 3/2 1]
[ -2 3 2]
[ 0 -3 -2]
```

```python
sage: A = matrix(QQ, 4, [2, 1, 1, -2, 2, 2, -1, -1, -1, -1,1,2,3,4,5,6,7])
sage: A.hessenbergize(); A
[ 2 -7/2 -19/5 -2]
[ 2 1/2 -17/5 -1]
[ 0  25/4 15/2  5/2]
[ 0  0  58/5  3]
```

```python
>>> from sage.all import *
```

```python
sage: A = matrix(QQ, Integer(4), [Integer(2), Integer(1), Integer(1), -Integer(2), Integer(2), Integer(2), -Integer(1), -Integer(1), -Integer(1), Integer(1),2,3,4,5,6,7])
>>> A.hessenbergize(); A
[ 2 -7/2 -19/5 -2]
[ 2 1/2 -17/5 -1]
[ 0  25/4 15/2  5/2]
[ 0  0  58/5  3]
```

You can’t Hessenbergize an immutable matrix:

```python
sage: A = matrix(QQ, 3, [1..9])
sage: A.set_immutable()
sage: A.hessenbergize()
Traceback (most recent call last):
...
```
ValueError: matrix is immutable; please change a copy instead (i.e., use copy(M) to change a copy of M).

```python
>>> from sage.all import *

>>> A = matrix(QQ, Integer(3), (ellipsis_range(Integer(1),Ellipsis, Integer(9))))

>>> A.set_immutable()

>>> A.hessenbergize()

Traceback (most recent call last):
...
ValueError: matrix is immutable; please change a copy instead (i.e., use copy(M) to change a copy of M).
```

**image()**

Return the image of the homomorphism on rows defined by right multiplication by this matrix: that is, the row-space.

**EXAMPLES:**

```python
sage: MS1 = MatrixSpace(ZZ, 4)
sage: MS2 = MatrixSpace(QQ, 6)
sage: A = MS1.matrix([3,4,5,6, 7,3,8,10, 14,5,6,7, 2,2,10,9])
sage: B = MS2.random_element()

>>> from sage.all import *

>>> image(A)
Free module of degree 4 and rank 4 over Integer Ring
Echelon basis matrix:
[ 1 0 0 426]
[ 0 1 0 518]
[ 0 0 1 293]
[ 0 0 0 687]
```

```python
sage: image(B) == B.row_module()
True

sage: image(B) == B.transpose().column_module()
True
```

383
def indefinite_factorization(self, algorithm='symmetric', check=True):
    """Decomposes an asymmetric or Hermitian matrix into a lower triangular matrix and a diagonal matrix."
    INPUT:
    - self -- a square matrix over a ring. The base ring must have an implemented fraction field.
    - algorithm -- default: 'symmetric'. Either 'symmetric' or 'hermitian', according to if the input matrix is symmetric or hermitian.
    - check -- (default: True); if True then performs the check that the matrix is consistent with the algorithm keyword.
    OUTPUT:
    A lower triangular matrix $L$ with each diagonal element equal to 1 and a vector of entries that form a diagonal matrix $D$. The vector of diagonal entries can be easily used to form the matrix, as demonstrated below in the examples.

    For a symmetric matrix, $A$, these will be related by
    \[
    A = LDL^T
    \]
    If $A$ is Hermitian matrix, then the transpose of $L$ should be replaced by the conjugate-transpose of $L$.

    If any leading principal submatrix (a square submatrix in the upper-left corner) is singular then this method will fail with a ValueError.

    ALGORITHM:
    The algorithm employed only uses field operations, but the computation of each diagonal entry has the potential for division by zero. The number of operations is of order $n^3/3$, which is half the count for an LU decomposition. This makes it an appropriate candidate for solving systems with symmetric (or Hermitian) coefficient matrices.

    See also:
    block_ldl()
Optionally, Hermitian matrices can be factored and the result has a similar property (but not identical). Here, the field is all complex numbers with rational real and imaginary parts. As theory predicts, the diagonal entries will be real numbers.

```python
>>> from sage.all import *
>>> A = matrix(QQ, [[ Integer(3), -Integer(6), Integer(9), Integer(6), -Integer(9)], ...
... [-Integer(6), Integer(11), -Integer(16), -Integer(11), Integer(17)], ...
... [-Integer(17)], ...
... [-Integer(16)], ...
... [-Integer(19)], ...
... [-Integer(40)], ...
... [-Integer(68)]])
>>> A.is_symmetric()
True
>>> L, d = A.indefinite_factorization()
>>> D = diagonal_matrix(d)
>>> L
[ 1 0 0 0 0]
[-2 1 0 0 0]
[ 3 -2 1 0 0]
[ 2 -1 0 1 0]
[-3 1 -3 1 1]
>>> D
[ 3 0 0 0 0]
[ 0 -1 0 0 0]
[ 0 0 5 0 0]
[ 0 0 0 -2 0]
[ 0 0 0 0 -1]
>>> A == L*D*L.transpose()
True
```
If a leading principal submatrix has zero determinant, this algorithm will fail. This will never happen with a positive definite matrix.

```sage
A = matrix(QQ, [[21, 15, 12, -2],
                [15, 12, 9, 6],
                [12, 9, 7, 3],
                [-2, 6, 3, 8]])
sage: A.is_symmetric()
True
sage: A[0:3,0:3].det() == 0
True
sage: A.indefinite_factorization()
Traceback (most recent call last):
  ... ValueError: 3x3 leading principal submatrix is singular, so cannot create indefinite factorization
```
```python
>>> from sage.all import *

>>> A = matrix(QQ, [[Integer(21), Integer(15), Integer(12), -Integer(2)],
                  [Integer(15), Integer(12), Integer(9), Integer(6)],
                  [Integer(12), Integer(9), Integer(7), Integer(3)],
                  [-Integer(2), Integer(6), Integer(3), Integer(8)]])

>>> A.is_symmetric()
True

>>> A[Integer(0):Integer(3), Integer(0):Integer(3)].det() == Integer(0)
True

>>> A.indefinite_factorization()
Traceback (most recent call last):
...
ValueError: 3x3 leading principal submatrix is singular,
so cannot create indefinite factorization
```

This algorithm only depends on field operations, so outside of the singular submatrix situation, any matrix may be factored. This provides a reasonable alternative to the Cholesky decomposition.

```python
sage: # needs sage.rings.finite_rings
sage: F.<a> = FiniteField(5^3)
sage: A = matrix(F,
        ....: [[a^2 + 2*a, 4*a^2 + 3*a + 4, 3*a^2 + a, 2*a^2 + 2*a + 1],
        ....: [4*a^2 + 3*a + 4, 4*a^2 + 2*a + 3*a^2 + 2*a + 3],
        ....: [3*a^2 + a, 3*a, 3*a^2 + 2 + 3*a^2 + 2*a + 3],
        ....: [2*a^2 + 2*a + 1, 2*a^2 + 4*a + 2, 3*a^2 + 2*a + 3, 3*a^2 + 2*a + 3]])

sage: A.is_symmetric()
True

sage: L, d = A.indefinite_factorization()

sage: D = diagonal_matrix(d)

sage: L
1 0 0 0
4*a^2 + 4*a + 3 1 0 0
3 4*a^2 + a + 2 1 0
4*a^2 + 4 2*a^2 + 3*a + 3 2*a^2 + 3*a + 1 1

sage: D
a^2 + 2*a 0 0 0
0 2*a^2 + 2*a + 4 0 0
0 0 3*a^2 + 4*a + 3 0
0 0 0 a^2 + 3*a

sage: A == L*D*L.transpose()
True
```

```python
from sage.all import *

# needs sage.rings.finite_rings

F = FiniteField(Integer(5)**Integer(3), names=('a',)); (a,) = F._first_ngens(1)

A = matrix(F,
        [[a**Integer(2) + Integer(2)*a, Integer(4)*a**Integer(2) + Integer(3)*a + Integer(4)*a**Integer(2) + Integer(3)*a + Integer(4)*a**Integer(2) + Integer(2)*a + Integer(1)],
        [Integer(3)*a + Integer(4), Integer(3)*a + Integer(3)*a + Integer(4), Integer(4)*a + Integer(2) + Integer(3)*a + Integer(4), Integer(4)*a + Integer(2) + Integer(3)*a + Integer(4)]]

# continues on next page
```
... [ Integer(3)*a**Integer(2) + a, Integer(3)*a, ...
\rightarrow Integer(3)*a**Integer(2) + Integer(2), Integer(3)*a**Integer(2) +...
\rightarrow Integer(2)*a + Integer(3)],[...
\rightarrow Integer(2)*a**Integer(2) + Integer(2)*a + Integer(1),...
\rightarrow Integer(2)*a**Integer(2) + Integer(4)*a + Integer(2),...
\rightarrow Integer(3)*a**Integer(2) + Integer(2)*a + Integer(3),...
\rightarrow Integer(3)*a**Integer(2) + Integer(2)*a + Integer(4)])

>>> A.is_symmetric()
True

>>> L, d = A.indefinite_factorization()

>>> diagonal_matrix(d)

>>> L
[ 1 0 0 0 ]
[ 4*a^2 + 4*a + 3 1 0 0 ]
[ 3 4*a^2 + a + 2 1 0 ]
[ 4*a^2 + 4 2*a^2 + 3*a + 3 2*a^2 + 3*a + 1 1 ]

>>> D
[ a^2 + 2*a 0 0 0 ]
[ 0 2*a^2 + 2*a + 4 0 0 ]
[ 0 0 3*a^2 + 4*a + 3 0 ]
[ 0 0 0 a^2 + 3*a ]

>>> A == L*D*L.transpose()
True

This works correctly for the 0x0 matrix:

sage: Matrix(0).indefinite_factorization()
([], ())

>>> from sage.all import *

>>> A = MatrixSpace(QQ, Integer(4))(range(Integer(16)))

>>> A.integer_kernel()
Free module of degree 4 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1 0 -3 2 ]
[ 0 1 -2 1 ]

integer_kernel (ring='ZZ')

Return the kernel of this matrix over the given ring (which should be either the base ring, or a PID whose
fraction field is the base ring).

Assume that the base field of this matrix has a numerator and denominator functions for its elements, e.g., it
is the rational numbers or a fraction field. This function computes a basis over the integers for the kernel of
self.

If the matrix is not coercible into QQ, then the PID itself should be given as a second argument, as in the
third example below.

EXAMPLES:

sage: A = MatrixSpace(QQ, 4)(range(16))
sage: A.integer_kernel()
Free module of degree 4 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1 0 -3 2 ]
[ 0 1 -2 1 ]

>>> from sage.all import *

>>> A = MatrixSpace(QQ, Integer(4))(range(Integer(16)))

>>> A.integer_kernel()

(continues on next page)
Free module of degree 4 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1 0 -3 2]
[ 0 1 -2 1]

The integer kernel even makes sense for matrices with fractional entries:

```python
sage: A = MatrixSpace(QQ, 2)([[1/2, 0, 0, 0]])
sage: A.integer_kernel()
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[0 1]
```

An example over a bigger ring:

```python
sage: # needs sage.rings.number_field
sage: x = polygen(ZZ, 'x')
sage: L.<w> = NumberField(x^2 - x + 2)
sage: OL = L.ring_of_integers()
sage: A = matrix(L, 2, [1, w/2])
sage: A.integer_kernel(OL)
Free module of degree 2 and rank 1 over
Maximal Order generated by w in Number Field in w
with defining polynomial x^2 - x + 2
Echelon basis matrix:
[ -1 -w + 1]
```

```python
>>> from sage.all import *
```

```python
>>> A = MatrixSpace(QQ, Integer(2))([[Integer(1)/Integer(2), Integer(0)],
                                      [Integer(0), Integer(0)]])
>>> A.integer_kernel()
Free module of degree 2 and rank 1 over Integer Ring
Echelon basis matrix:
[0 1]
```

inverse()

Returns the inverse of self, without changing self.

Note that one can use the Python inverse operator to obtain the inverse as well.

See also:

inverse_positive_definite()
EXAMPLES:

```python
sage: m = matrix([[1, 2], [3, 4]])
sage: m^(-1)
[ -2  1]
[ 3/2 -1/2]
sage: m.inverse()
[ -2  1]
[ 3/2 -1/2]
sage: ~m
[ -2  1]
[ 3/2 -1/2]
```

```python
>>> from sage.all import *

>>> m = matrix([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]), sparse=True)
>>> m^(-Integer(1))
[ -2  1]
[ 3/2 -1/2]
>>> m.inverse()
[ -2  1]
[ 3/2 -1/2]
>>> ~m
[ -2  1]
[ 3/2 -1/2]
```

```python
sage: m = matrix([[1, 2], [3, 4]], sparse=True)
sage: m^(-1)
[ -2  1]
[ 3/2 -1/2]
sage: m.inverse()
[ -2  1]
[ 3/2 -1/2]
sage: ~m
[ -2  1]
[ 3/2 -1/2]
```

```python
>>> from sage.all import *

>>> m = matrix([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]), sparse=True)
>>> m**(-Integer(1))
[ -2  1]
[ 3/2 -1/2]
>>> m.inverse()
[ -2  1]
[ 3/2 -1/2]
>>> ~m
[ -2  1]
[ 3/2 -1/2]
```

inverse_positive_definite()

Compute the inverse of a positive-definite matrix.

In accord with `is_positive_definite()`, only Hermitian matrices are considered positive-definite. Positive-definite matrices have several factorizations (Cholesky, LDLT, et cetera) that allow them to be inverted in a fast, numerically-stable way. This method uses an appropriate factorization, and is akin to the `cholinv` and `chol2inv` functions available in R, Octave, and Stata.

You should ensure that your matrix is positive-definite before using this method. When in doubt, use the generic `inverse()` method instead.
OUTPUT:

If the given matrix is positive-definite, the return value is the same as that of the inverse() method. If the matrix is not positive-definite, the behavior of this function is undefined.

See also:

inverse(), is_positive_definite(), cholesky(), indefinite_factorization()

EXAMPLES:

A simple two-by-two matrix with rational entries:

```python
sage: A = matrix(QQ, [[ 2, -1],
                   [-1, 2]])

sage: A.is_positive_definite()
True

sage: A.inverse_positive_definite()
[2/3 1/3]
[1/3 2/3]

sage: A.inverse_positive_definite() == A.inverse()
True
```

A matrix containing real roots:

```python
sage: # needs sage.rings.number_field sage.symbolic
sage: A = matrix(AA, [[1, 0, sqrt(2)],
                   [0, sqrt(3), 0],
                   [sqrt(2), 0, sqrt(5)]])

sage: A.is_positive_definite()
True

sage: B = matrix(AA, [[2*sqrt(5) + 5, 0, -sqrt(8*sqrt(5) + 18)],
                   [0, sqrt(1/3), 0],
                   [-sqrt(8*sqrt(5) + 18), 0, sqrt(5) + 2]])

sage: A.inverse_positive_definite() == B
True

sage: A*B == A.matrix_space().identity_matrix()
True
```

(continues on next page)
... ...

A Hermitian (but not symmetric) matrix with complex entries:

```
sage: # needs sage.rings.number_field sage.symbolic
sage: A = matrix(QQbar, [[1, 0, I],
...: [0, sqrt(5), 0],
...: [-I, 0, 3]])
```

```
sage: A.is_positive_definite()
True
```

```
sage: B = matrix(QQbar, [[3/2, 0, -I/2],
...: [0, sqrt(1/5), 0],
...: [I/2, 0, 1/2]])
```

```
sage: A.inverse_positive_definite() == B
True
```

```
sage: A*B == A.matrix_space().identity_matrix()
True
```

is_Z_operator_on($K$)

Determine if this matrix is a Z-operator on a cone.

We say that a matrix $L$ is a Z-operator on a closed convex cone $K$ if the inner product of $Lx$ and $s$ is nonpositive for all pairs of orthogonal vectors $x$ in $K$ and $s$ in the dual of $K$. This property need only be checked for generators of $K$ and its dual.

A matrix is a Z-operator on $K$ if and only if its negation is a cross-positive operator on $K$.

To reliably check whether or not this matrix is a Z operator, its base ring must be either exact (for example, the rationals) or the symbolic ring. An exact ring is more reliable, but in some cases a matrix whose entries contain symbolic constants like $e$ and $\pi$ will work.

INPUT:
• K – a polyhedral closed convex cone.

OUTPUT:

If the base ring of this matrix is exact, then True will be returned if and only if this matrix is a Z-operator on K.

If the base ring of this matrix is symbolic, then the situation is more complicated:

• True will be returned if it can be proven that this matrix is a Z-operator on K.
• False will be returned if it can be proven that this matrix is not a Z-operator on K.
• False will also be returned if we can’t decide; specifically if we arrive at a symbolic inequality that cannot be resolved.

See also:

is_positive_operator_on(), is_cross_positive_on(), is_lyapunov_like_on()

REFERENCES:

EXAMPLES:

Z-matrices are Z-operators on the nonnegative orthant:

```
sage: K = Cone([(1,0,0), (0,1,0), (0,0,1)])
# needs sage.geometry.polyhedron
sage: L = matrix(SR, [-1, -2, 0],
# needs sage.symbolic
....: [ 0, 2, -7],
....: [-3, 0, 3])
sage: L.is_Z_operator_on(K)
# needs sage.geometry.polyhedron sage.symbolic
True

>>> from sage.all import *
>>> K = Cone([(Integer(1),Integer(0),Integer(0)), (Integer(0),Integer(1),
# needs sage.geometry.polyhedron
Integer(0)), (Integer(0),Integer(0),Integer(1))])
>>> L = matrix(SR, [-Integer(1), -Integer(2), Integer(0)],
# needs sage.symbolic
...: [ Integer(0), Integer(2), -Integer(7)],
...: [-Integer(3), Integer(0), Integer(3)])
>>> L.is_Z_operator_on(K)
# needs sage.geometry.polyhedron sage.symbolic
True
```

Symbolic entries also work in some easy cases:

```
sage: K = Cone([(1,0,0), (0,1,0), (0,0,1)])
# needs sage.geometry.polyhedron
sage: L = matrix(SR, [-1, -e, 0],
# needs sage.symbolic
....: [ 0, 2, -pi],
....: [-sqrt(2), 0, 3])
sage: L.is_Z_operator_on(K)
# needs sage.geometry.polyhedron sage.symbolic
True
```
is_bistochastic (normalized=True)

Returns True if this matrix is bistochastic.

A matrix is said to be bistochastic if both the sums of the entries of each row and the sum of the entries of each column are equal to 1 and all entries are nonnegative.

INPUT:

* normalized – if set to True (default), checks that the sums are equal to 1. When set to False, checks that the row sums and column sums are all equal to some constant possibly different from 1.

EXAMPLES:

The identity matrix is clearly bistochastic:

```
sage: Matrix(5,5,1).is_bistochastic()
True
```

The same matrix, multiplied by 2, is not bistochastic anymore, though is verifies the constraints of normalized == False:

```
sage: (2 * Matrix(5,5,1)).is_bistochastic()
False
sage: (2 * Matrix(5,5,1)).is_bistochastic(normalized=False)
True
```

Here is a matrix whose row and column sums is 1, but not all entries are nonnegative:

```
sage: m = matrix([[-1,2],[2,-1]])
sage: m.is_bistochastic()
False
```

(continues on next page)
is_cross_positive_on($K$)

Determine if this matrix is cross-positive on a cone.

We say that a matrix $L$ is cross-positive on a closed convex cone $K$ if the inner product of $Lx$ and $s$ is nonnegative for all pairs of orthogonal vectors $x$ in $K$ and $s$ in the dual of $K$. This property need only be checked for generators of $K$ and its dual.

To reliably check whether or not this matrix is cross-positive, its base ring must be either exact (for example, the rationals) or the symbolic ring. An exact ring is more reliable, but in some cases a matrix whose entries contain symbolic constants like $e$ and $\pi$ will work.

**INPUT:**

- $K$ – a polyhedral closed convex cone.

**OUTPUT:**

If the base ring of this matrix is exact, then True will be returned if and only if this matrix is cross-positive on $K$.

If the base ring of this matrix is symbolic, then the situation is more complicated:

- True will be returned if it can be proven that this matrix is cross-positive on $K$.
- False will be returned if it can be proven that this matrix is not cross-positive on $K$.
- False will also be returned if we can’t decide; specifically if we arrive at a symbolic inequality that cannot be resolved.

**See also:**

is_positive_operator_on(), is_Z_operator_on(), is_lyapunov_like_on()

**REFERENCES:**

**EXAMPLES:**

Negative Z-matrices are cross-positive operators on the nonnegative orthant:

```python
sage: K = Cone([(1,0,0), (0,1,0), (0,0,1)])  # needs sage.geometry.polyhedron
sage: L = matrix(SR, [ [-1, 2, 0],  
    [ 0, 2, 7],  
    [ 3, 0, 3] ])  # needs sage.symbolic
sage: L.is_cross_positive_on(K)  # needs sage.geometry.polyhedron sage.symbolic
True
```

### is_diagonal()

Return True if this matrix is a diagonal matrix.

**OUTPUT:**

boolean

**EXAMPLES:**

```
sage: m = matrix(QQ, 2, 2, range(4))
sage: m.is_diagonal()
False
```

```
sage: m = matrix(QQ, 2, [5,0,0,5])
sage: m.is_diagonal()
True
```

```
sage: m = matrix(QQ, 2, [1,0,0,1])
sage: m.is_diagonal()
True
```

```
sage: m = matrix(QQ, 2, [1,1,1,1])
sage: m.is_diagonal()
True
```

```
>>> from sage.all import *
```

```
>>> m = matrix(QQ, Integer(2), Integer(2), [Integer(5),Integer(0),Integer(0),Integer(5)])
```

(continues on next page)
is_diagonalizable (base_field=None)

Determine if the matrix is similar to a diagonal matrix.

INPUT:

• base_field – a new field to use for entries of the matrix.

OUTPUT:

If self is the matrix $A$, then it is diagonalizable if there is an invertible matrix $P$ and a diagonal matrix $D$ such that

$$P^{-1}AP = D$$

This routine returns True if self is diagonalizable. The diagonal entries of the matrix $D$ are the eigenvalues of $A$.

A matrix not diagonalizable over the base field may become diagonalizable by extending the base field to contain all of the eigenvalues. Over the rationals, the field of algebraic numbers, sage.rings.qqbar is a good choice.

To obtain the matrices $D$ and $P$, use the diagonalization() method.

ALGORITHM:

For each eigenvalue, this routine checks that the algebraic multiplicity (number of occurrences as a root of the characteristic polynomial) is equal to the geometric multiplicity (dimension of the eigenspace), which is sufficient to ensure a basis of eigenvectors for the columns of $P$.

EXAMPLES:

A matrix that is diagonalizable over the rationals:

```python
sage: A = matrix(QQ, [[-7, 16, 12, 0, 6],
...: [-9, 15, 0, 12, -27],
...: [9, -8, 11, -12, 51],
...: [3, -4, 0, -1, 9],
...: [-1, 0, -4, 4, -12]])
```

```python
sage: A.is_diagonalizable()  # needs sage.libs.pari
True
```

```python
sage: A.diagonalization()  # needs sage.libs.pari
([ 2 0 0 0 0] [ 1 1 0 1 0]
 [ 0 3 0 0 0] [ 1/2 0 1 0 1]
 [ 0 0 3 0 0] [ 1/6 1 -3/2 2/3 -14/9]
 [ 0 0 0 -1 0] [ -1/6 0 -1/4 0 -1/3]
 [ 0 0 0 0 -1], [ -1/6 -1/3 1/3 -1/3 4/9])
```
>>> from sage.all import *

>>> A = matrix(QQ, [[-Integer(7), Integer(16), Integer(12), Integer(0), ...
                   Integer(6)],
                   ...
                   [-Integer(9), Integer(15), Integer(0), Integer(12), -
                   Integer(27)],
                   ...
                   [ Integer(9), -Integer(8), Integer(11), -Integer(12), -
                   Integer(51)],
                   ...
                   [ Integer(9), -Integer(4), Integer(0), -Integer(1), -
                   Integer(9)],
                   ...
                   [-Integer(1), Integer(0), -Integer(4), Integer(4), -
                   Integer(12)]]

>>> A.is_diagonalizable()   # needs sage.libs.pari
True

>>> A.diagonalization()     # needs sage.libs.pari
\((
\begin{array}{ccccc}
2 & 0 & 0 & 0 & 0 \\
0 & 3 & 0 & 0 & 0 \\
0 & 0 & 3 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 \\
0 & 0 & 0 & 0 & -1 \\
\end{array}
\) ,
\((
\begin{array}{ccccc}
1 & 1 & 0 & 1 & 0 \\
1/2 & 0 & 1 & 0 & 1 \\
1/6 & 1 & -3/2 & 2/3 & -14/9 \\
-1/6 & 0 & -1/4 & 0 & -1/3 \\
-1/6 & -1/3 & 1/3 & -1/3 & 4/9 \\
\end{array}
\))
\)

This is a matrix not diagonalizable over the rationals, but you can still get its Jordan form.

sage: A = matrix(QQ, [[-3, -14, 2, -1, 15],
                   ...
                   [4, 6, -2, 3, -8],
                   ...
                   [-2, -14, 0, 0, 10],
                   ...
                   [3, 13, -2, 0, -11],
                   ...
                   [-1, 6, 1, -3, 1]])

sage: A.is_diagonalizable()   # needs sage.libs.pari
False

sage: A.jordan_form(subdivide=False)   # needs sage.combinat saga.libs.pari
\((-1 1 0 0 0 \\
0 -1 0 0 0 \\
0 0 2 1 0 \\
0 0 0 2 1 \\
0 0 0 0 2)\)

>>> from sage.all import *

>>> A = matrix(QQ, [[-Integer(3), -Integer(14), Integer(2), -Integer(1), -
                   Integer(15)],
                   ...
                   [Integer(4), Integer(6), -Integer(2), Integer(3), -
                   Integer(8)],
                   ...
                   [-Integer(2), -Integer(14), Integer(0), Integer(0), -
                   Integer(10)],
                   ...
                   [Integer(3), Integer(13), -Integer(2), Integer(0), -
                   Integer(11)],
                   ...
                   [-Integer(1), Integer(6), Integer(1), -Integer(3), -
                   Integer(1)]])

>>> A.is_diagonalizable()   # needs sage.libs.pari
False

>>> A.jordan_form(subdivide=False)   # needs sage.combinat sage.libs.pari
(continues on next page)
If any eigenvalue of a matrix is outside the base ring, then this routine raises an error. However, the ring can be extended to contain the eigenvalues.

```python
#needs sage.combinat sage.libs.pari
[-1 1 0 0 0]
[ 0 -1 0 0 0]
[ 0 0 2 1 0]
[ 0 0 0 2 1]
[ 0 0 0 0 2]
```

```python
define needs
sage: A = matrix(QQ, [[1, 0, 1, 1, -1],
....: [0, 1, 0, 4, 8],
....: [2, 1, 3, 5, 1],
....: [2, -1, 1, 0, -2],
....: [0, -1, -1, -5, -8]])
```

```python
sage: [e in QQ for e in A.eigenvalues()]  # needs sage.rings.number_field
[False, False, False, False, False]
sage: A.is_diagonalizable()  # needs sage.libs.pari
False
sage: A.diagonalization()  # needs sage.libs.pari
Traceback (most recent call last):
... ValueError: not diagonalizable over Rational Field
```

```python
sage: [e in QQbar for e in A.eigenvalues()]  # needs sage.rings.number_field
[True, True, True, True, True]

(continues on next page)
A trivial matrix is diagonalizable, trivially.

```python
sage: A = matrix(QQ, 0, 0)
sage: A.is_diagonalizable()
# needs sage.libs.pari
True
```

A matrix must be square to be diagonalizable.

```python
sage: A = matrix(QQ, 3, 4)
sage: A.is_diagonalizable()  # needs sage.libs.pari
Traceback (most recent call last):
  ...
TypeError: not a square matrix
```

```python
>>> from sage.all import *

sage: A = matrix(QQ, Integer(3), Integer(4))
```

(continues on next page)
...TypeError: not a square matrix

The matrix must have entries from a field, and it must be an exact field.

```python
sage: A = matrix(ZZ, 4, range(16))
sage: A.is_diagonalizable()
Traceback (most recent call last):...
ValueError: matrix entries must be from a field
```

```python
sage: A = matrix(RDF, 4, range(16))
sage: A.is_diagonalizable()
Traceback (most recent call last):...
ValueError: base field must be exact, but Real Double Field is not
```

```python
>>> from sage.all import *

>>> A.is_diagonalizable()
Traceback (most recent call last):...
ValueError: matrix entries must be from a field
```

```python
>>> A = matrix(RDF, Integer(4), range(Integer(16)))

>>> A.is_diagonalizable()
Traceback (most recent call last):...
ValueError: base field must be exact, but Real Double Field is not
```

**is_lyapunov_like_on**($K$)

Determine if this matrix is Lyapunov-like on a cone.

We say that a matrix $L$ is Lyapunov-like on a closed convex cone $K$ if the inner product of $Lx$ and $s$ is zero for all pairs of orthogonal vectors $x$ in $K$ and $s$ in the dual of $K$. This property need only be checked for generators of $K$ and its dual.

An operator is Lyapunov-like on $K$ if and only if both the operator itself and its negation are cross-positive on $K$.

To reliably check whether or not this matrix is Lyapunov-like, its base ring must be either exact (for example, the rationals) or the symbolic ring. An exact ring is more reliable, but in some cases a matrix whose entries contain symbolic constants like $e$ and $\pi$ will work.

**INPUT:**

- $K$ – a polyhedral closed convex cone.

**OUTPUT:**

If the base ring of this matrix is exact, then `True` will be returned if and only if this matrix is Lyapunov-like on $K$.

If the base ring of this matrix is symbolic, then the situation is more complicated:

- `True` will be returned if it can be proven that this matrix is Lyapunov-like on $K$.
- `False` will be returned if it can be proven that this matrix is not Lyapunov-like on $K$. 

• False will also be returned if we can’t decide; specifically if we arrive at a symbolic inequality that cannot be resolved.

See also:

is_positive_operator_on(), is_cross_positive_on(), is_Z_operator_on()

REFERENCES:

• [Or2017]

EXAMPLES:

Diagonal matrices are Lyapunov-like operators on the nonnegative orthant:

```
sage: K = Cone([(1,0,0), (0,1,0), (0,0,1)])
# needs sage.geometry.polyhedron
sage: L = diagonal_matrix(random_vector(QQ, 3))
# needs sage.geometry.polyhedron
sage: L.is_lyapunov_like_on(K)
True
```

Symbolic entries also work in some easy cases:

```
sage: K = Cone([(1,0,0), (0,1,0), (0,0,1)])
# needs sage.geometry.polyhedron
sage: L = matrix(SR, [[e, 0, 0], [0, pi, 0], [0, 0, sqrt(2)]])
# needs sage.geometry.polyhedron
sage: L.is_lyapunov_like_on(K)
True
```

is_nilpotent()
Return if self is a nilpotent matrix.

A matrix $A$ is nilpotent if there exists a positive integer $k$ such that $A^k = 0$. We test this by using the Cayley-Hamilton theorem to see if the characteristic polynomial is $x^n = 0$. 

EXAMPLES:

```python
sage: A = matrix([[0, 2, 1, 6], [0, 0, 1, 2], [0, 0, 0, 3], [0, 0, 0, 0]])
sage: A.is_nilpotent()
True
sage: B = matrix([[2, 2, 2, 2, -4], [7, 1, 1, 1, -5], [1, 7, 1, 1, -5],
              [1, 1, 7, 1, -5], [1, 1, 1, 7, -5]])
sage: B.is_nilpotent()
True
sage: C = matrix(GF(7), [[1, 2], [2, 6]])
sage: C.is_nilpotent()
False
sage: D = matrix([[1, 0], [0, 0]])
sage: D.is_nilpotent()
False
sage: Z = matrix.zero(QQ, 5)
sage: Z.is_nilpotent()
True
```

```python
>>> from sage.all import *
>>> A = matrix([[Integer(0), Integer(2), Integer(1), Integer(6)], [Integer(0),
              Integer(0), Integer(1), Integer(2)], [Integer(0), Integer(0),
              Integer(3)], [Integer(0), Integer(0), Integer(0), Integer(0)]])
>>> A.is_nilpotent()
True
>>> B = matrix([[Integer(2), Integer(2), Integer(2), Integer(2), -Integer(4)],
              [Integer(7), Integer(1), Integer(1), Integer(1), -Integer(5)], [Integer(1),
              Integer(7), Integer(1), Integer(1), -Integer(5)], [Integer(1),
              Integer(1), Integer(7), Integer(1), -Integer(5)], [Integer(1),
              Integer(1), Integer(1), Integer(7), -Integer(5)]])
>>> B.is_nilpotent()
True
>>> C = matrix(GF(Integer(7)), [[Integer(1), Integer(2)], [Integer(2),
                Integer(6)]])
>>> C.is_nilpotent()
False
>>> D = matrix([[Integer(1), Integer(0)], [Integer(0), Integer(0)]]))
>>> D.is_nilpotent()
False
>>> Z = matrix.zero(QQ, Integer(5))
>>> Z.is_nilpotent()
True
```

`is_normal()`

Returns `True` if the matrix commutes with its conjugate-transpose.

**OUTPUT:**

True if the matrix is square and commutes with its conjugate-transpose, and False otherwise.

Normal matrices are precisely those that can be diagonalized by a unitary matrix.

This routine is for matrices over exact rings and so may not work properly for matrices over RR or CC. For matrices with approximate entries, the rings of double-precision floating-point numbers, RDF and CDF, are a better choice since the `sage.matrix.matrix_double_dense.Matrix_double_dense.is_normal()` method has a tolerance parameter. This provides control over allowing for minor discrepancies between entries when checking equality.

The result is cached.
EXAMPLES:

Hermitian matrices are normal.

```
sage: # needs sage.symbolic
sage: A = matrix(QQ, 5, 5, range(25)) + I*matrix(QQ, 5, 5, range(0, 50, 2))
sage: B = A*A.conjugate_transpose()
sage: B.is_hermitian()
True
sage: B.is_normal()
True
```

Circulant matrices are normal.

```
sage: # needs sage.graphs
sage: G = graphs.CirculantGraph(20, [3, 7])
sage: D = digraphs.Circuit(20)
sage: A = 3*D.adjacency_matrix() - 5*G.adjacency_matrix()
sage: A.is_normal()
True
```

Skew-symmetric matrices are normal.

```
sage: A = matrix(QQ, 5, 5, range(25))
sage: B = A - A.transpose()
sage: B.is_skew_symmetric()
True
sage: B.is_normal()
True
```

A small matrix that does not fit into any of the usual categories of normal matrices.
Matrices and Spaces of Matrices, Release 10.4

sage: A = matrix(ZZ, [[1, -1], [1, 1]])
sage: A.is_normal()
True
sage: not A.is_hermitian() and not A.is_skew_symmetric()
True

\[
\begin{pmatrix}
1 & -1 \\
1 & 1
\end{pmatrix}
\]

Sage has several fields besides the entire complex numbers where conjugation is non-trivial.

sage: # needs sage.rings.number_field
sage: F.<b> = QuadraticField(-7)
sage: C = matrix(F, [[-2*b - 3, 7*b - 6, -b + 3],
                   [-2*b - 3, -3*b + 2, -2*b],
                   [ b + 1, 0, -2]])
sage: C = C*C.conjugate_transpose()
sage: C.is_normal()
True

A matrix that is nearly normal, but for a non-real diagonal entry.

sage: # needs sage.rings.number_field
sage: A = matrix(QQbar, [[ 2, 2-I, 1+4*I],
                    [ 2+I, 3+I, 2-6*I],
                    [1-4*I, 2+6*I, 5]])
sage: A.is_normal()
False
sage: A[1,1] = 132
sage: A.is_normal()
True

\[
\begin{pmatrix}
2 & 2-I & 1+4*I \\
2+I & 3+I & 2-6*I \\
1-4*I & 2+6*I & 5
\end{pmatrix}
\]

(continues on next page)
Rectangular matrices are never normal.

```python
sage: A = matrix(QQbar, 3, 4)  # needs sage.rings.number_field
sage: A.is_normal()            # needs sage.rings.number_field
False
```

```
>>> from sage.all import *
```  

```
>>> A = matrix(QQbar, Integer(3), Integer(4))  # needs sage.rings.number_field
```  

```
>>> A.is_normal()            # needs sage.rings.number_field
False
```

A square, empty matrix is trivially normal.

```python
sage: A = matrix(QQ, 0, 0)
sage: A.is_normal()
True
```

```
>>> from sage.all import *
```  

```
>>> A = matrix(QQ, Integer(0), Integer(0))
```  

```
>>> A.is_normal()
True
```

**is_one()**

Return True if this matrix is the identity matrix.

**EXAMPLES:**

```python
sage: m = matrix(QQ, 2,2, range(4))
sage: m.is_one()  
False
```

```python
sage: m = matrix(QQ, 2, [5,0,0,5])
sage: m.is_one()  
False
```

```python
sage: m = matrix(QQ, 2, [1,0,0,1])
sage: m.is_one()  
True
```

```python
sage: m = matrix(QQ, 2, [1,1,1,1])
sage: m.is_one()  
False
```

```
>>> from sage.all import *
```  

```
>>> m = matrix(QQ, Integer(2),Integer(2), range(Integer(4)))
```  

```
>>> m.is_one()
(continues on next page)`
is_permutation_of (N, check=False)

Return True if there exists a permutation of rows and columns sending self to N and False otherwise.

INPUT:

• N – a matrix.

• check – boolean (default: False). If False return Boolean indicating whether there exists a permutation of rows and columns sending self to N and False otherwise. If True return a tuple of a Boolean and a permutation mapping self to N if such a permutation exists, and (False, None) if it does not.

OUTPUT:
A Boolean or a tuple of a Boolean and a permutation.

EXAMPLES:

```
sage: M = matrix(ZZ, [[1,2,3], [3,5,3], [2,6,4]])
sage: M
[1 2 3]
[3 5 3]
[2 6 4]
sage: N = matrix(ZZ, [[1,2,3], [2,6,4], [3,5,3]])
sage: N
[1 2 3]
[2 6 4]
[3 5 3]
sage: M.is_permutation_of(N)  # needs sage.graphs
True
```
Some examples that are not permutations of each other:

\begin{verbatim}
sage: N = matrix(ZZ, [[1,2,3], [4,5,6], [7,8,9]]); N
[[1 2 3]
 [4 5 6]
 [7 8 9]]
sage: M.is_permutation_of(N)
needs sage.graphs
False
sage: N = matrix(ZZ, [[1,2], [3,4]]); N
[[1 2]
 [3 4]]
sage: M.is_permutation_of(N)
False
>>> from sage.all import *

>>> N = matrix(ZZ, [[Integer(1),Integer(2),Integer(3)],
 [Integer(5),Integer(6)], [Integer(7),Integer(8),Integer(9)]]); N
[[1 2 3]
 [4 5 6]
 [7 8 9]]

>>> M.is_permutation_of(N)
needs sage.graphs
False

>>> N = matrix(ZZ, [[Integer(1),Integer(2)], [Integer(3),Integer(4)]]); N
[[1 2]
 [3 4]]

>>> M.is_permutation_of(N)
False
\end{verbatim}

And for when check is True:

\begin{verbatim}
sage: # needs sage.graphs sage.groups
sage: N = matrix(ZZ, [[3,5,3], [2,6,4], [1,2,3]]); N
[[3 5 3]
 [2 6 4]
 [1 2 3]]
sage: r = M.is_permutation_of(N, check=True)
sage: r
(True, ((1,2,3), ()))
sage: p = r[1]
sage: M.with_permuted_rows_and_columns(*p) == N
True
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> # needs sage.graphs sage.groups

>>> N = matrix(ZZ, [[Integer(3),Integer(5),Integer(3)],
 [Integer(5),Integer(6),Integer(4)], [Integer(1),Integer(2),Integer(3)]]); N
[[3 5 3]
 [2 6 4]
 [1 2 3]]

>>> r = M.is_permutation_of(N, check=True)

(continues on next page)
\end{verbatim}
is_positive_definite (certificate=False)

Determine if a matrix is positive-definite.

A matrix $A$ is positive definite if it is hermitian() and if, for every non-zero vector $x$,

$$\langle Ax, x \rangle > 0.$$

ALGORITHM:

A Hermitian matrix is positive-definite if and only if the diagonal blocks in its block_ldlt() factorization are all 1-by-1 and have positive entries. We first check that the matrix is hermitian(), and then compute this factorization.

INPUT:

• self – a matrix

• certificate – (default: False) return the lower-triangular and diagonal parts of the block_ldlt() factorization when the matrix is positive-definite. Deprecated.

OUTPUT:

This routine will return True if the matrix is Hermitian and meets the condition above for the quadratic form.

The base ring for the elements of the matrix must

1. Have a fraction field implemented; and
2. Be a subring of the real numbers, complex numbers, or symbolic ring.

If certificate is True, a triplet $(b, L, d)$ will be returned instead, with $b$ containing the result (true or false). If the matrix is positive-definite, then $L$ and $d$ will contain the lower-triangular and diagonal parts of the block_ldlt() factorization, respectively. Or if the matrix is not positive-definite (that is, if $b$ is False), then both $L$ and $d$ will be None.

See also:

block_ldlt(), is_hermitian(), is_positive_semidefinite()

EXAMPLES:

A real symmetric matrix that is positive-definite, as evidenced by the positive determinants of its leading principal submatrices:

```sage
A = matrix(QQ, [[4, -2, 4, 2],
                [-2, 10, -2, -7],
                [4, -2, 8, 4],
                [2, -7, 4, 7]])
sage: A.is_positive_definite()
True
sage: [A[i,i].determinant() for i in range(1, A.nrows() + 1)]
[4, 36, 144, 144]
```
A real symmetric matrix that is not positive-definite and a vector \( u \) that makes the corresponding quadratic form negative:

```
sage: A = matrix(QQ, [[ 3,  -6,   9,   6,  -9],
                   [-6,  11, -16, -11,  17],
                   [ 9, -16,  28,  16, -40],
                   [ 6, -11,  16,   9, -19],
                   [-9,  17, -40, -19,  68]])
sage: A.is_positive_definite()
False
sage: u = vector(QQ, [2, 2, 0, 1, 0])
sage: (A*u).inner_product(u)
-3
```

Another real symmetric matrix that is not positive-definite and a vector \( u \) that makes the corresponding quadratic form zero:

```
sage: A = matrix(QQ, [[ 21,  15,  12,  -2],
                   [ 15,  12,   9,   6],
                   [ 12,   9,   7,   3],
                   [ -2,   6,   3,   8]])
sage: A.is_positive_definite()
False
sage: u = vector(QQ, [1, 1, -3, 0])
sage: (A*u).inner_product(u)
0
```
A complex Hermitian matrix that is positive-definite, confirmed by the positive determinants of its leading principal submatrices:

```python
sage: # needs sage.rings.number_field
sage: x = polygen(ZZ, 'x')

sage: C.<I> = QuadraticField(x**2 + 1, embedding=CC(0,1))

sage: A = matrix(C, [[ 23, 17*I + 3, 24*I + 25, 21*I],
                  [ -17*I + 3, 38, -69*I + 89, 7*I + 15],
                  [ -24*I + 25, 69*I + 89, 976, 24*I + 6],
                  [ -21*I, -7*I + 15, -24*I + 6, 28]])

sage: A.is_positive_definite()
True

sage: [A[:i,:i].determinant() for i in range(1,A.nrows()+1)]
[23, 576, 359540, 2842600]
```

An Hermitian matrix that is not positive-definite and a vector \( u \) that makes the corresponding quadratic form negative:

```python
sage: # needs sage.rings.number_field
sage: x = polygen(ZZ, 'x')

sage: C = NumberField(x**2 + 1, names=(I,)); (I,) = C._first_ngens(1)

sage: A = matrix(C, [[ 2, 4 - 2*I, 2 + 2*I],
                  [ 4 + 2*I, 8, 10*I],
                  [ 2 - 2*I, -10*I, -3]])

sage: B = matrix(C, [[ 2, 4 - 2*I, 2 + 2*I],
                  [ 4 + 2*I, 8, 10*I],
                  [ 2 - 2*I, -10*I, -3]])

sage: u = vector(C, [-5 + 10*I, 4 - 3*I, 0])

sage: (B*u).hermitian_inner_product(u)
-50
```
A positive-definite matrix over an algebraically-closed field, confirmed by the positive determinants of its leading principal submatrices:

\[
\begin{align*}
A &= \begin{bmatrix}
2 & 4 + 2i & 6 - 4i \\
-2i + 4 & 11 & 10 - 12i \\
4i + 6 & 10 + 12i & 37
\end{bmatrix} \\
A &\text{is positive_definite() True}
\end{align*}
\]

is_positive_operator_on \((K1, K2=None)\)

Determine if this matrix is a positive operator on a cone.

A matrix is a positive operator on a cone if the image of the cone under the matrix is itself a subset of the cone. That concept can be extended to two cones: a matrix is a positive operator on a pair of cones if the image of the first cone is contained in the second cone.

To reliably check whether or not this matrix is a positive operator, its base ring must be either exact (for example, the rationals) or the symbolic ring. An exact ring is more reliable, but in some cases a matrix whose entries contain symbolic constants like \(e\) and \(\pi\) will work. Performance is best for integer or rational matrices, for which we can check the “is a subset of the other cone” condition quickly.

**INPUT:**

* K1 – a polyhedral closed convex cone.
• $K_2$ – (default: $K_1$) the codomain cone; this matrix is a positive operator if the image of $K_1$ is a subset of $K_2$.

OUTPUT:

If the base ring of this matrix is exact, then $\text{True}$ will be returned if and only if this matrix is a positive operator.

If the base ring of this matrix is symbolic, then the situation is more complicated:

• $\text{True}$ will be returned if it can be proven that this matrix is a positive operator.
• $\text{False}$ will be returned if it can be proven that this matrix is not a positive operator.
• $\text{False}$ will also be returned if we can’t decide; specifically if we arrive at a symbolic inequality that cannot be resolved.

REFERENCES:

EXAMPLES:

Nonnegative matrices are positive operators on the nonnegative orthant:

```
sage: K = Cone([(1,0,0), (0,1,0), (0,0,1)]) # needs sage.geometry.polyhedron
sage: L = random_matrix(QQ, 3).apply_map(abs)
sage: L.is_positive_operator_on(K) # needs sage.geometry.polyhedron
True

>>> from sage.all import *

>>> K = Cone([(Integer(1),Integer(0),Integer(0)), (Integer(0),Integer(1),
Integer(0)), (Integer(0),Integer(0),Integer(1))]) # needs sage.geometry.polyhedron
>>> L = random_matrix(QQ, Integer(3)).apply_map(abs)
>>> L.is_positive_operator_on(K) # needs sage.geometry.polyhedron
True
```

Symbolic entries also work in some easy cases:

```
sage: K = Cone([(1,0,0), (0,1,0), (0,0,1)]) # needs sage.geometry.polyhedron
sage: L = matrix(SR, [ [0, e, 0 ],
....: [0, 2, pi],
....: [sqrt(2), 0, 0 ] ]) # needs sage.symbolic
sage: L.is_positive_operator_on(K) # needs sage.geometry.polyhedron
True
```
Your matrix can be over any exact ring, for example the ring of univariate polynomials with rational coefficients:

```
sage: # needs sage.geometry.polyhedron
tsage: K = Cone([(1,0), (-1,0), (0,1), (0,-1)])
tsage: K.is_full_space()  
True
sage: x = polygen(ZZ, 'x')
tsage: L = matrix(QQ[x], [[x,0],[0,1]])
tsage: L.is_positive_operator_on(K)  
True
```

**is_positive_semidefinite()**

Returns whether or not this matrix is positive-semidefinite.

By SageMath convention, positive (semi)definite matrices must be either real symmetric or complex Hermitian.

**ALGORITHM:**

Bunch and Kaufman [BK1977] describe a fast, numerically-stable scheme for computing the “inertia” of a matrix by way Sylvester’s inertia theorem and a block-$LDL^T$ factorization. We perform this factorization, and read off the signs of the eigenvalues from the resulting diagonal blocks.

**REFERENCES:**

- [BK1977]

**See also:**

block_ldlt(), is_positive_definite()
Matrices and Spaces of Matrices, Release 10.4

sage: A = matrix(QQ, [[2,1], ...: [1,2] ] )
sage: A.eigenvalues()  # needs sage.rings.number_field
[3, 1]
sage: A.is_positive_semidefinite()
True

>>> from sage.all import *
>>> A = matrix(QQ, [[Integer(2),Integer(1)], ... Integer(1),Integer(2) ] )
>>> A.eigenvalues()  # needs sage.rings.number_field
[3, 1]
>>> A.is_positive_semidefinite()
True

A positive-semidefinite (but not positive-definite) matrix:

sage: A = matrix(QQ, [[1,1], ...: [1,1] ] )
sage: A.eigenvalues()  # needs sage.rings.number_field
[2, 0]
sage: A.is_positive_semidefinite()
True

>>> from sage.all import *
>>> A = matrix(QQ, [[Integer(1),Integer(1)], ... Integer(1),Integer(1) ] )
>>> A.eigenvalues()  # needs sage.rings.number_field
[2, 0]
>>> A.is_positive_semidefinite()
True

And finally, an indefinite matrix:

sage: A = matrix(QQ, [[0,1], ...: [1,0] ] )
sage: A.eigenvalues()  # needs sage.rings.number_field
[1, -1]
sage: A.is_positive_semidefinite()
False

>>> from sage.all import *
>>> A = matrix(QQ, [[Integer(0),Integer(1)], ... Integer(1),Integer(0) ] )
>>> A.eigenvalues()  # needs sage.rings.number_field
[1, -1]
>>> A.is_positive_semidefinite()
False

A non-Hermitian matrix cannot be positive-semidefinite, regardless of its eigenvalues:
```python
sage: A = matrix(QQ, [ [2,1], [0,0] ])
sage: A.eigenvalues()  # needs sage.rings.number_field
[2, 0]
sage: A.is_positive_semidefinite()
False
```

```python
>>> from sage.all import *

$$\begin{pmatrix}
2 & 1 \\
0 & 0
\end{pmatrix}$$

sage: A = matrix(QQ, [ [Integer(2),Integer(1)], [Integer(0),Integer(0)] ])
sage: A.eigenvalues()  # needs sage.rings.number_field
[2, 0]
sage: A.is_positive_semidefinite()
False
```

Any of the preceding examples are valid over inexact rings and with complex numbers as well:

```python
sage: # needs sage.rings.complex_double sage.symbolic
sage: A = matrix(CDF, [ [ 2, I], [-I, 2] ])

sage: A.is_positive_semidefinite()
True
```

```python
>>> from sage.all import *

$$\begin{pmatrix}
2 & \text{i} \\
-\text{i} & 2
\end{pmatrix}$$

sage: A = matrix(CDF, [ [ Integer(2), I], [-I, Integer(2)] ])

sage: A.is_positive_semidefinite()
True
```

```python
sage: # needs sage.rings.complex_double sage.symbolic
sage: A = matrix(CDF, [ [ 1, I], [-I, 1] ])

sage: A.is_positive_semidefinite()
True
```

```python
sage: A = matrix(CDF, [ [0,I], [I,0] ])

sage: A.is_positive_semidefinite()
False
```

```python
>>> from sage.all import *

$$\begin{pmatrix}
0 & \text{i} \\
\text{i} & 0
\end{pmatrix}$$

sage: A = matrix(CDF, [ [ Integer(0), I], [I,Integer(0)] ])

sage: A.is_positive_semidefinite()
False
```

```python
>>> from sage.all import *

$$\begin{pmatrix}
2 & \text{i} \\
0 & 0
\end{pmatrix}$$

sage: A = matrix(CDF, [ [Integer(2),I], [Integer(0),Integer(0)] ])

sage: A.is_positive_semidefinite()
False
```

```
\text{is\_scalar}\ (a=\text{None})
```
Return True if this matrix is a scalar matrix.

INPUT:
• base_ring element a, which is chosen as self[0][0] if a = None

OUTPUT:
• whether self is a scalar matrix (in fact the scalar matrix aI if a is input)

EXAMPLES:
```
sage: m = matrix(QQ, 2,2, range(4))
sage: m.is_scalar(5)
False
sage: m = matrix(QQ, 2, [5,0,0,5])
... m.is_scalar(5)
True
sage: m = matrix(QQ, 2, [1,0,0,1])
... m.is_scalar(1)
True
sage: m = matrix(QQ, 2, [1,1,1,1])
... m.is_scalar(1)
False
>>> from sage.all import *

>>> m = matrix(QQ, Integer(2),Integer(2), range(Integer(4)))
>>> m.is_scalar(Integer(5))
False
>>> m = matrix(QQ, Integer(2), [Integer(5),Integer(0),Integer(0),Integer(5)])
... m.is_scalar(Integer(5))
True
>>> m = matrix(QQ, Integer(2), [Integer(1),Integer(0),Integer(0),Integer(1)])
... m.is_scalar(Integer(1))
True
>>> m = matrix(QQ, Integer(2), [Integer(1),Integer(1),Integer(1),Integer(1)])
... m.is_scalar(Integer(1))
False
```

is_semisimple()
Return if self is semisimple.

A (square) matrix $A$ is semisimple if the minimal polynomial of $A$ is square-free.

If $A$ represents a linear map from $F^n \to F^n$ for some field $F$, then this is equivalent to every $A$-invariant subspace of $F^n$ has a complementary $A$-invariant subspace. This is also equivalent to saying the matrix is diagonalizable over $\bar{F}$, the algebraic closure of $F$.

EXAMPLES:
```
sage: A = matrix([[0, -1], [1, 0]]); A
[ 0 -1]
[ 1  0]
... A.is_semisimple()
True
... A.change_ring(QQ).is_diagonalizable()
False
... A.change_ring(CyclotomicField(4)).is_diagonalizable()
True
```
is_similar(other, transformation=False)

Return True if self and other are similar, i.e. related by a change-of-basis matrix.

INPUT:

- other – a matrix, which should be square, and of the same size as self.
- transformation – (default: False); if True, the output may include the change-of-basis matrix (also known as the similarity transformation). See below for an exact description.

OUTPUT:

Two matrices, $A$ and $B$ are similar if they are square matrices of the same size and there is an invertible matrix $S$ such that $A = S^{-1}BS$. $S$ can be interpreted as a change-of-basis matrix if $A$ and $B$ are viewed as matrix representations of the same linear transformation from a vector space to itself.

When transformation=False this method will return True if such a matrix $S$ exists, otherwise it will return False. When transformation=True the method returns a pair. The first part of the pair is True or False depending on if the matrices are similar. The second part of the pair is the change-of-basis matrix when the matrices are similar and None when the matrices are not similar.

When a similarity transformation matrix $S$ is requested, it will satisfy $self = S^{-1} * other * S$.

rings and coefficients

Inexact rings are not supported. Only rings having a fraction field can be used as coefficients.

The base rings for the matrices are promoted to a common field for the similarity check using rational form over this field.

If the fraction fields of both matrices are the same, this field is used. Otherwise, if the fraction fields are only related by a canonical coercion, the common coercion field is used.

In all cases, the result is about similarity over a common field.

similarity transformation

For computation of the similarity transformation, the matrices are first checked to be similar over their common field.

In this case, a similarity transformation is then searched for over the common field. If this fails, the matrices are promoted to the algebraic closure of their common field (whenever it is available) and a similarity transformation is looked for over the algebraic closure.

For example, matrices over the rationals may be promoted to the field of algebraic numbers ($\mathbb{Q}\bar{\mathbb{Q}}$) for computation of the similarity transformation.
Warning: When the two matrices are similar, this routine may fail to find the similarity transformation. A technical explanation follows.

The similarity check is accomplished with rational form, which will be successful for any pair of matrices over the same field. However, the computation of rational form does not provide a transformation. So we instead compute Jordan form, which does provide a transformation. But Jordan form will require that the eigenvalues of the matrix can be represented within Sage, requiring the existence of the appropriate extension field. When this is not possible, a RuntimeError is raised, as demonstrated in an example below.

EXAMPLES:
The two matrices in this example were constructed to be similar. The computations happen in the field of algebraic numbers, but we are able to convert the change-of-basis matrix back to the rationals (which may not always be possible).

```sage
A = matrix(ZZ, [[-5, 2, -11], [-6, 7, -42], [0, 1, -6]])
B = matrix(ZZ, [[1, 12, 3], [-1, -6, -1], [0, 6, 1]])
A.is_similar(B)
```

```
True
```

```
_, T = A.is_similar(B, transformation=True)
T
```

```
[ 1.0000000000000? + 0.?e-13*I 0.?e-13 + 0.?e-13*I 0.?e-13 + 0.?e-13*I]
-0.6666666666667? + 0.?e-13*I 0.16666666666667? + 0.?e-14*I -0.8333333333334?

```

(continues on next page)
Other exact fields are supported.

```python
sage: # needs sage.rings.finite_rings
sage: F.<a> = FiniteField(7^2)
```

```python
sage: A = matrix(F, [[2*a + 5, 6*a + 6, a + 3],
...: [ a + 3, 2*a + 2, 4*a + 2],
...: [2*a + 6, 5*a + 5, 3*a]]
```

```python
sage: B = matrix(F, [[5*a + 5, 6*a + 4, a + 1],
...: [ a + 5, 4*a + 3, 3*a + 3],
...: [3*a + 5, a + 4, 5*a + 6]])
```

```python
sage: A.is_similar(B)
```

```python
True
```

```python
sage: B.is_similar(A)
```

```python
True
```

```python
sage: _, T = A.is_similar(B, transformation=True)
```

```python
sage: T
```

```python
[ 1 0 0]
[6*a + 1 4*a + 3 4*a + 2]
[6*a + 3 3*a + 5 3*a + 6]
```

```python
sage: A == T.inverse() * B * T
```

```python
True
```

```python
>>> from sage.all import *
```

```python
>>> # needs sage.rings.finite_rings
```

```python
>>> F = FiniteField(Integer(7)**Integer(2), names=('a',)); (a,) = F._first_˓→ngens(1)
```

```python
>>> A = matrix(F, [[Integer(2)*a + Integer(5), Integer(6)*a + Integer(6), a˓→+ Integer(3)],
...: [ a + Integer(3), Integer(2)*a + Integer(2), Integer(4)*a˓→+ Integer(1)],
...: [Integer(2)*a + Integer(6), Integer(5)*a + Integer(5), ˓→ Integer(3)*a]])
```

```python
>>> B = matrix(F, [[Integer(5)*a + Integer(5), Integer(6)*a + Integer(4), a˓→+ Integer(1)],
...: [ a + Integer(5), Integer(4)*a + Integer(3), Integer(3)*a˓→+ Integer(3)],
...: [Integer(3)*a + Integer(5), a + Integer(4), Integer(5)*a˓→+ Integer(6)])])
```

```python
>>> A.is_similar(B)
```

```python
True
```

```python
>>> B.is_similar(A)
```

```python
True
```

```python
>>> _, T = A.is_similar(B, transformation=True)
```

```python
>>> T
```

```python
[ 1 0 0]
[6*a + 1 4*a + 3 4*a + 2]
```

(continues on next page)
Two matrices with different sets of eigenvalues, so they cannot possibly be similar.

```python
sage: A = matrix(QQ, [[ 2, 3, -3, -6],
...: [ 0, 1, -2, -8],
...: [-3, -3, 4, 3],
...: [-1, -2, 2, 6]])
sage: B = matrix(QQ, [[ 1, 1, 2, 4],
...: [-1, 2, -3, -7],
...: [-2, 3, -4, -7],
...: [ 0, -1, 0, 0]])
sage: A.eigenvalues() == B.eigenvalues()
False
```

Similarity is an equivalence relation, so this routine computes a representative of the equivalence class for each matrix, the rational form, as provided by `rational_form()`. The matrices below have identical eigenvalues (as evidenced by equal characteristic polynomials), but slightly different rational forms, and hence are not similar.

```python
sage: A = matrix(QQ, [[ 19, -7, -29],
...: [-16, 11, 30],
...: [ 15, -7, -25]])
sage: B = matrix(QQ, [[-38, -63, 42],
...: [ 14, 25, -14],
...: [-14, -21, 18]])
sage: A.charpoly() == B.charpoly()
True
```

(continues on next page)
Obtaining the transformation between two similar matrices requires the Jordan form, which requires computing the eigenvalues of the matrix, which may not lie in the field used for entries of the matrix. In this unfortunate case, the computation of the transformation may fail with a `RuntimeError`, EVEN when the matrices are similar. This is not the case for matrices over the integers, rationals or algebraic numbers, since the computations are done in the algebraically closed field of algebraic numbers. Here is an example where the similarity is obvious by design, but we are not able to resurrect a similarity transformation.

```
sage: F.<a> = FiniteField(7^2)
sage: C = matrix(F, [[ a + 2, 5*a + 4],
             [6*a + 6, 6*a + 4])
sage: S = matrix(F, [[0, 1],
             [1, 0])
sage: D = S.inverse()*C*S
sage: C.is_similar(D, transformation=True) #...
  needs sage.combinat
Traceback (most recent call last):
  ....RuntimeError: unable to compute transformation for similar matrices
sage: C.jordan_form() #...
  needs sage.combinat
Traceback (most recent call last):
  ...RuntimeError: Some eigenvalue does not exist in Finite Field in a of size 7^2.
```
An example over a finite field of prime order, which uses the algebraic closure of this field to find the change-of-basis matrix:

```
sage: # needs sage.combinat sage.graphs sage.rings.finite_rings
sage: cox = posets.TamariLattice(3).coxeter_transformation()
sage: M = cox.change_ring(GF(3))
sage: M.is_similar(M**3, True) # long time
{[1 0 0 0 0]
 [0 1 1 0 2]
 [0 0 0 1]
 [1 2 0 2 1]
 True, [0 0 1 0 0]
}
```

Inexact rings and fields are not supported.

```
sage: A = matrix(CDF, 2, 2, range(4))
sage: B = copy(A)
sage: A.is_similar(B)
Traceback (most recent call last):
```
...  
TypeError: matrix entries must come from an exact field,  
not Complex Double Field

```python
>>> from sage.all import *

>>> A = matrix(CDF, Integer(2), Integer(2), range(Integer(4)))

>>> B = copy(A)

>>> A.is_similar(B)
Traceback (most recent call last):
...
TypeError: matrix entries must come from an exact field,  
not Complex Double Field
```

Base rings for the matrices need to have a fraction field. So in particular, the ring needs to be at least an  
integral domain.

```python
sage: Z6 = Integers(6)
sage: A = matrix(Z6, 2, 2, range(4))
sage: A.is_similar(A)
Traceback (most recent call last):
...
ValueError: base ring of a matrix needs a fraction field,  
maybe the ring is not an integral domain
```

```python
>>> from sage.all import *

>>> Z6 = Integers(Integer(6))

>>> A = matrix(Z6, Integer(2), Integer(2), range(Integer(4)))

>>> A.is_similar(A)
Traceback (most recent call last):
...
ValueError: base ring of a matrix needs a fraction field,  
maybe the ring is not an integral domain
```

If the fraction fields of the entries are unequal and do not coerce in a common field, it is an error.

```python
sage: A = matrix(GF(3), 2, 2, range(4))
sage: B = matrix(GF(2), 2, 2, range(4))

sage: A.is_similar(B, transformation=True)
Traceback (most recent call last):
...
TypeError: no common canonical parent for objects with parents:  
'Full MatrixSpace of 2 by 2 dense matrices over Finite Field  
of size 3' and  
'Full MatrixSpace of 2 by 2 dense matrices over Finite Field  
of size 2'
```

```python
>>> from sage.all import *

>>> A = matrix(GF(Integer(3)), Integer(2), Integer(2), range(Integer(4)))

>>> B = matrix(GF(Integer(2)), Integer(2), Integer(2), range(Integer(4)))

>>> A.is_similar(B, transformation=True)
Traceback (most recent call last):
...
TypeError: no common canonical parent for objects with parents:  
'Full MatrixSpace of 2 by 2 dense matrices over Finite Field  
of size 3' and
```

(continues on next page)
A matrix over the integers and a matrix over the algebraic numbers will be compared over the algebraic numbers (by coercion of $\mathbb{Q}$ in $\mathbb{Q}\bar{\mathbb{Q}}$).

```python
sage: A = matrix(ZZ, 2, 2, range(4))
sage: B = matrix(QQbar, 2, 2, range(4))
# needs sage.rings.number_field
sage: A.is_similar(B)  # needs sage.rings.number_field
True
```

```python
>>> from sage.all import *
>>> A = matrix(ZZ, Integer(2), Integer(2), range(Integer(4)))
>>> B = matrix(QQbar, Integer(2), Integer(2), range(Integer(4)))
# needs sage.rings.number_field
>>> A.is_similar(B)  # needs sage.rings.number_field
True
```

**is_triangular** *(side='lower')*

Return True if this matrix is a triangular matrix.

**INPUT:**

- side – either "lower" (default) or "upper"

**OUTPUT:**

boolean

**EXAMPLES:**

```python
sage: m = matrix(QQ, 2, 2, range(4))
sage: m.is_triangular()
False
sage: m = matrix(QQ, 2, [5, 0, 0, 5])
sage: m.is_triangular()
True
sage: m = matrix(QQ, 2, [1, 2, 0, 1])
sage: m.is_triangular("upper")
True
sage: m.is_triangular("lower")
False
```

```python
>>> from sage.all import *
>>> m = matrix(QQ, Integer(2), Integer(2), range(Integer(4)))
>>> m.is_triangular()
False
>>> m = matrix(QQ, Integer(2), [Integer(5), Integer(0), Integer(0), Integer(5)])
>>> m.is_triangular()
True
>>> m = matrix(QQ, Integer(2), [Integer(1), Integer(2), Integer(0), Integer(1)])
>>> m.is_triangular("upper")
```

(continues on next page)
is_unitary()

Return True if the columns of the matrix are an orthonormal basis.

For a matrix with real entries this determines if a matrix is “orthogonal” and for a matrix with complex entries this determines if the matrix is “unitary.”

OUTPUT:

True if the matrix is square and its conjugate-transpose is its inverse, and False otherwise. In other words, a matrix is orthogonal or unitary if the product of its conjugate-transpose times the matrix is the identity matrix.

For numerical matrices a specialized routine available over RDF and CDF is a good choice.

EXAMPLES:

```python
>>> m.is_triangular("lower")
False
```
Asquare matrix far from unitary.

```python
sage: A = matrix(QQ, 4, range(16))
sage: A.is_unitary()
False
```

Rectangular matrices are never unitary.

```python
sage: A = matrix(QQbar, 3, 4)  # needs sage.rings.number_field
sage: A.is_unitary()
False
```

```

[ 0 0 0 0 0]
>>> S, N = A.jordan_decomposition()

```
Matrices and Spaces of Matrices, Release 10.4

>>> S.is_semisimple()
True
>>> N.is_nilpotent()
True
>>> A.jordan_form()
Traceback (most recent call last):
...
RuntimeError: Some eigenvalue does not exist in Rational Field.

```
jordan_form(base_ring=None, sparse=False, subdivide=True, transformation=False, eigenvalues=None, check_input=True)
```

Compute the Jordan normal form of this square matrix $A$, if it exists.

This computation is performed in a naive way using the ranks of powers of $A - xI$, where $x$ is an eigenvalue of the matrix $A$. If desired, a transformation matrix $P$ can be returned, which is such that the Jordan canonical form is given by $P^{-1}AP$; if the matrix is diagonalizable, this equals to eigendecomposition or spectral decomposition.

**INPUT:**

- `base_ring` – Ring in which to compute the Jordan form.
- `sparse` – (default False) If `sparse=True`, return a sparse matrix.
- `subdivide` – (default True) If `subdivide=True`, the subdivisions for the Jordan blocks in the matrix are shown.
- `transformation` – (default False) If `transformation=True`, computes also the transformation matrix.
- `eigenvalues` – (default None) A complete set of roots, with multiplicity, of the characteristic polynomial of $A$, encoded as a list of pairs, each having the form $(r, m)$ with $r$ a root and $m$ its multiplicity. If this is None, then Sage computes this list itself, but this is only possible over base rings in whose quotient fields polynomial factorization is implemented. Over all other rings, providing this list manually is the only way to compute Jordan normal forms.
- `check_input` – (default True) A Boolean specifying whether the list `eigenvalues` (if provided) has to be checked for correctness. Set this to False for a speedup if the eigenvalues are known to be correct.

**Note:** Currently, the Jordan normal form is not computed over inexact rings in any but the trivial cases when the matrix is either $0 \times 0$ or $1 \times 1$.

In the case of exact rings, this method does not compute any generalized form of the Jordan normal form, but is only able to compute the result if the characteristic polynomial of the matrix splits over the specific base ring.

Note that the base ring must be a field or a ring with an implemented fraction field.

**EXAMPLES:**

```
sage: # needs sage.combinat sage.libs.pari
tsage: a = matrix(22, 4, [1, 0, 0, 0, 0, 1, 0, 0,
....: 1, -1, 1, 0, 1, -1, 1, 2]); a
[ 1 0 0 0]
[ 0 1 0 0]
[ 0 -1 1 0]
[ 1 -1 1 0]
```
\begin{verbatim}
>>> from sage.all import *
>>> # needs sage.combinat sage.libs.pari
>>> a = matrix(ZZ, Integer(4), [Integer(1), Integer(0), Integer(0), Integer(0),
... Integer(0), Integer(1), Integer(0), Integer(0),
... Integer(1), -Integer(1), Integer(1), Integer(0),
... Integer(0), -Integer(1), Integer(1), Integer(0),
... Integer(1), -Integer(1), Integer(1), Integer(0),
... -Integer(1), Integer(1), Integer(1), Integer(2)]); a
[ 1 0 0 0]
[ 0 1 0 0]
[ 1 -1 1 0]
[ 1 -1 1 2]
>>> a.jordan_form()
[ 2 | 0 0 | 0]
[---+-]
[0 | 1 1 | 0]
[0 | 0 1 | 0]
[---+-]
[0 | 0 0 | 1]
>>> a.jordan_form(subdivide=False)
[ 2 0 0 0]
[ 0 1 1 0]
[ 0 0 1 0]
[ 0 0 0 1]
>>> b = matrix(ZZ, Integer(3), Integer(3), range(Integer(9))); b
[ 0 1 2]
[ 3 4 5]
[ 6 7 8]
>>> b.jordan_form()
Traceback (most recent call last):
  ... 
RuntimeError: Some eigenvalue does not exist in Rational Field.
>>> b.jordan_form(RealField(15))
Traceback (most recent call last):
  ... 
ValueError: Jordan normal form not implemented over inexact rings.
\end{verbatim}
Here we need to specify a field, since the eigenvalues are not defined in the smallest ring containing the matrix entries (Issue #14508):

```python
sage: c = matrix([[0,1,0], [0,0,1], [1,0,0]])
sage: c.jordan_form(CyclotomicField(3))
```

If you need the transformation matrix as well as the Jordan form of `self`, then pass the option `transformation=True`. For example:

```python
sage: m = matrix([[5, 4, 2, 1], [0, 1, -1, -1], [-1, -1, 3, 0], [1, 1, -1, 2]])
```

(continues on next page)
Note that for matrices over inexact rings, we do not attempt to compute the Jordan normal form, since it is not numerically stable:

```
>> from sage.all import *
>> b = matrix(ZZ, Integer(3), Integer(3), range(Integer(9)))
>> jf, p = b.jordan_form(RealField(Integer(15)), transformation=True)

ValueError: Jordan normal form not implemented over inexact rings.
```

The method `kernel()` is exactly equal to `left_kernel()`.

For inexact rings use `right_kernel_matrix()` with `basis='computed'` (on the transpose of the matrix) to avoid echolonizing.

**INPUT:**

- `algorithm` – (default: ‘default’); a keyword that selects the algorithm employed. Allowable values are:
  - ‘default’ – allows the algorithm to be chosen automatically
  - ‘generic’ – naive algorithm usable for matrices over any field
  - ‘flint’ – FLINT library code for matrices over the rationals or the integers
  - ‘pari’ – PARI library code for matrices over number fields or the integers

```
kernel (*args, **kwds)

Returns the left kernel of this matrix, as a vector space or free module. This is the set of vectors \( x \) such that \( x * self = 0 \).
```

Note: For the right kernel, use `right_kernel()`. The method `kernel()` is exactly equal to `left_kernel()`. 
– ‘padic’ – padic algorithm from IML library for matrices over the rationals and integers
– ‘pluq’ – PLUQ matrix factorization for matrices mod 2

• **basis** – (default: ‘echelon’): a keyword that describes the format of the basis used to construct the left kernel. Allowable values are:
  – ‘echelon’: the basis matrix is returned in echelon form
  – ‘pivot’: each basis vector is computed from the reduced row-echelon form of self by placing a single one in a non-pivot column and zeros in the remaining non-pivot columns. Only available for matrices over fields.
  – ‘LLL’: an LLL-reduced basis. Only available for matrices over the integers.

**OUTPUT:**
A vector space or free module whose degree equals the number of rows in self and which contains all the vectors x such that x* self = 0.

If self has 0 rows, the kernel has dimension 0, while if self has 0 columns the kernel is the entire ambient vector space.

The result is cached. Requesting the left kernel a second time, but with a different basis format, will return the cached result with the format from the first computation.

**Note:** For much more detailed documentation of the various options see right_kernel(), since this method just computes the right kernel of the transpose of self.

**EXAMPLES:**
Over the rationals with a basis matrix in echelon form.

```
sage: A = matrix(QQ, [[1, 2, 4, -7, 4],
                   ...: [1, 1, 0, 2, -1],
                   ...: [1, 0, 3, -3, 1],
                   ...: [0, -1, -1, 3, -2],
                   ...: [0, 0, -1, 2, -1]])
sage: A.left_kernel()
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[ 1 0 -1 2 -1]
[ 0 1 -1 1 -4]
```

```python
from sage.all import *
A = matrix(QQ, [[Integer(1), Integer(2), Integer(4), -Integer(7), Integer(4)],
                ...: [Integer(1), Integer(0), Integer(3), -Integer(3), Integer(1)],
                ...: [Integer(0), -Integer(1), Integer(3), -Integer(2), Integer(1)]]
>>> A.left_kernel()
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[ 1 0 -1 2 -1]
[ 0 1 -1 1 -4]
```
Over a finite field, with a basis matrix in “pivot” format.

```python
sage: A = matrix(FiniteField(7), [[5, 0, 5, 2, 4],
.....: [1, 3, 2, 3, 6],
.....: [1, 1, 6, 5, 3],
.....: [2, 5, 6, 0, 0]])
sage: A.kernel(basis='pivot')
Vector space of degree 4 and dimension 2 over Finite Field of size 7
User basis matrix:
[5 2 1 0]
[6 3 0 1]
```

The left kernel of a zero matrix is the entire ambient vector space whose degree equals the number of rows of self (i.e. everything).

```python
sage: A = MatrixSpace(QQ, 3, 4)(0)
sage: A.kernel()
Vector space of degree 3 and dimension 3 over Rational Field
Basis matrix:
[1 0 0]
[0 1 0]
[0 0 1]
```

We test matrices with no rows or columns.

```python
sage: A = matrix(QQ, 2, 0)
sage: A.left_kernel()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
sage: A = matrix(QQ, 0, 2)
sage: A.left_kernel()
```

(continues on next page)
Vector space of degree 0 and dimension 0 over Rational Field
Basis matrix:

>>> from sage.all import *
>>> A = matrix(QQ, Integer(2), Integer(0))
>>> A.left_kernel()
Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]

>>> A = matrix(QQ, Integer(0), Integer(2))
>>> A.left_kernel()
Vector space of degree 0 and dimension 0 over Rational Field
Basis matrix:
[]

The results are cached. Note that requesting a new format for the basis is ignored and the cached copy is returned. Work with a copy if you need a new left kernel, or perhaps investigate the right_kernel_matrix() method on the transpose, which does not cache its results and is more flexible.

```python
type: A = matrix(QQ, [[1,1],[2,2]])
type: K1 = A.left_kernel()
type: K1
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1/2]
type: K2 = A.left_kernel()
type: K1 is K2
True

type: K3 = A.left_kernel(basis='pivot')
type: K3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1/2]
type: B = copy(A)
type: K3 = B.left_kernel(basis='pivot')
type: K3
Vector space of degree 2 and dimension 1 over Rational Field
User basis matrix:
[-2 1]
type: K3 is K1
False
type: K3 == K1
True
```

```python
from sage.all import *

>>> A = matrix(QQ, [[Integer(1),Integer(1)],[Integer(2),Integer(2)]]))
>>> K1 = A.left_kernel()
>>> K1
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1/2]

>>> K2 = A.left_kernel()
>>> K1 is K2
True
```
>>> K3 = A.left_kernel(basis='pivot')
>>> K3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[   1 -1/2]
>>> B = copy(A)
>>> K3 = B.left_kernel(basis='pivot')
>>> K3
Vector space of degree 2 and dimension 1 over Rational Field
User basis matrix:
[-2   1]
>>> K3 is K1
False
>>> K3 == K1
True

kernel_on (V, poly=None, check=True)
Return the kernel of self restricted to the invariant subspace V. The result is a vector subspace of V, which is also a subspace of the ambient space.

INPUT:
• V – vector subspace
• check – (optional) default: True; whether to check that V is invariant under the action of self.
• poly – (optional) default: None; if not None, compute instead the kernel of poly(self) on V.

OUTPUT:
• a subspace

Warning: This function does not check that V is in fact invariant under self if check is False. With check False this function is much faster.

EXAMPLES:

sage: t = matrix(QQ, 4, [39, -10, 0, -12, 0, 2, 0, -1, 0, 1, -2, 0, 0, 2, 0, -2]); t
[ 39 -10  0 -12]
[  0  2  0 -1]
[  0  1 -2  0]
[  0  2  0 -2]
sage: t.fcp()        #...
(x - 39) * (x + 2) * (x^2 - 2)
sage: s = (t-39)*(t^2-2)
sage: V = s.kernel(); V
Vector space of degree 4 and dimension 3 over Rational Field
Basis matrix:
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
sage: s.restrict(V)
[0 0 0]
[0 0 0]
[0 0 0]
sage: s.kernel_on(V)
Vector space of degree 4 and dimension 3 over Rational Field
Basis matrix:
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
sage: k = t-39
sage: k.restrict(V)
[ 0 -10 -12]
[ 0 -37 -1]
[ 0 2 -41]
sage: ker = k.kernel_on(V); ker
Vector space of degree 4 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2/7 0 -2/7]
sage: ker.0 * k
(0, 0, 0, 0)

>>> from sage.all import *
>>> t = matrix(QQ, Integer(4), [Integer(39), -Integer(10), Integer(0),
    →Integer(12), Integer(0), Integer(2), Integer(0), Integer(1), Integer(0),
    →Integer(1), -Integer(2), Integer(0), Integer(0), Integer(2), Integer(0),
    →Integer(2)]); t
[39 -10 0 -12]
[0 2 0 -1]
[0 1 -2 0]
[0 2 0 -2]
>>> t.fcp()  # needs sage.libs.pari
(x - 39) * (x + 2) * (x^2 - 2)
>>> s = (t-Integer(39))*(t**Integer(2)-Integer(2))
>>> V = s.kernel(); V
Vector space of degree 4 and dimension 3 over Rational Field
Basis matrix:
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
>>> s.restrict(V)
[0 0 0]
[0 0 0]
[0 0 0]
>>> s.kernel_on(V)
Vector space of degree 4 and dimension 3 over Rational Field
Basis matrix:
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
>>> k = t-Integer(39)
>>> k.restrict(V)
[ 0 -10 -12]
[ 0 -37 -1]
[ 0 2 -41]
>>> ker = k.kernel_on(V); ker
Vector space of degree 4 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2/7 0 -2/7]
Test that Issue #9425 is fixed.

```python
sage: V = span([[1/7,0,0], [0,1,0]], ZZ); V
Free module of degree 3 and rank 2 over Integer Ring
Echelon basis matrix:
[1/7  0  0]
[ 0  1  0]
sage: T = matrix(ZZ,3,[1,0,0,0,0,0,0,0,0]); T
[1 0 0]
[0 0 0]
[0 0 0]
sage: W = T.kernel_on(V); W.basis()
[0, 1, 0]
sage: W.is_submodule(V)
True
```

```python
>>> from sage.all import *
```

```python
class LinearSpace(LinearRecurrenceSequence):
    def __init__(self, *args, **kwargs):
        super().__init__(*args, **kwargs)
        self._gen = Gen(self._term_gen)  # A generator
        self._gen._reset()  # Reset the generator
        self._gen._reset()  # Reset the generator
        self._gen._reset()  # Reset the generator

    def _gen(self):  # A generator
        yield from self._term_gen
```

**left_eigenmatrix**(other=None)

Return matrices $D$ and $P$, where $D$ is a diagonal matrix of eigenvalues and the rows of $P$ are corresponding eigenvectors (or zero vectors).

**INPUT:**

- other – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved

**OUTPUT:**

If `self` is a square matrix $A$, then the output is a diagonal matrix $D$ and a matrix $P$ such that

$$PA = DP,$$

where the rows of $P$ are eigenvectors of $A$ and the diagonal entries of $D$ are the corresponding eigenvalues.
If a matrix $B$ is passed as optional argument, the output is a solution to the generalized eigenvalue problem such that

$$PA = DB.$$

The ordinary eigenvalue problem is equivalent to the generalized one if $B$ is the identity matrix.

The generalized eigenvector decomposition is currently only implemented for matrices over RDF and CDF.

**EXAMPLES:**

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: D, P = A.eigenmatrix_left()
sage: D
[ 0 0 0]
[ 0 -1.348469228349535? 0]
[ 0 0 13.34846922834954?]
sage: P
[ 1 -2 1]
[ 1 0.3101020514433644? -0.3797958971132713?]
[ 1 1.289897948556636? 1.579795897113272?]
sage: P*A == D*P
True
```

Because $P$ is invertible, $A$ is diagonalizable.

```python
sage: A == (~P)*D*P # needs sage.rings.number_field
True
```

The matrix $P$ may contain zero rows corresponding to eigenvalues for which the algebraic multiplicity is greater than the geometric multiplicity. In these cases, the matrix is not diagonalizable.
sage: # needs sage.rings.number_field
sage: A = jordan_block(2, 3); A
[[2 1 0]
[0 2 1]
[0 0 2]]
sage: D, P = A.eigenmatrix_left()
sage: D
[[2 0 0]
[0 2 0]
[0 0 2]]
sage: P
[[0 0 1]
[0 0 0]
[0 0 0]]
sage: P*A == D*P
True

A generalized eigenvector decomposition:

sage: # needs scipy
sage: A = matrix(RDF, [[1, -2], [3, 4]])
sage: B = matrix(RDF, [[0, 7], [2, -3]])
sage: D, P = A.eigenmatrix_left(B)
sage: (P*A - D*P*B).norm() < 1e-14
True

The matrix $B$ in a generalized eigenvalue problem may be singular:

sage: # needs scipy sage.rings.complex_double sage.symbolic
sage: A = matrix.identity(CDF, 2)
sage: B = matrix(CDF, [[2, 1+I], [4, 2+2*I]])
(continues on next page)
In this case, we can still verify the eigenvector equation for the first eigenvalue and first eigenvector:

```python
sage: l = D[0, 0]
sage: v = P[0, :]
sage: (v * A - l * v * B).norm() < 1e-14
True
```

The second eigenvector is contained in the left kernel of $B$:

```python
sage: (P[1, :] * B).norm() < 1e-14
# needs scipy sage.rings.complex_double sage.symbolic
True
```

See also:

- `eigenvalues()`, `eigenvectors_left()`, `Matrix_double_dense`
- `eigenvectors_left()`, `eigenmatrix_right()`.

**left_eigenspaces** (`format='all'`, `var='a'`, `algebraic_multiplicity=False`)

Compute the left eigenspaces of a matrix.

Note that `eigenspaces_left()` and `left_eigenspaces()` are identical methods. Here “left” refers to the eigenvectors being placed to the left of the matrix.

**INPUT:**

- `self` – a square matrix over an exact field. For inexact matrices consult the numerical or symbolic matrix classes.
- `format` – one of:
- 'all' – Attempts to create every eigenspace. This will always be possible for matrices with rational entries.
- 'galois' – For each irreducible factor of the characteristic polynomial, a single eigenspace will be output for a single root/eigenvalue for the irreducible factor.
- None (default) – Uses the 'all' format if the base ring is contained in an algebraically closed field which is implemented. Otherwise, uses the 'galois' format.

- var – string (default: 'a'): variable name used to represent elements of the root field of each irreducible factor of the characteristic polynomial. If var='a', then the root fields will be in terms of a0, a1, a2, ..., where the numbering runs across all the irreducible factors of the characteristic polynomial, even for linear factors.
- algebraic_multiplicity – (boolean, default: False): whether to include the algebraic multiplicity of each eigenvalue in the output. See the discussion below.

**OUTPUT:**

If algebraic_multiplicity=False, return a list of pairs \( (\epsilon, V) \) where \( \epsilon \) is an eigenvalue of the matrix, and \( V \) is the corresponding left eigenspace. For Galois conjugates of eigenvalues, there may be just one representative eigenspace, depending on the format keyword.

If algebraic_multiplicity=True, return a list of triples \( (\epsilon, V, n) \) where \( \epsilon \) and \( V \) are as above and \( n \) is the algebraic multiplicity of the eigenvalue.

**Warning:** Uses a somewhat naive algorithm (simply factors the characteristic polynomial and computes kernels directly over the extension field).

**EXAMPLES:**

We compute the left eigenspaces of a \( 3 \times 3 \) rational matrix. First, we request 'all' of the eigenvalues, so the results are in the field of algebraic numbers, \( \mathbb{Q} \bar{\mathbb{Q}} \). Then we request just one eigenspace per irreducible factor of the characteristic polynomial with format='galois'.

```
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenspaces_left(format='all'); es  # needs sage.rings.number_field

>>> A = ModularSymbols(Integer(43), base_ring=GF(Integer(11)), sign=Integer(1)).T(Integer(2)).matrix(); A

```
This method is only applicable to exact matrices. The “eigenmatrix” routines for matrices with double-precision floating-point entries (RDF, CDF) are the best alternative. (Since some platforms return eigenvectors that are the negatives of those given here, this one example is not tested here.) There are also “eigenmatrix” routines for matrices with symbolic entries.

```
sage: A = matrix(QQ, 3, 3, range(9))
sage: A.change_ring(RR).eigenspaces_left()
Traceback (most recent call last):
...  
NotImplementedError: eigenspaces cannot be computed reliably
for inexact rings such as Real Field with 53 bits of precision,
consult numerical or symbolic matrix classes for other options

sage: # needs scipy
sage: em = A.change_ring(RDF).eigenmatrix_left()
sage: eigenvalues = em[0]; eigenvalues.dense_matrix()  # abs tol 1e-13
[13.348469228349522 0.0 0.0]

[ 0.0 0.0 0.0]

sage: eigenvectors = em[1]; eigenvectors # not tested
[0.440242867... 0.567868371... 0.695493875...]
[0.897878732... 0.278434036... -0.341010658...]
[0.408248290... -0.816496580... 0.408248290...]

sage: # needs sage.symbolic
sage: x, y = var('x y')
sage: S = matrix([[x, y], [y, 3*x^2]])
sage: em = S.eigenmatrix_left()
sage: eigenvalues = em[0]; eigenvalues
[3/2*x^2 + 1/2*x - 1/2*sqrt(9*x^4 - 6*x^3 + x^2 + 4*y^2) → 0]
[ 2*sqrt(9*x^4 - 6*x^3 + x^2 + 4*y^2)]

sage: eigenvectors = em[1]; eigenvectors
[1 1/2*(3*x^2 - x -
→sqrt(9*x^4 - 6*x^3 + x^2 + 4*y^2))/y]
[1 1/2*(3*x^2 - x +
→sqrt(9*x^4 - 6*x^3 + x^2 + 4*y^2))/y]
```

**Note:** The output from the symbolic computations is not shown in the text. The computation includes the use of `sqrt` and `var` for symbolic variables, and the resulting eigenvalues and eigenvectors are given in terms of `x` and `y`. The `eigenvalues` and `eigenvectors` are computed and displayed, with some of the symbolic expressions left in their symbolic form. The examples use a mix of `matrix` for creating matrices, and `change_ring` for changing the ring to `RR`, `RDF`, or `QQ`, as appropriate. The `eigenspaces_left` and `eigenmatrix_left` methods are used for computing eigenspaces and eigenmatrices, respectively.
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> eigenvalues = em[Integer(0)]; eigenvalues.dense_matrix() # abs tol 1e-13
[13.348469228349522 0.0 0.0]
[0.0 -1.348469228349534 0.0]

  User basis matrix:
  [1 6*b*a0 + 3*b + 1]) ]
```

left_eigenvectors (other=None, extend=True)

Compute the left eigenvectors of a matrix.

**INPUT:**

- `other` – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved (currently supported only if the base ring of `self` is RDF or CDF)
- `extend` – boolean (default: True)

**OUTPUT:**

For each distinct eigenvalue, returns a list of the form $(e, V, n)$ where $e$ is the eigenvalue, $V$ is a list of eigenvectors forming a basis for the corresponding left eigenspace, and $n$ is the algebraic multiplicity of the eigenvalue.

If the option `extend` is set to False, then only the eigenvalues that live in the base ring are considered.

**EXAMPLES:**

We compute the left eigenvectors of a $3 \times 3$ rational matrix.

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenvectors_left(); es
[(0, [(1, -2, 1)], 1),
 (-1.348469228349535?, [(1, 0.3101020514433644?, -0.3797958971132713?)], 1),
 (13.34846922834954?, [(1, 1.289897948556636?, 1.579795897113272?)], 1)]
sage: eval, [evec], mult = es[0]
sage: delta = eval*evec - evec*A
sage: abs(abs(delta)) < 1e-10
True
```

```python
>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> A = matrix(QQ, Integer(3), Integer(3), range(Integer(9))); A
[0 1 2]
[3 4 5]
[6 7 8]
>>> es = A.eigenvectors_left(); es
[(0, [(1, -2, 1)], 1),
 (-1.348469228349535?, [(1, 0.3101020514433644?, -0.3797958971132713?)], 1),
 (13.34846922834954?, [(1, 1.289897948556636?, 1.579795897113272?)], 1)]
```
Notice the difference between considering ring extensions or not.

```python
sage: M = matrix(QQ, [[0,-1,0], [1,0,0], [0,0,2]])
sage: M.eigenvectors_left() # needs sage.rings.number_field
[(2, [(0, 0, 1)], 1),
 (-1*I, [(1, -1*I, 0)], 1),
 (1*I, [(1, 1*I, 0)], 1)]
sage: M.eigenvectors_left(extend=False) # needs sage.rings.number_field
[(2, [(0, 0, 1)], 1)]
```

```python
from sage.all import *
```

```python
>>> eval, [evec], mult = es[Integer(0)]
>>> delta = eval*evec - evec*A
>>> abs(abs(delta)) < RealNumber('1e-10')
True
```

`left_kernel(*args, **kwds)`

Returns the left kernel of this matrix, as a vector space or free module. This is the set of vectors \( x \) such that \( x \times self = 0 \).

**Note:** For the right kernel, use `right_kernel()`. The method `kernel()` is exactly equal to `left_kernel()`.

For inexact rings use `right_kernel_matrix()` with `basis='computed'` (on the transpose of the matrix) to avoid echolonizing.

**INPUT:**

- `algorithm` – (default: 'default'); a keyword that selects the algorithm employed. Allowable values are:
  - 'default' – allows the algorithm to be chosen automatically
  - 'generic' – naive algorithm usable for matrices over any field
  - 'flint' – FLINT library code for matrices over the rationals or the integers
  - 'pari' – PARI library code for matrices over number fields or the integers
  - 'padic' – padic algorithm from IML library for matrices over the rationals and integers
  - 'pluq' – PLUQ matrix factorization for matrices mod 2

- `basis` – (default: 'echelon'); a keyword that describes the format of the basis used to construct the left kernel. Allowable values are:
Matrices and Spaces of Matrices, Release 10.4

- ‘echelon’: the basis matrix is returned in echelon form
- ‘pivot’: each basis vector is computed from the reduced row-echelon form of \texttt{self} by placing a single one in a non-pivot column and zeros in the remaining non-pivot columns. Only available for matrices over fields.
- ‘LLL’: an LLL-reduced basis. Only available for matrices over the integers.

OUTPUT:

A vector space or free module whose degree equals the number of rows in \texttt{self} and which contains all the vectors \(x\) such that \(x*\texttt{self} = 0\).

If \texttt{self} has 0 rows, the kernel has dimension 0, while if \texttt{self} has 0 columns the kernel is the entire ambient vector space.

The result is cached. Requesting the left kernel a second time, but with a different basis format, will return the cached result with the format from the first computation.

**Note:** For much more detailed documentation of the various options see \texttt{right_kernel()}, since this method just computes the right kernel of the transpose of \texttt{self}.

**EXAMPLES:**

Over the rationals with a basis matrix in echelon form.

\begin{verbatim}
sage: A = matrix(QQ, [[1, 2, 4, -7, 4], [1, 1, 0, 2, -1], [1, 0, 3, -3, 1], [0, -1, -1, 3, -2], [0, 0, -1, 2, -1]])
sage: A.left_kernel()
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[ 1 0 -1 2 -1]
[ 0 1 -1 1 -4]
\end{verbatim}

Over a finite field, with a basis matrix in “pivot” format.

\begin{verbatim}
sage: A = matrix(FiniteField(7), [[5, 0, 5, 2, 4], [1, 3, 2, 3, 6], [1, 0, 3, -3, 1], [0, -1, -1, 3, -2], [0, 0, -1, 2, -1]])
\end{verbatim}
The left kernel of a zero matrix is the entire ambient vector space whose degree equals the number of rows of self (i.e. everything).

We test matrices with no rows or columns.
The results are cached. Note that requesting a new format for the basis is ignored and the cached copy is returned. Work with a copy if you need a new left kernel, or perhaps investigate the right_kernel_matrix() method on the transpose, which does not cache its results and is more flexible.

```python
sage: A = matrix(QQ, [[1,1],[2,2]])
sage: K1 = A.left_kernel()
sage: K1
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1/2]
sage: K2 = A.left_kernel()
sage: K1 is K2
True
sage: K3 = A.left_kernel(basis='pivot')
sage: K3
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[ 1 -1/2]
sage: B = copy(A)
sage: K3 = B.left_kernel(basis='pivot')
sage: K3
Vector space of degree 2 and dimension 1 over Rational Field
User basis matrix:
[-2  1]
sage: K3 is K1
False
sage: K3 == K1
True
```
Matrices and Spaces of Matrices, Release 10.4

>>> B = copy(A)
>>> K3 = B.left_kernel(basis='pivot')
>>> K3
Vector space of degree 2 and dimension 1 over Rational Field
User basis matrix:
[-2  1]
>>> K3 is K1
False
>>> K3 == K1
True

left_kernel_matrix(*args, **kwds)

Returns a matrix whose rows form a basis for the left kernel of self.

This method is a thin wrapper around right_kernel_matrix(). For supported parameters and input/output formats, see there.

EXAMPLES:

sage: M = matrix([[1,2],[3,4],[5,6]])
sage: K = M.left_kernel_matrix(); K
[ 1 -2  1]
[ 0  0]

>>> from sage.all import *

sage: M = matrix([[Integer(1),Integer(2)],
               [Integer(3),Integer(4)],
               [Integer(5),
               Integer(6)]])

sage: K = M.left_kernel_matrix(); K
[ 1 -2  1]
[ 0  0]

left_nullity()

Return the (left) nullity of this matrix, which is the dimension of the (left) kernel of this matrix acting from the right on row vectors.

EXAMPLES:

sage: M = Matrix(QQ, [[1,0,0,1], [0,1,1,0], [1,1,1,0]])

sage: M.nullity()
0

sage: M.left_nullity()
0

>>> from sage.all import *

sage: M = Matrix(QQ, [[Integer(1),Integer(0),Integer(0),Integer(1)],
                    [Integer(0),Integer(1),Integer(1),Integer(0)],
                    [Integer(1),Integer(1),Integer(0),Integer(1)]])

sage: M.nullity()
0

sage: M.left_nullity()
0

sage: A = M.transpose()

sage: A.nullity()

(continues on next page)
\begin{verbatim}
>>> from sage.all import *

>>> A = M.transpose()
>>> A.nullity()
1

sage: M = M.change_ring(ZZ)

sage: M.nullity()
0

sage: A = M.transpose()

sage: A.nullity()
1

>>> from sage.all import *

>>> M = M.change_ring(ZZ)

>>> M.nullity()
0

>>> A = M.transpose()

>>> A.nullity()
1
\end{verbatim}

\texttt{matrix\_window}(row=0, col=0, nrows=-1, ncols=-1, check=1)

Return the requested matrix window.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = matrix(QQ, 3, 3, range(9))
sage: A.matrix_window(1,1, 2, 1)
Matrix window of size 2 x 1 at (1,1):
[0 1 2]
[3 4 5]
[6 7 8]

>>> from sage.all import *

>>> A = matrix(QQ, Integer(3), Integer(3), range(Integer(9)))

>>> A.matrix_window(Integer(1),Integer(1), Integer(2), Integer(1))
Matrix window of size 2 x 1 at (1,1):
[0 1 2]
[3 4 5]
[6 7 8]
\end{verbatim}

We test the optional check flag.

\begin{verbatim}
sage: matrix([[1]]).matrix_window(0,1,1,1, check=False)
Matrix window of size 1 x 1 at (0,1):
[1]
sage: matrix([[1]]).matrix_window(0,1,1,1)
Traceback (most recent call last):
...
IndexError: matrix window index out of range
\end{verbatim}
Matrices and Spaces of Matrices, Release 10.4

```python
>>> from sage.all import *

>>> matrix([Integer(1)]).matrix_window(Integer(0), Integer(1), Integer(1),
     → Integer(1), check=False)
Matrix window of size 1 x 1 at (0,1):
[1]
>>> matrix([Integer(1)]).matrix_window(Integer(0), Integer(1), Integer(1),
     → Integer(1))
Traceback (most recent call last):
...
IndexError: matrix window index out of range
```

Another test of bounds checking:

```python
sage: matrix([1]).matrix_window(1,1,1,1)
Traceback (most recent call last):
...
IndexError: matrix window index out of range
```

```python
>>> from sage.all import *

>>> matrix([Integer(1)]).matrix_window(Integer(1), Integer(1), Integer(1),
     → Integer(1))
Traceback (most recent call last):
...
IndexError: matrix window index out of range
```

`maxspin(v)`

Computes the largest integer n such that the list of vectors $S = [v, v \cdot A, ..., v \cdot A^n]$ are linearly independent, and returns that list.

**INPUT:**
- `self` – Matrix
- `v` – Vector

**OUTPUT:**
- `list` – list of Vectors

**ALGORITHM:** The current implementation just adds vectors to a vector space until the dimension doesn't grow. This could be optimized by directly using matrices and doing an efficient Echelon form. Also, when the base is $\mathbb{Q}$, maybe we could simultaneously keep track of what is going on in the reduction modulo $p$, which might make things much faster.

**EXAMPLES:**

```python
sage: t = matrix(QQ, 3, 3, range(9)); t
[0 1 2]
[3 4 5]
[6 7 8]
sage: v = (QQ^3).0
sage: t.maxspin(v)
[(1, 0, 0), (0, 1, 2), (15, 18, 21)]
sage: k = t.kernel(); k
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2 1]
sage: t.maxspin(k.0)
[(1, -2, 1)]
```
from sage.all import *

>>> t = matrix(QQ, Integer(3), Integer(3), range(Integer(9))); t
[0 1 2]
[3 4 5]
[6 7 8]

>>> v = (QQ**Integer(3)).gen(0)
>>> t.maxspin(v)
[(1, 0, 0), (0, 1, 2), (15, 18, 21)]

>>> k = t.kernel(); k
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2 1]

>>> t.maxspin(k.gen(0))
[(1, -2, 1)]

minimal_polynomial (var='x', **kwds)
This is a synonym for self.minpoly

EXAMPLES:

sage: a = matrix(QQ, 4, 4, range(16))
sage: a.minimal_polynomial('z')
# needs sage.libs.pari
z^3 - 30*z^2 - 80*z

sage: a.minpoly()
# needs sage.libs.pari
x^3 - 30*x^2 - 80*x

minors (k)
Return the list of all \( k \times k \) minors of self.

Let \( A \) be an \( m \times n \) matrix and \( k \) an integer with \( 0 \leq k \leq m \) and \( k \leq n \). A \( k \times k \) minor of \( A \) is the determinant of a \( k \times k \) matrix obtained from \( A \) by deleting \( m - k \) rows and \( n - k \) columns. There are no \( k \times k \) minors of \( A \) if \( k \) is larger than either \( m \) or \( n \).

The returned list is sorted in lexicographical row major ordering, e.g., if \( A \) is a \( 3 \times 3 \) matrix then the minors returned are with these rows/columns: [0, 1]x[0, 1], [0, 1]x[0, 2], [0, 1]x[1, 2], [0, 2]x[0, 1], [0, 2]x[0, 2], [0, 2]x[1, 2], [1, 2]x[0, 1], [1, 2]x[0, 2], [1, 2]x[1, 2].

INPUT:
• \( k \) – integer

EXAMPLES:

sage: A = Matrix(ZZ, 2, 3, [1,2,3,4,5,6]); A
[1 2 3]
[4 5 6]
sage: A.minors(2)
Matrices and Spaces of Matrices, Release 10.4

([[-3, -6, -3]
  sage: A.minors(1)
  [1, 2, 3, 4, 5, 6]
  sage: A.minors(0)
  [1]
  sage: A.minors(5)
  []

>>> from sage.all import *
>>> A = Matrix(ZZ, Integer(2),Integer(3), [Integer(1),Integer(2),Integer(3), Integer(4),Integer(5),Integer(6)]); A
[1 2 3]
[4 5 6]
>>> A.minors(Integer(2))
[-3, -6, -3]
>>> A.minors(Integer(1))
[1, 2, 3, 4, 5, 6]
>>> A.minors(Integer(0))
[1]
>>> A.minors(Integer(5))
[]

sage: k = GF(37)
sage: P.<x0,x1,x2> = PolynomialRing(k)
sage: A = Matrix(P, 2, 3, [x0*x1, x0, x1, x2, x2 + 16, x2 + 5*x1])
sage: A.minors(2)
# needs sage.rings.finite_rings
[x0*x1*x2 + 16*x0*x1 - x0*x2,
  5*x0*x1^2 + x0*x1*x2 - x1*x2,
  5*x0*x1 + x0*x2 - x1*x2 - 16*x1]

This test addresses an issue raised at Issue #20512:

sage: A.minors(0)[0].parent() == P
True

>>> from sage.all import *
>>> A.minors(Integer(0))[Integer(0)].parent() == P
True

minpoly (var='x', **kwds)
Return the minimal polynomial of self.
This uses a simplistic - and potentially very very slow - algorithm that involves computing kernels to determine
the powers of the factors of the charpoly that divide the minpoly.

EXAMPLES:

```
sage: # needs sage.rings.finite_rings
sage: A = matrix(GF(9, 'c'), 4, [1,1,0,0, 0,1,0,0, 0,0,5,0, 0,0,0,5])
sage: factor(A.minpoly())
(x + 1) * (x + 2)^2
sage: A.minpoly()(A) == 0
True
sage: factor(A.charpoly())
(x + 1)^2 * (x + 2)^2
```

```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = matrix(GF(Integer(9), 'c'), Integer(4), [Integer(1),Integer(1),
   →Integer(0),Integer(0),Integer(0),Integer(1),Integer(0),Integer(0),
   →Integer(0),Integer(0),Integer(5),Integer(0),Integer(0),Integer(0),
   →Integer(0),Integer(5)])
>>> factor(A.minpoly())
(x + 1) * (x + 2)^2
>>> A.minpoly()(A) == Integer(0)
True
>>> factor(A.charpoly())
(x + 1)^2 * (x + 2)^2
```

The default variable name is \( x \), but you can specify another name:

```
sage: factor(A.minpoly('y'))
# needs sage.rings.finite_rings
(y + 1) * (y + 2)^2
```

```
>>> from sage.all import *
>>> factor(A.minpoly('y'))
# needs sage.rings.finite_rings
(y + 1) * (y + 2)^2
```

**norm** \((p=2)\)

Return the \( p \)-norm of this matrix, where \( p \) can be 1, 2, \( \infty \), or the Frobenius norm.

**INPUT:**

- **self** – a matrix whose entries are coercible into \( \text{CDF} \)
- **p** – one of the following options:
  - 1 – the largest column-sum norm
  - 2 (default) – the Euclidean norm
  - \( \infty \) – the largest row-sum norm
  - 'frob' – the Frobenius (sum of squares) norm

**OUTPUT:** RDF number

**See also:**

- `sage.misc.functional.norm()`

**EXAMPLES:**
Norms of numerical matrices over high-precision reals are computed by this routine. Faster routines for double precision entries from \(\text{RDF}\) or \(\text{CDF}\) are provided by the \texttt{Matrix\_double\_dense} class.
nullity()

Return the (left) nullity of this matrix, which is the dimension of the (left) kernel of this matrix acting from the right on row vectors.

EXAMPLES:

```sage
sage: M = Matrix(QQ, [[1,0,0,1], [0,1,1,0], [1,1,1,0]])
sage: M.nullity()
0
sage: M.left_nullity()
0

>>> from sage.all import *
>>> M = Matrix(QQ, [[Integer(1),Integer(0),Integer(0),Integer(1)],
... [Integer(0),Integer(1),Integer(1),Integer(0)], [Integer(1),Integer(1),
... Integer(1),Integer(0)]])
>>> M.nullity()
0
>>> M.left_nullity()
0

sage: A = M.transpose()
sage: A.nullity()
1
sage: A.left_nullity()
1
```

```sage
>>> from sage.all import *
>>> A = M.transpose()
>>> A.nullity()  # continues on next page
```
Numerical approximation \( \texttt{numerical\_approx(\texttt{prec=None, digits=None, algorithm=None})} \)

Return a numerical approximation of \texttt{self} with \texttt{prec} bits (or decimal \texttt{digits}) of precision.

**INPUT:**
- \texttt{prec} – precision in bits
- \texttt{digits} – precision in decimal digits (only used if \texttt{prec} is not given)
- \texttt{algorithm} – ignored for matrices

**OUTPUT:** A matrix converted to a real or complex field

**EXAMPLES:**

```python
sage: # needs sage.symbolic
sage: d = matrix([[3, 0], [0, sqrt(2)]])
sage: b = matrix([[1, -1], [2, 2]]); e = b * d * b.inverse(); e
[ 1/2*sqrt(2) + 3/2 -1/4*sqrt(2) + 3/4]
[ -sqrt(2) + 3 1/2*sqrt(2) + 3/2]
sage: e.numerical_approx(53)
[ 2.20710678118655 0.396446609406726]
[ 1.58578643762690 2.20710678118655]
sage: e.numerical_approx(20)
[ 2.2071 0.39645]
[ 1.5858 2.2071]
sage: (e - I).numerical_approx(20)
[2.2071 - 1.0000*I 0.39645]
[ 1.5858 2.2071 - 1.0000*I]
```

```python
>>> from sage.all import *
>>> d = matrix([[Integer(3), Integer(0)], [Integer(0), sqrt(Integer(2))]])
>>> b = matrix([[Integer(1), -Integer(1)], [Integer(2), Integer(2)]]); e = b...
[ 1/2*sqrt(2) + 3/2 -1/4*sqrt(2) + 3/4]
[ -sqrt(2) + 3 1/2*sqrt(2) + 3/2]
>>> e.numerical_approx(Integer(53))
```

465
We check that Issue #29700 is fixed:

```python
sage: M = matrix(3, [1,1,1,1,0,0,0,1,0])
sage: A, B = M.diagonalization(QQbar)  # needs sage.rings.number_field
sage: _ = A.n()  # needs sage.rings.number_field
```

permanent \((algorithm='Ryser')\)

Return the permanent of this matrix.

Let \(A = (a_{i,j})\) be an \(m \times n\) matrix over any commutative ring with \(m \leq n\). The permanent of \(A\) is

\[
\text{per}(A) = \sum_{\pi} a_{1,\pi(1)}a_{2,\pi(2)} \cdots a_{m,\pi(m)}
\]

where the summation extends over all one-to-one functions \(\pi\) from \(\{1, \ldots, m\}\) to \(\{1, \ldots, n\}\).

The product \(a_{1,\pi(1)}a_{2,\pi(2)} \cdots a_{m,\pi(m)}\) is called diagonal product. So the permanent of an \(m \times n\) matrix \(A\) is the sum of all the diagonal products of \(A\).

By default, this method uses Ryser's algorithm, but setting \(algorithm\) to “ButeraPernici” you can use the algorithm of Butera and Pernici (which is well suited for band matrices, i.e. matrices whose entries are concentrated near the diagonal).

INPUT:

- \(A\) – matrix of size \(m \times n\) with \(m \leq n\)
- \(algorithm\) – either “Ryser” (default) or “ButeraPernici”. The Butera-Pernici algorithm takes advantage of presence of zeros and is very well suited for sparse matrices.

ALGORITHM:

The Ryser algorithm is implemented in the method `_permanent_ryser()`. It is a modification of theorem 7.1.1. from Brualdi and Ryser: Combinatorial Matrix Theory. Instead of deleting columns from \(A\), we choose columns from \(A\) and calculate the product of the row sums of the selected submatrix.

The Butera-Pernici algorithm is implemented in the function `permanental_minor_polynomial()`. It takes advantage of cancellations that may occur in the computations.

EXAMPLES:
sage: A = ones_matrix(4,4)
sage: A.permanent()
24

sage: A = matrix(3,6, [1,1,1,1,0,0,0,1,1,1,0,0,1,1,1,1])
sage: A.permanent()
36
sage: B = A.change_ring(RR)
sage: B.permanent()
36.0000000000000

>>> from sage.all import *
>>> A = ones_matrix(Integer(4),Integer(4))
>>> A.permanent()
24

>>> A = matrix(Integer(3),Integer(6), [Integer(1),Integer(1),Integer(1),
Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),Integer(1),
Integer(1),Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),
Integer(1),Integer(1),Integer(1)])
>>> A.permanent()
36
>>> B = A.change_ring(RR)
>>> B.permanent()
36.0000000000000

The permanent above is directed to the Sloane’s sequence OEIS sequence A079908 ("The Dancing School Problems") for which the third term is 36:

sage: oeis(79908)  # optional -- internet
A079908: Solution to the Dancing School Problem with 3 girls and n+3 boys:
f(3,n).
sage: _(3)  # optional -- internet
36

>>> from sage.all import *
>>> oeis(Integer(79908))  # optional -- internet
A079908: Solution to the Dancing School Problem with 3 girls and n+3 boys:
f(3,n).
>>> _(Integer(3))  # optional -- internet
36

sage: A = matrix(4,5, [1,1,0,1,1,0,1,1,1,0,1,1,1,0,1,1,1,0,1,1])
sage: A.permanent()
32

>>> from sage.all import *
>>> A = matrix(Integer(4),Integer(5), [Integer(1),Integer(1),Integer(1),
Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),
Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),Integer(1),
Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),Integer(0)])
>>> A.permanent()
32

A huge permanent that cannot be reasonably computed with the Ryser algorithm (a 50 × 50 band matrix with width 5):
Matrices and Spaces of Matrices, Release 10.4

sage: n, w = 50, 5
sage: A = matrix(ZZ, n, n, lambda i,j: (i+j)%5 + 1 if abs(i-j) <= w else 0)
sage: A.permanent(algorithm="ButeraPernici")
5776972735511097036962481710892268404670105604676932908

>>> from sage.all import *
>>> n, w = Integer(50), Integer(5)
>>> A = matrix(ZZ, n, n, lambda i,j: (i+j)%Integer(5) + Integer(1) if abs(i-j) <= w else Integer(0))
>>> A.permanent(algorithm="ButeraPernici")
5776972735511097036962481710892268404670105604676932908

See Minc: Permanents, Example 2.1, p. 5.

sage: A = matrix(QQ, 2,2, [1/5,2/7,3/2,4/5])
sage: A.permanent()
103/175

>>> from sage.all import *
>>> A = matrix(QQ, Integer(2),Integer(2), [Integer(1)/Integer(5),Integer(2)/Integer(7),Integer(3)/Integer(2),Integer(4)/Integer(5)])
>>> A.permanent()
103/175

sage: R.<a> = PolynomialRing(ZZ)
sage: A = matrix(R, 2,2, [a,1,a,a+1])
sage: A.permanent()
a^2 + 2*a

>>> from sage.all import *
>>> R = PolynomialRing(ZZ, names=(a,)); (a,) = R._first_ngens(1)
>>> A = matrix(R, Integer(2),Integer(2), [a,Integer(1),a,a+Integer(1)])
>>> A.permanent()
a^2 + 2*a

sage: R.<x,y> = PolynomialRing(ZZ, 2)
sage: A = matrix(R, 2,2, [x, y, x^2, y^2])
sage: A.permanent()
x^2*y + x*y^2

>>> from sage.all import *
>>> R = PolynomialRing(ZZ, Integer(2), names=('x', 'y',)); (x, y,) = R._first_ngens(2)
>>> A = matrix(R, Integer(2),Integer(2), [x, y, x**Integer(2), y**Integer(2)])
>>> A.permanent()
x^2*y + x*y^2

permanental_minor(k, algorithm='Ryser')

Return the permanental \(k\)-minor of this matrix.

The permanental \(k\)-minor of a matrix \(A\) is the sum of the permanents of all possible \(k\) by \(k\) submatrices of \(A\). Note that the maximal permanental minor is just the permanent.

For a \((0,1)\)-matrix \(A\) the permanental \(k\)-minor counts the number of different selections of \(k\) 1’s of \(A\) with no two of the 1’s on the same row and no two of the 1’s on the same column.
See Brualdi and Ryser: Combinatorial Matrix Theory, p. 203. Note the typo $p_0(A) = 0$ in that reference! For applications see Theorem 7.2.1 and Theorem 7.2.4.

See also:
The method `rook_vector()` returns the list of all permanental minors.

INPUT:

- $k$ – the size of the minor
- `algorithm` – either “Ryser” (default) or “ButeraPernici”. The Butera-Pernici algorithm is well suited for band matrices.

EXAMPLES:

```python
sage: A = matrix(4, [1,0,1,0,1,0,1,0,1,0,1,0,10,10,1,0,1,1])
sage: A.permanental_minor(2)
114
```

```python
>>> from sage.all import *
>>> A = matrix(Integer(4), [Integer(1),Integer(0),Integer(1),Integer(0),
                          -> Integer(1),Integer(0),Integer(1),Integer(0),
                          -> Integer(10),Integer(10),Integer(1),Integer(0),Integer(1),Integer(1)])
>>> A.permanental_minor(Integer(2))
114
```

```python
sage: A = matrix(3,6, [1,1,1,1,0,0,0,1,1,1,1,0,0,0,1,1,1,1])
sage: A.permanental_minor(0)
1
sage: A.permanental_minor(1)
12
sage: A.permanental_minor(2)
40
sage: A.permanental_minor(3)
36
```

```python
>>> from sage.all import *
>>> A = matrix(Integer(3),Integer(6), [Integer(1),Integer(1),Integer(1),
                                     -> Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),
                                     -> Integer(1),Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),
                                     -> Integer(1),Integer(1),Integer(1)])
>>> A.permanental_minor(Integer(0))
1
>>> A.permanental_minor(Integer(1))
12
>>> A.permanental_minor(Integer(2))
40
>>> A.permanental_minor(Integer(3))
36
```

Note that if $k = m = n$, the permanent $k$-minor equals $\text{per}(A)$:

```python
sage: A.permanent()
36
```

```python
>>> from sage.all import *
>>> A.permanent()
36
```
The permanental minors of the “complement” matrix of $A$ is related to the permanent of $A$:

```sage
sage: m, n = 3, 6
sage: C = matrix(m, n, lambda i,j: 1 - A[i,j])
sage: sum((-1)^k * C.permanental_minor(k)*factorial(n-k)/factorial(n-m) 
    ....:     for k in range(m+1))
36
```

See Theorem 7.2.1 of Brualdi and Ryser: Combinatorial Matrix Theory: per(A)

**permutation_normal_form**(check=False)

Take the set of matrices that are self permuted by any row and column permutation, and return the maximal one of the set where matrices are ordered lexicographically going along each row.

**INPUT:**

- check – (default: False) If True return a tuple of the maximal matrix and the permutations taking self to the maximal matrix. If False, return only the maximal matrix.

**OUTPUT:**

The maximal matrix.

**EXAMPLES:**

```sage
sage: M = matrix(ZZ, [[0, 0, 1], [1, 0, 2], [0, 0, 0]])
sage: M
[0 0 1]
[1 0 2]
[0 0 0]
sage: M.permutation_normal_form()
[2 1 0]
[1 0 0]
[0 0 0]
sage: M = matrix(ZZ, [[-1, 3], [-1, 5], [2, 4]])
sage: M
[-1 3]
[-1 5]
[ 2 4]
sage: M.permutation_normal_form(check=True) 
#<@
needs sage.graphs sage.groups
( ([ 5 -1]
  [ 4 2]
  [ 3 -1],
  ((1,2,3), (1,2)))
)```
from sage.all import *

M = matrix(ZZ, [[Integer(0), Integer(0), Integer(1)], [Integer(1), Integer(0), Integer(2)], [Integer(0), Integer(0), Integer(0)]])

M

M.permutation_normal_form()

M = matrix(ZZ, [[-Integer(1), Integer(3)], [-Integer(1), Integer(5)], [Integer(2), Integer(4)]])

M

M.permutation_normal_form(check=True)

# needs sage.graphs sage.groups

pfaffian(algorithm=None, check=True)

Return the Pfaffian of self, assuming that self is an alternating matrix.

The result is cached.

INPUT:

- algorithm (default: None) – string, the algorithm to use; currently the following algorithms have been implemented:
  - 'bfl' – using the Bär-Faddeev-LeVerrier algorithm
  - 'definition' – using the definition given by perfect matchings

- check (default: True) – boolean determining whether to check self for alternatingness and squareness. This has to be set to False if self is defined over a non-discrete ring.

The Pfaffian of an alternating matrix is defined as follows:

Let $A$ be an alternating $k \times k$ matrix over a commutative ring. (Here, “alternating” means that $A^T = -A$ and that the diagonal entries of $A$ are zero.) If $k$ is odd, then the Pfaffian of the matrix $A$ is defined to be 0. Let us now define it when $k$ is even. In this case, set $n = k/2$ (this is an integer). For every $i$ and $j$, we denote the $(i,j)$-th entry of $A$ by $a_{ij}$. Let $M$ denote the set of all perfect matchings of the set $\{1, 2, \ldots, 2n\}$ (see sage.combinat.perfect_matching.PerfectMatchings). For every matching $m \in M$, define the sign $\text{sign}(m)$ of $m$ by writing $m$ as $\{\{i_1, j_1\}, \{i_2, j_2\}, \ldots, \{i_n, j_n\}\}$ with $i_k < j_k$ for all $k$, and setting $\text{sign}(m)$ to be the sign of the permutation $(i_1, j_1, i_2, j_2, \ldots, i_n, j_n)$ (written here in one-line notation). For every matching $m \in M$, define the weight $w(m)$ of $m$ by writing $m$ as $\{\{i_1, j_1\}, \{i_2, j_2\}, \ldots, \{i_n, j_n\}\}$ with $i_k < j_k$ for all $k$, and setting $w(m) = a_{i_1,j_1} a_{i_2,j_2} \cdots a_{i_n,j_n}$. Now, the Pfaffian of the matrix $A$ is defined
to be the sum

$$\sum_{m \in M} \text{sign}(m)w(m).$$

The Pfaffian of $A$ is commonly denoted by $\text{Pf}(A)$. It is well-known that $(\text{Pf}(A))^2 = \det A$ for every alternating matrix $A$, and that $\text{Pf}(U^T A U) = \det U \cdot \text{Pf}(A)$ for any $n \times n$ matrix $U$ and any alternating $n \times n$ matrix $A$.

See [Knu1995], [DW1995] and [Rot2001], [Baer2020], just to name a few sources, for further properties of Pfaffians.

ALGORITHM:

If the matrix is small, namely up to size $4 \times 4$, the naive formulas are always used.

The Bär-Faddeev-LeVerrier algorithm can be accessed using ‘bfl’. It works over any $\mathbb{Q}$-algebra or ring whose fraction field is an $\mathbb{Q}$-algebra (see [Baer2020] for details). If that check fails, the implementation raises an error because correct results cannot be guaranteed.

To access the algorithm using the above definition, use 'definition'. However, notice that this algorithm is usually very slow.

By default, i.e. if no options are set, the implementation tries to apply the BFL algorithm first. If BFL is not applicable, it uses the definition by perfect matchings.

The alternatingness of the matrix $\text{self}$ is checked only if $\text{check}$ is $\text{True}$ (this is important because even if $\text{self}$ is alternating, a non-discrete base ring might prevent Sage from being able to check this).

EXAMPLES:

A $3 \times 3$ alternating matrix has Pfaffian 0 independently of its entries:

```
sage: MSp = MatrixSpace(Integers(27), 3)
sage: A = MSp([0, 2, -3, -2, 0, 8, 3, -8, 0])
sage: A.pfaffian()
0
sage: parent(A.pfaffian())
Ring of integers modulo 27
```

```
>>> from sage.all import *

>>> MSp = MatrixSpace(Integers(Integer(27)), Integer(3))
>>> A = MSp([Integer(0), Integer(2), -Integer(3), -Integer(2), Integer(0),
           -Integer(8), Integer(3), -Integer(8), Integer(0)])
>>> A.pfaffian()
0
>>> parent(A.pfaffian())
Ring of integers modulo 27
```

The Pfaffian of a $2 \times 2$ alternating matrix is just its northeast entry:

```
sage: MSp = MatrixSpace(QQ, 2)
sage: A = MSp([0, 4, -4, 0])
sage: A.pfaffian()
4
sage: parent(A.pfaffian())
Rational Field
```

```
>>> from sage.all import *

>>> MSp = MatrixSpace(QQ, Integer(2))
>>> (continues on next page)
```
The Pfaffian of an alternating matrix squares to its determinant:

```sage```
A = [[Integer(0) * 6 for i in range(6)]
for i in range(6):
    for j in range(i):
        u = floor(random() * 10)
```
\[ A_{ij} = u \]
\[ A_{ji} = -u \]
\[ A_{ii} = 0 \]
\[
\text{sage: } \text{AA} = \text{Matrix}(\mathbb{Z}Z, \ A)
\]
\[
\text{sage: } \text{AA}.\text{pfaffian()} \times 2 == \text{AA}.\text{det()}
\]

```
>>> \text{from sage.all import *} \\
>>> \text{A} = [[\text{Integer}(0)] \times \text{Integer}(6) \text{ for } i \text{ in range(}\text{Integer}(6))] \\
>>> \text{for } i \text{ in range(}\text{Integer}(6)): \\
... \text{for } j \text{ in range}(i): \\
... \quad u = \text{floor}(\text{random()} \times \text{Integer}(10)) \\
... \quad A[i][j] = u \\
... \quad A[j][i] = -u \\
... \quad A[i][i] = \text{Integer}(0) \\
>>> \text{AA} = \text{Matrix}(\mathbb{Z}Z, \ A) \\
>>> \text{AA}.\text{pfaffian()} \times \text{Integer}(2) == \text{AA}.\text{det()}
```

In order to use the Bär-Faddeev-LeVerrier algorithm, the base ring must have characteristic zero:

```
\text{sage: } \text{A} = \text{matrix}(\text{GF}(\text{5}), \ [(0, 3, 4, 1, 3, 4), \ (2, 0, 2, 0, 1, 0), \ (1, 3, 0, 4, 1, 0), \ (4, 0, 1, 0, 2, 0), \ (2, 4, 4, 3, 0, 0), \ (1, 0, 0, 0, 0, 0)])
\text{sage: } \text{A}.\text{pfaffian(algorithm='bfl')} \\
```

Traceback (most recent call last):
...
TypeError: Bär-Faddeev-LeVerrier algorithm not applicable, use another algorithm instead

```
>>> \text{from sage.all import *} \\
>>> \text{A} = \text{matrix}(\text{GF(}\text{Integer}(5), \ [(\text{Integer}(0), \text{Integer}(3), \text{Integer}(4)), \ (\text{Integer}(1), \text{Integer}(0)), \ (\text{Integer}(1), \text{Integer}(3), \text{Integer}(0), \text{Integer}(4)), \ (\text{Integer}(1), \text{Integer}(0)), \ (\text{Integer}(2), \text{Integer}(0), \text{Integer}(1), \text{Integer}(0)), \ (\text{Integer}(0), \text{Integer}(0))])
>>> \text{A}.\text{pfaffian(algorithm='bfl')} \\
```

Traceback (most recent call last):
...
TypeError: Bär-Faddeev-LeVerrier algorithm not applicable, use another algorithm instead

In that case, the definition by perfect matchings is used instead:

```
\text{sage: } \text{A}.\text{pfaffian()} \\
```

#...
pivot_rows()

Return the pivot row positions for this matrix, which are a topmost subset of the rows that span the row space and are linearly independent.

OUTPUT: a tuple of integers

EXAMPLES:

```python
sage: A = matrix(QQ, 3,3, [0,0,0,1,2,3,2,4,6]); A
[0 0 0]
[1 2 3]
[2 4 6]
sage: A.pivot_rows()
(1,)
sage: A.pivot_rows() # testing cached value
(1,)
```

plot(*args, **kwds)

A plot of this matrix.

Each (ith, jth) matrix element is given a different color value depending on its relative size compared to the other elements in the matrix.

The tick marks drawn on the frame axes denote the (ith, jth) element of the matrix.

This method just calls matrix_plot.*args and **kwds are passed to matrix_plot.

EXAMPLES:

A matrix over ZZ colored with different grey levels:

```python
sage: A = matrix([[1,3,5,1],[2,4,5,6],[1,3,5,7]])
sage: A.plot() #...  
˓→needs sage.plot
Graphics object consisting of 1 graphics primitive
```

```python
>>> from sage.all import *  
>>> A = matrix([Integer(1),Integer(3),Integer(5),Integer(1)],[Integer(2),Integer(4),Integer(5),Integer(6)],[Integer(1),Integer(3),Integer(5),Integer(5)],
(continues on next page)```
Here we make a random matrix over RR and use cmap='hsv' to color the matrix elements different RGB colors (see documentation for matrix_plot for more information on cmaps):

\[
\begin{align*}
\text{sage: } & A = \text{random_matrix(RDF, 50)} \\
\text{sage: } & \text{plot}(A, \text{ cmap='hsv'}) \\
\end{align*}
\]

Another random plot, but over GF(389):

\[
\begin{align*}
\text{sage: } & A = \text{random_matrix(GF(389), 10)} \\
\text{sage: } & \text{plot}(A, \text{ cmap='Oranges'}) \\
\end{align*}
\]

principal_square_root (check_positivity=True)

Return the principal square root of a positive definite matrix.

A positive definite matrix \( A \) has a unique positive definite matrix \( M \) such that \( M^2 = A \).

See Wikipedia article Square_root_of_a_matrix.

\[
\begin{align*}
\text{sage: } & A = \text{Matrix([[1,-1/2,0], [-1/2,1,-1/2], [0,-1/2,1]])} \\
\text{sage: } & B = A.\text{principal_square_root()} \\
\text{sage: } & A == B^2 \\
\end{align*}
\]

prod_of_row_sums (cols)

Calculate the product of all row sums of a submatrix of \( A \) for a list of selected columns \( cols \).
EXAMPLES:

```python
sage: a = matrix(QQ, 2, 2, [1,2,3,2]); a
[1 2]
[3 2]
sage: a.prod_of_row_sums([0,1])
15
```

```python
>>> from sage.all import *

>>> a = matrix(QQ, Integer(2), Integer(2), [Integer(1), Integer(2), Integer(3), Integer(2)]); a
[1 2]
[3 2]
>>> a.prod_of_row_sums([Integer(0), Integer(1)])
15
```

Another example:

```python
sage: a = matrix(QQ, 2,3, [1,2,3,2,5,6]); a
[1 2 3]
[2 5 6]
sage: a.prod_of_row_sums([1,2])
55
```

```python
>>> from sage.all import *

>>> a = matrix(QQ, Integer(2), Integer(3), [Integer(1), Integer(2), Integer(3), Integer(2), Integer(5), Integer(6)]); a
[1 2 3]
[2 5 6]
>>> a.prod_of_row_sums([Integer(1), Integer(2)])
55
```

**pseudoinverse**(algorithm=None)

Return the Moore-Penrose pseudoinverse of this matrix.

INPUT:

- algorithm (default: guess) – one of the following:
  - "numpy" – Use numpy's linalg.pinv() which is suitable over real or complex fields.
  - "exact" – Use a simple algorithm which is not numerically stable but useful over exact fields. Assume that no conjugation is needed, that the conjugate transpose is just the transpose.
  - "exactconj" – Like exact but use the conjugate transpose.

OUTPUT: a matrix

EXAMPLES:

```python
sage: # needs sage.rings.complex_double sage.symbolic
sage: M = diagonal_matrix(CDF, [0, I, 1+I]); M
[ 0.0 0.0 0.0]
[ 0.0 1.0*I 0.0]
[ 0.0 0.0 1.0 + 1.0*I]
sage: M.pseudoinverse()  # tol 1e-15
[ 0.0 0.0 0.0]
[ 0.0 -1.0*I 0.0]
[ 0.0 0.0 0.5 - 0.5*I]
```
We check the properties of the pseudoinverse over an exact field:

```python
sage: M = random_matrix(QQ, 6, 3) * random_matrix(QQ, 3, 5)
sage: Mx = M.pseudoinverse()
sage: M * Mx * M == M
True
sage: Mx * M * Mx == Mx
True
sage: (M * Mx).is_symmetric()
True
sage: (Mx * M).is_symmetric()
True
```

Beware that the `exact` algorithm is not numerically stable, but the default `numpy` algorithm is:

```python
sage: M = matrix.hilbert(12, ring=RR)
sage: (~M * M).norm()  # a considerable error
1.3...
sage: Mx = M.pseudoinverse(algorithm="exact")
sage: (Mx * M).norm()  # huge error
11.5...
sage: Mx = M.pseudoinverse(algorithm="numpy")
sage: (Mx * M).norm()  # still OK
1.00...
```

(continues on next page)
When multiplying the given matrix with the pseudoinverse, the result is symmetric for the `exact` algorithm or hermitian for the `exactconj` algorithm:

```python
>>> from sage.all import *
```
Numpy gives a strange answer due to rounding errors:

```python
sage: M.pseudoinverse(algorithm="numpy")  # random
needs numpy
[-1286742750677287/643371375338643 1000799917193445/1000799917193444]
[ 519646110850445/346430740566963 -300239975158034/600479950316067]
```

Although it is not too far off:

```python
sage: (~M - M.pseudoinverse(algorithm="numpy").norm() < 1e-14  # needs numpy
True
```

```python
>>> from sage.all import *

sage: (~M - M.pseudoinverse(algorithm="numpy").norm() < RealNumber('1e-14')  # needs numpy
True
```

$q\text{det}$ ($q=\text{None}$)

Return the quantum determinant of $\text{self}$.

The quantum determinant of a matrix $M = (m_{ij})_{i,j=1}^n$ is defined by

$$\det_q(M) = \sum_{\sigma \in S_n} (-q)^{\ell(\sigma)} M_{\sigma(i), \sigma(j)},$$

where $S_n$ is the symmetric group on $\{1, \ldots, n\}$ and $\ell(\sigma)$ denotes the length of $\sigma$ written as simple transpositions (equivalently the number of inversions when written in one-line notation).

**INPUT:**

- $q$ – the parameter $q$; the default is $q \in F[q]$, where $F$ is the base ring of $\text{self}$

**EXAMPLES:**

```python
sage: A = matrix(SR, 2, lambda i, j: f'a(i)(j)'); A
needs sage.symbolic
[ a00  a01]
[ a10  a11]
sage: A.quantum_determinant()  # needs sage.symbolic
-a01*a10*q + a00*a11
```

```python
sage: A = matrix(SR, 3, lambda i, j: f'a(i)(j)'); A
needs sage.symbolic
[ a02 a12 a20]*q^3 + (a01*a12*a20 + a02*a10*a21)*q^2
+ (-a00*a12*a21 - a01*a10*a22)*q + a00*a11*a22
```

```python
sage: R.<q> = LaurentPolynomialRing(ZZ)
sage: MS = MatrixSpace(Integers(8), 3)
```
sage: A = MS([[1,7,3, 1,1,1, 3,4,5]])
sage: A.det()
6
sage: A.quantum_determinant(q^-2)
7*q^-6 + q^-4 + q^-2 + 5

sage: S.<x,y> = PolynomialRing(GF(7))
sage: R.<q> = LaurentPolynomialRing(S)
sage: MS = MatrixSpace(S, 3, sparse=True)
sage: A = MS([[x, y, 3], [4, 2+y, x^2], [0, 1-x, x+y]])
sage: A.det()
x^4 - x^3 + x^2*y + x*y^2 + 2*x^2 - 2*x*y + 3*y^2 + 2*x - 2
sage: A.quantum_determinant()
(2*x - 2)*q^2 + (x^4 - x^3 + 3*x*y + 3*y^2)*q + x^2*y + x*y^2 + 2*x^2 + 2*x*y
sage: A.quantum_determinant(int(2))
2*x^4 - 2*x^3 + x^2*y + x*y^2 + 2*x^2 + x*y - y^2 + x - 1
sage: A.quantum_determinant(q^x + q^-y)
(2*x*y^2 - 2*y^2)*q^-2 + (x^4*y - x^3*y + 3*x*y^2 + 3*y^3)*q^-1
+ (-2*x^2*y + x*y^2 - 2*x^2 - 2*x*y)
+ (x^5 - x^4 + 3*x^2*y + 3*x*y^2)*q + (2*x^3 - 2*x^2)*q^2

from sage.all import *

>>> A = matrix(SR, Integer(2), lambda i, j: f'A_{i}{j}'); A
...
# needs sage.symbolic
[a00 a01]
[a10 a11]
>>> A.quantum_determinant()  #...
# needs sage.symbolic
-a01*a10*q + a00*a11

>>> A = matrix(SR, Integer(3), lambda i, j: f'A_{i}{j}'); A
...
# needs sage.symbolic
-a02*a11*a20*q^3 + (a01*a12*a20 + a02*a10*a21)*q^2
+ (-a00*a12*a21 - a01*a10*a22)*q + a00*a11*a22

>>> R = LaurentPolynomialRing(ZZ, names=('q',)); (q, r) = R._first_ngens(1)
>>> MS = MatrixSpace(Integer(8), Integer(3))
>>> A = MS([[Integer(1),Integer(7),Integer(3), Integer(1),Integer(1),
Integer(1), Integer(3),Integer(4),Integer(5)]]
>>> A.det()
6
>>> A.quantum_determinant(q**-Integer(2))
7*q^-6 + q^-4 + q^-2 + 5

>>> S = PolynomialRing(GF(Integer(7)), names=('x', 'y')); (x, y) = S._first_ngens(2)
>>> R = LaurentPolynomialRing(S, names=('q',)); (q, r) = R._first_ngens(1)
>>> MS = MatrixSpace(S, Integer(3), sparse=True)
>>> A = MS([[x, y, Integer(3)], [Integer(4), Integer(2)+y, x**Integer(2)],
Integer(0), Integer(1)-x, x+y])
>>> A.det()
x^4 - x^3 + x^2*y + x*y^2 + 2*x^2 - 2*x*y + 3*y^2 + 2*x - 2
>>> A.quantum_determinant()
(2*x - 2)*q^2 + (x^4 - x^3 + 3*x*y + 3*y^2)*q + x^2*y + x*y^2 + 2*x^2 + 2*x*y

(continues on next page)
quantum_determinant \( (q=\text{None}) \)

Return the quantum determinant of \( \text{self} \).

The quantum determinant of a matrix \( M = (m_{ij})_{n \times n} \) is defined by

\[
\det_q(M) = \sum_{\sigma \in S_n} (-q)^{\ell(\sigma)} M_{\sigma(i),j},
\]

where \( S_n \) is the symmetric group on \( \{1, \ldots, n\} \) and \( \ell(\sigma) \) denotes the length of \( \sigma \) written as simple transpositions (equivalently the number of inversions when written in one-line notation).

INPUT:

- \( q \) – the parameter \( q \); the default is \( q \in F[q] \), where \( F \) is the base ring of \( \text{self} \).

EXAMPLES:

```plaintext
sage: A = matrix(SR, 2, lambda i, j: i*j); A

\[
\begin{pmatrix}
0 & 1
1 & 2
\end{pmatrix}
\]

sage: A.quantum_determinant()

\(-a01*a10*q + a00*a11\)

sage: A = matrix(SR, 3, lambda i, j: i*j); A

\[
\begin{pmatrix}
0 & 1 & 2
1 & 2 & 3
2 & 3 & 4
\end{pmatrix}
\]

sage: A.quantum_determinant()

\[-a02*a11*a20*q^3 + (a01*a12*a20 + a02*a10*a21)*q^2 + (-a00*a12*a21 + a01*a10*a22)*q + a00*a11*a22\]

sage: R.<q> = Laurent PolynomialRing(ZZ)

sage: MS = MatrixSpace(Integers(8), 3)

sage: A = MS([[1,7,3],[1,1,1],[3,4,5]])

>>> A.quantum_determinant(q*x + q**-Integer(1)*y)
(2*x*y^2 - 2*y^2)*q^{-2} + (x^4*y - x^3*y + 3*x*y^2 + 3*y^3)*q^{-1} + (-2*x^2*y + x*y^2 + 2*x^2 - 2*x*y) + (x^5 - x^4 + 3*x^2*y + 3*x*y^2)*q + (2*x^3 - 2*x^2)*q^2

randomize(density=1, nonzero=False, *args, **kwds)

Replace a proportion of the entries of a matrix by random elements, leaving the remaining entries unchanged.

Note: The locations of the entries of the matrix to change are determined randomly, with the total number of locations determined by the density keyword. These locations are not guaranteed to be distinct. So it is possible that the same position can be chosen multiple times, especially for a very small matrix. The exception is when density = 1, in which case every entry of the matrix will be changed.

INPUT:
• density — float (default: 1); upper bound for the proportion of entries that are changed
• nonzero — Bool (default: False); if True, then new entries will be nonzero
• *args, **kwds — Remaining parameters may be passed to the random_element function of the base ring

EXAMPLES:

We construct the zero matrix over a polynomial ring.

```sage
a = matrix(QQ['x'], 3); a

[0 0 0]
[0 0 0]
[0 0 0]
```

```python
>>> from sage.all import *
>>> a = matrix(QQ['x'], Integer(3)); a

[0 0 0]
[0 0 0]
[0 0 0]
```

We then randomize roughly half the entries:

```sage
a.randomize(0.5)
a.density() <= 0.5

True
```

```python
>>> from sage.all import *
>>> a.randomize(RealNumber('0.5'))
>>> a.density() <= RealNumber('0.5')

True
```

Now we randomize all the entries of the resulting matrix:

```sage
while a.density() < 0.9:
    a = matrix(QQ['x'], 3)
    a.randomize()
```

```python
>>> while a.density() < RealNumber('0.9'):
...     a = matrix(QQ['x'], Integer(3))
...     a.randomize()
```

We create the zero matrix over the integers:

```sage
a = matrix(ZZ, 2); a
```

```python
>>> a = matrix(ZZ, Integer(2)); a

[0 0]
[0 0]
```

Then we randomize it; the x and y keywords, which determine the size of the random elements, are passed
on to the random_element method for ZZ.
rational_form(\texttt{format='right', subdivide=True})

Returns the rational canonical form, also known as Frobenius form.

INPUT:

- \texttt{self} – a square matrix with entries from an exact field.
- \texttt{format} – (default: ‘right’); one of ‘right’, ‘bottom’, ‘left’, ‘top’ or ‘invariants’. The first four will cause a matrix to be returned with companion matrices dictated by the keyword. The value ‘invariants’ will cause a list of lists to be returned, where each list contains coefficients of a polynomial associated with a companion matrix.
- \texttt{subdivide} – (default: ‘True’); if ‘True’ and a matrix is returned, then it contains subdivisions delineating the companion matrices along the diagonal.

OUTPUT:

The rational form of a matrix is a similar matrix composed of submatrices (“blocks”) placed on the main diagonal. Each block is a companion matrix. Associated with each companion matrix is a polynomial. In rational form, the polynomial of one block will divide the polynomial of the next block (and thus, the polynomials of all subsequent blocks).

Rational form, also known as Frobenius form, is a canonical form. In other words, two matrices are similar if and only if their rational canonical forms are equal. The algorithm used does not provide the similarity transformation matrix (also known as the change-of-basis matrix).

Companion matrices may be written in one of four styles, and any such style may be selected with the \texttt{format} keyword. See the companion matrix constructor, \texttt{sage.matrix.constructor.companion_matrix()}, for more information about companion matrices.

If the ‘invariants’ value is used for the \texttt{format} keyword, then the return value is a list of lists, where each list is the coefficients of the polynomial associated with one of the companion matrices on the diagonal. These coefficients include the leading one of the monic polynomial and are ready to be coerced into any polynomial ring over the same field (see examples of this below). This return value is intended to be the most compact representation and the easiest to use for testing equality of rational forms.

Because the minimal and characteristic polynomials of a companion matrix are the associated polynomial, it is easy to see that the product of the polynomials of the blocks will be the characteristic polynomial and the final polynomial will be the minimal polynomial of the entire matrix.

ALGORITHM:

We begin with ZigZag form, which is due to Arne Storjohann and is documented at \texttt{zigzag_form()}. Then we eliminate “corner” entries enroute to rational form via an additional algorithm of Storjohann’s [Sto2011].

EXAMPLES:
The lists of coefficients returned with the `invariants` keyword are designed to easily convert to the polynomials associated with the companion matrices. This is illustrated by the construction below of the `polys` list. Then we can test the divisibility condition on the list of polynomials. Also the minimal and characteristic polynomials are easy to determine from this list.

```
sage: A = matrix(QQ, 
              [[ 11, 14, -15, -4, -38, -29, 1, 23, 14, -63, 17, ...
              →24, 36, 32],
               ....:
               →13, 17, 24],
               ....:
               →31, 39, 37],
               ....:
               →20, -42, -31],
               ....:
               →20, -53, -62],
               ....:
               →-3, -10, -18],
               ....:

```
Rational form is a canonical form. Any two matrices are similar if and only if their rational forms are equal. By starting with Jordan canonical forms, the matrices $C$ and $D$ below were built as similar matrices, while $E$ was built to be just slightly different. All three matrices have equal characteristic polynomials though $E$'s minimal polynomial differs.

$$

The principal feature of rational canonical form is that it can be computed over any field using only field
operations. Other forms, such as Jordan canonical form, are complicated by the need to determine the eigenvalues of the matrix, which can lie outside the field. The following matrix has all of its eigenvalues outside the rationals - some are irrational ($\pm \sqrt{2}$) and the rest are complex ($-1 \pm 2i$).

\begin{verbatim}

```

```bash
>>> from sage.all import *
```
restrict \( V, \text{check=True} \)

Returns the matrix that defines the action of self on the chosen basis for the invariant subspace \( V \). If \( V \) is an ambient, returns self (not a copy of self).

**INPUT:**

- \( V \) – vector subspace
- \( \text{check} \) – (optional) default: True; if False may not check that \( V \) is invariant (hence can be faster).

**OUTPUT:** a matrix

**Warning:** This function returns an \( nn \times n \) matrix, where \( V \) has dimension \( n \). It does *not* check that \( V \) is in fact invariant under self, unless check is True.

**EXAMPLES:**

```python
sage: V = VectorSpace(QQ, 3)
sage: M = MatrixSpace(QQ, 3)
sage: A = M([[1,2,0], [3,4,0], [0,0,0]])
sage: W = V.subspace([[1,0,0], [0,1,0]])
sage: A.restrict(W)
[1 2]
[3 4]
sage: A.restrict(W, check=True)
[1 2]
[3 4]
```

```python
>>> from sage.all import *
>>> V = VectorSpace(QQ, Integer(3))
>>> M = MatrixSpace(QQ, Integer(3))
>>> A = M([[Integer(1),Integer(2),Integer(0)], [Integer(0),Integer(4),Integer(0)], [Integer(0),Integer(0),Integer(3)]])
>>> W = V.subspace([[Integer(1),Integer(0),Integer(0)], [Integer(0),Integer(0),Integer(1)]])
>>> A.restrict(W)
[1 2]
[3 4]
>>> A.restrict(W, check=True)
[1 2]
[3 4]
```

We illustrate the warning about invariance not being checked by default, by giving a non-invariant subspace.
With the default check=False this function returns the 'restriction' matrix, which is meaningless as check=True reveals.

```
sage: W2 = V.subspace([[1,0,0], [0,1,1]])
sage: A.restrict(W2, check=False)
[1 2]
[3 4]
sage: A.restrict(W2, check=True)
Traceback (most recent call last):
...
ArithmeticError: subspace is not invariant under matrix
```

```
>>> from sage.all import *
>>> W2 = V.subspace([[Integer(1),Integer(0),Integer(0)], [Integer(0),
˓→Integer(1),Integer(1)]])
>>> A.restrict(W2, check=False)
[1 2]
[3 4]
>>> A.restrict(W2, check=True)
Traceback (most recent call last):
...
ArithmeticError: subspace is not invariant under matrix
```

**restrict_codomain(V)**

Suppose that self defines a linear map from some domain to a codomain that contains V and that the image of self is contained in V. This function returns a new matrix A that represents this linear map but as a map to V, in the sense that if x is in the domain, then x*A is the linear combination of the elements of the basis of V that equals v*self.

**INPUT:**

- V – vector space (space of degree self ncols()) that contains the image of self.

**See also:**

restrict(), restrict_domain()

**EXAMPLES:**

```
sage: A = matrix(QQ, 3, [1..9])
sage: V = (QQ^3).span([[1,2,3], [7,8,9]]); V
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1 0 -1]
[ 0 1 2]
sage: z = vector(QQ,[1,2,5])
sage: B = A.restrict_codomain(V); B
[1 2]
[4 5]
[7 8]
sage: z*B
(44, 52)
sage: z*A
(44, 52, 60)
sage: 44*V.0 + 52*V.1
(44, 52, 60)
```
Matrices and Spaces of Matrices, Release 10.4

```python
>>> from sage.all import *

>>> A = matrix(QQ, Integer(3), (ellipsis_range(Integer(1), Ellipsis, Integer(9))))

>>> V = (QQ**Integer(3)).span([[Integer(1), Integer(2), Integer(3)], [Integer(7), Integer(8), Integer(9)]]); V
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1 0 -1]
[ 0 1 2]

>>> z = vector(QQ, [Integer(1), Integer(2), Integer(5)])

>>> B = A.restrict_codomain(V); B

[1 2]
[4 5]
[7 8]

>>> z*B
(44, 52)

>>> z*A
(44, 52, 60)

>>> Integer(44)*V.gen(0) + Integer(52)*V.gen(1)
(44, 52, 60)
```

**restrict_domain(V)**

Compute the matrix relative to the basis for V on the domain obtained by restricting self to V, but not changing the codomain of the matrix. This is the matrix whose rows are the images of the basis for V.

**INPUT:**

- V – vector space (subspace of ambient space on which self acts)

**See also:**

*restrict()

**EXAMPLES:**

```python
sage: V = QQ^3
sage: A = matrix(QQ, 3, [1,2,0, 3,4,0, 0,0,0])
sage: W = V.subspace([[1,0,0], [1,2,3]])
sage: A.restrict_domain(W)
[1 2 0]
[3 4 0]

sage: W2 = V.subspace_with_basis([[1,0,0], [1,2,3]])
sage: A.restrict_domain(W2)
```

(continues on next page)
right_eigenmatrix (other=None)

Return matrices $D$ and $P$, where $D$ is a diagonal matrix of eigenvalues and the columns of $P$ are corresponding eigenvectors (or zero vectors).

INPUT:

- `other` – a square matrix $B$ (default: `None`) in a generalized eigenvalue problem; if `None`, an ordinary eigenvalue problem is solved

OUTPUT:

If `self` is a square matrix $A$, then the output is a diagonal matrix $D$ and a matrix $P$ such that

$$AP = PD,$$

where the columns of $P$ are eigenvectors of $A$ and the diagonal entries of $D$ are the corresponding eigenvalues.

If a matrix $B$ is passed as optional argument, the output is a solution to the generalized eigenvalue problem such that

$$AP = BPD.$$

The ordinary eigenvalue problem is equivalent to the generalized one if $B$ is the identity matrix.

The generalized eigenvector decomposition is currently only implemented for matrices over RDF and CDF.

EXAMPLES:

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: D, P = A.eigenmatrix_right()
sage: D
[ 0  0  0]
[ 0 -1.348469228349535?  0]
[ 0  0 13.34846922834954?]  
sage: P
[ 1  1  1]
[ 0 -2 0.1303061543300932?  3.069693845669907?]
[ 0 -1.7393876913398137?  5.139387691339814?]
sage: A*P == P*D
True
```

```python
>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> A = matrix(QQ, Integer(3), Integer(3), range(Integer(9))); A
[0 1 2]
[3 4 5]
[6 7 8]
>>> D, P = A.eigenmatrix_right()
>>> D
[ 0  0  0]
[ 0 -1.348469228349535?  0]
```

(continues on next page)
Because \( P \) is invertible, \( A \) is diagonalizable.

The matrix \( P \) may contain zero columns corresponding to eigenvalues for which the algebraic multiplicity is greater than the geometric multiplicity. In these cases, the matrix is not diagonalizable.
A generalized eigenvector decomposition:

```
sage: # needs scipy
declare:
A = matrix(RDF, [[1, -2], [3, 4]])
B = matrix(RDF, [[0, 7], [2, -3]])
D, P = A.eigenmatrix_right(B)
(A * P - B * P * D).norm() < 1e-14
True
```

The matrix $B$ in a generalized eigenvalue problem may be singular:

```
sage: # needs scipy
A = matrix.identity(RDF, 2)
B = matrix(RDF, [[3, 5], [6, 10]])
D, P = A.eigenmatrix_right(B); D # tol 1e-14
[[0.07692307692307694 0.0]
 [ 0.0 +infinity]]
```

In this case, we can still verify the eigenvector equation for the first eigenvalue and first eigenvector:

```
sage: l = D[0, 0]
v = P[:, 0]
(A * v - B * v * l).norm() < 1e-14
True
```

The second eigenvector is contained in the right kernel of $B$:

```
sage: (B * P[:, 1]).norm() < 1e-14 # needs scipy
True
```
See also:

eigenvalues(), eigenvectors_right(), Matrix_double_dense.
eigenvectors_right(), eigenmatrix_left().

right_eigenspaces (format='all', var='a', algebraic_multiplicity=False)

Compute the right eigenspaces of a matrix.

Note that eigenspaces_right() and right_eigenspaces() are identical methods. Here “right” refers to the eigenvectors being placed to the right of the matrix.

INPUT:

• self – a square matrix over an exact field. For inexact matrices consult the numerical or symbolic matrix classes.

• format – default: None
  
  - 'all' – attempts to create every eigenspace. This will always be possible for matrices with rational entries.

  - 'galois' – for each irreducible factor of the characteristic polynomial, a single eigenspace will be output for a single root/eigenvalue for the irreducible factor.

  - None – Uses the ‘all’ format if the base ring is contained in an algebraically closed field which is implemented. Otherwise, uses the ‘galois’ format.

• var – (default: 'a'); variable name used to represent elements of the root field of each irreducible factor of the characteristic polynomial. If var='a', then the root fields will be in terms of a0, a1, a2, ..., where the numbering runs across all the irreducible factors of the characteristic polynomial, even for linear factors.

• algebraic_multiplicity – (default: False); whether or not to include the algebraic multiplicity of each eigenvalue in the output. See the discussion below.

OUTPUT:

If algebraic_multiplicity=False, return a list of pairs (e, V) where e is an eigenvalue of the matrix, and V is the corresponding left eigenspace. For Galois conjugates of eigenvalues, there may be just one representative eigenspace, depending on the format keyword.

If algebraic_multiplicity=True, return a list of triples (e, V, n) where e and V are as above and n is the algebraic multiplicity of the eigenvalue.

Warning: Uses a somewhat naive algorithm (simply factors the characteristic polynomial and computes kernels directly over the extension field).

EXAMPLES:

Right eigenspaces are computed from the left eigenspaces of the transpose of the matrix. As such, there is a greater collection of illustrative examples at the eigenspaces_left().

We compute the right eigenspaces of a $3 \times 3$ rational matrix.

```

(continues on next page)
This method is only applicable to exact matrices. The “eigenmatrix” routines for matrices with double-precision floating-point entries (RDF, CDF) are the best alternative. (Since some platforms return eigenvectors that are the negatives of those given here, this one example is not tested here.) There are also “eigenmatrix” routines for matrices with symbolic entries.

```
sage: B = matrix(RR, 3, 3, range(9))
sage: B.eigenspaces_right()
Traceback (most recent call last):
...  
NotImplementedError: eigenspaces cannot be computed reliably for inexact rings such as Real Field with 53 bits of precision, consult numerical or symbolic matrix classes for other options

```

right_eigenvectors (other=None, extend=True)

Compute the right eigenvectors of a matrix.

INPUT:

- `other` – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved (currently supported only if the base ring of `self` is RDF or CDF)
- `extend` – boolean (default: True)

OUTPUT:

For each distinct eigenvalue, returns a list of the form $(e,V,n)$ where $e$ is the eigenvalue, $V$ is a list of eigenvectors forming a basis for the corresponding right eigenspace, and $n$ is the algebraic multiplicity of the eigenvalue. If `extend` = True (the default), this will return eigenspaces over the algebraic closure of the base field where this is implemented; otherwise it will restrict to eigenvalues in the base field.

EXAMPLES:

We compute the right eigenvectors of a $3 \times 3$ rational matrix.

```python
sage: # needs sage.rings.number_field
sage: A = matrix(QQ, 3, 3, range(9)); A
[0 1 2]
[3 4 5]
```
sage: es = A.eigenvectors_right(); es
[(0, [(1, -2, 1)], 1),
 (-1.348469228349535?, [(1, 0.1303061543300932?, -0.7393876913398137?)], 1),
 (13.34846922834954?, [(1, 3.069693845669907?, 5.139387691339814?)], 1)]

sage: A.eigenvectors_right(extend=False)
[(0, [(1, -2, 1)], 1)]

sage: eval, [evec], mult = es[0]
sage: delta = eval*evec - A*evec
sage: abs(abs(delta)) < 1e-10
True

>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> A = matrix(QQ, Integer(3), Integer(3), range(Integer(9))); A
[0 1 2]
[3 4 5]
[6 7 8]

>>> es = A.eigenvectors_right(); es
[(0, [(1, -2, 1)], 1),
 (-1.348469228349535?, [(1, 0.1303061543300932?, -0.7393876913398137?)], 1),
 (13.34846922834954?, [(1, 3.069693845669907?, 5.139387691339814?)], 1)]

>>> A.eigenvectors_right(extend=False)
[(0, [(1, -2, 1)], 1)]

>>> eval, [evec], mult = es[Integer(0)]
>>> delta = eval*evec - A*evec
>>> abs(abs(delta)) < RealNumber('1e-10')
True

right_kernel(*args, **kwargs)

Returns the right kernel of this matrix, as a vector space or free module. This is the set of vectors x such that self*x = 0.

Note: For the left kernel, use left_kernel(). The method kernel() is exactly equal to left_kernel().

For inexact rings use right_kernel_matrix() with basis='computed' to avoid echolonizing.

INPUT:

- **algorithm** – (default: ‘default’); a keyword that selects the algorithm employed. Allowable values are:
  - ‘default’ – allows the algorithm to be chosen automatically
  - ‘generic’ – naive algorithm usable for matrices over any field
  - ‘flint’ – FLINT library code for matrices over the rationals or the integers
  - ‘pari’ – PARI library code for matrices over number fields or the integers
  - ‘padic’ – padic algorithm from IML library for matrices over the rationals and integers
  - ‘pluq’ – PLUQ matrix factorization for matrices mod 2
- **basis** – (default: ‘echelon’); a keyword that describes the format of the basis used to construct the right kernel. Allowable values are:
  - ‘echelon’: the basis matrix is returned in echelon form
Matrices and Spaces of Matrices, Release 10.4

– ‘pivot’: each basis vector is computed from the reduced row-echelon form of self by placing a single one in a non-pivot column and zeros in the remaining non-pivot columns. Only available for matrices over fields.

– ‘LLL’: an LLL-reduced basis. Only available for matrices over the integers.

OUTPUT:
A vector space or free module whose degree equals the number of columns in self and which contains all the vectors \( \mathbf{x} \) such that \( \text{self} \mathbf{x} = 0 \).

If \( \text{self} \) has 0 columns, the kernel has dimension 0, while if \( \text{self} \) has 0 rows the kernel is the entire ambient vector space.

The result is cached. Requesting the right kernel a second time, but with a different basis format, will return the cached result with the format from the first computation.

**Note:** For more detailed documentation on the selection of algorithms used and a more flexible method for computing a basis matrix for a right kernel (rather than computing a vector space), see `right_kernel_matrix()`, which powers the computations for this method.

**EXAMPLES:**

```python
sage: A = matrix(QQ, [[0, 0, 1, 2, 2, -5, 3],
                   [-1, 5, 2, 2, 1, -7, 5],
                   [0, 0, -2, -3, -3, 8, -5],
                   [-1, 5, 0, -1, -2, 1, 0]])

sage: K = A.right_kernel(); K
Vector space of degree 7 and dimension 4 over Rational Field
Basis matrix:
[ 1 0 0 -1 -1 -1]
[ 0 1 0 5 5 5]
[ 0 0 1 -1 -2 -3]
[ 0 0 0 1 0 1 1]

sage: A * K.basis_matrix().transpose() == zero_matrix(QQ, 4, 4)
True
```

The default is basis vectors that form a matrix in echelon form. A “pivot basis” instead has a basis matrix
where the columns of an identity matrix are in the locations of the non-pivot columns of the original matrix. This alternate format is available whenever the base ring is a field.

```python
sage: A = matrix(QQ, [[0, 0, 1, 2, -5, 3],
                   [-1, 5, 2, 1, -7, 5],
                   [0, 0, -2, -3, 8, -5],
                   [-1, 5, 0, -1, -2, 1]],
             (1, 4, 5, 6))
```

```python
sage: A.rref()
[ 1 -5 0 0 1 1 -1]
[ 0 0 1 0 0 -1 1]
[ 0 0 0 1 1 -2 1]
[ 0 0 0 0 0 0 0]
sage: A.nonpivots()
(1, 4, 5, 6)
sage: K = A.right_kernel(basis='pivot'); K
Vector space of degree 7 and dimension 4 over Rational Field
User basis matrix:
[ 5 1 0 0 0 0 0]
[-1 0 0 -1 1 0 0]
[-1 0 1 2 0 1 0]
[ 1 0 -1 -1 0 0 1]
sage: A * K.basis_matrix().transpose() == zero_matrix(QQ, 4, 4)
True
```

Matrices may have any field as a base ring. Number fields are computed by PARI library code, matrices over \(GF(2)\) are computed by the M4RI library, and matrices over the rationals are computed by the IML library. For any of these specialized cases, general-purpose code can be called instead with the keyword setting `algorithm='generic'`.

Over an arbitrary field, with two basis formats. Same vector space, different bases.
sage: # needs sage.rings.finite_rings
sage: F.<a> = FiniteField(5^2)

sage: A = matrix(F, 3, 4, [[1, a, 1+a, a^3+a^5],
                       [a, a^4, a+a^4, a^4+a^8],
                       [a^2, a^6, a^2+a^6, a^5+a^10]])

sage: K = A.right_kernel(); K
Vector space of degree 4 and dimension 2
over Finite Field in a of size 5^2
Basis matrix:
[ 1 0 3*a + 4 2*a + 2]
[ 0 1 2*a 3*a + 3]

sage: A * K.basis_matrix().transpose() == zero_matrix(F, 3, 2)
True

In the following test, we have to force usage of Matrix_generic_dense, since the option basis = 'pivot' would simply yield the same result as the previous test, if the optional meataxe package is installed.

sage: from sage.matrix.matrix_generic_dense import Matrix_generic_dense
sage: B = Matrix_generic_dense(A.parent(), A.list(), False, False)

sage: P = B.right_kernel(basis='pivot'); P  # needs sage.rings.finite_rings
Vector space of degree 4 and dimension 2
over Finite Field in a of size 5^2
User basis matrix:
[ 4  4  1  0]
[ a + 2 3*a + 3  0  1]

sage: from sage.all import *

>>> from sage.matrix.matrix_generic_dense import Matrix_generic_dense

>>> A = matrix(F, Integer(3), Integer(4), [[Integer(1), a, ...
                       [a, a**Integer(4), a+a**Integer(4), ...
                       [a**Integer(4)+a**Integer(8)],
                       [a**Integer(2)+a**Integer(6)],
                       [a**Integer(1)+a, a**Integer(3)+a**Integer(5)],
                       [a**Integer(4)+a**Integer(8)],
                       [a**Integer(2), a**Integer(6),...
                       [a**Integer(2)+a**Integer(6), a**Integer(5)+a**Integer(10)]])

>>> K = A.right_kernel(); K
Vector space of degree 4 and dimension 2
over Finite Field in a of size 5^2
Basis matrix:
[ 1 0 3*a + 4 2*a + 2]
[ 0 1 2*a 3*a + 3]

>>> A * K.basis_matrix().transpose() == zero_matrix(F, Integer(3), Integer(2))
True
If the optional meataxe package is installed, we again have to make sure to work with a copy of \( B \) that has the same type as \( P.basis_matrix() \):

```
sage: (B.parent()(B.list()) * P.basis_matrix().transpose())  # needs sage.rings.finite_rings
    == zero_matrix(F, 3, 2))
True

sage: K == P  # needs sage.rings.finite_rings
True
```

Over number fields, PARI is used by default, but general-purpose code can be requested. Same vector space, same bases, different code.:

```
sage: # needs sage.rings.number_field
sage: Q = QuadraticField(-7)
sage: a = Q.gen(0)
sage: A = matrix(Q, [[ 2, 5 - a, 15 - a, 16 + 4*a],
                          [2 + a, a, -7 + 5*a, -3 + 3*a]])
    
Vector space of degree 4 and dimension 2 over Number Field in a with defining polynomial x^2 + 7 with a = 2.
Basis matrix:
[ 1 0 7/88*a + 3/88 -3/176*a - 39/176]
[ 0 1 -1/88*a - 13/88 13/176*a - 7/176]

sage: A * K.basis_matrix().transpose() == zero_matrix(Q, 2, 2)
True

sage: B = copy(A)
sage: G = A.right_kernel(algorithm='generic'); G
    
Vector space of degree 4 and dimension 2 over Number Field in a with defining polynomial x^2 + 7 with a = 2.

Basis matrix:
[ 1 0 7/88*a + 3/88 -3/176*a - 39/176]
[ 0 1 -1/88*a - 13/88 13/176*a - 7/176]

sage: B * G.basis_matrix().transpose() == zero_matrix(Q, 2, 2)
True

sage: K == G
True
```

```
For matrices over the integers, several options are possible. The basis can be an LLL-reduced basis or an
echelon basis. The pivot basis is not available. A heuristic will decide whether to use a p-adic algorithm
from the IML library or an algorithm from the PARI library. Note how specifying the algorithm can mildly
influence the LLL basis.

```
sage: A = matrix(ZZ, [[0, -1, -1, 2, 9, 4, -4],
....: [-1, 1, 0, -2, -7, -1, 6],
....: [2, 0, 1, 0, 1, -5, -2],
....: [-1, -1, -1, 3, 10, 10, -9],
....: [-1, 2, 0, -3, -7, 1, 6])
sage: A.right_kernel(basis='echelon')
Free module of degree 7 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1 5 -8 3 -1 -1 -1]
[ 0 11 -19 5 -2 -3 -3]
sage: B = copy(A)
sage: B.right_kernel(basis='LLL')
Free module of degree 7 and rank 2 over Integer Ring
User basis matrix:
[ 2 -1 3 1 0 1 1]
[-5 -3 2 -5 1 -1 -1]
sage: C = copy(A)
sage: C.right_kernel(basis='pivot')
Traceback (most recent call last):
...
ValueError: pivot basis only available over a field, not over Integer Ring
sage: D = copy(A)
sage: D.right_kernel(algorithm='pari')
Free module of degree 7 and rank 2 over Integer Ring
Echelon basis matrix:
[ 1 5 -8 3 -1 -1 -1]
[ 0 11 -19 5 -2 -3 -3]
sage: E = copy(A)
```
Besides the integers, rings may be as general as principal ideal domains. Results are then free modules.

```sage
R.<y> = QQ[]
sage: A = matrix(R, [[ 1, y, 1+y^2],
[ y^3, y^2, 2*y^3]])
```

Free module of degree 3 and rank 1 over Univariate Polynomial Ring in y over Rational Field
Echelon basis matrix:
```
[-1 -y 1]
[ y^3, y^2, 2*y^3]]
```
Matrices over non-commutative rings are not a good idea either. These are the “usual” quaternions.

```
sage: Q.<i,j,k> = QuaternionAlgebra(-1,-1)
sage: A = matrix(Q, 2, [i,j,-1,k])
sage: A.right_kernel()
Traceback (most recent call last):
  ...
NotImplementedError: Cannot compute a matrix kernel over Quaternion Algebra (-1, -1) with base ring Rational Field
```
Sparse matrices, over the rationals and the integers, use the same routines as the dense versions.

```sage
A = matrix(ZZ, [[0, -1, 1, 1, 2], [1, -2, 0, 1, 3], [-1, 2, 0, -1, -3]], sparse=True)
sage: A.
Free module of degree 5 and rank 3 over Integer Ring
Echelon basis matrix:
[ 1 0 0 2 -1]
[ 0 1 0 -1 1]
[ 0 0 1 -3 1]
sage: B = A.change_ring(QQ)
sage: B.is_sparse()
True
sage: B.
Vector space of degree 5 and dimension 3 over Rational Field
Basis matrix:
[ 1 0 0 2 -1]
[ 0 1 0 -1 1]
[ 0 0 1 -3 1]
```

With no columns, the kernel can only have dimension zero. With no rows, every possible vector is in the kernel.

```sage
A = matrix(QQ, 2, 0)
sage: A.
Vector space of degree 0 and dimension 0 over Rational Field
```
Every vector is in the kernel of a zero matrix, the dimension is the number of columns.

```python
sage: A = zero_matrix(QQ, 10, 20)
sage: A.right_kernel()
Vector space of degree 20 and dimension 20 over Rational Field
Basis matrix:
20 x 20 dense matrix over Rational Field
```

Results are cached as the right kernel of the matrix. Subsequent requests for the right kernel will return the cached result, without regard for new values of the algorithm or format keyword. Work with a copy if you need a new right kernel, or perhaps investigate the `right_kernel_matrix()` method, which does not cache its results and is more flexible.

```python
sage: A = matrix(QQ, 3, 3, range(9))
sage: K1 = A.right_kernel(basis='echelon')
sage: K1
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
sage: K2 = A.right_kernel(basis='pivot')
sage: K2
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2  1]
sage: K1 is K2
True
sage: B = copy(A)
```
sage: K3 = B.kernel(basis='pivot')
sage: K3
Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2 1]
sage: K3 is K1
False
sage: K3 == K1
True

>>> from sage.all import *
>>> A = matrix(QQ, Integer(3), Integer(3), range(Integer(9)))
>>> K1 = A.right_kernel(basis='echelon')
>>> K1
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2 1]
>>> K2 = A.right_kernel(basis='pivot')
>>> K2
Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
[ 1 -2 1]
>>> K1 is K2
True
>>> B = copy(A)
>>> K3 = B.kernel(basis='pivot')
>>> K3
Vector space of degree 3 and dimension 1 over Rational Field
User basis matrix:
[ 1 -2 1]
>>> K3 is K1
False
>>> K3 == K1
True

**`right_kernel_matrix(*args, **kwds)`**

Returns a matrix whose rows form a basis for the right kernel of `self`.

**INPUT:**

- `algorithm` – (default: `default`); a keyword that selects the algorithm employed. Allowable values are:
  - `default` (default: `default`); a keyword that selects the algorithm employed. Allowable values are:
    - `default` – allows the algorithm to be chosen automatically
    - `generic` – naive algorithm usable for matrices over any field
    - `flint` – FLINT library code for matrices over the rationals or the integers
    - `pari` – PARI library code for matrices over number fields or the integers
    - `padic` – padic algorithm from IML library for matrices over the rationals and integers
    - `pluq` – PLUQ matrix factorization for matrices mod 2
  
- `basis` – (default: `default`); a keyword that describes the format of the basis returned. Allowable values are:
  - `default` (default: `default`); a keyword that describes the format of the basis returned. Allowable values are:
    - `default`: uses `echelon` over fields; `computed` otherwise.
    - `echelon`: the basis matrix is returned in echelon form.
– ‘pivot’: each basis vector is computed from the reduced row-echelon form of self by placing a single one in a non-pivot column and zeros in the remaining non-pivot columns. Only available for matrices over fields.

– ‘LLL’: an LLL-reduced basis. Only available for matrices over the integers.

– ‘computed’: no work is done to transform the basis, it is returned exactly as provided by whichever routine actually computed the basis. Request this for the least possible computation possible, but with no guarantees about the format of the basis. This option is recommended for inexact rings.

OUTPUT:
A matrix X whose rows are an independent set spanning the right kernel of self. So self*X. transpose() is a zero matrix.

The output varies depending on the choice of algorithm and the format chosen by basis.

The results of this routine are not cached, so you can call it again with different options to get possibly different output (like the basis format). Conversely, repeated calls on the same matrix will always start from scratch.

Note: If you want to get the most basic description of a kernel, with a minimum of overhead, then ask for the right kernel matrix with the basis format requested as ‘computed’. You are then free to work with the output for whatever purpose. For a left kernel, call this method on the transpose of your matrix.

For greater convenience, plus cached results, request an actual vector space or free module with right_kernel() or left_kernel().

EXAMPLES:
Over the Rational Numbers:
Kernels are computed by the IML library in _right_kernel_matrix(). Setting the algorithm keyword to ‘default’, ‘padic’ or unspecified will yield the same result, as there is no optional behavior. The ‘computed’ format of the basis vectors are exactly the negatives of the vectors in the ‘pivot’ format.
We verify that the rational matrix code is called for both dense and sparse rational matrices, with equal result.

```
sage: A = matrix(QQ, [[1, 0, 1, -3, 1],
....:                   [5, 0, 0, -4, 6],
....:                   [0, -1, 1, 1, 1]])
sage: G = A.right_kernel_matrix(algorithm='generic', basis='echelon'); G
[ 1 0 1 1/2 -1/2]
[ 0 1 -1/2 -1/4 -1/4]
sage: A * G.transpose() == zero_matrix(QQ, 4, 2)
True
```

Since the rationals are a field, we can call the general code available for any field by using the 'generic' keyword.

```
sage: A = matrix(QQ, [[1, 0, 1, -3, 1],
....:                   [5, 0, 0, -4, 6],
....:                   [0, -1, 1, 1, 1]])
sage: G = A.right_kernel_matrix(algorithm='generic', basis='echelon'); G
[ 1 0 1 1/2 -1/2]
[ 0 1 -1/2 -1/4 -1/4]
sage: A * G.transpose() == zero_matrix(QQ, 4, 2)
True
```
....:        [-5, 1, 0, 7, -3],
....:        [0, -1, -4, 6, -2],
....:        [4, -1, 0, -6, 2],
....: sparse=False)
sage: B = copy(A).sparse_matrix()
sage: from sage.misc.verbose import set_verbose

                     [Integer(4), -Integer(1), Integer(0), -Integer(6),
                      Integer(2)],
                     sparse=False])
>>> B = copy(A).sparse_matrix()
>>> from sage.misc.verbose import set_verbose
>>> set_verbose(Integer(2))
>>> D = A.right_kernel(); D
verbose 2 (<module>) computing a right kernel for 4x5 matrix over Rational Field
...
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[ 1 0 1 1/2 -1/2]
[ 0 1 -1/2 -1/4 -1/4]
>>> S = B.right_kernel(); S
verbose 2 (<module>) computing a right kernel for 4x5 matrix over Rational Field
...
Vector space of degree 5 and dimension 2 over Rational Field
Basis matrix:
[ 1 0 1 1/2 -1/2]
[ 0 1 -1/2 -1/4 -1/4]
Over Number Fields:

Kernels are by default computed by PARI, (except for exceptions like the rationals themselves). The raw results from PARI are a pivot basis, so the `basis` keywords 'computed' and 'pivot' will return the same results.

```
sage: # needs sage.rings.number_field
sage: Q = QuadraticField(-7)
sage: a = Q.gen(0)
sage: A = matrix(Q, \[
[2, 5-a, 15-a, 16+4*a],
[2+a, a, -7 + 5*a, -3+3*a]
\])
sage: C = A.right_kernel_matrix(algorithm='default', basis='computed'); C
[ -a -3 1 0]
[ -2 -a -1 0 1]
sage: A*C.transpose() == zero_matrix(Q, 2, 2)
True
sage: P = A.right_kernel_matrix(algorithm=pari, basis=pivot); P
[ -a -3 1 0]
[ -2 -a -1 0 1]
sage: A*P.transpose() == zero_matrix(Q, 2, 2)
True
sage: E = A.right_kernel_matrix(algorithm='default', basis='echelon'); E
[ 1 0 7/88*a + 3/88 -3/176*a - 39/176]
[ 0 1 -1/88*a - 13/88 13/176*a - 7/176]
sage: A*E.transpose() == zero_matrix(Q, 2, 2)
True
```
We can bypass using PARI for number fields and use Sage's general code for matrices over any field. The basis vectors as computed are in pivot format.

```
\begin{verbatim}
sage: # needs sage.rings.number_field
sage: Q = QuadraticField(-7)
sage: a = Q.gen(0)
sage: A = matrix(Q, \[
[ [2, 5-a, 15-a, 16+4*a], [2+a, a, -7 + 5*a, -3+3*a]]
\] )
sage: G = A.right_kernel_matrix(algorithm='generic', basis='computed'); G
[ -a -3 1 0]
[ -2 -a - 1 0 1]
sage: A*G.transpose() == zero_matrix(Q, 2, 2)
True
\end{verbatim}
```

We check that number fields are handled by the right routine as part of typical right kernel computation.

```
\begin{verbatim}
sage: # needs sage.rings.number_field
sage: Q = QuadraticField(-7)
sage: a = Q.gen(0)
sage: A = matrix(Q, \[
[ [2, 5-a, 15-a, 16+4*a], [2+a, a, -7 + 5*a, -3+3*a]]
\] )
sage: set_verbose(2)

Over the Finite Field of Order 2:
Kernels are computed by the M4RI library using PLUQ matrix decomposition in the _right_kernel_matrix() method. There are no options for the algorithm used.

```python
sage: A = matrix(GF(2),[[0, 1, 1, 0, 0, 0],
[1, 0, 0, 0, 1, 1],
[1, 0, 0, 0, 1, 1]])
sage: E = A.right_kernel_matrix(algorithm='default', format='echelon'); E
[1 0 0 0 0 1]
[0 1 1 0 0 0]
[0 0 0 1 0 0]
[0 0 0 0 1 1]
sage: A*E.transpose() == zero_matrix(GF(2), 3, 4)
True
```

```python
>>> from sage.all import *
>>> A = matrix(GF(Integer(2)),[[Integer(0), Integer(1), Integer(1),
Integer(0), Integer(0), Integer(0)],
[Integer(1), Integer(0), Integer(0), Integer(0),
Integer(1), Integer(1)],
[Integer(1), Integer(0), Integer(0), Integer(0),
Integer(1), Integer(1)]])
>>> E = A.right_kernel_matrix(algorithm='default', format='echelon'); E
[1 0 0 0 0 1]
[0 1 1 0 0 0]
[0 0 0 1 0 0]
[0 0 0 0 1 1]
>>> A*E.transpose() == zero_matrix(GF(Integer(2)), Integer(3), Integer(4))
True
```

Since GF(2) is a field we can route this computation to the generic code and obtain the ‘pivot’ form of the basis. The algorithm keywords, ‘pluq’, ‘default’ and unspecified, all have the same effect as there is no optional behavior.

```python
sage: A = matrix(GF(2), [[0, 1, 1, 0, 0, 0],
[1, 0, 0, 0, 1, 1],
[1, 0, 0, 0, 1, 1]])
sage: P = A.right_kernel_matrix(algorithm='generic', basis='pivot'); P
[0 1 1 0 0 0]
[0 0 0 1 0 0]
[1 0 0 0 1 0]
```

Over Arbitrary Fields:

For kernels over fields not listed above, totally general code will compute a set of basis vectors in the pivot format. These could be returned as a basis in echelon form.

sage: # needs sage.rings.finite_rings
sage: F.<a> = FiniteField(5^2)
sage: A = matrix(F, 3, 4, [[[1, a, 1+a, a^3+a^5],
                       ...: [a, a^4, a^a^4, a^4+a^8],
                       ...: [a^2, a^6, a^2+a^6, a^5+a^10]])

sage: P = A.right_kernel_matrix(algorithm='default', basis='pivot'); P
[ 4  4 1 0]
[ a + 2 3*a + 3 0 1]
sage: A*P.transpose() == zero_matrix(F, 3, 2)
True
sage: E = A.right_kernel_matrix(algorithm='default', basis='echelon'); E
[ 1 0 3*a + 4 2*a + 2]
[ 0 1 2*a 3*a + 3]
sage: A*E.transpose() == zero_matrix(F, 3, 2)
True

...
This general code can be requested for matrices over any field with the `algorithm` keyword 'generic'. Normally, matrices over the rationals would be handled by specific routines from the IML library. The default format is an echelon basis, but a pivot basis may be requested, which is identical to the computed basis.

We test that the generic code is called for matrices over fields, lacking any more specific routine.
Matrices and Spaces of Matrices, Release 10.4

>>> from sage.all import *

"# needs sage.rings.rational
>>> A = matrix(ZZ, [[8, 0, 7, 1, 3, 4, 6],
... [
... [4, 0, 3, 4, 2, 7, 7],
... [1, 4, 6, 1, 2, 8, 5],
... [0, 3, 1, 2, 3, 6, 2]]
...)

sage: A = matrix(ZZ, [[8, 0, 7, 1, 3, 4, 6],
...                  [4, 0, 3, 4, 2, 7, 7],
...                  [1, 4, 6, 1, 2, 8, 5],
...                  [0, 3, 1, 2, 3, 6, 2]])

sage: X = A.right_kernel_matrix(algorithm='default', basis='echelon'); X

\[

0 & 0 & 7 & 12 & -3 & -1 & -8
\end{pmatrix}
\]

sage: A*X.transpose() == zero_matrix(ZZ, 4, 3)

Over the Integers:

Either the IML or PARI libraries are used to provide a set of basis vectors. The algorithm keyword can be used to select either, or when set to 'default' a heuristic will choose between the two. Results can be returned in the 'compute' format, straight out of the libraries. Unique to the integers, the basis vectors can be returned as an LLL basis. Note the similarities and differences in the results. The 'pivot' format is not available, since the integers are not a field.

sage: A = matrix(ZZ, [[8, 0, 7, 1, 3, 4, 6],
...                  [4, 0, 3, 4, 2, 7, 7],
...                  [1, 4, 6, 1, 2, 8, 5],

[ 0 35 0 25 -1 -31 17]
[ 0 0 7 12 -3 -1 -8]
>>> D == S
True
```

Over Principal Ideal Domains:

Kernels can be computed using Smith normal form. Only the default algorithm is available, and the ‘pivot’ basis format is not available.

```python
sage: R.<y> = QQ[]
sage: A = matrix(R, [[ 1, y, 1+y^2],
   ....: [y^3, y^2, 2*y^3]])
sage: E = A.right_kernel_matrix(algorithm='default', basis='echelon'); E
[[-1 -y 1]

sage: A*E.transpose() == zero_matrix(ZZ, 2, 1)
True
```

```python
>>> from sage.all import *
>>> R = QQ['y']; (y,) = R._first_ngens(1)
>>> A = matrix(R, [[ Integer(1), y, Integer(1)+y*Integer(2)],
   ... [y**Integer(3), y**Integer(2), Integer(2)*y**Integer(3)]]
>>> E = A.right_kernel_matrix(algorithm='default', basis='echelon'); E
[-1 -y 1]
>>> A*E.transpose() == zero_matrix(ZZ, Integer(2), Integer(1))
True
```
It can be computationally expensive to determine if an integral domain is a principal ideal domain. The Smith normal form routine can fail for non-PIDs, as in this example.

```
sage: D.<x> = ZZ[]
sage: A = matrix(D, 2, 2, [[x^2 - x, -x + 5],
                           [x^2 - 8, -x + 2]])
sage: A.right_kernel_matrix()
Traceback (most recent call last):
  ...:
ArithmeticError: Ideal Ideal (x^2 - x, x^2 - 8) of
  Univariate Polynomial Ring in x over Integer Ring not principal
```

We test that the domain code is called for domains that lack any extra structure.

```
sage: R.<y> = QQ[]
sage: A = matrix(R, [[ 1, y, 1+y^2],
                      [y^3, y^2, 2*y^3]])
sage: set_verbose(2)
sage: A.right_kernel(algorithm=default, basis=echelon)
verbose ...

\[-1 -y 1\]

```
>>> set_verbose(Integer(0))
```

Over inexact rings:

For inexact rings one should avoid echelonizing if possible:

```
sage: A = Matrix(
      ....: [[ 0.0,  0.5,  0.8090169944],
      ....:  [ 0.0,  0.5, -0.8090169944],
      ....:  [ 0.0, -0.5,  0.8090169944],
      ....:  [ 0.0, -0.5, -0.8090169944],
      ....:  [ 0.5,  0.8090169944,   0.0],
      ....:  [ 0.5, -0.8090169944,   0.0],
      ....:  [-0.5,  0.8090169944,   0.0],
      ....:  [-0.5, -0.8090169944,   0.0],
      ....:  [ 0.8090169944,   0.0,  0.5],
      ....:  [-0.8090169944,   0.0, -0.5],
      ....:  [ 0.8090169944,   0.0, -0.5],
      ....:  [-0.8090169944,   0.0,  0.5]],
   ....: ).transpose()

sage: (A * A.right_kernel_matrix().transpose()).norm() > Integer(2)
True
sage: (A * A.right_kernel_matrix(basis='computed').transpose()).norm() < 1e-15
True
```

```
>>> from sage.all import *
```

```
>>> A = Matrix(
     ....: [[ RealNumber('0.0'), RealNumber('0.5'), RealNumber('0.8090169944')],
     ....:  [ RealNumber('0.0'), RealNumber('0.5'), -RealNumber('0.8090169944')],
     ....:  [ RealNumber('0.0'), -RealNumber('0.5'), RealNumber('0.8090169944')],
     ....:  [ RealNumber('0.0'), -RealNumber('0.5'), -RealNumber('0.8090169944')],
     ....:  [ RealNumber('0.5'), RealNumber('0.8090169944'),   0.0],
     ....:  [ RealNumber('0.5'), -RealNumber('0.8090169944'),   0.0],
     ....:  [-RealNumber('0.5'), RealNumber('0.8090169944'),   0.0],
     ....:  [-RealNumber('0.5'), -RealNumber('0.8090169944'),   0.0],
     ....:  [ RealNumber('0.8090169944'),   0.0,  0.5],
     ....:  [-RealNumber('0.8090169944'),   0.0, -0.5],
     ....:  [ RealNumber('0.8090169944'),   0.0, -0.5],
     ....:  [-RealNumber('0.8090169944'),   0.0,  0.5]],
    ....: ).transpose()

>>> (A * A.right_kernel_matrix().transpose()).norm() > Integer(2)
True
```

(continues on next page)
Trivial Cases:
We test two trivial cases. Any possible values for the keywords (algorithm, basis) will return identical results.

```python
sage: A = matrix(ZZ, 0, 2)
sage: A.right_kernel_matrix()
\[
\begin{bmatrix}
1 & 0 \\
0 & 1
\end{bmatrix}
\]
sage: A = matrix(FiniteField(7), 2, 0)
sage: A.right_kernel_matrix().parent()
Full MatrixSpace of 0 by 0 dense matrices over Finite Field of size 7
```

```python
>>> from sage.all import *
>>> A = matrix(ZZ, Integer(0), Integer(2))
>>> A.right_kernel_matrix()
\[
\begin{bmatrix}
1 & 0 \\
0 & 1
\end{bmatrix}
\]
```

```
right_nullity()
Return the right nullity of this matrix, which is the dimension of the right kernel.

EXAMPLES:
```
```python
sage: A = MatrixSpace(QQ,3,2)(range(6))
sage: A.right_nullity()
0
```

```python
>>> from sage.all import *
```
The rook vector of the matrix $A$ is the list consisting of $r_0, r_1, \ldots, r_h$, where $h = \min(m, n)$. The rook polynomial is defined by $r(x) = \sum_{k=0}^{h} r_k x^k$.

The rook vector can be generalized to matrices defined over any rings using permanental minors. Among the available algorithms, only “Godsil” needs the condition on the entries to be either 0 or 1.

See Wikipedia article Rook_polynomial for more information and also the method permanental_minor() to compute individual permanental minor.

See also sage.matrix.matrix2.permanental_minor_polynomial and the graph method matching_polynomial.

**INPUT:**

- **self** – an $m$ by $n$ matrix
- **algorithm** – a string which must be either “Ryser” or “ButeraPernici” (default) or “Godsil”; Ryser one might be faster on simple and small instances. Godsil only accepts input in 0,1.
- **complement** – boolean (default: False) whether we consider the rook vector of the complement matrix. If set to True then the matrix must have entries in \{0, 1\} and the complement matrix is the one for which the 0's are replaced by 1's and 1's by 0's.
- **use_complement** – Boolean (default: None) whether to compute the rook vector of a (0,1)-matrix from its complement. By default this is determined by the density of ones in the matrix.

**EXAMPLES:**

The standard chessboard is an 8 by 8 grid in which any positions is allowed. In that case one gets that the number of ways to position 4 non-attacking rooks is 117600 while for 8 rooks it is 40320:

```
sage: ones_matrix(8,8).rook_vector()
[1, 64, 1568, 18816, 117600, 376320, 564480, 322560, 40320]
```

```
>>> from sage.all import *
>>> ones_matrix(Integer(8),Integer(8)).rook_vector()
[1, 64, 1568, 18816, 117600, 376320, 564480, 322560, 40320]
```

These numbers are the coefficients of a modified Laguerre polynomial:

```
sage: x = polygen(QQ)
sage: factorial(8) * laguerre(8,-x) # needs sage.symbolic
x^8 + 64*x^7 + 1568*x^6 + 18816*x^5 + 117600*x^4 + 376320*x^3 + 564480*x^2 + 322560*x + 40320
```

```
>>> from sage.all import *
>>> x = polygen(QQ)
>>> factorial(Integer(8)) * laguerre(Integer(8),-x) # needs sage.symbolic
x^8 + 64*x^7 + 1568*x^6 + 18816*x^5 + 117600*x^4 + 376320*x^3 + 564480*x^2 + 322560*x + 40320
```

The number of derangements of length $n$ is the permanent of a matrix with 0 on the diagonal and 1 elsewhere; for $n = 21$ it is 18795307255050944540 (see OEIS sequence A000166):

```
sage: A = identity_matrix(21)  sage: A.rook_vector(complement=True)[-1]
18795307255050944540
```

```
sage: Derangements(21).cardinality()  # needs sage.combinat
18795307255050944540
```

An other example that we convert into a rook polynomial:
sage: A = matrix(3,6, [1,1,1,0,0,0,1,1,1,0,0,0,1,1,1,0,0,0,1,1,1,1,0,0,0,1,1,1,1,0,0,0])
sage: A
[1 1 1 1 0 0]
[0 1 1 1 1 0]
[0 0 1 1 1 1]
sage: A.rook_vector()
[1, 12, 40, 36]
sage: R = PolynomialRing(ZZ, 'x')
sage: R(A.rook_vector())
36*x^3 + 40*x^2 + 12*x + 1

>>> from sage.all import *
>>> A = matrix(Integer(3),Integer(6), [Integer(1),Integer(1),Integer(1),
–> Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),Integer(1),
–> Integer(1),Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),
–> Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)])
>>> A
[1 1 1 0 0]
[0 1 1 1 0]
[0 0 1 1 1]
>>> A.rook_vector()
[1, 12, 40, 36]

Different algorithms are available:

sage: A = matrix([[1,0,0,1],[0,1,1,0],[0,1,1,0],[1,0,0,1]])
sage: A.rook_vector(algorithm="ButeraPernici")
[1, 8, 20, 16, 4]
sage: A.rook_vector(algorithm="Ryser")
[1, 8, 20, 16, 4]
sage: A.rook_vector(algorithm="Godsil")
# needs sage.graphs sage.libs.flint
[1, 8, 20, 16, 4]

When the matrix $A$ has more ones then zeroes it is usually faster to compute the rook polynomial of the complementary matrix, with zeroes and ones interchanged, and use the inclusion-exclusion theorem, giving for a $m \times n$ matrix $A$ with complementary matrix $B$

$$r_k(A) = \sum_{j=0}^{k} (-1)^j \binom{m-j}{k-j} \binom{n-j}{k-j} (k-j)! r_j(B)$$
see [Rio1958] or the introductory text [AS2011]. This can be done setting the argument \texttt{use\_complement} to \texttt{True}.

An example with an exotic matrix (for which only Butera-Pernici and Ryser algorithms are available):

```sage
sage: R.<x,y> = PolynomialRing(GF(5))
sage: A = matrix(R, [[1, x, y], [x*y, x**2+y, 0]])
sage: A.rook_vector(algorithm="ButeraPernici")
[1, x^2 + x*y + x + 2*y + 1, 2*x^2*y + x*y^2 + x^2 + y^2 + y]
sage: A.rook_vector(algorithm="Ryser")
[1, x^2 + x*y + x + 2*y + 1, 2*x^2*y + x*y^2 + x^2 + y^2 + y]
sage: A.rook_vector(algorithm="Godsil")
Traceback (most recent call last):
...
ValueError: coefficients must be zero or one, but we have 'x' in position (0, 1).
sage: B = A.transpose()

```

```sage
sage: B = A.transpose()
sage: B.rook_vector(algorithm="ButeraPernici")
[1, x^2 + x*y + x + 2*y + 1, 2*x^2*y + x*y^2 + x^2 + y^2 + y]
sage: B.rook_vector(algorithm="Ryser")
[1, x^2 + x*y + x + 2*y + 1, 2*x^2*y + x*y^2 + x^2 + y^2 + y]
```

```sage
>>> from sage.all import *

```

```sage
>>> R = PolynomialRing(GF(Integer(5)), names=('x', 'y')); (x, y,) = R._first_ngens(2)

```

```sage
>>> A = matrix(R, [[Integer(1), x, y], [x*y, x**Integer(2)+y, Integer(0)]])

```

```sage
>>> A.rook_vector(algorithm="ButeraPernici")
[1, x^2 + x*y + x + 2*y + 1, 2*x^2*y + x*y^2 + x^2 + y^2 + y]

```

```sage
>>> A.rook_vector(algorithm="Ryser")
[1, x^2 + x*y + x + 2*y + 1, 2*x^2*y + x*y^2 + x^2 + y^2 + y]

```

```sage
>>> A.rook_vector(algorithm="Godsil")
Traceback (most recent call last):
...
ValueError: coefficients must be zero or one, but we have 'x' in position (0, 1).

```

```sage
>>> B = A.transpose()

```

```sage
>>> B.rook_vector(algorithm="ButeraPernici")
[1, x^2 + x*y + x + 2*y + 1, 2*x^2*y + x*y^2 + x^2 + y^2 + y]

```

```sage
>>> B.rook_vector(algorithm="Ryser")
[1, x^2 + x*y + x + 2*y + 1, 2*x^2*y + x*y^2 + x^2 + y^2 + y]
```

### row_module (base\_ring=None)

Return the free module over the base ring spanned by the rows of self.

EXAMPLES:

```sage
sage: A = MatrixSpace(IntegerRing(), 2)([1,2,3,4])
sage: A.row_module()
Free module of degree 2 and rank 2 over Integer Ring
Echelon basis matrix:
[1 0]
[0 2]

```

```sage
>>> from sage.all import *

```

```sage
>>> A = MatrixSpace(IntegerRing(), Integer(2))([[Integer(1)],Integer(2),
    Integer(3),Integer(4)])

```

```sage
>>> A.row_module()
Free module of degree 2 and rank 2 over Integer Ring
```

Echelon basis matrix:
\[
\begin{bmatrix}
1 & 0 \\
0 & 2 \\
\end{bmatrix}
\]

\*row_space\* (*base_ring=None*)

Return the row space of this matrix. (Synonym for self.row_module().)

**EXAMPLES:**

```sage
sage: t = matrix(QQ, 3, 3, range(9)); t
[ 0  1  2]
[ 3  4  5]
[ 6  7  8]
sage: t.row_space()
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]
```

```python
>>> from sage.all import *
```

```python
>>> t = matrix(QQ, Integer(3), Integer(3), range(Integer(9))); t
[ 0  1  2]
[ 3  4  5]
[ 6  7  8]
```

```python
>>> t.row_space()
Vector space of degree 3 and dimension 2 over Rational Field
Basis matrix:
[ 1  0 -1]
[ 0  1  2]
```

```sage
sage: m = Matrix(Integers(5), 2, 2, [2, 2, 2, 2])
sage: m.row_space()
Vector space of degree 2 and dimension 1 over Ring of integers modulo 5
Basis matrix:
[1 1]
```

```python
>>> from sage.all import *
```

```python
>>> m = Matrix(Integers(Integer(5)), Integer(2), Integer(2), [Integer(2),
˓→Integer(2), Integer(2), Integer(2)])
```

```python
>>> m.row_space()
Vector space of degree 2 and dimension 1 over Ring of integers modulo 5
Basis matrix:
[1 1]
```

\*rref\* (*args, **kwds*)

Return the reduced row echelon form of the matrix, considered as a matrix over a field.

If the matrix is over a ring, then an equivalent matrix is constructed over the fraction field, and then row reduced.

All arguments are passed on to \texttt{echelon_form()}.

**Note:** Because the matrix is viewed as a matrix over a field, every leading coefficient of the returned matrix will be one and will be the only nonzero entry in its column.
EXAMPLES:

```
sage: A = matrix(3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.rref()
[ 1 0 -1]
[ 0 1 2]
[ 0 0 0]
```

```python
>>> from sage.all import *
>>> A = matrix(Integer(3),range(Integer(9))); A
[0 1 2]
[3 4 5]
[6 7 8]
>>> A.rref()
[ 1 0 -1]
[ 0 1 2]
[ 0 0 0]
```

Note that there is a difference between `rref()` and `echelon_form()` when the matrix is not over a field (in this case, the integers instead of the rational numbers):

```
sage: A.base_ring()
Integer Ring
sage: A.echelon_form()
[ 3 0 -3]
[ 0 1 2]
[ 0 0 0]
```

```
sage: B = random_matrix(QQ, 3, num_bound=10)
sage: while B.rank() != 3:
    ....:    B = random_matrix(QQ, 3, num_bound=10)

sage: B.rref()
[1 0 0]
[0 1 0]
[0 0 1]
```

```python
>>> from sage.all import *
>>> A.base_ring()
Integer Ring
>>> A.echelon_form()
[ 3 0 -3]
[ 0 1 2]
[ 0 0 0]
```

```
>>> B = random_matrix(QQ, Integer(3), num_bound=Integer(10))
>>> while B.rank() != Integer(3):
    ...    B = random_matrix(QQ, Integer(3), num_bound=Integer(10))

>>> B.rref()
[1 0 0]
[0 1 0]
[0 0 1]
```

In this case, since `B` is a matrix over a field (the rational numbers), `rref()` and `echelon_form()` are exactly the same:
Matrices and Spaces of Matrices, Release 10.4

```python
sage: B.echelon_form()
[1 0 0]
[0 1 0]
[0 0 1]
sage: B.echelon_form() is B.rref()
True

>>> from sage.all import *
>>> B.echelon_form()
[1 0 0]
[0 1 0]
[0 0 1]
>>> B.echelon_form() is B.rref()
True
```

Since `echelon_form()` is not implemented for every ring, sometimes behavior varies, as here:

```python
sage: R.<x> = ZZ[]
sage: C = matrix(3, [2,x,x^2, x+1,3-x,-1, 3,2,1])
sage: C.rref()
[1 0 0]
[0 1 0]
[0 0 1]
sage: C.base_ring()
Univariate Polynomial Ring in x over Integer Ring
sage: C.echelon_form()
Traceback (most recent call last):
...
NotImplementedError: Ideal Ideal (2, x + 1) of Univariate Polynomial Ring in x over Integer Ring not principal
Echelon form not implemented over 'Univariate Polynomial Ring in x over Integer Ring'.
sage: C = matrix(3, [2,x,x^2,x+1,3-x,-1,3,2,1/2])
sage: C.echelon_form()
[ 2 x -]
[ x^2 0 1 -]
[15*x^2 - 3/2*x - 31/2]
[ 0 0 5/2*x^3 -]
[15/4*x^2 - 9/4*x + 7/2]
sage: C.rref()
[1 0 0]
[0 1 0]
[0 0 1]
```

```python
>>> from sage.all import *
>>> R = ZZ['x']; (x,) = R._first_ngens(1)
>>> C = matrix(Integer(3), [Integer(2),x,x**Integer(2), x+Integer(1),
-Integer(3)*x,-Integer(1), Integer(3),Integer(2),Integer(1)])
>>> C.rref()
[1 0 0]
[0 1 0]
```

(continues on next page)
[0 0 1]
>>> C.base_ring()
Univariate Polynomial Ring in x over Integer Ring
>>> C.echelon_form()
Traceback (most recent call last):
... 
NotImplementedError: Ideal Ideal (2, x + 1) of Univariate Polynomial Ring in x over Integer Ring not principal
Echelon form not implemented over 'Univariate Polynomial Ring in x over Integer Ring'.
>>> C = matrix(Integer(3), [Integer(2), x, x**Integer(2), x+Integer(1), Integer(3)-x, -Integer(1), Integer(3), Integer(2), Integer(1)/Integer(2)])
>>> C.echelon_form()
\[
\begin{bmatrix}
2 & x & \_ \\
-15*x^2 - 3/2*x - 31/2 & 0 & 1 & \_ \\
-15/4*x^2 - 9/4*x + 7/2 & 0 & 0 & 5/2*x^3 & \_ \\
\end{bmatrix}
\]
>>> C.rref()
\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
\end{bmatrix}
\]

set_block (row, col, block)
Sets the sub-matrix of self, with upper left corner given by row, col to block.

EXAMPLES:

\[
\begin{bmatrix}
0 & 100 & 1 \\
3/2 & 200 & 5/2 \\
3 & 7/2 & 4 \\
\end{bmatrix}
\]

>>> from sage.all import *
>>> A = matrix(QQ, Integer(3), Integer(3), range(Integer(9)))/Integer(2)
>>> B = matrix(ZZ, Integer(2), Integer(1), [Integer(100), Integer(200)])
>>> A.set_block(Integer(0), Integer(1), B)
>>> A
\[
\begin{bmatrix}
0 & 100 & 1 \\
3/2 & 200 & 5/2 \\
3 & 7/2 & 4 \\
\end{bmatrix}
\]

We test that an exception is raised when the block is out of bounds:

\[
\begin{bmatrix}
1 \\
2 \\
3 \\
\end{bmatrix}
\]

Traceback (most recent call last):
IndexError: matrix window index out of range

```python
>>> from sage.all import *
>>> matrix([Integer(1)]).set_block(Integer(0),Integer(1),matrix([Integer(1)]))
Traceback (most recent call last):
... IndexError: matrix window index out of range
```

**smith_form** *(transformation=True, integral=None, exact=True)*

Return a Smith normal form of this matrix.

For a matrix $M$, a Smith normal form is a matrix $S = UMV$ such that:

- $U$ and $V$ are invertible matrices
- the only non-vanishing entries of $S$ are located on the diagonal (though $S$ might not be a square matrix)
- if $d_i$ denotes the entry of $S$ at $(i, i)$, then $d_i$ divides $d_{i+1}$ for all $i$, i.e., the $d_i$ are the ordered *elementary_divisors()* of $M$

Note that the matrices $U$ and $V$ are not uniquely determined and the $d_i$ are only uniquely determined up to units. For some base rings, such as local rings, the $d_i$ might be further normalized, see LOCAL RINGS below.

If the base ring is not a PID, the routine might work, or else it will fail having found an example of a non-principal ideal. Note that we do not call any methods to check whether or not the base ring is a PID, since this might be quite expensive (e.g. for rings of integers of number fields of large degree).

**INPUT:**

- transformation – a boolean (default: True); whether the matrices $U$ and $V$ should be returned
- integral – a subring of the base ring, boolean or None (default: None); the entries of $U$ and $V$ are taken from this subring. If True, the ring is taken to be the ring of integers of the base ring; if False the fraction field of the base ring; if None the base ring itself. When a subring is specified, multiplying by the denominator must map the entries into the subring; in this case the transformation matrices will have entries in this subring.
- exact – a boolean (default: True), only used for local rings/fields. See LOCAL RINGS for more details.

**OUTPUT:**

The matrices $S, U, V$ or the matrix $S$ depending on transformation.

**ALGORITHM:**

If the base ring has a method _matrix_smith_form, use it; note that _matrix_smith_form might choose to further normalize the output.

Otherwise, use the algorithm from Wikipedia article Smith_normal_form.

**LOCAL RINGS:**

Over local rings, we normalize $S$ to only contain powers of the uniformizer.

In order to simplify the precision handling, we truncate the absolute precision of the input matrix to the minimum absolute precision of any of its entries. As long as all of the elementary divisors are nonzero modulo this precision, they can be determined exactly since they are defined to be powers of the uniformizer. In this case, which is specified by the keyword exact=True, one of the transformation matrices will be inexact: $U$ in the case that the number of rows is at least the number of columns, and $V$ otherwise.
If `exact=False`, we instead return an inexact Smith form. Now the transformation matrices are exact and we can deal gracefully with elementary divisors that are zero modulo the working precision. However, the off-diagonal entries of the smith form carry a precision that can affect the precision of future calculations.

See `_matrix_smith_form` on the base ring for more detail.

**EXAMPLES:**

An example over the ring of integers of a number field (of class number 1):

```python
sage: # needs sage.rings.number_field
sage: x = polygen(ZZ, 'x')
sage: OE.<w> = EquationOrder(x^2 - x + 2)
sage: m = Matrix([[1, w], [w, 7]])
sage: d, u, v = m.smith_form()
sage: (d, u, v)

```

(continued on next page)
An example over a field:

```python
sage: m = matrix(GF(17), 3, 3, [11, 5, 1, 3, 6, 8, 1, 16, 0])
sage: d, u, v = m.smith_form()
sage: d
[1 0 0]
[0 1 0]
[0 0 0]
sage: u * m * v == d
True
```

When the base ring has a `ring_of_integers` method and supports denominators, you can get an integral version of the smith form:

```python
sage: m = matrix(QQ, 2, 2, [17/6, 47/6, 25/6, 23/2])
sage: m.smith_form()
(...)
([1/6 0] [ 3 -2] [ 1 3]
[ 0 1/3], [-25 17], [ 0 -1])
```

(continues on next page)
Some examples over non-PID’s work anyway:

```sage
# needs sage.rings.number_field
R.<s> = EquationOrder(x^2 + 5)  # class number 2
A = matrix(R, 2, 2, [s - 1, -s, -s, 2*s + 1])
D, U, V = A.smith_form()
D, U, V

# needs sage.rings.number_field
R = EquationOrder(x**2 + Integer(5), names=('s',)); (s,) = R._first_ngens(1)
A = matrix(R, Integer(2), Integer(2), [s - Integer(1), -s, -2*s, -s - 2])
D, U, V = A.smith_form()
D == U * A * V

from sage.all import *
```
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

True
sage: m = MatrixSpace(OE, 0,0)(0)
sage: d, u, v = m.smith_form(); u * m * v == d
True

>>> from sage.all import *
>>> # needs sage.rings.number_field
>>> m = MatrixSpace(OE, Integer(2),Integer(0))(Integer(0))
>>> d, u, v = m.smith_form(); u * m * v == d
True
>>> m = MatrixSpace(OE, Integer(0),Integer(2))(Integer(0))
>>> d, u, v = m.smith_form(); u * m * v == d
True
>>> m = MatrixSpace(OE, Integer(0),Integer(0))(Integer(0))
>>> d, u, v = m.smith_form(); u * m * v == d
True

Some pathological cases that crashed earlier versions:

sage: # needs sage.rings.number_field
sage: m = Matrix(OE, [[ 2*w, 2*w - 1, -w + 1],
....: [ 2*w + 2, -2*w - 1, w - 1],
....: [-2*w - 1, -2*w - 2, 2*w - 1]])
sage: d, u, v = m.smith_form(); u * m * v == d
True

sage: m = matrix(OE, [[ Integer(2)*w, Integer( 2)*w - Integer(1), -w + Integer(1)],
....: [ Integer(2)*w + Integer(2), -Integer(2)*w - Integer(1), w - Integer(1)],
....: [-Integer(2)*w - Integer(1), -Integer(2)*w - Integer(2), Integer(2)*w - Integer(1)]])
>>> d, u, v = m.smith_form(); u * m * v == d
True

sage: m = matrix(OE, [[ Integer(5)*w - Integer(1), -Integer(2)*w - Integer(2), -Integer(4)*w - Integer(10)],
....: [ Integer(8)*w, -w, w - Integer(1)],
....: [ Integer(1), Integer(1), -Integer(8)]])
>>> d, u, v = m.smith_form(); u * m * v == d
True

Over local fields, we can request the transformation matrices to be integral:

sage: K = Qp(2, 5, print_mode='terse') # needs sage.rings.padics
sage: M = matrix(K, 2, 3,
[1/2, 1, 2, 1/3, 1, 3]) # needs sage.rings.padics
sage: M.smith_form(integral=True) # needs
sage.rings.padics

solve_left( B, check=True, extend=True )
Try to find a solution $X$ to the equation $XA = B$.

If `self` is a matrix $A$, then this function returns a vector or matrix $X$ such that $XA = B$. If $B$ is a vector then $X$ is a vector and if $B$ is a matrix, then $X$ is a matrix.

Over inexact rings, the output of this function may not be an exact solution. For example, over the real or complex double field, this method computes a least-squares solution if the system is not square.

**INPUT:**

- `B` – a matrix or vector
- `extend` – boolean (default: `True`); when set to `True`, some solvers will return solutions over a larger ring than the base ring of the inputs (a typical case are rational solutions for integer linear systems). When set to `False`, a solution over the base ring is returned, with a `ValueError` being raised if none exists.
- `check` – boolean (default: `True`); verify the answer if the system is non-square or rank-deficient, and if its entries lie in an exact ring. Meaningless over most inexact rings, or when the system is square and of full rank.

**OUTPUT:**

If the system is square and has full rank, the unique solution is returned, and no check is done on the answer. Over inexact rings, you should expect this answer to be inexact. Moreover, due to the numerical issues involved, an error may be thrown in this case – specifically if the system is singular but if SageMath fails to notice that.

If the system is not square or does not have full rank, then a solution is attempted via other means. For example, over `RDF` or `CDF` a least-squares solution is returned, as with MATLAB’s “backslash” operator. For most inexact rings, the `check` parameter is ignored because an approximate solution will be returned in any case. Over exact rings, on the other hand, setting the `check` parameter results in an additional test to determine whether or not the answer actually solves the system exactly. If a symbolic system involves only exact elements, its solution can still be checked.

If $B$ is a vector, the result is returned as a vector, as well, and as a matrix, otherwise.

**See also:**

`solve_right()`

**EXAMPLES:**

```python
sage: A = matrix(QQ, 4, 2, [0, -1, 1, 0, -2, 2, 1, 0])
sage: B = matrix(QQ, 2, 2, [1, 0, 1, -1])
sage: X = A.solve_left(B)
sage: X*A == B
True
sage: X == B/A
True
```

```python
>>> from sage.all import *
>>> A = matrix(QQ, Integer(4), Integer(2), [Integer(0), -Integer(1), Integer(1), Integer(0), -Integer(2), Integer(2), Integer(1), Integer(0)])
>>> B = matrix(QQ, Integer(2), Integer(2), [Integer(1), Integer(0), Integer(1), Integer(0)])
>>> X = A.solve_left(B)
>>> X*A == B
True
```
```python
>>> X == B / A
True
```

```python
sage: A = matrix([[3, -1, 0, 0], (1, 1, -2, 0), (0, 0, 0, -3)])
sage: B = matrix(QQ, 3, 1, [0, 0, -1])
sage: A.solve_left(B)
Traceback (most recent call last):
... ValueError: number of columns of self must equal number of columns of right-hand side
```

```python
>>> from sage.all import *
```

```python
sage: A = matrix((Integer(3), -Integer(1), Integer(0), Integer(0)), ...
               (Integer(1), Integer(1), -Integer(2), Integer(0)), ...
               (Integer(0), Integer(0), Integer(0), -Integer(3)))
>>> B = matrix(QQ, Integer(3), Integer(1), [Integer(0), Integer(0), -
                                           Integer(1)])
>>> A.solve_left(B)
Traceback (most recent call last):
... ValueError: number of columns of self must equal number of columns of right-hand side
```

Over the reals:

```python
sage: A = matrix(RDF, 3,3, [1,2,5,7.6,2.3,1,1,2,-1]); A
[ 1.0 2.0 5.0]
[ 7.6 2.3 1.0]
[ 1.0 2.0 -1.0]
sage: b = vector(RDF,[1,2,3])
sage: x = A.solve_left(b); x.zero_at(2e-17) # fix noisy zeroes
# needs scipy
(0.6666666666666666, 0.0, 0.3333333333333333)
sage: x.parent() # needs scipy
Vector space of dimension 3 over Real Double Field
```

```python
>>> from sage.all import *
```

```python
sage: A = matrix(RDF, Integer(3),Integer(3), [Integer(1),Integer(2),Integer(5), ...
                                          RealNumber('7.6'),RealNumber('2.3'),Integer(1),Integer(1),Integer(2),-
                                          Integer(1))]; A
[ 1.0 2.0 5.0]
[ 7.6 2.3 1.0]
[ 1.0 2.0 -1.0]
>>> b = vector(RDF,[Integer(1),Integer(2),Integer(3)])
>>> x = A.solve_left(b); x.zero_at(RealNumber('2e-17')) # fix noisy zeroes
# needs scipy
(0.6666666666666666, 0.0, 0.3333333333333333)
>>> x.parent() # needs scipy
Vector space of dimension 3 over Real Double Field
```

(continues on next page)
Over the complex numbers:

```python
sage: # needs sage.rings.complex_double sage.symbolic
sage: A = matrix(CDF, 
[ [ 0, -1 + 2*I, 1 - 3*I, I],
  [2 + 4*I, -2 + 3*I, -1 + 2*I, -1 - I],
  [ 2 + I, 1 - I, -1, 5],
  [ 3*I, -1 - I, -1 + I, -3 + I]])

sage: b = vector(CDF, [2 -3*I, 3, -2 + 3*I, 8])

sage: x = A.solve_left(b); x
(-1.55765124... - 0.644483985...*I, 0.183274021... + 0.286476868...*I,
 0.270818505... + 0.246619217...*I, -1.69003558... - 0.828113879...*I)

sage: x.parent()
Vector space of dimension 4 over Complex Double Field

sage: abs(x*A - b) < 1e-14
True
```

If \(b\) is given as a matrix, the result will be a matrix, as well:

```python
>>> from sage.all import *

>>> A = matrix(CDF, 
[ [ Integer(0), -Integer(1) + Integer(2)*I, 
  Integer(1) - Integer(3)*I, I],
  [Integer(2) + Integer(4)*I, -Integer(2) + Integer(3)*I, 
  Integer(1) + Integer(2)*I, -Integer(1) - I],
  [ Integer(2) + I, Integer( 1) - I, -Integer(1), 
  Integer(5)],
  [ Integer(3)*I, -Integer(1) - I, -Integer(1) + I, 
  -Integer(3) + I]])

>>> b = vector(CDF, [Integer(2) -Integer(3)*I, Integer(3), -Integer(2) + 
  Integer(3)*I, Integer(8)])

>>> x = A.solve_left(b); x
(-6.495454545454545 4.068181818181818 3.1363636363636354
 0.5277272727272727 -0.2340909090909091 -0.36818181818181817)

>>> x.parent()
Vector space of dimension 4 over Complex Double Field

>>> abs(x*A - b) < RealNumber('1e-14')
True
```

If \(b\) is given as a matrix, the result will be a matrix, as well:
If $A$ is a non-square matrix, the result is a least-squares solution. For a tall matrix, this may give a solution with a least-squares error of almost zero:

```python
sage: A = matrix(RDF, 3, 2, [1, 3, 4, 2, 0, -3])
sage: b = vector(RDF, [5, 6])
sage: x = A.solve_left(b)  # needs scipy
sage: (x * A - b).norm() < 1e-14  # needs scipy
True
```

For a wide matrix $A$, the error is usually not small:

```python
sage: A = matrix(RDF, 2, 3, [1, 3, 4, 2, 0, -3])
sage: b = vector(RDF, [5, 6, 1])
sage: x = A.solve_left(b)  # needs scipy
sage: (x * A - b).norm() < 1e-14  # needs scipy
0.9723055853282466
```

Try to find a solution $X$ to the equation $AX = B$.

If `self` is a matrix $A$, then this function returns a vector or matrix $X$ such that $AX = B$. If $B$ is a vector then $X$ is a vector and if $B$ is a matrix, then $X$ is a matrix.

Over inexact rings, the output of this function may not be an exact solution. For example, over the real or complex double field, this method computes a least-squares solution if the system is not square.
INPUT:

- B – a matrix or vector
- extend – boolean (default: True); when set to True, some solvers will return solutions over a larger ring than the base ring of the inputs (a typical case are rational solutions for integer linear systems). When set to False, a solution over the base ring is returned, with a ValueError being raised if none exists.
- check – boolean (default: True); verify the answer if the system is non-square or rank-deficient, and if its entries lie in an exact ring. Meaningless over most inexact rings, or when the system is square and of full rank.

OUTPUT:

If the system is square and has full rank, the unique solution is returned, and no check is done on the answer. Over inexact rings, you should expect this answer to be inexact. Moreover, due to the numerical issues involved, an error may be thrown in this case – specifically if the system is singular but if SageMath fails to notice that.

If the system is not square or does not have full rank, then a solution is attempted via other means. For example, over RDF or CDF a least-squares solution is returned, as with MATLAB’s “backslash” operator. For most inexact rings, the check parameter is ignored because an approximate solution will be returned in any case. Over exact rings, on the other hand, setting the check parameter results in an additional test to determine whether or not the answer actually solves the system exactly. If a symbolic system involves only exact elements, its solution can still be checked.

If B is a vector, the result is returned as a vector, as well, and as a matrix, otherwise.

See also:
solve_left() 

EXAMPLES:

```python
sage: A = matrix(QQ, 3, [1,2,3,-1,2,5,2,3,1])
sage: b = vector(QQ, [1,2,3])
sage: x = A.solve_right(b); x
(-13/12, 23/12, -7/12)
sage: A * x
(1, 2, 3)
```
sage: A*X == B
True

>>> from sage.all import *

>>> A = matrix(QQ, Integer(2),Integer(4), [Integer(0), -Integer(1),
   ←Integer(1), Integer(0), -Integer(2), Integer(2), Integer(1), Integer(0)])
>>> B = matrix(QQ, Integer(2),Integer(2), [Integer(1), Integer(0), Integer(1),
   ←-Integer(1)])
>>> X = A.solve_right(B); X
[-3/2 1/2]
[ -1 0]
[ 0 0]
[ 0 0]

>>> A*X == B
True

Another nonsingular example:

sage: A = matrix(QQ,2,3, [1,2,3,2,4,6]); v = vector([-1/2,-1])
sage: x = A.solve_right(v); x
(-1/2, 0, 0)
sage: A*x == v
True

>>> from sage.all import *

>>> A = matrix(QQ,Integer(2),Integer(3), [Integer(1),Integer(2),Integer(3),
   ←Integer(2),Integer(4),Integer(6)]); v = vector([-Integer(1)/Integer(2),-
   ←Integer(1)])
>>> x = A.solve_right(v); x
(-1/2, 0, 0)

An example in which there is no solution:

sage: A = matrix(QQ,2,3, [1,2,3,2,4,6]); v = vector([1,1])
sage: A.solve_right(v)
Traceback (most recent call last):
  ...
ValueError: matrix equation has no solutions

>>> from sage.all import *

>>> A = matrix(QQ,Integer(2),Integer(3), [Integer(1),Integer(2),Integer(3),
   ←Integer(2),Integer(4),Integer(6)]), Integer(3), [Integer(1),Integer(2),Integer(3),
   ←Integer(2),Integer(4),Integer(6)]); v = vector([-Integer(1),-Integer(2)])
>>> A.solve_right(v)
(-1, 0, 0)

An example in which there is no solution:

sage: A = matrix(QQ,2,3, [1,2,3,2,4,6]); v = vector([1,1])
sage: A.solve_right(v)
Traceback (most recent call last):
  ...
ValueError: matrix equation has no solutions

>>> from sage.all import *

>>> A = matrix(QQ,Integer(2),Integer(3), [Integer(1),Integer(2),Integer(3),
   ←Integer(2),Integer(4),Integer(6)]), Integer(3), [Integer(1),Integer(2),Integer(3),
   ←Integer(2),Integer(4),Integer(6)]); v = vector([-Integer(1),-Integer(2)])

(continues on next page)
A `ValueError` is raised if the input is invalid:

```python
sage: A = matrix(QQ, 4,2, [0, -1, 1, 0, -2, 2, 1, 0])
sage: B = matrix(QQ, 2,2, [1, 0, 1, -1])
sage: X = A.solve_right(B)
```

Traceback (most recent call last):
...
ValueError: number of rows of self must equal number of rows of right-hand side

We solve with A singular:

```python
sage: A = matrix(QQ, 2,3, 
[1,2,3,2,4,6]); B = matrix(QQ, 2,2, 
[6, -6, 12, -12])
sage: X = A.solve_right(B); X
```

```python
[ 6 -6
[ 0 0]
[ 0 0]
sage: A*X == B
True
```

We illustrate left associativity, etc., of the `solve_right` operator.

```python
sage: A = matrix(QQ, 2, [1,2,3,4])
sage: A.solve_right(A)
```

```python
[1 0]
[0 1]
sage: (A.solve_right(A)).solve_right(A)
```

Solving a system over the p-adics:

```python
sage: # needs sage.rings.padics
sage: k = Qp(5, 4)
sage: a = matrix(k, 3, [1,7,3, 2,5,4, 1,1,2]); a
[ 1 + O(5^4) 2 + 5 + O(5^4) 3 + O(5^4)]
[ 2 + O(5^4) 5 + O(5^5) 4 + O(5^4)]
[ 1 + O(5^4) 1 + O(5^4) 2 + O(5^4)]
sage: v = vector(k, 3, [1,2,3])
sage: x = a.solve_right(v); x
(4 + 5 + 5^2 + 3*5^3 + O(5^4), 2 + 5 + 3*5^2 + 5^3 + O(5^4), 1 + 5 + O(5^4))
sage: a * x == v
True
```

Solving a system of linear equations symbolically using symbolic matrices:

```python
sage: # needs sage.symbolic
sage: var('a,b,c,d,x,y')
(a, b, c, d, x, y)
sage: A = matrix(SR, 2, [a,b,c,d]); A
[a b]
[c d]
sage: result = vector(SR, [3,5]); result
(3, 5)
sage: soln = A.solve_right(result); soln
(-b*(3*c/a - 5)/(a*b*c/a - d)) + 3/a, (3*c/a - 5)/(b*c/a - d))
sage: (a*x + b*y).subs(x=soln[0], y=soln[1]).simplify_full()
3
sage: (c*x + d*y).subs(x=soln[0], y=soln[1]).simplify_full()
5
sage: (A*soln).apply_map(lambda x: x.simplify_full())
(3, 5)
```

(continues on next page)
Over inexact rings, the output of this function may not be an exact solution. For example, over the real or complex double field, this computes a least-squares solution:

```python
sage: A = matrix(RDF, 3, 2, [1, 3, 4, 2, 0, -3])
sage: b = vector(RDF, [5, 6, 1])
sage: A.solve_right(b)  # tol 1e-14
(1.4782608695652177, 0.35177865612648235)
sage: -(A.T * A) * A.T * b  # closed form solution, tol 1e-14
(1.4782608695652177, 0.35177865612648235)
```

Over the reals:

```python
sage: A = matrix(RDF, 3, 3, [1,2,5,7.6,2.3,1,1,2,-1]); A
[ 1.0 2.0 5.0]
[ 7.6 2.3 1.0]
[ 1.0 2.0 -1.0]
sage: b = vector(RDF, [1,2,3])
sage: x = A.solve_right(b); x  # tol 1e-14
(-0.1136950904392765, 1.3901808785529717, -0.33333333333333337)
sage: x.parent()  # needs scipy

\]

\[
\text{# needs scipy}
\]

\[
\text{Vector space of dimension 4 over Complex Double Field}
\]

\[
\text{abs}(A^x - b) < 1e-14
\]

\[
\text{True}
\]
If \( b \) is given as a matrix, the result will be a matrix, as well:

```
sage: A = matrix(RDF, 3, 3, [1, 2, 2, 3, 4, 5, 2, 2, 2])
sage: b = matrix(RDF, 3, 2, [3, 2, 3, 2, 3, 2])
sage: A.solve_right(b)  # tol 1e-14
\[-3.0 -2.0\]
```

If \( A \) is a non-square matrix, the result is a least-squares solution. For a wide matrix, this may give a solution with a least-squares error of almost zero:

```
sage: A = matrix(RDF, 2, 3, [1, 3, 4, 2, 0, -3])
sage: b = vector(RDF, [5, 6])
sage: x = A.solve_right(b)
```

```
sage: (A * x - b).norm() < 1e-14
True
```

For a tall matrix \( A \), the error is usually not small:

```
sage: A = matrix(RDF, 3, 2, [1, 3, 4, 2, 0, -3])
sage: b = vector(RDF, [5, 6, 1])
sage: x = A.solve_right(b)
```

```
sage: (A * x - b).norm()  # tol 1e-14
3.2692119900020438
```

---

(continues on next page)
x = A.solve_right(b)  # needs scipy
(A * x - b).norm()  # tol 1e-14  # needs scipy
3.2692119900020438

subdivide(row_lines=None, col_lines=None)

Divides self into logical submatrices which can then be queried and extracted.

If a subdivision already exists, this method forgets the previous subdivision and flushes the cache.

INPUT:

• row_lines—None, an integer, or a list of integers (lines at which self must be split)
• col_lines—None, an integer, or a list of integers (columns at which self must be split)

OUTPUT: None but changes self

Note: One may also pass a tuple into the first argument which will be interpreted as (row_lines, col_lines).

EXAMPLES:

sage: # needs sage.libs.pari
sage: M = matrix(5, 5, prime_range(100))
sage: M.subdivide(2,3); M

[31|37 41|43 47]
[+--------+-]
[53|59 61|67 71]
[+--------+-]
[73|79 83|89 97]
```

**subdivision** *(i, j)*

Returns an immutable copy of the *(i,j)*th submatrix of self, according to a previously set subdivision.

Before a subdivision is set, the only valid arguments are (0,0) which returns self.

**EXAMPLES:**
Matrices and Spaces of Matrices, Release 10.4

...it handles size-zero subdivisions as well.

>>> from sage.all import *

>>> M = matrix(Integer(3), Integer(4), range(Integer(12)))

>>> M.subdivide([Integer(0)], [Integer(0), Integer(2), Integer(2), Integer(4)]); M

It handles size-zero subdivisions as well.

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```
>>> M.subdivision(Integer(0),Integer(0))
[]
>>> M.subdivision(Integer(1),Integer(1))
[0 1]

sage: M.subdivision_entry(1,0,0,0)
15
sage: M.subdivision_entry(1,1,1,1)
24

```
Even though this entry exists in the matrix, the index is invalid for the submatrix.

```
sage: M.subdivision_entry(0,0,4,0)
Traceback (most recent call last):
...
IndexError: Submatrix 0,0 has no entry 4,0
```

```
>>> from sage.all import *

>>> M.subdivision_entry(Integer(0),Integer(0),Integer(4),Integer(0))
Traceback (most recent call last):
...
IndexError: Submatrix 0,0 has no entry 4,0
```

**subdivisions()**

Returns the current subdivision of self.

**EXAMPLES:**

```
sage: M = matrix(5, 5, range(25))
sage: M.subdivisions()
([], [])
sage: M.subdivide(2,3)
sage: M.subdivisions()
([2], [3])
sage: N = M.parent()(1)
sage: N.subdivide(M.subdivisions()); N
[1 0 0|0 0]
[0 1 0|0 0]
[-----+---]
[0 0 1|0 0]
[0 0 0|1 0]
[0 0 0|0 1]
```

```
>>> from sage.all import *

>>> M = matrix(Integer(5), Integer(5), range(Integer(25)))

>>> M.subdivisions()
([], [])

>>> M.subdivide(Integer(2),Integer(3))

>>> M.subdivisions()
([2], [3])

>>> N = M.parent()(Integer(1))

>>> N.subdivide(M.subdivisions()); N
[1 0 0|0 0]
[0 1 0|0 0]
[-----+---]
[0 0 1|0 0]
[0 0 0|1 0]
[0 0 0|0 1]
```

**subs(***args, **kwds)**

Substitute values to the variables in that matrix.

All the arguments are transmitted unchanged to the method `subs` of the coefficients.

**EXAMPLES:**

```
sage: # needs sage.symbolic
sage: var('a,b,d,e')
```

(continues on next page)
The parent of the newly created matrix might be different from the initial one. It depends on what the method `.subs` does on coefficients (see Issue #19045):

```
sage: x = polygen(ZZ)
sage: m = matrix([[x]])
sage: m2 = m.subs(x=2)
sage: m2.parent()
Full MatrixSpace of 1 by 1 dense matrices over Integer Ring
sage: m1 = m.subs(x=RDF(Integer(1)))
sage: m1.parent()
Full MatrixSpace of 1 by 1 dense matrices over Real Double Field
```

However, sparse matrices remain sparse:

```
sage: m = matrix({(3,2): -x, (59,38): x^2 + 2}, nrows=1000, ncols=1000)
sage: m1 = m.subs(x=1)
sage: m1.is_sparse()
True
```
symplectic_form()

Find a symplectic form for self if self is an anti-symmetric, alternating matrix defined over a field.

Returns a pair (F, C) such that the rows of C form a symplectic basis for self and F = C * self * C.transpose().

Raises a ValueError if not over a field, or self is not anti-symmetric, or self is not alternating.

Anti-symmetric means that $M = -M^t$. Alternating means that the diagonal of $M$ is identically zero.

A symplectic basis is a basis of the form $e_1, \ldots, e_j, f_1, \ldots f_j, z_1, \ldots, z_k$ such that

- $z_i M v^t = 0$ for all vectors $v$
- $e_i M e_j^t = 0$ for all $i, j$
- $f_i M f_j^t = 0$ for all $i, j$
- $e_i M f_i^t = 1$ for all $i$
- $e_i M f_j^t = 0$ for all $i$ not equal $j$.

See the example for a pictorial description of such a basis.

EXAMPLES:

```python
sage: E = matrix(QQ, 8, 8, [0, -1/2, -2, 1/2, 2, 0, -2, 1, 1/2, 0, -1, -3, 0, ...
-2, 5/2, -3, 2, 1, 0, 3/2, -1, 0, -1, -2, -1/2, 3, -3/2, 0, 1, 3/2, -1/2, -1/2, -2, -2, 0, 1, -1, 0, 0, -3/2, 0, 0, 1/2, -2, 2, -5/2, 1, 1/2, 0]); E
sage: F, C = E.symplectic_form(); F
[ 0 0 0 0 0 0 0 0]
[ 0 0 0 0 0 0 0 0]

\end{bmatrix}
\]

>>> F == C * E * C.transpose()
True

tensor_product (A, subdivide=True)

Returns the tensor product of two matrices.

INPUT:

- A – a matrix
- subdivide – (default: True); whether or not to return natural subdivisions with the matrix

OUTPUT:

Replace each element of self by a copy of A, but first create a scalar multiple of A by the element it replaces. So if self is an m \times n matrix and A is a p \times q matrix, then the tensor product is an mp \times nq matrix. By default, the matrix will be subdivided into submatrices of size p \times q.

EXAMPLES:

\[
\begin{bmatrix}
\begin{pmatrix}
-1 & 0 \\
\end{pmatrix}, \begin{pmatrix}
-1/2 & -1 & 0 & 1/2 & 0 & 0 & -1/2 & -1/2
\end{pmatrix}
\end{bmatrix}
\]

Matrices and Spaces of Matrices, Release 10.4

from sage.all import *

M1=Matrix(QQ, [[-Integer(1),Integer(0),-Integer(1)/Integer(2)],[Integer(1),-Integer(1)],-Integer(1)])
M2=Matrix(ZZ, [[Integer(1),-Integer(1),Integer(2)],[-Integer(2),Integer(4),-Integer(2)],-Integer(2)])

M1.tensor_product(M2)

M2.tensor_product(M1)

Subdivisions can be optionally suppressed.

sage: M1.tensor_product(M2, subdivide=False)

Different base rings are handled sensibly.

sage: A = matrix(ZZ, 2, 3, range(6))
sage: B = matrix(FiniteField(23), 3, 4, range(12))
sage: C = matrix(FiniteField(29), 4, 5, range(20))
sage: D = A.tensor_product(B)
sage: E = C.tensor_product(B)

Traceback (most recent call last):
...TypeError: unsupported operand parent(s) for *:
'Finite Field of size 29' and
'Full MatrixSpace of 3 by 4 dense matrices over Finite Field of size 23'
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> range(Integer(12))
>>> C = matrix(FiniteField(Integer(29)), Integer(4), Integer(5),
>>>     range(Integer(20)))
>>> D = A.tensor_product(B)
>>> D.parent()
Full MatrixSpace of 6 by 12 dense matrices over Finite Field of size 23
>>> E = C.tensor_product(B)
Traceback (most recent call last):
... TypeError: unsupported operand parent(s) for *:
'Finite Field of size 29' and
'Full MatrixSpace of 3 by 4 dense matrices over Finite Field of size 23'
```

The input is checked to be sure it is a matrix.

```python
sage: A = matrix(QQ, 2, 2, range(4))
sage: A.tensor_product('junk')
Traceback (most recent call last):
... TypeError: tensor product requires a second matrix, not junk
```}

```python
>>> from sage.all import *
>>> A = matrix(Integer(3), Integer(3), range(Integer(9))); a
[0 1 2]
[3 4 5]
[6 7 8]
```

```
trace()

Return the trace of self, which is the sum of the diagonal entries of self.

INPUT:

• self – a square matrix

OUTPUT: element of the base ring of self

EXAMPLES:

```
sage: a = matrix(3, 3, range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.trace()
12
```

```
sage: a = matrix({(1,1): 10, (2,1): -3, (2,2): 4/3}); a
[ 0  0  0]
[ 0 10  0]
[ 0 -3 4/3]
sage: a.trace()
34/3
```
```
```
trace_of_product (other)

Returns the trace of self \* other without computing the entire product.

EXAMPLES:

```python
sage: M = random_matrix(ZZ, 10, 20)
sage: N = random_matrix(ZZ, 20, 10)
sage: M.trace_of_product(N) == (M*N).trace()
True
```

```python
from sage.all import *
```

```python
>>> M = random_matrix(ZZ, Integer(10), Integer(20))
>>> N = random_matrix(ZZ, Integer(20), Integer(10))
>>> M.trace_of_product(N) == (M*N).trace()
True
```

visualize_structure (maxsize=512)

Visualize the non-zero entries

White pixels are put at positions with zero entries. If 'maxsize' is given, then the maximal dimension in either x or y direction is set to 'maxsize' depending on which is bigger. If the image is scaled, the darkness of the pixel reflects how many of the represented entries are nonzero. So if e.g. one image pixel actually represents a 2x2 submatrix, the dot is darker the more of the four values are nonzero.

INPUT:

- maxsize – integer (default: 512). Maximal dimension in either x or y direction of the resulting image. If None or a maxsize larger than max(self.nrows(), self.ncols()) is given the image will have the same pixelsize as the matrix dimensions.

OUTPUT:

Bitmap image as an instance of Image.

EXAMPLES:

```python
sage: # needs sage.rings.real_mpfr
sage: M = random_matrix(CC, 5, 7)
sage: for i in range(5): M[i,i] = 0
sage: M[4, 0] = M[0, 6] = M[4, 6] = 0
sage: img = M.visualize_structure(); img
# needs pillow
7x5px 24-bit RGB image
```

```python
from sage.all import *
```

```python
>>> from sage.all import *
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> M = random_matrix(CC, Integer(5), Integer(7))
>>> for i in range(Integer(5)): M[i,i] = Integer(0)
>>> M[Integer(4), Integer(0)] = M[Integer(0), Integer(6)] = M[Integer(4), Integer(6)] = Integer(0)
>>> img = M.visualize_structure(); img  # needs pillow
7x5px 24-bit RGB image
```

You can use `save()` to save the resulting image:

```python
sage: # needs pillow sage.rings.real_mpfr
sage: filename = tmp_filename(ext='.png')
sage: img.save(filename)
```

```python
>>> from sage.all import *
>>> # needs pillow sage.rings.real_mpfr
>>> filename = tmp_filename(ext='.png')
```n
```python
>>> with open(filename, 'rb') as fobj:
...     fobj.read().startswith(b'\x89PNG')
True
```n

**wiedemann** (*i, t=0*)

Application of Wiedemann’s algorithm to the *i*-th standard basis vector.

**INPUT:**

- `i` – an integer
- `t` – an integer (default: 0) if `t` is nonzero, use only the first `t` linear recurrence relations.

**IMPLEMENTATION:** This is a toy implementation.

**EXAMPLES:**

```python
sage: t = matrix(QQ, 3, 3, range(9)); t
[0 1 2]
[3 4 5]
[6 7 8]
sage: t.wiedemann(0)
x^2 - 12*x - 18
sage: t.charpoly()  # needs sage.libs.pari
x^3 - 12*x^2 - 18*x
```

```python
>>> from sage.all import *
>>> t = matrix(QQ, Integer(3), Integer(3), range(Integer(9))); t
[0 1 2]
[3 4 5]
[6 7 8]
```n
```python
>>> t.wiedemann(Integer(0))
x^2 - 12*x - 18
>>> t.charpoly()  # needs sage.libs.pari
x^3 - 12*x^2 - 18*x
```n
**zigzag_form**(subdivide=True, transformation=False)

Find a matrix in ZigZag form that is similar to self.

**INPUT:**

- **self** – a square matrix with entries from an exact field.
- **transformation** – (default: False); if True return a change-of-basis matrix relating the matrix and its ZigZag form.
- **subdivide** – (default: True); if True the ZigZag form matrix is subdivided according to the companion matrices described in the output section below.

**OUTPUT:**

A matrix in ZigZag form has blocks on the main diagonal that are companion matrices. The first companion matrix has ones just below the main diagonal. The last column has the negatives of coefficients of a monic polynomial, but not the leading one. Low degree monomials have their coefficients in the earlier rows. The second companion matrix is like the first only transposed. The third is like the first. The fourth is like the second. And so on.

These blocks on the main diagonal define blocks just off the diagonal. To the right of the first companion matrix, and above the second companion matrix is a block that is totally zero, except the entry of the first row and first column may be a one. Below the second block and to the left of the third block is a block that is totally zero, except the entry of the first row and first column may be one. This alternating pattern continues. It may now be apparent how this form gets its name. Any other entry of the matrix is zero. So this form is reminiscent of rational canonical form and is a good precursor to that form.

If transformation is True, then the output is a pair of matrices. The first is the form $Z$ and the second is an invertible matrix $U$ such that $U^{-1}*self*U$ equals $Z$. In other words, the representation of self with respect to the columns of $U$ will be $Z$.

If subdivide is True then the matrix returned as the form is partitioned according to the companion matrices and these may be manipulated by several different matrix methods.

For output that may be more useful as input to other routines, see the helper method _zigzag_form().

**Note:** An effort has been made to optimize computation of the form, but no such work has been done for the computation of the transformation matrix, so for fastest results do not request the transformation matrix.

**ALGORITHM:**

ZigZag form, and its computation, are due to Arne Storjohann and are described in [Sto2000] and [Sto1998], where the former is more representative of the code here.

**EXAMPLES:**

Two examples that illustrate ZigZag form well. Notice that this is not a canonical form. The two matrices below are similar, since they have equal Jordan canonical forms, yet their ZigZag forms are quite different. In other words, while the computation of the form is deterministic, the final result, when viewed as a property of a linear transformation, is dependent on the basis used for the matrix representation.

```python
sage: A = matrix(QQ, [[-68, 69, -27, -11, -65, 9, -181, -32],
....: [-52, 52, -27, -8, -52, -16, -133, -14],
....: [ 92, -97, 47, 14, 90, 32, 241, 18],
....: [139, -144, 60, 18, 148, -10, 362, 77],
....: [ 40, -41, 12, 6, 45, -24, 105, 42],
....: [-46, 48, -20, -7, -47, 0, -122, -22],
....: [-26, 27, -13, -4, -29, -6, -66, -14],
....: [ 9, -27, 11, -85, -14, 4, -101, -17]]
```

  -\text{Integer}(9), & \text{Integer}(13), & \text{Integer}(17), & -\text{Integer}(3), & \\
\end{bmatrix}) \]

\[ Z, U = D.\text{zigzag_form}(\text{transformation} = \text{True}) \]

\[ Z \approx \begin{matrix}
  & 0 & -4 & 0 & 0 & 0 & 0 & 0 \\
 1 & 4 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{matrix} \]
ZigZag form is achieved entirely with the operations of the field, so while the eigenvalues may lie outside the field, this does not impede the computation of the form.
Subdivisions are optional.

```
sage: F.<a> = GF(5^4)                   # needs sage.rings.finite_rings
sage: A = matrix(F, [[ a, 0, 0, a + 3],       # needs sage.rings.finite_rings
                [ 0, a^2 + 1, 0, 0],
                [ 0, 0,a^3, 0],
                [a^2 +4 , 0, 0,a + 2]])
sage: A.zigzag_form(subdivide=False)     # needs sage.rings.finite_rings
```

```
>>> from sage.all import *

>>> F = GF(Integer(5)**Integer(4), names=('a',)); (a,) = F._first_ngens(1)# needs sage.rings.finite_rings
>>> A = matrix(F, [[ a, Integer(0), Integer(0), a + Integer(3)],       # needs sage.rings.finite_rings
                [ 0, a^2 + 1, 0, 0],
                [ 0, 0,a^3, 0],
                [a^2 +Integer(4) , 0, 0, a + 2]])

>>> A.zigzag_form(subdivide=False)     # needs sage.rings.finite_rings
```

NotImplementedError: algebraic closures of finite fields are only implemented for prime fields
exception sage.matrix.matrix2.NotFullRankError

Bases: ValueError

An error that indicates that a matrix is not of full rank.

The fact that a square system is rank-deficient sometimes only becomes apparent while attempting to solve it. The methods Matrix.solve_left() and Matrix.solve_right() defer to Matrix._solve_right_nonsingular_square() for square systems, and that method raises this error if the system turns out to be singular.

sage.matrix.matrix2.decomp_seq(v)

This function is used internally be the decomposition matrix method. It takes a list of tuples and produces a sequence that is correctly sorted and prints with carriage returns.

EXAMPLES:

```python
sage: from sage.matrix.matrix2 import decomp_seq
sage: V = [(QQ^3, 2), (QQ^2, 1)]
sage: decomp_seq(V)
[(Vector space of dimension 2 over Rational Field, 1),
 (Vector space of dimension 3 over Rational Field, 2)]
```

```python
>>> from sage.all import *
>>> from sage.matrix.matrix2 import decomp_seq

>>> V = [(QQ**Integer(3), Integer(2)), (QQ**Integer(2), Integer(1))]
>>> decomp_seq(V)
[(Vector space of dimension 2 over Rational Field, 1),
 (Vector space of dimension 3 over Rational Field, 2)]
```

sage.matrix.matrix2.ideal_or_fractional(R, *args)
Sage implements asymptotically fast echelon form and matrix multiplication algorithms.

```python
class sage.matrix.strassen.int_range(indices=None, range=None):
    Bases: object

    Represent a list of integers as a list of integer intervals.

    **Note:** Repetitions are not considered.
```

Useful class for dealing with pivots in the strassen echelon, could have much more general application

**INPUT:**
It can be one of the following:

- `indices` – integer, start of the unique interval
- `range` – integer, length of the unique interval

**OR**

- `indices` – list of integers, the integers to wrap into intervals

**OR**

- `indices` – None (default), shortcut for an empty list

**OUTPUT:**
An instance of `int_range`, i.e. a list of pairs `(start, length)`.

**EXAMPLES:**

From a pair of integers:

```python
sage: from sage.matrix.strassen import int_range
sage: int_range(2, 4)
[(2, 4)]
```

```python
>>> from sage.all import *
>>> from sage.matrix.strassen import int_range
>>> int_range(Integer(2), Integer(4))
[(2, 4)]
```

Default:
sage: int_range()
[]

>>> from sage.all import *

>>> int_range()
[]

From a list of integers:

sage: int_range([1,2,3,4])
[(1, 4)]
sage: int_range([1,2,3,4,6,7,8])
[(1, 4), (6, 3)]
sage: int_range([1,2,3,4,100,101,102])
[(1, 4), (100, 3)]
sage: int_range([1,1000,2,101,3,4,100,102])
[(1, 4), (100, 3), (1000, 1)]

>>> from sage.all import *

>>> int_range([Integer(1),Integer(2),Integer(3),Integer(4)])
[(1, 4)]
>>> int_range([Integer(1),Integer(2),Integer(3),Integer(4),Integer(6),Integer(7),
Integer(8)])
[(1, 4), (6, 3)]
>>> int_range([Integer(1),Integer(2),Integer(3),Integer(4),Integer(100),
Integer(101),Integer(102)])
[(1, 4), (100, 3)]
>>> int_range([Integer(1),Integer(1000),Integer(2),Integer(101),Integer(3),
Integer(4),Integer(100),Integer(102)])
[(1, 4), (100, 3), (1000, 1)]

Repetitions are not considered:

sage: int_range([1,2,3])
[(1, 3)]

sage: int_range([1,1,1,1,2,2,2,3])
[(1, 3)]

>>> from sage.all import *

>>> int_range([Integer(1),Integer(2),Integer(3)])
[(1, 3)]
>>> int_range([Integer(1),Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
Integer(2),Integer(3)])
[(1, 3)]

AUTHORS:

• Robert Bradshaw

intervals()

Return the list of intervals.

OUTPUT:

A list of pairs of integers.

EXAMPLES:
sage: from sage.matrix.strassen import int_range
sage: I = int_range([4, 5, 6, 20, 21, 22, 23])
sage: I.intervals()
[(4, 3), (20, 4)]
sage: type(I.intervals())
<... 'list'>

```python
>>> from sage.all import *
>>> from sage.matrix.strassen import int_range
>>> I = int_range([Integer(4), Integer(5), Integer(6), Integer(20), Integer(21),
                 Integer(22), Integer(23)])
>>> I.intervals()
[(4, 3), (20, 4)]
>>> type(I.intervals())
<... 'list'>
```

**to_list()**

Return the (sorted) list of integers represented by this object.

**OUTPUT:**

A list of integers.

**EXAMPLES:**

```python
sage: from sage.matrix.strassen import int_range
sage: I = int_range([6, 20, 21, 4, 5, 22, 23])
sage: I.to_list()
[4, 5, 6, 20, 21, 22, 23]
```

```python
>>> from sage.all import *
>>> from sage.matrix.strassen import int_range
>>> I = int_range([Integer(6), Integer(20), Integer(21), Integer(4), Integer(5),
                 Integer(22), Integer(23)])
>>> I.to_list()
[4, 5, 6, 20, 21, 22, 23]
```

```python
sage: I = int_range(34, 9)
sage: I.to_list()
[34, 35, 36, 37, 38, 39, 40, 41, 42]
```

```python
>>> from sage.all import *
>>> from sage.matrix.strassen import int_range
>>> I = int_range(Integer(34), Integer(9))
>>> I.to_list()
[34, 35, 36, 37, 38, 39, 40, 41, 42]
```

Repetitions are not considered:

```python
sage: I = int_range([1, 1, 1, 1, 2, 2, 2, 3])
sage: I.to_list()
[1, 2, 3]
```

```python
>>> from sage.all import *
>>> from sage.matrix.strassen import int_range
>>> I = int_range([Integer(1), Integer(1), Integer(1), Integer(1), Integer(2),
                 Integer(2), Integer(2), Integer(3)])
>>> I.to_list()
[1, 2, 3]
```
sage.matrix.strassen.strassen_echelon(A, cutoff)

Compute echelon form, in place. Internal function, call with M.echelonize(algorithm=\"strassen\") Based on work of Robert Bradshaw and David Harvey at MSRI workshop in 2006.

INPUT:

- A – matrix window
- cutoff – size at which algorithm reverts to naive Gaussian elimination and multiplication must be at least 1.

OUTPUT: The list of pivot columns

EXAMPLES:

```sage
A = matrix(QQ, 7, [5, 0, 0, 0, 0, -1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, -1, 3, 1,
-2, 0, -1, 0, -1, 0, 1, 2, -1, 1, 0, -1, 0, 1, 3, -1, 1, 0, 0, -2, 0, 2, 0, 1, 0,
-2, 0, -1, 0, 1, 0, 1])
B = A.__copy__(); B._echelon_strassen(1); B
[ 1 0 0 0 0 0 0]
[ 0 1 0 -1 0 1 0]
[ 0 0 1 0 0 0 0]
[ 0 0 0 0 1 0 0]
[ 0 0 0 0 0 0 1]
[ 0 0 0 0 0 0 0]
[ 0 0 0 0 0 0 0]
sage: C = A.__copy__(); C._echelon_strassen(2); C == B
True
sage: C = A.__copy__(); C._echelon_strassen(4); C == B
True
sage: n = 32; A = matrix(Integers(389), n, range(n^2))
sage: B = A.__copy__(); B._echelon_in_place_classical()
sage: C = A.__copy__(); C._echelon_strassen(2)
sage: B == C
True
```
AUTHORS:

- Robert Bradshaw

sage.matrix.strassen.strassen_window_multiply(C, A, B, cutoff)

Multiplies the submatrices specified by A and B, places result in C. Assumes that A and B have compatible dimensions to be multiplied, and that C is the correct size to receive the product, and that they are all defined over the same ring.

Uses strassen multiplication at high levels and then uses MatrixWindow methods at low levels. EXAMPLES: The following matrix dimensions are chosen especially to exercise the eight possible parity combinations that could occur while subdividing the matrix in the strassen recursion. The base case in both cases will be a (4x5) matrix times a (5x6) matrix.

AUTHORS:

- David Harvey
- Simon King (2011-07): Improve memory efficiency; Issue #11610

sage.matrix.strassen.test(n, m, R, c=2)

INPUT:

- n – integer
- m – integer
- R – ring
- c – integer (default:2)

EXAMPLES:
>>> from sage.all import *
>>> from sage.matrix.strassen import test
>>> for n in range(Integer(5)):
...     print("{}").format(n, test(Integer(2)*n,n,Frac(QQ['x']),Integer(2))))
0 True
1 True
2 True
3 True
4 True
MINIMAL POLYNOMIALS OF LINEAR RECURRENCE SEQUENCES

AUTHORS:
• William Stein

\texttt{sage.matrix.berlekamp_massey.berlekamp_massey}(a)

Use the Berlekamp-Massey algorithm to find the minimal polynomial of a linear recurrence sequence \(a\).

The minimal polynomial of a linear recurrence \(\{a_r\}\) is by definition the unique monic polynomial \(g\), such that if \(\{a_r\}\) satisfies a linear recurrence \(a_j + b_{j-1}a_{j-1} + \cdots + b_0a_k = 0\) (for all \(k \geq 0\)), then \(g\) divides the polynomial \(x^j + \sum_{i=0}^{j-1} b_i x^i\).

INPUT:
• \(a\) – a list of even length of elements of a field (or domain)

OUTPUT:
the minimal polynomial of the sequence, as a polynomial over the field in which the entries of \(a\) live

Warning: The result is only guaranteed to be correct on the full sequence if there exists a linear recurrence of length less than half the length of \(a\).

EXAMPLES:

\begin{verbatim}
sage: from sage.matrix.berlekamp_massey import berlekamp_massey
sage: berlekamp_massey([1,2,1,2,1,2])
x^2 - 1
sage: berlekamp_massey([GF(7)(1), 19, 1, 19])
x^2 + 6
sage: berlekamp_massey([2,2,1,2,1,191,393,132])
x^4 - 36727/11711*x^3 + 34213/5019*x^2 + 7024942/35133*x - 335813/1673
sage: berlekamp_massey(prime_range(2, 38))
# needs sage.libs.pari
\end{verbatim}

\begin{verbatim}
# from sage.all import *
>> from sage.matrix.berlekamp_massey import berlekamp_massey
>> berlekamp_massey([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1),
-> Integer(2)])
x^2 - 1
>> berlekamp_massey([GF(Integer(7))(Integer(1)), Integer(19), Integer(19),Integer(1),
-> Integer(19)])
x^2 + 6
\end{verbatim}

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> berlekamp_massey([Integer(2), Integer(2), Integer(1), Integer(2), Integer(1),
       Integer(191), Integer(393), Integer(132)])
\ x^4 - 36727/11711*x^3 + 34213/5019*x^2 + 7024942/35133*x - 335813/1673
```  

```python
>>> berlekamp_massey(prime_range(Integer(2), Integer(38)))  
    # needs sage.libs.pari
\ x^6 - 14/9*x^5 - 7/9*x^4 + 157/54*x^3 - 25/27*x^2 - 73/18*x + 37/9
```
class sage.matrix.matrix_dense.Matrix_dense

    Bases: Matrix

    antitranspose()

    Returns the antitranspose of self, without changing self.

    EXAMPLES:

    sage: A = matrix(2,3,range(6)); A
    [0 1 2]
    [3 4 5]
    sage: A.antitranspose()
    [5 2]
    [4 1]
    [3 0]

    >>> from sage.all import *
    >>> A = matrix(Integer(2),Integer(3),range(Integer(6))); A
    [0 1 2]
    [3 4 5]
    >>> A.antitranspose()
    [5 2]
    [4 1]
    [3 0]

    sage: A.subdivide(1,2); A
    [0 1 2]
    [---+-]
    [3 4 5]
    sage: A.antitranspose()
    [5|2]
    [---+-]
    [4|1]
    [3|0]

    >>> from sage.all import *
    >>> A.subdivide(Integer(1),Integer(2)); A
    [0 1|2]
    [---+-]
    [3 4|5]
    >>> A.antitranspose()
    [5|2]
    [---+-]
    [4|1]
    [3|0]

    (continues on next page)
transpose()

Returns the transpose of self, without changing self.

EXAMPLES: We create a matrix, compute its transpose, and note that the original matrix is not changed.

```python
sage: M = MatrixSpace(QQ, 2)
sage: A = M([1,2,3,4])
sage: B = A.transpose()
sage: print(B)
[1 3]
[2 4]
sage: print(A)
[1 2]
[3 4]
```

.T is a convenient shortcut for the transpose:

```python
sage: A.T
[1 3]
[2 4]
```

```python
>>> from sage.all import *
>>> M = MatrixSpace(QQ, Integer(2))
>>> A = M([Integer(1),Integer(2),Integer(3),Integer(4)])
>>> B = A.transpose()
>>> print(B)
[1 3]
[2 4]
>>> print(A)
[1 2]
[3 4]
```

```python
>>> from sage.all import *
>>> A.subdivide(None, 1); A
[1|2]
[3|4]
sage: A.transpose()
[1 3]
[---]
[2 4]
```

```python
>>> from sage.all import *
>>> A.subdivide(None, Integer(1)); A
[1|2]
[3|4]
>>> A.transpose()
[1 3]
[---]
[2 4]
```
class sage.matrix.matrix_sparse.Matrix_sparse
    Bases: Matrix

    antitranspose()

    Return the antitranspose of self, without changing self.

    This is the mirror image along the other diagonal.

    EXAMPLES:

    sage: M = MatrixSpace(QQ, 2, sparse=True)
    sage: A = M([1,2,3,4]); A
    [1 2]
    [3 4]
    sage: A.antitranspose()
    [4 2]
    [3 1]

>>> from sage.all import *
>>> M = MatrixSpace(QQ, Integer(2), sparse=True)
>>> A = M([Integer(1),Integer(2),Integer(3),Integer(4)]); A
[1 2]
[3 4]
>>> A.antitranspose()
[4 2]
[3 1]

See also:

    transpose()

    apply_map(phi, R=None, sparse=True)

    Apply the given map phi (an arbitrary Python function or callable object) to this matrix.

    If R is not given, automatically determine the base ring of the resulting matrix.

    INPUT:

    • phi -- arbitrary Python function or callable object
    • R -- (optional) ring
    • sparse -- (default: True) whether to return a sparse or a dense matrix

    OUTPUT: a matrix over R

    EXAMPLES:
Matrices and Spaces of Matrices, Release 10.4

```python
sage: m = matrix(ZZ, 10000, {(1,2): 17}, sparse=True)
sage: # needs sage.rings.finite_rings
sage: k.<a> = GF(9)
sage: f = lambda x: k(x)
sage: n = m.apply_map(f)
sage: n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices
over Finite Field in a of size 3^2
sage: n[1, 2]
2
```

```
>>> from sage.all import *
>>> m = matrix(ZZ, Integer(10000), {(Integer(1),Integer(2)): Integer(17)},
              sparse=True)
>>> # needs sage.rings.finite_rings
>>> k = GF(Integer(9), names=('a',)); (a,) = k._first_ngens(1)
>>> f = lambda x: k(x)
>>> n = m.apply_map(f)
>>> n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices
over Finite Field in a of size 3^2
>>> n[Integer(1), Integer(2)]
2
```

An example where the codomain is explicitly specified.

```python
sage: n = m.apply_map(lambda x: x%3, GF(3))
sage: n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices
over Finite Field of size 3
sage: n[1, 2]
2
```

```
>>> from sage.all import *
>>> n = m.apply_map(lambda x: x%Integer(3), GF(Integer(3)))
>>> n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices
over Finite Field of size 3
>>> n[Integer(1), Integer(2)]
2
```

If we did not specify the codomain, the resulting matrix in the above case ends up over \( \mathbb{Z} \) again:

```python
sage: n = m.apply_map(lambda x: x%3)
sage: n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices over Integer Ring
sage: n[1, 2]
2
```

```
>>> from sage.all import *
>>> n = m.apply_map(lambda x: x%Integer(3))
>>> n.parent()
Full MatrixSpace of 10000 by 10000 sparse matrices over Integer Ring
>>> n[Integer(1), Integer(2)]
2
```

Chapter 12. Base class for sparse matrices

594
If self is subdivided, the result will be as well:

```python
sage: m = matrix(2, 2, [0, 0, 3, 0])
sage: m.subdivide(None, 1); m
[0|0]
[3|0]
sage: m.apply_map(lambda x: x*x)
[0|0]
[9|0]
```

If the map sends zero to a non-zero value, then it may be useful to get the result as a dense matrix.

```python
sage: m = matrix(ZZ, 3, 3, [0] * 7 + [1,2], sparse=True); m
[0 0 0]
[0 0 0]
[0 1 2]
sage: parent(m)
Full MatrixSpace of 3 by 3 sparse matrices over Integer Ring
sage: n = m.apply_map(lambda x: x+polygen(QQ), sparse=False); n
[ x x x]
[ x x x]
[ x x + 1 x + 2]
sage: parent(n)
Full MatrixSpace of 3 by 3 dense matrices over Univariate Polynomial Ring in...
```

apply_morphism(\(\phi\))

Apply the morphism \(\phi\) to the coefficients of this sparse matrix.

The resulting matrix is over the codomain of \(\phi\).

**INPUT:**

```python
>>> from sage.all import *
>>> m = matrix(ZZ, 3, 3, [Integer(0)] * Integer(7) + [Integer(1),Integer(2)], sparse=True); m
[0 0 0]
[0 0 0]
[0 1 2]
```
• \( \phi \) – a morphism, so \( \phi \) is callable and
\( \phi.\text{domain()} \) and \( \phi.\text{codomain()} \) are defined. The codomain must be a ring.

OUTPUT: a matrix over the codomain of \( \phi \)

EXAMPLES:

```
sage: M = MatrixSpace(QQ, 2, 2, sparse=True)
sage: A = M([[1, 2], [3, 4]])
sage: A
[1 2]
[3 4]
sage: N = MatrixSpace(QQ, 2, 1, sparse=True)
sage: B = N([9, 8])
sage: B
[9]
[8]
sage: A.augment(B)
[1 2 9]
[3 4 8]
sage: B.augment(A)
[9 1 2]
[8 3 4]
```

```Python
>>> from sage.all import *
```
A vector may be augmented to a matrix.

```python
sage: A = matrix(QQ, 3, 4, range(12), sparse=True)
sage: v = vector(QQ, 3, range(3), sparse=True)
sage: A.augment(v)
[ 0 1 2 3 0]
[ 4 5 6 7 1]
[ 8 9 10 11 2]
```

The `subdivide` option will add a natural subdivision between `self` and `right`. For more details about how subdivisions are managed when augmenting, see `sage.matrix.matrix1.Matrix.augment()`.

```python
sage: A = matrix(QQ, 3, 5, range(15), sparse=True)
sage: B = matrix(QQ, 3, 3, range(9), sparse=True)
sage: A.augment(B, subdivide=True)
[ 0 1 2 3 4| 0 1 2]
[ 5 6 7 8 9| 3 4 5]
[10 11 12 13 14| 6 7 8]
```

`change_ring(ring)`

Return the matrix obtained by coercing the entries of this matrix into the given ring.

Always returns a copy (unless `self` is immutable, in which case returns `self`).

EXAMPLES:
Matrices and Spaces of Matrices, Release 10.4

sage: x = polygen(ZZ, 'x')
sage: A = matrix(QQ['x,y'], 2, [0,-1,2*x,-2], sparse=True); A
[ 0 -1]
[2*x -2]
sage: A.change_ring(QQ['x,y,z'])
[ 0 -1]
[2*x -2]

Subdivisions are preserved when changing rings:

sage: A.subdivide([2],[]); A
[ 0 -1]
[2*x -2]
[------]
sage: A.change_ring(RR['x,y'])
[ 0 -1.00000000000000]
[2.00000000000000*x -2.00000000000000]
[---------------------------]

>>> from sage.all import *

>>> x = polygen(ZZ, 'x')

>>> A = matrix(QQ['x,y'], Integer(2), [Integer(0),-Integer(1),Integer(2)*x,-Integer(2)], sparse=True); A
[ 0 -1]
[2*x -2]

>>> A.change_ring(QQ['x,y,z'])
[ 0 -1]
[2*x -2]

charpoly(var='x', **kwds)

Return the characteristic polynomial of this matrix.

Note: the generic sparse charpoly implementation in Sage is to just compute the charpoly of the corresponding dense matrix, so this could use a lot of memory. In particular, for this matrix, the charpoly will be computed using a dense algorithm.

EXAMPLES:

sage: A = matrix(ZZ, 4, range(16), sparse=True)
sage: A.charpoly()
x^4 - 30*x^3 - 80*x^2
sage: A.charpoly(y)
y^4 - 30*y^3 - 80*y^2
sage: A.charpoly()
x^4 - 30*x^3 - 80*x^2
>>> from sage.all import *
>>> A = matrix(ZZ, Integer(4), range(Integer(16)), sparse=True)
>>> A.charpoly()
\(x^4 - 30*x^3 - 80*x^2\)
>>> A.charpoly('y')
\(y^4 - 30*y^3 - 80*y^2\)
>>> A.charpoly()
\(x^4 - 30*x^3 - 80*x^2\)

density()
Return the density of the matrix.

By density we understand the ratio of the number of nonzero positions and the number \self.nrows() \ast \self.ncols(), i.e. the number of possible nonzero positions.

EXAMPLES:

```
sage: a = matrix([],[],[],[], sparse=True); a.density()
0
sage: a = matrix(5000,5000,{(1,2): 1}); a.density()
1/25000000
```

```
>>> from sage.all import *

>>> a = matrix([],[],[],[], sparse=True); a.density()
0
>>> a = matrix(Integer(5000),Integer(5000),{(Integer(1),Integer(2)): Integer(1)}); a.density()
1/25000000
```

determinant(**kwds)
Return the determinant of this matrix.

Note: the generic sparse determinant implementation in Sage is to just compute the determinant of the corresponding dense matrix, so this could use a lot of memory. In particular, for this matrix, the determinant will be computed using a dense algorithm.

EXAMPLES:

```
sage: A = matrix(ZZ, 4, range(16), sparse=True)
sage: B = A + identity_matrix(ZZ, 4, sparse=True)
sage: B.det()
-49
```

```
>>> from sage.all import *

>>> A = matrix(ZZ, Integer(4), range(Integer(16)), sparse=True)
>>> B = A + identity_matrix(ZZ, Integer(4), sparse=True)
>>> B.det()
-49
```

matrix_from_rows_and_columns(rows, columns)
Return the matrix constructed from \self from the given rows and columns.

EXAMPLES:
Matrices and Spaces of Matrices, Release 10.4

sage: M = MatrixSpace(Integers(8),3,3, sparse=True)
sage: A = M(range(9)); A

\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 0 \\
\end{bmatrix}
\]

sage: A.matrix_from_rows_and_columns([1], [0,2])

\[
\begin{bmatrix}
3 & 5 \\
\end{bmatrix}
\]

sage: A.matrix_from_rows_and_columns([1,2], [1,2])

\[
\begin{bmatrix}
4 & 5 \\
7 & 0 \\
\end{bmatrix}
\]

>>> from sage.all import *

>>> M = MatrixSpace(Integers(Integer(8)),Integer(3),Integer(3), sparse=True)

>>> A = M(range(Integer(9))); A

\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 0 \\
\end{bmatrix}
\]

>>> A.matrix_from_rows_and_columns([Integer(1)], [Integer(0),Integer(2)])

\[
\begin{bmatrix}
3 & 5 \\
\end{bmatrix}
\]

>>> A.matrix_from_rows_and_columns([Integer(1),Integer(2)], [Integer(1), Integer(2)])

\[
\begin{bmatrix}
4 & 5 \\
7 & 0 \\
\end{bmatrix}
\]

Note that row and column indices can be reordered or repeated:

sage: A.matrix_from_rows_and_columns([2,1], [2,1])

\[
\begin{bmatrix}
0 & 7 \\
5 & 4 \\
\end{bmatrix}
\]

>>> from sage.all import *

>>> A.matrix_from_rows_and_columns([Integer(2),Integer(1)], [Integer(2), Integer(1)])

\[
\begin{bmatrix}
0 & 7 \\
5 & 4 \\
\end{bmatrix}
\]

For example here we take from row 1 columns 2 then 0 twice, and do this 3 times.

sage: A.matrix_from_rows_and_columns([1,1,1],[2,0,0])

\[
\begin{bmatrix}
5 & 3 & 3 \\
5 & 3 & 3 \\
5 & 3 & 3 \\
\end{bmatrix}
\]

>>> from sage.all import *

>>> A.matrix_from_rows_and_columns([Integer(1),Integer(1),Integer(1)], [Integer(2),Integer(0),Integer(0)])

\[
\begin{bmatrix}
5 & 3 & 3 \\
5 & 3 & 3 \\
5 & 3 & 3 \\
\end{bmatrix}
\]

We can efficiently extract large submatrices:

sage: A = random_matrix(ZZ, 100000, density=.00005, sparse=True)  # long time

\[
\text{(4s on sage.math, 2012)}
\]

sage: B = A[50000:,:50000]  # long time

sage: count = 0

(continues on next page)
We must pass in a list of indices:

```
sage: A = random_matrix(ZZ,100,density=.02,sparse=True)
sage: A.matrix_from_rows_and_columns([1], [2,3])
Traceback (most recent call last):
  ... TypeError: 'sage.rings.integer.Integer' object is not iterable
```

```
sage: A.matrix_from_rows_and_columns([1,2], 3)
Traceback (most recent call last):
  ... TypeError: 'sage.rings.integer.Integer' object is not iterable
```

```
>>> from sage.all import *
>>> A = random_matrix(ZZ, Integer(100), density=RealNumber('.02'), sparse=True)
>>> A.matrix_from_rows_and_columns([Integer(1),Integer(2)],Integer(3))
Traceback (most recent call last):
  ... TypeError: 'sage.rings.integer.Integer' object is not iterable
```

```
>>> A.matrix_from_rows_and_columns([Integer(1),Integer(2)], Integer(3))
Traceback (most recent call last):
  ... TypeError: 'sage.rings.integer.Integer' object is not iterable
```

AUTHORS:

`transpose()`

Return the transpose of `self`, without changing `self`.

EXAMPLES: We create a matrix, compute its transpose, and note that the original matrix is not changed.
Matrices and Spaces of Matrices, Release 10.4

```
sage: M = MatrixSpace(QQ, 2, sparse=True)
sage: A = M([1,2,3,4]); A
[1 2]
[3 4]
sage: B = A.transpose(); B
[1 3]
[2 4]

>>> from sage.all import *

>>> M = MatrixSpace(QQ, Integer(2), sparse=True)

>>> A = M([Integer(1),Integer(2),Integer(3),Integer(4)]); A
[1 2]
[3 4]

>>> B = A.transpose(); B
[1 3]
[2 4]

.T is a convenient shortcut for the transpose:

sage: A.T
[1 3]
[2 4]

>>> from sage.all import *

>>> A.T
[1 3]
[2 4]

See also:

antitranspose()
```
class sage.matrix.matrix_generic_dense.Matrix_generic_dense

Bases: Matrix_dense

The Matrix_generic_dense class derives from Matrix, and defines functionality for dense matrices over any base ring. Matrices are represented by a list of elements in the base ring, and element access operations are implemented in this class.

EXAMPLES:

```python
sage: A = random_matrix(Integers(25)['x'], 2)
sage: type(A)
<class 'sage.matrix.matrix_generic_dense.Matrix_generic_dense'>
sage: TestSuite(A).run(skip='_test_minpoly')
```

```python
>>> from sage.all import *

>>> A = random_matrix(Integers(Integer(25))['x'], Integer(2))

>>> type(A)
<class 'sage.matrix.matrix_generic_dense.Matrix_generic_dense'>

>>> TestSuite(A).run(skip='_test_minpoly')
```

Test comparisons:

```python
sage: A = random_matrix(Integers(25)['x'], 2)
sage: A == A
True
sage: A < A + 1 or A[0, 0].coefficients()[0] == 24
True
sage: A+1 < A and A[0, 0].coefficients()[0] != 24
False
```

```python
>>> from sage.all import *

>>> A = random_matrix(Integers(Integer(25))['x'], Integer(2))

>>> A == A
True

>>> A < A + Integer(1) or A[Integer(0), Integer(0)].coefficients()[Integer(0)] == Integer(24)
True

>>> A+Integer(1) < A and A[Integer(0), Integer(0)].coefficients()[Integer(0)] != Integer(24)
False
```

Test hashing:
```
sage: A = random_matrix(Integers(25)['x'], 2)
sage: hash(A)
Traceback (most recent call last):
...
TypeError: mutable matrices are unhashable
sage: A.set_immutable()
sage: H = hash(A)

>>> from sage.all import *
>>> A = random_matrix(Integers(Integer(25))['x'], Integer(2))
>>> hash(A)
Traceback (most recent call last):
...
TypeError: mutable matrices are unhashable
>>> A.set_immutable()
>>> H = hash(A)
```

class sage.matrix.matrix_generic_sparse.Matrix_generic_sparse
Bases: Matrix_sparse

Generic sparse matrix.

The `Matrix_generic_sparse` class derives from `Matrix_sparse`, and defines functionality for sparse matrices over any base ring. A generic sparse matrix is represented using a dictionary whose keys are pairs of integers (i, j) and values in the base ring. The values of the dictionary must never be zero.

EXAMPLES:

```python
sage: R.<a,b> = PolynomialRing(ZZ,a,b)
sage: M = MatrixSpace(R,5,5,sparse=True)
sage: M({(0,0):5*a+2*b, (3,4): -a})
[5*a + 2*b 0 0 0 0]
[0 0 0 0 0]
[0 0 0 0 0]
[0 0 0 0 -a]
[0 0 0 0 0]

sage: M(3)
[3 0 0 0 0]
[0 3 0 0 0]
[0 0 3 0 0]
[0 0 0 3 0]
[0 0 0 0 3]
```

```python
>>> from sage.all import *

>>> R = PolynomialRing(ZZ,'a,b', names=('a', 'b',)); (a, b,) = R._first_ngens(2)
>>> M = MatrixSpace(R,Integer(5),Integer(5),sparse=True)
>>> M({(Integer(0),Integer(0)):Integer(5)*a+Integer(2)*b, (Integer(3),
    ->Integer(4)): -a})
[[5*a + 2*b 0 0 0 0]
[0 0 0 0 0]
[0 0 0 0 0]
[0 0 0 0 -a]
[0 0 0 0 0]
```
Note: The datastructure can potentially be optimized. Firstly, as noticed in Issue #17663, we lose time in using 2-tuples to store indices. Secondly, there is no fast way to access non-zero elements in a given row/column.

sage.matrix.matrix_generic_sparse.Matrix_sparse_from_rows(X)

INPUT:

• X – nonempty list of SparseVector rows

OUTPUT: Sparse_matrix with those rows.

EXAMPLES:

>>> V = VectorSpace(QQ, 20, sparse=True)
>>> v = V(0)
>>> v[9] = 4

>>> from sage.matrix.matrix_generic_sparse import Matrix_sparse_from_rows

sage: Matrix_sparse_from_rows([v])
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 4]

sage: Matrix_sparse_from_rows([v, v, v, V(0)])
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]

>>> from sage.all import *

>>> V = VectorSpace(QQ, Integer(20), sparse=True)
>>> v = V(Integer(0))
>>> v[Integer(9)] = Integer(4)

>>> from sage.matrix.matrix_generic_sparse import Matrix_sparse_from_rows

sage: Matrix_sparse_from_rows([v])
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 4]

sage: Matrix_sparse_from_rows([v, v, v, V(Integer(0))])
[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
CHAPTER
FIFTEEN

DENSE MATRICES OVER THE INTEGER RING

AUTHORS:

• William Stein
• Robert Bradshaw
• Marc Masdeu (August 2014). Implemented using FLINT, see Issue #16803.
• Jeroen Demeyer (October 2014): lots of fixes, see Issue #17090 and Issue #17094.
• Vincent Delecroix (February 2015): make it faster, see Issue #17822.
• Vincent Delecroix (May 2017): removed duplication of entries and cleaner linbox interface

EXAMPLES:

```python
sage: a = matrix(ZZ, 3, 3, range(9)); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: a.det()
0
sage: a[0,0] = 10; a.det()
-30
sage: a.charpoly()
x^3 - 22*x^2 + 102*x + 30
sage: b = -3*a
sage: a == b
False
sage: b < a
True
```

```python
>>> from sage.all import *
>>> a = matrix(ZZ, Integer(3), Integer(3), range(Integer(9))); a
[0 1 2]
[3 4 5]
[6 7 8]
>>> a.det()
0
>>> a[Integer(0), Integer(0)] = Integer(10); a.det()
-30
>>> a.charpoly()
x^3 - 22*x^2 + 102*x + 30
>>> b = -Integer(3)*a
>>> a == b
False
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

>>> b < a
True

class sage.matrix.matrix_integer_dense.Matrix_integer_dense
    Bases: Matrix_dense

Matrix over the integers, implemented using FLINT.

On a 32-bit machine, they can have at most $2^{32} - 1$ rows or columns. On a 64-bit machine, matrices can have at most $2^{64} - 1$ rows or columns.

EXAMPLES:

sage: a = MatrixSpace(ZZ,3)(2); a
[2 0 0]
[0 2 0]
[0 0 2]
sage: a = matrix(ZZ,1,3, [1,2,-3]); a
[ 1 2 -3]
sage: a = MatrixSpace(ZZ,2,4)(2); a
Traceback (most recent call last):
  ...TypeError: nonzero scalar matrix must be square

>>> from sage.all import *

>>> a = MatrixSpace(ZZ,Integer(3))(Integer(2)); a
[2 0 0]
[0 2 0]
[0 0 2]

>>> a = matrix(ZZ,Integer(1),Integer(3), [Integer(1),Integer(2),-Integer(3)]); a
[ 1 2 -3]

>>> a = MatrixSpace(ZZ,Integer(2),Integer(4))(Integer(2)); a
Traceback (most recent call last):
  ...TypeError: nonzero scalar matrix must be square

BKZ (delta=None, algorithm='fpLLL', fp=None, block_size=10, prune=0, use_givens=False, precision=0, proof=None, **kwds)

Return the result of running Block Korkin-Zolotarev reduction on self interpreted as a lattice.

INPUT:

- delta -(default: 0.99) LLL parameter
- algorithm -(default: "fpLLL") "fpLLL" or "NTL"
- fp - floating point number implementation
  - None - NTL's exact reduction or fpLLL's wrapper (default)
  - 'fp' - double precision: NTL's FP or fpLLL's double
  - 'ld' - long doubles (fpLLL only)
  - 'qd' - NTL's QP
- 'qd1' - quad doubles: Uses quad_float precision
to compute Gram-Schmidt, but uses double precision in the search phase of the block reduction algorithm. This seems adequate for most purposes, and is faster than 'qd', which uses quad_float precision uniformly throughout (NTL only).
Matrices and Spaces of Matrices, Release 10.4

– 'xd' – extended exponent: NTL’s XD or fpLLL’s dpe
– 'rr' – arbitrary precision: NTL RR or fpLLL’s MPFR

• block_size – (default: 10) Specifies the size of the blocks in the reduction. High values yield shorter vectors, but the running time increases double exponentially with block_size. block_size should be between 2 and the number of rows of self.

• proof – (default: same as proof.linear_algebra()) Insist on full BKZ reduction. If disabled and fplll is called, reduction is much faster but the result is not fully BKZ reduced.

NTL SPECIFIC INPUT:

• prune – (default: 0) The optional parameter prune can be set to any positive number to invoke the Volume Heuristic from [SH1995]. This can significantly reduce the running time, and hence allow much bigger block size, but the quality of the reduction is of course not as good in general. Higher values of prune mean better quality, and slower running time. When prune is 0, pruning is disabled. Recommended usage: for block_size==30, set 10 <= prune <= 15.

• use_givens – Use Givens orthogonalization. Only applies to approximate reduction using NTL. This is a bit slower, but generally much more stable, and is really the preferred orthogonalization strategy. For a nice description of this, see Chapter 5 of [GL1996].

fpLLL SPECIFIC INPUT:

• precision – (default: 0 for automatic choice) bit precision to use if fp='rr' is set
• **kwds – keywords to be passed to fpylll. See fpylll.BKZ.Param for details.

Also, if the verbose level is at least 2, some output is printed during the computation.

EXAMPLES:

```python
sage: A = Matrix(ZZ,3,3,range(1,10))
sage: A.BKZ()
[ 0 0 0]
[ 2 1 0]
[-1 1 3]
sage: A = Matrix(ZZ,3,3,range(1,10))
sage: A.BKZ(use_givens=True)
[ 0 0 0]
[ 2 1 0]
[-1 1 3]
sage: A = Matrix(ZZ,3,3,range(1,10))
sage: A.BKZ(fp="fp")
[ 0 0 0]
[ 2 1 0]
[-1 1 3]
```

```python
>>> from sage.all import *
>>> A = Matrix(ZZ,Integer(3),Integer(3),range(Integer(1),Integer(10)))
>>> A.BKZ()
[ 0 0 0]
[ 2 1 0]
[-1 1 3]
>>> A = Matrix(ZZ,Integer(3),Integer(3),range(Integer(1),Integer(10)))
>>> A.BKZ(use_givens=True)
```

(continues on next page)
ALGORITHM:

Calls either NTL or fpLLL.

LLL (delta=None, eta=None, algorithm='fpLLL:wrapper', fp=None, early_red=False, use_givens=False, use_siegel=False, transformation=False, **kwds)

Return LLL-reduced or approximated LLL reduced matrix $R$ of the lattice generated by the rows of self.

A set of vectors $(b_1, b_2, ..., b_d)$ is $(\delta, \eta)$-LLL-reduced if the following two conditions hold:

- For any $i > j$, we have $|\mu_{i,j}| \leq \eta$.
- For any $i < d$, we have $\delta |b_i^*|^2 \leq |b_{i+1}^* + \mu_{i+1,i} b_i^*|^2$,

where $\mu_{i,j} = \langle b_i, b_j^* \rangle / \langle b_j^*, b_j^* \rangle$ and $b_i^*$ is the $i$-th vector of the Gram-Schmidt orthogonalisation of $(b_1, b_2, ..., b_d)$.

The default reduction parameters are $\delta = 0.99$ and $\eta = 0.501$. The parameters $\delta$ and $\eta$ must satisfy $0.25 < \delta \leq 1.0$ and $0.5 \leq \eta < \sqrt{\delta}$. Polynomial time complexity is only guaranteed for $\delta < 1$. Not every algorithm admits the case $\delta = 1$.

If the matrix has a nonzero kernel, the LLL-reduced matrix will contain zero rows, so that the output has the same dimensions as the input. The transformation matrix is always invertible over the integers.

Also the rank of self is cached if it is computed during the reduction. Note that in general this only happens when self.rank() == self.ncols() and the exact algorithm is used.

INPUT:

- **delta** – (default: 0.99) $\delta$ parameter as described above, ignored by pari
- **eta** – (default: 0.501) $\eta$ parameter as described above, ignored by NTL and pari
- **algorithm** – string; one of the algorithms listed below (default: "fpLLL:wrapper").
- **fp** – floating point number implementation, ignored by pari:
  - None – NTL’s exact reduction or fpLLL’s wrapper
  - ’fp’ – double precision: NTL’s FP or fpLLL’s double
  - ’ld’ – long doubles (fpLLL only)
  - ’qd’ – NTL’s QP
  - ’xd’ – extended exponent: NTL’s XD or fpLLL’s dpe
  - ’rr’ – arbitrary precision: NTL’s RR or fpLLL’s MPFR
- **prec** – (default: auto choose) precision, ignored by NTL and pari
- **early_red** – (default: False) perform early reduction, ignored by NTL and pari
- **use_givens** – (default: False) use Givens orthogonalization. Only applies to approximate reduction using NTL. This is slower but generally more stable.
• **use_siegel** – (default: False) use Siegel’s condition instead of Lovász’s condition, ignored by NTL and pari

• **transformation** – (default: False) also return transformation matrix.

• **kwds** – keywords to be passed to fpylll. See fpylll.LLL.reduction() for details.

Also, if the verbose level is at least 2, some output is printed during the computation.

**AVAILABLE ALGORITHMS:**

• 'NTL:LLL' – NTL’s LLL + choice of fp.

• 'fpLLL:heuristic' – fpLLL’s heuristic + choice of fp.

• 'fpLLL:fast' – fpLLL’s fast + choice of fp.

• 'fpLLL:proved' – fpLLL’s proved + choice of fp.

• 'fpLLL:wrapper' – fpLLL’s automatic choice (default).

• 'pari' – pari’s qflll.

**OUTPUT:**

A matrix over the integers.

**EXAMPLES:**

```python
sage: A = Matrix(ZZ,3,3,range(1,10))
sage: A.LLL()
[ 0 0 0]
[ 2 1 0]
[-1 1 3]
```

```python
>>> from sage.all import *
>>> A = Matrix(ZZ,Integer(3),Integer(3),range(Integer(1),Integer(10)))
>>> A.LLL()
[ 0 0 0]
[ 2 1 0]
[-1 1 3]
```

We compute the extended GCD of a list of integers using LLL, this example is from the Magma handbook:

```python
sage: Q = [ 67015143, 248934363018, 109210, 25590011055, 74631449,
.....: 10230248, 709487, 68965012139, 972065, 864972271 ]
sage: n = len(Q)
sage: S = 100
sage: X = Matrix(ZZ, n, n + 1)
sage: for i in range(n):
.....: X[i, i + 1] = 1
sage: for i in range(n):
.....: X[i, 0] = S * Q[i]
sage: L = X.LLL()
sage: M = L.row(n-1).list()[1:]
sage: M
[-3, -1, 13, -1, -4, 2, 3, 4, 5, -1]
sage: add(Q[i]*M[i] for i in range(n))
-1
```
Matrices and Spaces of Matrices, Release 10.4

>>> from sage.all import *

>>> Q = [ Integer(67015143), Integer(248934363018), Integer(109210),
        Integer(25590011055), Integer(74631449),
        ...  Integer(10230248), Integer(709487), Integer(68965012139),
        ...  Integer(972065), Integer(864972271) ]

>>> n = len(Q)

>>> S = Integer(100)

>>> X = Matrix(ZZ, n, n + Integer(1))

>>> for i in range(n):
    ...    X[i, i + Integer(1)] = Integer(1)

>>> for i in range(n):
    ...    X[i, Integer(0)] = S * Q[i]

>>> L = X.LLL()

>>> M = L.row(n-Integer(1)).list()[Integer(1):]

>>> M

[-3, -1, 13, -1, -4, 2, 3, 4, 5, -1]

>>> add(Q[i]*M[i] for i in range(n))

-1

The case $\delta = 1$ is not always supported:

sage: L = X.LLL(delta=2)
Traceback (most recent call last):
...
TypeError: delta must be <= 1

sage: L = X.LLL(delta=1)  # not tested, will eat lots of ram
Traceback (most recent call last):
...
RuntimeError: infinite loop in LLL

sage: L = X.LLL(delta=1, algorithm='NTL:LLL')

sage: L[-1]

(-100, -3, -1, 13, -1, -4, 2, 3, 4, 5, -1)

We return the transformation matrix:

sage: A = random_matrix(ZZ, 10, 20)

sage: R, U = A.LLL(transformation=True)

sage: U * A == R

True

sage: R, U = A.LLL(algorithm="NTL:LLL", transformation=True)

sage: U * A == R

True

(continues on next page)
Example with a nonzero kernel:

```python
sage: M = matrix(4, 3, [1, 2, 3, 2, 4, 6, 7, 0, 1, -1, -2, -3])
sage: M.LLL()[:2]
[0 0 0]
[0 0 0]
sage: M.LLL(algorithm="NTL:LLL")[:2]
[0 0 0]
[0 0 0]
sage: M.LLL(algorithm="pari")[:2]
[0 0 0]
[0 0 0]
```
antitranspose()

Return the antitranspose of self, without changing self.

EXAMPLES:

```sage
sage: A = matrix(2, 3, range(6))
sage: type(A)
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>
sage: A.antitranspose()
[5 2]
[4 1]
[3 0]
sage: A
[0 1 2]
[3 4 5]
sage: A.subdivide(1,2); A
[0 1|2]
[---+-]
[3 4|5]
sage: A.antitranspose()
[5|2]
[-+-]
[4|1]
[3|0]
```

```>>> from sage.all import *
>>> A = matrix(Integer(2),Integer(3),range(Integer(6)))
>>> type(A)
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>
>>> A.antitranspose()
[5 2]
[4 1]
[3 0]
```

```>>> A.subdivide(Integer(1),Integer(2)); A
[0 1|2]
[---+-]
[3 4|5]
>>> A.antitranspose()
[5|2]
[-+-]
[4|1]
[3|0]
```

augment(right, subdivide=False)

Return a new matrix formed by appending the matrix (or vector) right on the right side of self.

INPUT:

- right – a matrix, vector or free module element, whose dimensions are compatible with self.
- subdivide – default: False – request the resulting matrix to have a new subdivision, separating self from right.

OUTPUT:
A new matrix formed by appending right onto the right side of self. If right is a vector (or free module element) then in this context it is appropriate to consider it as a column vector. (The code first converts a vector to a 1-column matrix.)

**EXAMPLES:**

```python
sage: A = matrix(ZZ, 4, 5, range(20))
sage: B = matrix(ZZ, 4, 3, range(12))
sage: A.augment(B)
[ 0 1 2 3 4 0 1 2]
[ 5 6 7 8 9 3 4 5]
[10 11 12 13 14 6 7 8]
[15 16 17 18 19 9 10 11]
```

A vector may be augmented to a matrix.

```python
sage: A = matrix(ZZ, 3, 5, range(15))
sage: v = vector(ZZ, 3, range(3))
sage: A.augment(v)
[ 0 1 2 3 4 0]
[ 5 6 7 8 9 1]
[10 11 12 13 14 2]
```

The `subdivide` option will add a natural subdivision between self and right. For more details about how subdivisions are managed when augmenting, see `sage.matrix.matrix1.Matrix.augment()`.

```python
sage: A = matrix(ZZ, 3, 5, range(15))
sage: B = matrix(ZZ, 3, 3, range(9))
sage: A.augment(B, subdivide=True)
[ 0 1 2 3 4| 0 1 2]
[ 5 6 7 8 9| 3 4 5]
[10 11 12 13 14| 6 7 8]
```
Errors are raised if the sizes are incompatible.

```
sage: A = matrix(ZZ, [[1, 2], [3, 4]])
sage: B = matrix(ZZ, [[10, 20], [30, 40], [50, 60]])
sage: A.augment(B)
Traceback (most recent call last):
  ... 
TypeError: number of rows must be the same, not 2 != 3
```

```
>>> from sage.all import *

>>> A = matrix(ZZ, [[Integer(1), Integer(2)], [Integer(3), Integer(4)]])
>>> B = matrix(ZZ, [[Integer(10), Integer(20)], [Integer(30), Integer(40)], ...
                [Integer(50), Integer(60)]])
>>> A.augment(B)
Traceback (most recent call last):
  ... 
TypeError: number of rows must be the same, not 2 != 3
```

### charpoly \( (\text{var}='x', \text{algorithm}=\text{None}) \)

**Note:** The characteristic polynomial is defined as \( \text{det}(xI - A) \).

**INPUT:**

- \text{var} – a variable name
- \text{algorithm} – (optional) either 'generic', 'flint' or 'linbox'. Default is set to 'linbox'.

**EXAMPLES:**

```
sage: A = matrix(ZZ, 6, range(36))
sage: f = A.charpoly(); f
x^6 - 105*x^5 - 630*x^4
sage: f(A) == 0
True
sage: g = A.charpoly(algorithm='flint')
sage: f == g
True
sage: n=Integer(20); A = Mat(ZZ,n)(range(n^2))
sage: A.charpoly()
x^20 - 3990*x^19 - 266000*x^18
```

```
>>> from sage.all import *

>>> A = matrix(ZZ, Integer(6), range(Integer(36)))

>>> A = matrix(ZZ, Integer(6), range(Integer(36)))

>>> A = matrix(ZZ, Integer(6), range(Integer(36)))
```

(continues on next page)
On non square matrices, this method raises an ArithmeticError:

```python
sage: matrix(ZZ, 2, 1).charpoly()
Traceback (most recent call last):
  ...  
ArithmeticError: only valid for square matrix
```
decomposition(**kwds)

Return the decomposition of the free module on which this matrix $A$ acts from the right (i.e., the action is $x$ goes to $x A$), along with whether this matrix acts irreducibly on each factor. The factors are guaranteed to be sorted in the same way as the corresponding factors of the characteristic polynomial, and are saturated as $\mathbb{Z}$ modules.

**INPUT:**

- self – a matrix over the integers
- **kwds – these are passed onto to the decomposition over QQ command.

**EXAMPLES:**

```python
sage: t = ModularSymbols(11, sign=1).hecke_matrix(2)
sage: w = t.change_ring(ZZ)
sage: w
[ 3 -2]
[ 0 -2]
sage: w.charpoly().factor()
(x - 3) * (x + 2)
sage: w.decomposition()
[(Free module of degree 2 and rank 1 over Integer Ring
  Echelon basis matrix:
  [ 5 -2], True),
  (Free module of degree 2 and rank 1 over Integer Ring
  Echelon basis matrix:
  [0 1], True)]
```

```python
>>> from sage.all import *
```

```python
sage: t = ModularSymbols(Integer(11), sign=Integer(1)).hecke_matrix(Integer(2))
>>> w = t.change_ring(ZZ)
>>> w
[ 3 -2]
[ 0 -2]
>>> w.charpoly().factor()
(x - 3) * (x + 2)
>>> w.decomposition()
[(Free module of degree 2 and rank 1 over Integer Ring
  Echelon basis matrix:
  [ 5 -2], True),
  (Free module of degree 2 and rank 1 over Integer Ring
  Echelon basis matrix:
  [0 1], True)]
```
**determinant** (*algorithm='default', proof=None, stabilize=2*)

Return the determinant of this matrix.

**INPUT:**

- **algorithm**
  - 'default' – use flint
  - 'flint' – let flint do the determinant
  - 'padic' – uses a p-adic / multimodular algorithm that relies on code in IML and linbox
  - 'linbox' – calls linbox det (you must set proof=False to use this!)
  - 'ntl' – calls NTL's det function
  - 'pari' – uses PARI

- **proof** – bool or None; if None use proof.linear_algebra(); only relevant for the padic algorithm.

**Note:** It would be VERY VERY hard for det to fail even with proof=False.

- **stabilize** – if proof is False, require det to be the same for this many CRT primes in a row. Ignored if proof is True.

**ALGORITHM:** The p-adic algorithm works by first finding a random vector v, then solving $A x = v$ and taking the denominator $d$. This gives a divisor of the determinant. Then we compute $\det(A)/d$ using a multimodular algorithm and the Hadamard bound, skipping primes that divide $d$.

**EXAMPLES:**

```python
sage: A = matrix(ZZ, 8, 8, [3..66])
sage: A.determinant()
0
```

```python
>>> from sage.all import *
>>> A = matrix(ZZ, Integer(8), Integer(8), (ellipsis_range(Integer(3), Ellipsis, →Integer(66))))
>>> A.determinant()
0
```

```python
sage: A = random_matrix(ZZ, 20, 20)
sage: D1 = A.determinant()
sage: A._clear_cache()
sage: D2 = A.determinant(algorithm='ntl')
sage: D1 == D2
True
```

```python
>>> from sage.all import *
>>> A = random_matrix(ZZ, Integer(20), Integer(20))
>>> D1 = A.determinant()
>>> A._clear_cache()
>>> D2 = A.determinant(algorithm='ntl')
>>> D1 == D2
True
```
We have a special-case algorithm for 4x4 determinants:

```python
sage: A = matrix(ZZ,4,[1,2,3,4,4,3,2,1,0,5,0,1,9,1,2,3])
sage: A.determinant()
270

```
A bigger example:

```
sage: A = random_matrix(ZZ,30)
sage: d = A.determinant()
sage: A._clear_cache()
sage: A.determinant(algorithm='linbox',proof=False) == d
True
```

```
>>> from sage.all import *
>>> A = random_matrix(ZZ,Integer(30))
>>> d = A.determinant()
>>> A._clear_cache()
>>> A.determinant(algorithm='linbox',proof=False) == d
True
```

**echelon_form** *(algorithm='default', proof=None, include_zero_rows=True, transformation=False, D=None)*

Return the echelon form of this matrix over the integers, also known as the hermite normal form (HNF).

**INPUT:**

- **algorithm** – String. The algorithm to use. Valid options are:
  - 'default' – Let Sage pick an algorithm (default). Up to 75 rows or columns with no transformation matrix, use pari with flag 0; otherwise, use flint.
  - 'flint' – use flint
  - 'ntl' – use NTL (only works for square matrices of full rank!)
  - 'padic' – an asymptotically fast p-adic modular algorithm. If your matrix has large coefficients and is small, you may also want to try this.
  - 'pari' – use PARI with flag 1
  - 'pari0' – use PARI with flag 0
  - 'pari1' – use PARI with flag 1
  - 'pari4' – use PARI with flag 4 (use heuristic LLL)

- **proof** – (default: True); if proof=False certain determinants are computed using a randomized hybrid p-adic multimodular strategy until it stabilizes twice (instead of up to the Hadamard bound). It is incredibly unlikely that one would ever get an incorrect result with proof=False.

- **include_zero_rows** – (default: True) if False, don’t include zero rows

- **transformation** – if given, also compute transformation matrix; only valid for flint and padic algorithm

- **D** – (default: None) if given and the algorithm is ‘ntl’, then D must be a multiple of the determinant and this function will use that fact.
OUTPUT:

The Hermite normal form (=echelon form over \(\mathbb{Z}\)) of self as an immutable matrix.

EXAMPLES:

```
sage: A = MatrixSpace(ZZ,2)([1,2,3,4])
sage: A.echelon_form()
[1 0]
[0 2]
sage: A = MatrixSpace(ZZ,5)(range(25))
sage: A.echelon_form()
[ 5 0 -5 -10 -15]
[ 0 1 2 3 4]
[ 0 0 0 0 0]
[ 0 0 0 0 0]
[ 0 0 0 0 0]
```

```
>>> from sage.all import *
>>> A = MatrixSpace(ZZ,Integer(2))([Integer(1),Integer(2),Integer(3),
˓→Integer(4)])
>>> A.echelon_form()
[1 0]
[0 2]
>>> A = MatrixSpace(ZZ,Integer(5))(range(Integer(25)))
>>> A.echelon_form()
[ 5 0 -5 -10 -15]
[ 0 1 2 3 4]
[ 0 0 0 0 0]
[ 0 0 0 0 0]
[ 0 0 0 0 0]
```

Getting a transformation matrix in the nonsquare case:

```
sage: A = matrix(ZZ,5,3,\[1..15\])
sage: H, U = A.hermite_form(transformation=True, include_zero_rows=False)
sage: H
[1 2 3]
[0 3 6]
sage: U
[ 0 0 0 4 -3]
[ 0 0 0 13 -10]
sage: U*A == H
True
```

```
>>> from sage.all import *
>>> A = matrix(ZZ,Integer(5),Integer(3),\(\text{ellipsis}\_\text{range}(Integer(1),\text{ellipsis},
˓→Integer(15))))
>>> H, U = A.hermite_form(transformation=True, include_zero_rows=False)
>>> H
[1 2 3]
[0 3 6]
>>> U
[ 0 0 0 4 -3]
[ 0 0 0 13 -10]
>>> U*A == H
True
```
Note: If ‘ntl’ is chosen for a non square matrix this function raises a ValueError.

Special cases: 0 or 1 rows:

```
sage: a = matrix(ZZ, 1,2,[0,-1])
sage: a.hermite_form()
[0 1]
sage: a.pivots()
(1,)
sage: a = matrix(ZZ, 1,2,[0,0])
sage: a.hermite_form()
[0 0]
sage: a.pivots()
()  
```

```
sage: a = matrix(ZZ, 1,3); a
[0 0 0]
sage: a.echelon_form(include_zero_rows=False)
[]
sage: a.echelon_form(include_zero_rows=True)
[0 0 0]
```

Illustrate using various algorithms:

```
>>> from sage.all import *

>>> a = matrix(ZZ, Integer(1),Integer(2),[Integer(0),-Integer(1)])

>>> a.hermite_form()
[0 1]

>>> a.pivots()
(1,)

>>> a = matrix(ZZ, Integer(1),Integer(2),[Integer(0),Integer(0)])

>>> a.hermite_form()
[0 0]

>>> a.pivots()
()

>>> a = matrix(ZZ,Integer(1),Integer(3)); a
[0 0 0]

>>> a.echelon_form(include_zero_rows=False)
[]

>>> a.echelon_form(include_zero_rows=True)
[0 0 0]
```

(continues on next page)
The 'ntl' algorithm doesn't work on matrices that do not have full rank.:
Return the elementary divisors of self, in order.

**Warning:** This is MUCH faster than the `smith_form()` function.

The elementary divisors are the invariants of the finite abelian group that is the cokernel of left multiplication of this matrix. They are ordered in reverse by divisibility.

**INPUT:**

- `self` – matrix
- `algorithm` – (default: 'pari')
  - 'pari': works robustly, but is slower.
  - 'linbox' – use linbox (currently off, broken)

**OUTPUT:** list of integers

**Note:** These are the invariants of the cokernel of left multiplication:

```
sage: M = Matrix([[3,0,1],[0,1,0]])
sage: M
[3 0 1]
[0 1 0]
sage: M.elementary_divisors()
[1, 1]
sage: M.transpose().elementary_divisors()
[1, 1, 0]
```

**EXAMPLES:**

```
sage: matrix(3, range(9)).elementary_divisors()
[1, 3, 0]
sage: matrix(3, range(9)).elementary_divisors(algorithm='pari')
[1, 3, 0]
sage: C = MatrixSpace(ZZ,4)([3,4,5,6,7,3,8,10,14,5,6,7,2,2,10,9])
sage: C.elementary_divisors()
[1, 1, 1, 687]
```

>>> from sage.all import *
>>> M = Matrix([[Integer(3),Integer(0),Integer(1)],
[Integer(0),Integer(1),
-Integer(0)]]))
>>> M
[3 0 1]
[0 1 0]
>>> M.elementary_divisors()
[1, 1]
>>> M.transpose().elementary_divisors()
[1, 1, 0]`
>>> matrix(Integer(3), range(Integer(9))).elementary_divisors(algorithm='pari →')
[1, 3, 0]
>>> C = MatrixSpace(ZZ,Integer(4))([[Integer(3),Integer(4),Integer(5),
  →Integer(6),Integer(7),Integer(3),Integer(8),Integer(10),Integer(14),
  →Integer(5),Integer(6),Integer(7),Integer(2),Integer(2),Integer(10),
  →Integer(9)])
>>> C.elementary_divisors()
[1, 1, 1, 687]

sage: M = matrix(ZZ, 3, [1,5,7, 3,6,9, 0,1,2])
sage: M.elementary_divisors()
[1, 1, 6]

This returns a copy, which is safe to change:

sage: edivs = M.elementary_divisors()
sage: edivs.pop()
6
sage: M.elementary_divisors()
[1, 1, 6]

sage: from sage.all import *

>>> M = matrix(ZZ, Integer(3), [Integer(1),Integer(5),Integer(7), Integer(3),
  →Integer(6),Integer(9), Integer(0),Integer(1),Integer(2)])
>>> M.elementary_divisors()
[1, 1, 6]

See also:
smith_form()
frobenius (*args, **kwds)

Deprecated: Use frobenius_form() instead. See Issue #36396 for details.
frobenius_form(flag=0, var='x')

Return the Frobenius form (rational canonical form) of this matrix.

INPUT:

• flag – 0 (default), 1 or 2 as follows:
  – 0 – (default) return the Frobenius form of this matrix.
  – 1 – return only the elementary divisor polynomials, as polynomials in var.
  – 2 – return a two-components vector \([F,B]\) where \(F\) is the Frobenius form and \(B\) is the basis change so that \(M = B^{-1}FB\).

• var – a string (default: ‘x’)
ALGORITHM: uses PARI's pari:matfrobenius

EXAMPLES:

```python
sage: A = MatrixSpace(ZZ, 3)(range(9))
sage: A.frobenius_form(0)
[ 0 0 0]
[ 1 0 18]
[ 0 1 12]
sage: A.frobenius_form(1)
[x^3 - 12*x^2 - 18*x]
sage: A.frobenius_form(1, var='y')
[y^3 - 12*y^2 - 18*y]
sage: F, B = A.frobenius_form(2)
sage: A == B^(-1)*F*B
True
sage: a=matrix([])
sage: a.frobenius_form(2)
([], [])
sage: a.frobenius_form(0)
[]
sage: a.frobenius_form(1)
[]
sage: B = random_matrix(ZZ,2,3)
sage: B.frobenius_form()
Traceback (most recent call last):
  ... ArithmeticError: frobenius matrix of non-square matrix not defined.
```

```
>>> from sage.all import *
>>> A = MatrixSpace(ZZ, Integer(3))(range(Integer(9)))
>>> A.frobenius_form(Integer(0))
[ 0 0 0]
[ 1 0 18]
[ 0 1 12]
>>> A.frobenius_form(Integer(1))
[x^3 - 12*x^2 - 18*x]
>>> A.frobenius_form(Integer(1), var='y')
[y^3 - 12*y^2 - 18*y]
>>> F, B = A.frobenius_form(Integer(2))
>>> A == B**(-Integer(1))*F*B
True
>>> a=matrix([])
>>> a.frobenius_form(Integer(2))
([], [])

```

AUTHORS:

- Martin Albrecht (2006-04-02)
TODO: - move this to work for more general matrices than just over \( \mathbb{Z} \). This will require fixing how PARI polynomials are coerced to Sage polynomials.

**gcd()**

Return the gcd of all entries of self; very fast.

**EXAMPLES:**

```
sage: a = matrix(ZZ, 2, [6, 15, -6, 150])
sage: a.gcd()
3
```

```
>>> from sage.all import *
>>> a = matrix(ZZ, Integer(2), [Integer(6), Integer(15), Integer(-6), Integer(150)])
>>> a.gcd()
3
```

**height()**

Return the height of this matrix, i.e., the max absolute value of the entries of the matrix.

**OUTPUT:** A nonnegative integer.

**EXAMPLES:**

```
sage: a = Mat(ZZ, 3)(range(9))
sage: a.height()
8
```

```
sage: a = Mat(ZZ, 2, 3)([-17, 3, -389, 15, -1, 0]); a
[ -17 3 -389]
[ 15 -1 0]
sage: a.height()
389
```

```
>>> from sage.all import *

>>> a = Mat(ZZ, Integer(3))(range(Integer(9)))
>>> a.height()
8
```

```
>>> a = Mat(ZZ, Integer(2), Integer(3))([-Integer(17), Integer(3), -Integer(389),
                                           -Integer(15), Integer(1), Integer(0)]); a
[ -17 3 -389]
[ 15 -1 0]
>>> a.height()
389
```

**hermite_form(algorithm='default', proof=None, include_zero_rows=True, transformation=False, D=None)**

Return the echelon form of this matrix over the integers, also known as the hermite normal form (HNF).

**INPUT:**

- `algorithm` -- String. The algorithm to use. Valid options are:
  - 'default' – Let Sage pick an algorithm (default). Up to 75 rows or columns with no transformation matrix, use pari with flag 0; otherwise, use flint.
  - 'flint' – use flint
  - 'ntl' – use NTL (only works for square matrices of full rank!)
  - 'padic' – an asymptotically fast p-adic modular algorithm. If your matrix has large coefficients and is small, you may also want to try this.
- 'pari' – use PARI with flag 1
- 'pari0' – use PARI with flag 0
- 'pari1' – use PARI with flag 1
- 'pari4' – use PARI with flag 4 (use heuristic LLL)

- **proof** – (default: True); if proof=False certain determinants are computed using a randomized hybrid p-adic multimodular strategy until it stabilizes twice (instead of up to the Hadamard bound). It is incredibly unlikely that one would ever get an incorrect result with proof=False.

- **include_zero_rows** – (default: True) if False, don’t include zero rows

- **transformation** – if given, also compute transformation matrix; only valid for flint and padic algorithm

- **D** – (default: None) if given and the algorithm is 'ntl', then D must be a multiple of the determinant and this function will use that fact.

**OUTPUT:**

The Hermite normal form (=echelon form over \( \mathbb{Z} \)) of self as an immutable matrix.

**EXAMPLES:**

```
sage: A = MatrixSpace(ZZ,2)([1,2,3,4])
sage: A.echelon_form()
[1 0]
[0 2]
sage: A = MatrixSpace(ZZ,5)(range(25))
sage: A.echelon_form()
[ 5 0 -5 -10 -15]
[ 0 1 2 3 4]
[ 0 0 0 0 0]
[ 0 0 0 0 0]
[ 0 0 0 0 0]
```

```python
>>> from sage.all import *

>>> A = MatrixSpace(ZZ,Integer(2))([Integer(1),Integer(2),Integer(3),Integer(4)])

>>> A.echelon_form()
[1 0]
[0 2]
```

Getting a transformation matrix in the nonsquare case:

```
sage: A = matrix(ZZ,5,3,\[1..15\])
sage: H, U = A.hermite_form(transformation=True, include_zero_rows=False)
sage: H
[1 2 3]
[0 3 6]
sage: U
[0 0 0 4 -3]
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

\[
\begin{bmatrix}
0 & 0 & 0 & 13 & -10
\end{bmatrix}
\]

```
sage: U*A == H
True
```

```python
>>> from sage.all import *
>>> A = matrix(ZZ,Integer(5),Integer(3),
           ellipsis_range(Integer(1),Ellipsis,
                        →Integer(15)))
>>> H, U = A.hermite_form(transformation=True, include_zero_rows=False)
>>> H
\[
\begin{bmatrix}
1 & 2 & 3
0 & 3 & 6
\end{bmatrix}
\]
>>> U
\[
\begin{bmatrix}
0 & 0 & 0 & 4 & -3
0 & 0 & 0 & 13 & -10
\end{bmatrix}
\]
>>> U*A == H
True
```

**Note:** If 'ntl' is chosen for a non square matrix this function raises a `ValueError`.

Special cases: 0 or 1 rows:

```
sage: a = matrix(ZZ, 1,2,[0,-1])
sage: a.hermite_form()
[0 1]
sage: a.pivots()
(1,)
sage: a = matrix(ZZ, 1,2,[0,0])
sage: a.hermite_form()
[0 0]
sage: a.pivots()
()  
```

```python
>>> from sage.all import *
>>> a = matrix(ZZ, Integer(1),Integer(2),[Integer(0),-Integer(1)])
>>> a.hermite_form()
[0 1]
```
Illustrate using various algorithms:

```python
sage: matrix(ZZ, 3, [1..9]).hermite_form(algorithm='pari')
[1 2 3]
[0 3 6]
[0 0 0]
sage: matrix(ZZ, 3, [1..9]).hermite_form(algorithm='pari0')
[1 2 3]
[0 3 6]
[0 0 0]
sage: matrix(ZZ, 3, [1..9]).hermite_form(algorithm='pari4')
[1 2 3]
[0 3 6]
[0 0 0]
sage: matrix(ZZ, 3, [1..9]).hermite_form(algorithm='padic')
[1 2 3]
[0 3 6]
[0 0 0]
sage: matrix(ZZ, 3, [1..9]).hermite_form(algorithm='default')
[1 2 3]
[0 3 6]
[0 0 0]
```

The 'ntl' algorithm doesn't work on matrices that do not have full rank:

```python
>>> from sage.all import *

>>> matrix(ZZ, Integer(3), (ellipsis_range(Integer(1), Ellipsis, Integer(9)))).hermite_form(algorithm='pari')
[1 2 3]
[0 3 6]
[0 0 0]
```

(continues on next page)
ValueError: ntl only computes HNF for square matrices of full rank.
sage: matrix(ZZ, 3, [0] + [2..9]).hermite_form(algorithm='ntl')
\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 3 \\
\end{bmatrix}
\]

>>> from sage.all import *

>>> matrix(ZZ, Integer(3), [Integer(0)] + (ellipsis_range(Integer(2), Ellipsis, Integer(9)))).hermite_form(algorithm='ntl')
\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 3 \\
\end{bmatrix}
\]

index_in_saturation (proof=None)

Return the index of self in its saturation.

INPUT:

- proof - (default: use proof.linear_algebra()); if False, the determinant calculations are done with proof=False.

OUTPUT:

- positive integer – the index of the row span of this matrix in its saturation

ALGORITHM: Use Hermite normal form twice to find an invertible matrix whose inverse transforms a matrix with the same row span as self to its saturation, then compute the determinant of that matrix.

EXAMPLES:

sage: A = matrix(ZZ, 2, 3, [1..6]); A
\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{bmatrix}
\]
sage: A.index_in_saturation()
3
sage: A.saturation()
\[
\begin{bmatrix}
1 & 2 & 3 \\
1 & 1 & 1 \\
\end{bmatrix}
\]

>>> from sage.all import *

>>> A = matrix(ZZ, Integer(2), Integer(3), (ellipsis_range(Integer(1), Ellipsis, Integer(6)))); A
\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{bmatrix}
\]

>>> A.index_in_saturation()
3

>>> A.saturation()
\[
\begin{bmatrix}
1 & 2 & 3 \\
1 & 1 & 1 \\
\end{bmatrix}
\]

insert_row (index, row)

Create a new matrix from self with.
**INPUT:**

- `index` – integer
- `row` – a vector

**EXAMPLES:**

```
sage: X = matrix(ZZ,3,range(9)); X
[0 1 2]
[3 4 5]
[6 7 8]
sage: X.insert_row(1, [1,5,-10])
[ 0 1 2]
[ 1 5 -10]
[ 3 4 5]
[ 6 7 8]
sage: X.insert_row(0, [1,5,-10])
[ 1 5 -10]
[ 0 1 2]
[ 3 4 5]
[ 6 7 8]
sage: X.insert_row(3, [1,5,-10])
[ 0 1 2]
[ 3 4 5]
[ 6 7 8]
[ 1 5 -10]
```

```
>>> from sage.all import *

>>> X = matrix(ZZ,Integer(3),range(Integer(9))); X
[0 1 2]
[3 4 5]
[6 7 8]

>>> X.insert_row(Integer(1), [Integer(1),Integer(5),-Integer(10)])
[ 0 1 2]
[ 1 5 -10]
[ 3 4 5]
[ 6 7 8]

>>> X.insert_row(Integer(0), [Integer(1),Integer(5),-Integer(10)])
[ 1 5 -10]
[ 0 1 2]
[ 3 4 5]
[ 6 7 8]

>>> X.insert_row(Integer(3), [Integer(1),Integer(5),-Integer(10)])
[ 0 1 2]
[ 3 4 5]
[ 6 7 8]
[ 1 5 -10]
```

**integer_valued_polynomials_generators()**

Determine the generators of the ring of integer valued polynomials on this matrix.

**OUTPUT:**

A pair \((\mu_B, \mathcal{P})\) where \(\mathcal{P}\) is a list of polynomials in \(\mathbb{Q}[X]\) such that

\[
\{ f \in \mathbb{Q}[X] \mid f(B) \in M_n(\mathbb{Z}) \} = \mu_B \mathbb{Q}[X] + \sum_{g \in \mathcal{P}} g\mathbb{Z}[X]
\]

where \(B\) is this matrix.

635
EXAMPLES:

```python
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: B.integer_valued_polynomials_generators()
(x^3 + x^2 - 12*x - 20, [1, 1/4*x^2 + 3/4*x + 1/2])
```

```python
>>> from sage.all import *

>>> B = matrix(ZZ, [[Integer(1), Integer(0), Integer(1)],
                  [Integer(1), -Integer(2), -Integer(1)],
                  [Integer(10), Integer(0), Integer(0)]])

>>> B.integer_valued_polynomials_generators()
(x^3 + x^2 - 12*x - 20, [1, 1/4*x^2 + 3/4*x + 1/2])
```

See also:
```
compute_J_ideal, integer_valued_polynomials_generators()
```

**inverse_of_unit()**

If self is a matrix with determinant 1 or \(-1\) return the inverse of self as a matrix over \(\mathbb{Z}\).

EXAMPLES:

```python
sage: m = matrix(ZZ, 2, [2,1,1,1]).inverse_of_unit()
sage: m
[ 1 -1]
[-1 2]
sage: parent(m)
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring
```

```python
sage: matrix(2, [2,1,0,1]).inverse_of_unit()  # non-invertible matrix
Traceback (most recent call last):
  ...  
ArithmeticError: non-invertible matrix
```

```python
>>> from sage.all import *

>>> m = matrix(ZZ, Integer(2), [Integer(2),Integer(1),Integer(1),Integer(1)]).inverse_of_unit()

>>> m
[ 1 -1]
[-1 2]

>>> parent(m)
Full MatrixSpace of 2 by 2 dense matrices over Integer Ring
```

```python
>>> matrix(Integer(2), [Integer(2),Integer(1),Integer(0),Integer(1)]).inverse_of_unit()  # non-invertible matrix
Traceback (most recent call last):
  ... 
ArithmeticError: non-invertible matrix
```

**is_LLL_reduced**(delta=None, eta=None)

Return True if this lattice is \((\delta, \eta)\)-LLL reduced. See self.LLL for a definition of LLL reduction.

**INPUT:**

- delta – (default: 0.99) parameter \(\delta\) as described above
- eta – (default: 0.501) parameter \(\eta\) as described above

**EXAMPLES:**
```python
sage: A = random_matrix(ZZ, 10, 10)
sage: L = A.LLL()
sage: A.is_LLL_reduced()
False
sage: L.is_LLL_reduced()
True

>>> from sage.all import *
>>> A = random_matrix(ZZ, Integer(10), Integer(10))
>>> L = A.LLL()
>>> A.is_LLL_reduced()
False
>>> L.is_LLL_reduced()
True
```

**is_one()**

Test whether self is the identity matrix.

**EXAMPLES:**

```python
sage: matrix(2, [1,0,0,1]).is_one()
True
sage: matrix(2, [1,1,0,1]).is_one()
False
sage: matrix(2, 3, [1,0,0,0,1,0]).is_one()
False
```

```python
>>> from sage.all import *
>>> matrix(Integer(2), [Integer(1),Integer(0),Integer(0),Integer(1)]).is_one()
True
>>> matrix(Integer(2), [Integer(1),Integer(1),Integer(0),Integer(1)],
   ,Integer(0),Integer(1),Integer(0)]).is_one()
False
```

**is_primitive()**

Test whether the matrix is primitive.

An integral matrix $A$ is primitive if all its entries are non-negative and for some positive integer $n$ the matrix $A^n$ has all its entries positive.

**EXAMPLES:**

```python
sage: m = matrix(3, [1,1,0,0,0,1,1,0,0])
sage: m.isPrimitive()
True
sage: m**4
[3 2 1]
[1 1 1]
[2 1 1]
```

```python
sage: m = matrix(4, [[1,1,0,0],[0,0,1,0],[0,0,0,1],[1,0,0,0]])
sage: m.isPrimitive()
True
sage: m**6
[4 3 2 1]
```

(continues on next page)
[1 1 1 1]
[2 1 1 1]
[3 2 1 1]
sage: m = matrix(4, [[0,1,0,1],[1,0,1,0],[0,1,0,1],[1,0,1,0]])
sage: m.is_primitive()
False

>>> from sage.all import *
>>> m = matrix(Integer(3), [Integer(1),Integer(1),Integer(0),Integer(0),
→Integer(0),Integer(1),Integer(1),Integer(0),Integer(0)])
>>> m.is_primitive()
True
>>> m**Integer(4)
[3 2 1]
[1 1 1]
[2 1 1]

>>> m = matrix(Integer(4), [[Integer(1),Integer(1),Integer(0),Integer(0)],
→[Integer(0),Integer(0),Integer(1),Integer(0)],[Integer(0),Integer(1),
→Integer(0),Integer(1)],[Integer(1),Integer(1),Integer(0),Integer(0)]])
>>> m.is_primitive()
True
>>> m**Integer(6)
[4 3 2 1]
[1 1 1 1]
[2 1 1 1]
[3 2 1 1]

Testing extremal matrices:

sage: def matrix1(d):
....:     m = matrix(d)
....:     m[0,0] = 1
....:     for i in range(d-1):
....:         m[i,i+1] = m[i+1,i] = 1
....:     return m
sage: all(matrix1(d).is_primitive() for d in range(2,20))
True

sage: def matrix2(d):
....:     m = matrix(d)
....:     for i in range(d-1):
....:         m[i,i+1] = 1
....:     m[d-1,0] = m[d-1,1] = 1
....:     return m
sage: all(matrix2(d).is_primitive() for d in range(2,20))
True
from sage.all import *
def matrix1(d):
    m = matrix(d)
    m[0,0] = 1
    for i in range(d-1):
        m[i,i+1] = 1
    return m

all(matrix1(d).is_primitive() for d in range(2,20))

from sage.all import *
def matrix2(d):
    m = matrix(d)
    for i in range(d-1):
        m[i,i+1] = 1
        m[d-1,0] = m[d-1,1] = 1
    return m

all(matrix2(d).is_primitive() for d in range(2,20))

def matrix3(d):
    m = matrix(d)
    m[0,0] = 1
    for i in range(d-1):
        m[i,i+1] = 1
    return m

any(matrix3(d).is_primitive() for d in range(2,20))

minpoly(var='x', algorithm=None)

INPUT:

- var - a variable name
- algorithm - (optional) either 'linbox' (default) or 'generic'

EXAMPLES:

sage: A = matrix(ZZ, 6, range(36))
sage: A.minpoly()
x^3 - 105*x^2 - 630*x

sage: A = Mat(ZZ, 6)([k^2 for k in range(36)])
sage: A.minpoly(algorithm='linbox')
x^4 - 2695*x^3 - 257964*x^2 + 1693440*x
sage: A.minpoly(algorithm='generic')
x^4 - 2695*x^3 - 257964*x^2 + 1693440*x
On non square matrices, this method raises an ArithmeticError:

```
sage: matrix(ZZ, 2, 1).minpoly()
Traceback (most recent call last):
...  
ArithmeticError: only valid for square matrix
```

### null_ideal \((b=0)\)

Return the \((b)\)-ideal of this matrix.

Let \(B\) be a \(n \times n\) matrix. The null ideal modulo \(b\), or \((b)\)-ideal, is

\[
N_{(b)}(B) = \{ f \in \mathbb{Z}[X] \mid f(B) \in M_n(b\mathbb{Z}) \}.
\]

**INPUT:**

- \(b\) – an element of \(\mathbb{Z}\) (default: 0)

**OUTPUT:**

An ideal in \(\mathbb{Z}[X]\).

**EXAMPLES:**

```
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: B.null_ideal()
Principal ideal (x^3 + x^2 - 12*x - 20) of
Univariate Polynomial Ring in x over Integer Ring
```

(continues on next page)
>>> B.null_ideal(Integer(8))
Ideal (8, x^3 + x^2 - 12*x - 20, 2*x^2 + 6*x + 4) of
Univariate Polynomial Ring in x over Integer Ring

>>> B.null_ideal(Integer(6))
Ideal (6, 2*x^3 + 2*x^2 - 24*x - 40, 3*x^2 + 3*x) of
Univariate Polynomial Ring in x over Integer Ring

See also:
compute_J_ideal, null_ideal()

p_minimal_polynomials (p, s_max=None)
Compute \( (p^s) \)-minimal polynomials \( \nu_s \) of this matrix.

For \( s \geq 0 \), a \( (p^s) \)-minimal polynomial of a matrix \( B \) is a monic polynomial \( f \in \mathbb{Z}[X] \) of minimal degree such that all entries of \( f(B) \) are divisible by \( p^s \).

Compute a finite subset \( S \) of the positive integers and \( (p^s) \)-minimal polynomials \( \nu_s \) for \( s \in S \).

For \( 0 < t \leq \max S \), a \( (p^t) \)-minimal polynomial is given by \( \nu_s \) where \( s = \min \{ r \in S \mid r \geq t \} \). For \( t > \max S \), the minimal polynomial of \( B \) is also a \( (p^t) \)-minimal polynomial.

INPUT:
- \( p \) – a prime in \( \mathbb{Z} \)
- \( s \_ max \) – a positive integer (default: None); if set, only \( (p^s) \)-minimal polynomials for \( s \leq s \_ max \) are computed (see below for details)

OUTPUT:
A dictionary. Keys are the finite set \( S \), the values are the associated \( (p^s) \)-minimal polynomials \( \nu_s \), \( s \in S \).

Setting \( s \_ max \) only affects the output if \( s \_ max \) is at most \( \max S \) where \( S \) denotes the full set. In that case, only those \( \nu_s \) with \( s \leq s \_ max \) are returned where \( s \_ max \) is always included even if it is not included in the full set \( S \).

EXAMPLES:

```
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: B.p_minimal_polynomials(2)
{2: x^2 + 3*x + 2}
```

See also:
compute_J_ideal, p_minimal_polynomials()

pivots()
Return the pivot column positions of this matrix.

OUTPUT: a tuple of Python integers: the position of the first nonzero entry in each row of the echelon form.

EXAMPLES:
prod_of_row_sums(cols)

Return the product of the sums of the entries in the submatrix of self with given columns.

INPUT:

- cols – a list (or set) of integers representing columns of self

OUTPUT: an integer

EXAMPLES:

sage: a = matrix(ZZ,2,3,[1..6]); a
[1 2 3]
[4 5 6]
sage: a.prod_of_row_sums([0,2])
40
sage: (1+3)*(4+6)
40
sage: a.prod_of_row_sums(set([0,2]))
40

randomize(density=1, x=None, y=None, distribution=None, nonzero=False)

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.
The parameters are the same as the ones for the integer ring’s `random_element` function.

If \(x\) and \(y\) are given, randomized entries of this matrix have to be between \(x\) and \(y\) and have density 1.

**INPUT:**
- `self` – a mutable matrix over \(\mathbb{Z}\).
- `density` – a float between 0 and 1
- `x, y` – if not None, these are passed to the \(\mathbb{Z}.\text{random_element}\) function as the upper and lower endpoints in the uniform distribution
- `distribution` – would also be passed into \(\mathbb{Z}.\text{random_element}\) if given
- `nonzero` – bool (default: False); whether the new entries are guaranteed to be zero

**OUTPUT:**
- None, the matrix is modified in-place

**EXAMPLES:**

```
sage: A = matrix(ZZ, 2, 3, [1..6])
sage: ranks = [True, True, True]
sage: while any(ranks):
    ...
    A.randomize()
    ...
    ranks[A.rank()] = False

sage: mini = 0
sage: maxi = 0
sage: while mini != -30 and maxi != 30:
    ...
    A.randomize(x=-30, y=30)
    ...
    mini = min(min(A.list()), mini)
    ...
    maxi = min(min(A.list()), maxi)
```

```python
>>> from sage.all import *
```

```python
>>> A = matrix(ZZ, Integer(2), Integer(3), (ellipsis_range(Integer(1), Ellipsis, Integer(6))))
>>> ranks = [True, True, True]
>>> while any(ranks):
...     A.randomize()
...     ranks[A.rank()] = False
```

```
>>> mini = Integer(0)
>>> maxi = Integer(0)
>>> while mini != -Integer(30) and maxi != Integer(30):
...     A.randomize(x=-Integer(30), y=Integer(30))
...     mini = min(min(A.list()), mini)
...     maxi = min(min(A.list()), maxi)
```

`rank (algorithm='modp')`

Return the rank of this matrix.

**INPUT:**
- `algorithm` – either 'modp' (default) or 'flint' or 'linbox'

**OUTPUT:**
- a nonnegative integer – the rank
Note: The rank is cached.

ALGORITHM:
If set to 'modp', first check if the matrix has maximum possible rank by working modulo one random prime. If not, call LinBox's rank function.

EXAMPLES:

```python
sage: a = matrix(ZZ,2,3,[1..6]); a
[1 2 3]
[4 5 6]
sage: a.rank()
2
sage: a = matrix(ZZ,3,3,[1..9]); a
[1 2 3]
[4 5 6]
[7 8 9]
sage: a.rank()
2
```

```python
>>> from sage.all import *

>>> a = matrix(ZZ,Integer(2),Integer(3),(ellipsis_range(Integer(1),Ellipsis, →Integer(6)))); a
[1 2 3]
[4 5 6]

>>> a.rank()
2

>>> a = matrix(ZZ,Integer(3),Integer(3),(ellipsis_range(Integer(1),Ellipsis, →Integer(9)))); a
[1 2 3]
[4 5 6]
[7 8 9]

>>> a.rank()
2
```

Here is a bigger example - the rank is of course still 2:

```python
sage: a = matrix(ZZ,100,[1..100^2]); a.rank()
2
```

```python
>>> from sage.all import *

>>> a = matrix(ZZ,Integer(100),(ellipsis_range(Integer(1),Ellipsis, →Integer(100)**Integer(2)))); a.rank()
2
```

**rational_reconstruction** \((N)\)

Use rational reconstruction to lift self to a matrix over the rational numbers (if possible), where we view self as a matrix modulo \(N\).

INPUT:

- \(N\) – an integer

OUTPUT:

- matrix – over QQ or raise a ValueError
EXAMPLES: We create a random 4x4 matrix over \( \mathbb{Z} \).

```
sage: A = matrix(ZZ, 4, [4, -4, 7, 1, -1, 12, -1, 1, -1, -3, 1, 5, -1])
```

There isn’t a unique rational reconstruction of it:

```
sage: A.rational_reconstruction(11)
Traceback (most recent call last):
... ValueError: rational reconstruction does not exist
```

We throw in a denominator and reduce the matrix modulo 389 - it does rationally reconstruct.

```
sage: B = (A/3 % 389).change_ring(ZZ)
sage: B.rational_reconstruction(389) == A/3
True
```

```
row(i, from_list=False)
```

Return the i-th row of this matrix as a dense vector.

**INPUT:**

- `i` – integer
- `from_list` – ignored

**EXAMPLES:**

```
sage: m = matrix(ZZ, 2, [1, -2, 3, 4])
sage: m.row(0)
(1, -2)
sage: m.row(1)
(3, 4)
sage: m.row(1, from_list=True)
(3, 4)
sage: m.row(-2)
(1, -2)
sage: m.row(2)
Traceback (most recent call last):
```

(continues on next page)
... IndexError: row index out of range

```python
sage: m.row(-3)
Traceback (most recent call last):
...
IndexError: row index out of range
```

```python
>>> from sage.all import *

>>> m = matrix(ZZ, Integer(2), [Integer(1), -Integer(2), Integer(3),
-> Integer(4)]

>>> m.row(Integer(0))
(1, -2)

>>> m.row(Integer(1))
(3, 4)

>>> m.row(Integer(1), from_list=True)
(3, 4)

>>> m.row(-Integer(2))
(1, -2)

>>> m.row(Integer(2))
Traceback (most recent call last):
...
IndexError: row index out of range

>>> m.row(-Integer(3))
Traceback (most recent call last):
...
IndexError: row index out of range
```

```
saturation (p=0, proof=None, max_dets=5)

Return a saturation matrix of self, which is a matrix whose rows span the saturation of the row span of self. This is not unique.

The saturation of a \( \mathbb{Z} \) module \( M \) embedded in \( \mathbb{Z}^n \) is a module \( S \) that contains \( M \) with finite index such that \( \mathbb{Z}^n / S \) is torsion free. This function takes the row span \( M \) of self, and finds another matrix of full rank with row span the saturation of \( M \).

**INPUT:**

- \( p \) – (default: 0); if nonzero given, saturate only at the prime \( p \), i.e., return a matrix whose row span is a \( \mathbb{Z} \)-module \( S \) that contains self and such that the index of \( S \) in its saturation is coprime to \( p \). If \( p \) is None, return full saturation of self.
- \( proof \) – (default: use proof.linear_algebra()); if False, the determinant calculations are done with proof=False.
- \( max_dets \) – (default: 5); technical parameter - max number of determinant to compute when bounding prime divisor of self in its saturation.

**OUTPUT:**

- matrix – a matrix over ZZ.

**Note:** The result is not cached.

**ALGORITHM:** 1. Replace input by a matrix of full rank got from a subset of the rows. 2. Divide out any common factors from rows. 3. Check max_dets random dets of submatrices to see if their GCD (with...
p) is 1 - if so matrix is saturated and we’re done. 4. Finally, use that if A is a matrix of full rank, then
\(hnf(\text{transpose}(A))^{-1} \cdot A\) is a saturation of A.

EXAMPLES:

```sage
A = matrix(ZZ, 3, 5, [-51, -1509, -71, -109, -593, -19, -341, 4, 86, 98, 0, -246, -11, 65, 217])
A.echelon_form()

[ 1 5 2262 20364 56576]
[ 0 6 35653 320873 891313]
[ 0 0 42993 386937 1074825]

S = A.saturation(); S

[ -51 -1509 -71 -109 -593]
[ -19 -341 4 86 98]
[ 35 994 43 51 347]
```

Notice that the saturation spans a different module than A.

```sage
S.echelon_form()

[ 1 2 0 8 32]
[ 0 3 0 -2 -6]
[ 0 0 1 9 25]
```

```sage
V = A.row_space(); W = S.row_space()
V.is_submodule(W)
True
V.index_in(W)
85986
V.index_in_saturation()
85986
```

We illustrate each option:
sage: S = A.saturation(p=2)
sage: S = A.saturation(proof=False)
sage: S = A.saturation(max_dets=2)

>>> from sage.all import *
>>> S = A.saturation(p=Integer(2))
>>> S = A.saturation(proof=False)
>>> S = A.saturation(max_dets=Integer(2))

smith_form (transformation=True, integral=None)

Return the smith normal form of this matrix, that is the diagonal matrix \( S \) with diagonal entries the ordered elementary divisors of this matrix.

INPUT:

- transformation – a boolean (default: True); whether to return the transformation matrices \( U \) and \( V \) such that \( S = U \cdot \text{self} \cdot V \).
- integral – a subring of the base ring or True (default: None); ignored for matrices with integer entries.

Note: The elementary_divisors() function, which returns the diagonal entries of \( S \), is VASTLY faster than this function.

The elementary divisors are the invariants of the finite abelian group that is the cokernel of this matrix. They are ordered in reverse by divisibility.

EXAMPLES:

```python
sage: A = MatrixSpace(IntegerRing(), 3)(range(9))
sage: D, U, V = A.smith_form()
sage: D
[1 0 0]
[0 3 0]
[0 0 0]
sage: U
[ 0 2 -1]
[ 0 -1 1]
[ 1 -2 1]
sage: V
[ 0 0 1]
[-1 2 -2]
[ 1 -1 1]
sage: U*A*V
[1 0 0]
[0 3 0]
[0 0 0]
```

```python
>>> from sage.all import *
>>> A = MatrixSpace(IntegerRing(), Integer(3))(range(Integer(9)))
>>> D, U, V = A.smith_form()
>>> D
[1 0 0]
[0 3 0]
[0 0 0]
>>> U
```

(continues on next page)
It also makes sense for nonsquare matrices:

```
sage: A = Matrix(ZZ, 3, 2, range(6))
sage: D, U, V = A.smith_form()
sage: D
[1 0]
[0 2]
[0 0]
sage: U
[ 0 2 -1]
[ 0 -1 1]
[ 1 -2 1]
sage: V
[-1 1]
[ 1 0]
sage: U * A * V
[1 0]
[0 2]
[0 0]
```

Empty matrices are handled sensibly (see Issue #3068):

```
sage: m = MatrixSpace(ZZ, 2, 0)(0); d, u, v = m.smith_form(); u*m*v == d
True
sage: m = MatrixSpace(ZZ, 0, 2)(0); d, u, v = m.smith_form(); u*m*v == d
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

\[
\begin{array}{c}
\textbf{True:} \quad m = \text{MatrixSpace}(\mathbb{Z}, 0,0)(0); \quad d,u,v = m.\text{smith_form}(); \quad u^*m^*v = d \\
\textbf{True}
\end{array}
\]

\[
\begin{array}{c}
>>> \text{from sage.all import *} \\
>>> m = \text{MatrixSpace}(\mathbb{Z}, \text{Integer}(2),\text{Integer}(0))(\text{Integer}(0)); \quad d,u,v = m.\text{smith_form}(); \quad u^*m^*v = d \\
\textbf{True} \\
>>> m = \text{MatrixSpace}(\mathbb{Z}, \text{Integer}(0),\text{Integer}(2))(\text{Integer}(0)); \quad d,u,v = m.\text{smith_form}(); \quad u^*m^*v = d \\
\textbf{True} \\
>>> m = \text{MatrixSpace}(\mathbb{Z}, \text{Integer}(0),\text{Integer}(0))(\text{Integer}(0)); \quad d,u,v = m.\text{smith_form}(); \quad u^*m^*v = d \\
\textbf{True}
\end{array}
\]

See also:
\texttt{elementary_divisors()}
\texttt{symplectic_form()}

\texttt{symplectic_form()}

Find a symplectic basis for \texttt{self} if \texttt{self} is an anti-symmetric, alternating matrix.

Return a pair (F, C) such that the rows of C form a symplectic basis for \texttt{self} and \(F = C \ast self \ast C.\text{transpose}()\).

Raise a \texttt{ValueError} if \texttt{self} is not anti-symmetric, or \texttt{self} is not alternating.

Anti-symmetric means that \(M = -M^t\). Alternating means that the diagonal of \(M\) is identically zero.

A symplectic basis is a basis of the form \(e_1, \ldots, e_j, f_1, \ldots f_j, z_1, \ldots, z_k\) such that

- \(z_iMv^t = 0\) for all vectors \(v\)
- \(e_iMe_j^t = 0\) for all \(i, j\)
- \(f_iMf_j^t = 0\) for all \(i, j\)
- \(e_iMf_i^t = 1\) for all \(i\)
- \(e_iMf_j^t = 0\) for all \(i \neq j\).

The ordering for the factors \(d_i|d_{i+1}\) and for the placement of zeroes was chosen to agree with the output of \texttt{smith_form()}.

See the example for a pictorial description of such a basis.

\texttt{EXAMPLES:}

\[
\begin{array}{c}
\textbf{sage:} \quad E = \text{matrix}(\mathbb{Z}, 5, 5, [0, 14, 0, -8, -2, -14, 0, -3, -11, 4, 0, 3, 0, 0, -8, 11, 0, 0, 8, 2, -4, 0, -8, 0]); \quad E \\
\begin{bmatrix}
0 & 14 & 0 & -8 & -2 \\
-14 & 0 & -3 & -11 & 4 \\
0 & 3 & 0 & 0 & 0 \\
8 & 11 & 0 & 0 & 8 \\
2 & -4 & 0 & -8 & 0
\end{bmatrix} \\
\textbf{sage:} \quad F, C = E.\text{symplectic_form}() \\
\textbf{sage:} \quad F \\
\begin{bmatrix}
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 2 & 0 \\
-1 & 0 & 0 & 0 & 0
\end{bmatrix}
\end{array}
\]

(continues on next page)

(continued from previous page)

```
[ 0  -2  0  0  0]
[ 0   0  0  0  0]
sage: F == C * E * C.transpose()
True
sage: E.smith_form()[0]
[1  0  0  0  0]
[0  1  0  0  0]
[0  0  2  0  0]
[0  0  0  2  0]
[0  0  0  0  0]
```

```
>>> from sage.all import *
>>> E = matrix(ZZ, Integer(5), Integer(5), [Integer(0), Integer(14),
-Integer(0), -Integer(8), -Integer(2), -Integer(14), Integer(0), -Integer(3),
-Integer(11), Integer(4), Integer(0), Integer(3), Integer(0), Integer(0),
-Integer(0), Integer(8), Integer(11), Integer(0), Integer(0), Integer(0),
-Integer(2), -Integer(4), Integer(0), -Integer(8), Integer(0)]); E
[ 0 14 0 -8 -2]
[-14 0 -3 -11 4]
[ 0 3 0 0 0]
[ 8 11 0 0 8]
[ 2 -4 0 -8 0]

>>> F, C = E.symplectic_form()
>>> F
[ 0  0  1  0  0]
[ 0  0  0  2  0]
[-1  0  0  0  0]
[ 0  -2  0  0  0]
[ 0  0  0  0  0]
>>> F == C * E * C.transpose()
True
>>> E.smith_form()[Integer(0)]
[1  0  0  0  0]
[0  1  0  0  0]
[0  0  2  0  0]
[0  0  0  2  0]
[0  0  0  0  0]
```

### transpose()

Return the transpose of self, without changing self.

**EXAMPLES:**

We create a matrix, compute its transpose, and note that the original matrix is not changed.

```
sage: A = matrix(ZZ, 2, 3, range(6))
sage: type(A)
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>
sage: B = A.transpose()
sage: print(B)
[0 3]
[1 4]
[2 5]
sage: print(A)
[0 1 2]
[3 4 5]```
Matrices and Spaces of Matrices, Release 10.4

```python
>>> from sage.all import *

>>> A = matrix(ZZ, Integer(2), Integer(3), range(Integer(6)))

>>> type(A)
<class 'sage.matrix.matrix_integer_dense.Matrix_integer_dense'>

>>> B = A.transpose()

>>> print(B)
[0 3]
[1 4]
[2 5]

>>> print(A)
[0 1 2]
[3 4 5]

.T is a convenient shortcut for the transpose:

```text
sage: A.T
[0 3]
[1 4]
[2 5]
```

```python
>>> from sage.all import *

>>> A.T
[0 3]
[1 4]
[2 5]

sage: A.subdivide(None, 1); A
[0|1 2]
[3|4 5]

sage: A.transpose()
[0 3]
[---]
[1 4]
[2 5]
```

```python
>>> from sage.all import *

>>> A.subdivide(None, Integer(1)); A
[0|1 2]
[3|4 5]

>>> A.transpose()
[0 3]
[---]
[1 4]
[2 5]
```

```

```
Chapter Sixteen

Sparse Integer Matrices

Authors:
- William Stein (2007-02-21)
- Soroosh Yazdani (2007-02-21)

```python
class sage.matrix.matrix_integer_sparse.Matrix_integer_sparse
    Bases: Matrix_sparse

Create a sparse matrix over the integers.

INPUT:
- parent – a matrix space over \( \mathbb{Z} \)
- entries – see `matrix()`
- copy – ignored (for backwards compatibility)
- coerce – if False, assume without checking that the entries are of type `Integer`.

`charpoly(var='x', algorithm=None)`

Return the characteristic polynomial of this matrix.

INPUT:
- var – (default: 'x') the name of the variable of the polynomial
- algorithm – (default: None) one of None, 'linbox', or an algorithm accepted by `sage.matrix.matrix_integer_sparse.Matrix_integer_sparse.charpoly()`

Examples:
```
sage: M = MatrixSpace(ZZ, 4, sparse=True)
sage: m = M()
sage: m[0,0] = m[1,2] = m[2,3] = m[3,3] = 1
sage: m[0,2] = m[1,3] = m[2,0] = m[3,0] = -3
sage: m[1,1] = 2
sage: m
[ 1  0 -3  0]
[ 0  2  1 -3]
[-3  0  0  1]
[-3  0  0  1]
sage: m.charpoly()
x^4 - 4*x^3 + 4*x^2 + 16*x
```
```python
>>> from sage.all import *
>>> M = MatrixSpace(ZZ, Integer(4), sparse=True)
>>> m = M()
>>> m[Integer(0),Integer(0)] = m[Integer(1),Integer(2)] = m[Integer(2),
˓→Integer(3)] = m[Integer(3),Integer(3)] = Integer(1)
>>> m[Integer(0),Integer(2)] = m[Integer(1),Integer(3)] = m[Integer(2),
˓→Integer(0)] = m[Integer(3),Integer(0)] = -Integer(3)
>>> m[Integer(1),Integer(1)] = Integer(2)
>>> m
[ 1  0 -3  0]
[ 0  2  1 -3]
[-3  0  0  1]
[-3  0  0  1]
```

```python
>>> m.charpoly()
x^4 - 4*x^3 - 4*x^2 + 16*x
```

**elementary_divisors** *(algorithm='pari')*

Return the elementary divisors of self, in order.

The elementary divisors are the invariants of the finite abelian group that is the cokernel of left multiplication by this matrix. They are ordered in reverse by divisibility.

**INPUT:**

- **self** – matrix
- **algorithm** – (default: ‘pari’)
  - ‘pari’: works robustly, but is slower.
  - ‘linbox’ – use linbox (currently off, broken)

**OUTPUT:**

list of integers

**EXAMPLES:**

```python
sage: matrix(3, range(9),sparse=True).elementary_divisors()
[1, 3, 0]
sage: M = matrix(ZZ, 3, [1,5,7, 3,6,9, 0,1,2], sparse=True)
sage: M.elementary_divisors()
[1, 1, 6]
```

This returns a copy, which is safe to change:

```python
sage: edivs = M.elementary_divisors()
sage: edivs.pop()
6
sage: M.elementary_divisors()
[1, 1, 6]
```
See also:

smith_form()

hermite_form(algorithm='default', cutoff=0, **kwds)

Return the echelon form of self.

**Note:** This row reduction does not use division if the matrix is not over a field (e.g., if the matrix is over the integers). If you want to calculate the echelon form using division, then use \texttt{rref()}, which assumes that the matrix entries are in a field (specifically, the field of fractions of the base ring of the matrix).

**INPUT:**

- \texttt{algorithm} -- string. Which algorithm to use. Choices are
  - 'default': Let Sage choose an algorithm (default).
  - 'classical': Gauss elimination.
  - 'partial_pivoting': Gauss elimination, using partial pivoting (if base ring has absolute value)
  - 'scaled_partial_pivoting': Gauss elimination, using scaled partial pivoting (if base ring has absolute value)
  - 'scaled_partial_pivoting_valuation': Gauss elimination, using scaled partial pivoting (if base ring has valuation)
  - 'strassen': use a Strassen divide and conquer algorithm (if available)
- \texttt{cutoff} -- integer. Only used if the Strassen algorithm is selected.
- \texttt{transformation} -- boolean. Whether to also return the transformation matrix. Some matrix backends do not provide this information, in which case this option is ignored.

**OUTPUT:**

The reduced row echelon form of self, as an immutable matrix. Note that self is not changed by this command. Use \texttt{echelonize()} to change self in place.

If the optional parameter \texttt{transformation=True} is specified, the output consists of a pair \((E, T)\) of matrices where \(E\) is the echelon form of self and \(T\) is the transformation matrix.

**EXAMPLES:**

```python
gf = GF(19)  
MS = MatrixSpace(gf, 2, 3)  
C = MS.matrix([[1, 2, 3, 4, 5, 6]])  
C.rank()  
2  
C.nullity()  
0  
C.echelon_form()  
[ 1 0 18]  
[ 0 1 2]
```
Matrices and Spaces of Matrices, Release 10.4

```python
>>> from sage.all import *

>>> MS = MatrixSpace(GF(Integer(19)), Integer(2), Integer(3))
>>> C = MS.matrix([Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(6)])

>>> C.rank()
2
>>> C.nullity()
0
>>> C.echelon_form()
[ 1 0 18]
[ 0 1  2]

The matrix library used for \(\mathbb{Z}/p\)-matrices does not return the transformation matrix, so the transformation option is ignored:

```python
sage: C.echelon_form(transformation=True)
[ 1 0 18]
[ 0 1  2]
```

```python
sage: D = matrix(ZZ, 2, 3, [1,2,3,4,5,6])
sage: D.echelon_form(transformation=True)
( [ 1  2  3] [ 1  0]
 [ 0  3  6], [ 4 -1]
)
sage: E, T = D.echelon_form(transformation=True)
sage: T*D == E
True
```

```python
>>> from sage.all import *

>>> C.echelon_form(transformation=True)
[ 1 0 18]
[ 0 1  2]

>>> D = matrix(ZZ, Integer(2), Integer(3), [1,2,3,4,5,6])
>>> D.echelon_form(transformation=True)
( [ 1  2  3] [ 1  0]
 [ 0  3  6], [ 4 -1]
)
```

```python
>>> E, T = D.echelon_form(transformation=True)
>>> T*D == E
True
```

\textbf{minpoly}(\textit{var}='x', \textit{algorithm}=None)

Return the minimal polynomial of this matrix.

\textbf{INPUT:}

- \textit{var} – (default: 'x') the name of the variable of the polynomial
- \textit{algorithm} – (default: None) one of None, 'linbox', or an algorithm accepted by \textit{sage}.matrix.matrix_sparse.Matrix_sparse.minpoly()

\textbf{EXAMPLES:}
Matrices and Spaces of Matrices, Release 10.4

```python
sage: M = MatrixSpace(ZZ, 4, sparse=True)
sage: m = M({(0, 0):2, (1, 1):1, (2, 1):-8, (2, 2):2, (2, 3):-1, (3, 3):1})
sage: m
[ 2 0 0 0]
[ 0 1 0 0]
[ 0 -8 2 -1]
[ 0 0 0 1]
sage: m.minpoly()
x^2 - 3*x + 2
>>>
```

```python
>>> from sage.all import *

>>> M = MatrixSpace(ZZ, Integer(4), sparse=True)

>>> m = M({(Integer(0), Integer(0)):Integer(2), (Integer(1), Integer(1)):Integer(1), (Integer(2), Integer(1)):Integer(-8), (Integer(2), Integer(2)):Integer(2), (Integer(2), Integer(3)):Integer(-1), (Integer(3), Integer(3)):Integer(1)})

>>> m
[ 2 0 0 0]
[ 0 1 0 0]
[ 0 -8 2 -1]
[ 0 0 0 1]
>>> m.minpoly()
x^2 - 3*x + 2
```

```python
rank (algorithm=None)

Compute the rank of this matrix.

INPUT:

- algorithm – (optional) one of None, 'linbox' or 'generic'

EXAMPLES:

```python
sage: M = MatrixSpace(ZZ, 3, 2, sparse=True)
sage: m = M([1, 0, 2, 3, -1, 0])
sage: m.rank()
2
```

```python
>>> from sage.all import *

>>> M = MatrixSpace(ZZ, Integer(3), Integer(2), sparse=True)

>>> m = M([Integer(1), Integer(0), Integer(2), Integer(3), Integer(-1), Integer(0)])

>>> m.rank()
2
```

rational_reconstruction (N)

Use rational reconstruction to lift self to a matrix over the rational numbers (if possible), where we view self as a matrix modulo N.

EXAMPLES:

```python
sage: A = matrix(ZZ, 3, 4, [(1/3)%500, 2, 3, (-4)%500,
....: 7, 2, 2, 3,
....: 4, 3, 4, (5/7)%500], sparse=True)
sage: A.rational_reconstruction(500)
[1/3  2  3   4]
[ 7  2  2  3]
[ 4  3  4  5/7]
```

rank (algorithm=None)

Compute the rank of this matrix.

INPUT:

- algorithm – (optional) one of None, 'linbox' or 'generic'

EXAMPLES:

```python
sage: M = MatrixSpace(ZZ, 3, 2, sparse=True)
sage: m = M([1, 0, 2, 3, -1, 0])
sage: m.rank()
2
```

```python
>>> from sage.all import *

>>> M = MatrixSpace(ZZ, Integer(3), Integer(2), sparse=True)

>>> m = M([Integer(1), Integer(0), Integer(2), Integer(3), Integer(-1), Integer(0)])

>>> m.rank()
2
```

rational_reconstruction (N)

Use rational reconstruction to lift self to a matrix over the rational numbers (if possible), where we view self as a matrix modulo N.

EXAMPLES:

```python
sage: A = matrix(ZZ, 3, 4, [(1/3)%500, 2, 3, (-4)%500,
....: 7, 2, 2, 3,
....: 4, 3, 4, (5/7)%500], sparse=True)
sage: A.rational_reconstruction(500)
[1/3  2  3   4]
[ 7  2  2  3]
[ 4  3  4  5/7]
```
Matrices and Spaces of Matrices, Release 10.4

```
>>> from sage.all import *

>>> A = matrix(ZZ, Integer(3), Integer(4), [(Integer(1)/Integer(3)) % Integer(500), Integer(2), Integer(3), (-Integer(4)) % Integer(500), ...
   Integer(7), Integer(2), Integer(2), Integer(3), ...
   Integer(4), Integer(3), Integer(4), (Integer(5)/Integer(7)) % Integer(500)], sparse=True)

>>> A.rational_reconstruction(Integer(500))

\[
\begin{bmatrix}
\frac{1}{3} & 2 & 3 & -4 \\
7 & 2 & 2 & 3 \\
4 & 3 & 4 & \frac{5}{7}
\end{bmatrix}
\]

```

**smith_form** *(transformation=True, integral=None)*

Return the smith normal form of this matrix, that is the diagonal matrix $S$ with diagonal entries the ordered elementary divisors of this matrix.

**INPUT:**

- **transformation** – a boolean (default: True); whether to return the transformation matrices $U$ and $V$ such that $S = U \cdot \text{self} \cdot V$.
- **integral** – a subring of the base ring or True (default: None); ignored for matrices with integer entries.

This version is for sparse matrices and simply makes the matrix dense and calls the version for dense integer matrices.

**Note:** The `elementary_divisors()` function, which returns the diagonal entries of $S$, is VASTLY faster than this function.

The elementary divisors are the invariants of the finite abelian group that is the cokernel of this matrix. They are ordered in reverse by divisibility.

**EXAMPLES:**

```
sage: A = MatrixSpace(IntegerRing(), 3, sparse=True)(range(9))
sage: D, U, V = A.smith_form()
sage: D

\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 3 & 0 \\
0 & 0 & 0
\end{bmatrix}
\]

sage: U

\[
\begin{bmatrix}
0 & 2 & -1 \\
0 & -1 & 1 \\
1 & -2 & 1
\end{bmatrix}
\]

sage: V

\[
\begin{bmatrix}
0 & 0 & 1 \\
-1 & 2 & -2 \\
1 & -1 & 1
\end{bmatrix}
\]

sage: U*A*V

\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 3 & 0 \\
0 & 0 & 0
\end{bmatrix}
\]

```
It also makes sense for nonsquare matrices:

```
sage: A = Matrix(ZZ,3,2,range(6), sparse=True)
sage: D, U, V = A.smith_form()
sage: D
[1 0]
[0 2]
[0 0]

sage: U
[ 0 2 -1]
[ 0 -1 1]
[ 1 -2 1]

sage: V
[-1 1]
[ 1 0]

sage: U * A * V
[1 0]
[0 2]
[0 0]
```

The examples above show that Issue #10626 has been implemented.

`elementary_divisors()`
MODULAR ALGORITHM TO COMPUTE HERMITE NORMAL FORMS OF INTEGER MATRICES

AUTHORS:
• Clement Pernet and William Stein (2008-02-07): initial version

`sage.matrix.matrix_integer_dense_hnf.add_column(B, H_B, a, proof)`  
The add column procedure.  

**INPUT:**  
• B – a square matrix (may be singular)  
• H_B – the Hermite normal form of B  
• a – an n x 1 matrix, where B has n rows  
• proof – bool; whether to prove result correct, in case we use fallback method.  

**OUTPUT:**  
• x – a vector such that H' = H_B.augment(x) is the HNF of A = B.augment(a).  

**EXAMPLES:**

```python
sage: B = matrix(ZZ, 3, 3, [1,2,5, 0,-5,3, 1,1,2])
sage: H_B = B.echelon_form()
sage: a = matrix(ZZ, 3, 1, [1,8,-2])
sage: import sage.matrix.matrix_integer_dense_hnf as hnf
tsage: x = hnf.add_column(B, H_B, a, True); x
[18]
[3]
[23]
sage: H_B.augment(x)
[ 1 0 17 18]
[ 0 1 3 3]
[ 0 0 18 23]
sage: B.augment(a).echelon_form()
[ 1 0 17 18]
[ 0 1 3 3]
[ 0 0 18 23]
```

```python
>>> from sage.all import *
>>>
>>> B = matrix(ZZ, Integer(3), Integer(3), [Integer(1),Integer(2),Integer(5),-Integer(0),-Integer(5),Integer(3), Integer(1),Integer(1),Integer(2)])
>>> H_B = B.echelon_form()
>>> a = matrix(ZZ, Integer(3), Integer(1), [Integer(1),Integer(8),-Integer(2)])
```

(continues on next page)
Simplistic version of add_column, in case the powerful clever one fails (e.g., B is singular).

INPUT:

B – a square matrix (may be singular) a – an n x 1 matrix, where B has n rows proof – bool; whether to prove result correct

OUTPUT:

x – a vector such that $H' = H_B.augment(x)$ is the HNF of $A = B.augment(a)$.

EXAMPLES:

```
sage: B = matrix(ZZ, 3, [-1, -1, 1, -3, 8, -2, -1, -1, -1])
sage: a = matrix(ZZ, 3, 1, [1, 2, 3])
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: matrix_integer_dense_hnf.add_column_fallback(B, a, True)
[-3]
[-7]
[-2]
sage: matrix_integer_dense_hnf.add_column_fallback(B, a, False)
[-3]
[-7]
[-2]
sage: B.augment(a).hermite_form()
[ 1 1 1 -3]
[ 0 11 1 -7]
[ 0 0 2 -2]
```
sage.matrix.matrix_integer_dense_hnf.add_row(A, b, pivots, include_zero_rows)

The add row procedure.

INPUT:

• A – a matrix in Hermite normal form with n column
• b – an n x 1 row matrix
• pivots – sorted list of integers; the pivot positions of A.

OUTPUT:

• H – the Hermite normal form of A.stack(b).
• new_pivots – the pivot columns of H.

EXAMPLES:

sage: import sage.matrix.matrix_integer_dense_hnf as hnf
sage: A = matrix(ZZ, 2, 3, [-21, -7, 5, 1, 20, -7])
sage: b = matrix(ZZ, 1, 3, [-1, 1, -1])
sage: hnf.add_row(A, b, A.pivots(), True)
([ 1 6 29]
 [ 0 7 28]
 [ 0 0 46], [0, 1, 2])
sage: A.stack(b).echelon_form()
([ 1 6 29]
 [ 0 7 28]
 [ 0 0 46])

sage.matrix.matrix_integer_dense_hnf.benchmark_hnf(nrange, bits=4)

Run benchmark program.

EXAMPLES:
EXAMPLES:

```python
sage: import sage.matrix.matrix_integer_dense_hnf as hnf
sage: hnf.benchmark_magma_hnf([50,100],32)  # optional - magma
('magma', 50, 32, ...),
('magma', 100, 32, ...),
```

This is used for internal purposes for computing determinants quickly (with the hybrid p-adic / multimodular algorithm).

**INPUT:**

- A – a square matrix
- d – a divisor of the determinant of A
- p – a prime
- z_mod – values of det/d (mod …)
- moduli – the moduli so far
- z_so_far – for a modulus p in the list moduli, (z_so_far mod p) is the determinant of A modulo p.
- N_so_far – N_so_far is the product over the primes in the list moduli.

**OUTPUT:**

- A triple (det bound, new z_so_far, new N_so_far).

**EXAMPLES:**

```python
sage: a = matrix(ZZ, 3, [6, 1, 2, -56, -2, -1, -11, 2, -3])
sage: factor(a.det())
(-1) * 13 * 29
sage: d = 13
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
```
sage.matrix.matrix_integer_dense_hnf.det_given_divisor (A, d, proof=True, stabilize=2)

Given a divisor d of the determinant of A, compute the determinant of A.

INPUT:

• A – a square integer matrix
• d – a nonzero integer that is assumed to divide the determinant of A
• proof – bool (default: True) compute det modulo enough primes so that the determinant is computed provably correctly (via the Hadamard bound). It would be VERY hard for det() to fail even with proof=False.
• stabilize – int (default: 2) if proof = False, then compute the determinant modulo p until stabilize successive modulo determinant computations stabilize.

OUTPUT:

integer – determinant

EXAMPLES:

sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: a = matrix(ZZ,3,[[-1, -1, -1, -20, 4, 1, -1, 1, 2]])
sage: matrix_integer_dense_hnf.det_given_divisor(a, 3)
-30
sage: matrix_integer_dense_hnf.det_given_divisor(a, 3, proof=False)
-30
sage: matrix_integer_dense_hnf.det_given_divisor(a, 3, proof=False, stabilize=1)
-30
sage: a.det()
-30

>>> from sage.all import *
>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
>>> a = matrix(ZZ,Integer(3),[-Integer(1), -Integer(1), -Integer(1), -Integer(20), Integer(4), 1, -1, 1, 2])
>>> matrix_integer_dense_hnf.det_given_divisor(a, Integer(3))
-30
>>> matrix_integer_dense_hnf.det_given_divisor(a, Integer(3), proof=False)
-30
>>> matrix_integer_dense_hnf.det_given_divisor(a, Integer(3), proof=False, ...
Here we illustrate $\text{proof}=\text{False}$ giving a wrong answer:

```python
sage: p = matrix_integer_dense_hnf.max_det_prime(2)
sage: q = previous_prime(p)
sage: a = matrix(ZZ, 2, [p, 0, 0, q])
sage: p * q
7036842188091
```

```python
sage: matrix_integer_dense_hnf.det_given_divisor(a, 1, proof=False, stabilize=2)
0
```

This still works, because we do not work modulo primes that divide the determinant bound, which is found using a $p$-adic algorithm:

```python
sage: a.det(proof=False, stabilize=2)
7036842188091
```

3 primes is enough:

```python
sage: matrix_integer_dense_hnf.det_given_divisor(a, 1, proof=False, stabilize=3)
7036842188091
sage: matrix_integer_dense_hnf.det_given_divisor(a, 1, proof=False, stabilize=5)
7036842188091
sage: matrix_integer_dense_hnf.det_given_divisor(a, 1, proof=True)
7036842188091
```

```python
>>> from sage.all import *
```

```python
>>> p = matrix_integer_dense_hnf.max_det_prime(Integer(2))
>>> q = previous_prime(p)
>>> a = matrix(ZZ, Integer(2), [p, Integer(0), Integer(0), q])
>>> p * q
7036842188091
>>> matrix_integer_dense_hnf.det_given_divisor(a, Integer(1), proof=False, stabilze=2)
0
```

```python
>>> from sage.all import *
```

```python
>>> a.det(proof=False, stabilze=Integer(2))
7036842188091
```

```python
>>> from sage.all import *
```

```python
>>> a.det(proof=False, stabilze=Integer(2))
7036842188091
```

```python
```

`sage.matrix.matrix_integer_dense_hnf.det_padic(A, proof=True, stabilize=2)`

Return the determinant of $A$, computed using a $p$-adic/multimodular algorithm.
INPUT:

- A – a square matrix
- proof – boolean
- stabilize (default: 2) – if proof False, number of successive primes so that CRT det must stabilize.

EXAMPLES:

```
sage: import sage.matrix.matrix_integer_dense_hnf as h
sage: a = matrix(ZZ, 3, [1..9])
h: det_padic(a)...
```

```
>>> from sage.all import *
>>> import sage.matrix.matrix_integer_dense_hnf as h
... a = matrix(ZZ, Integer(3), (ellipsis_range(Integer(1),Ellipsis,Integer(9))))
h: det_padic(a)...
```

```
sage.matrix.matrix_integer_dense_hnf.double_det(A, b, c, proof)
```

Compute the determinants of the stacked integer matrices A.stack(b) and A.stack(c).

INPUT:

- A – an (n-1) x n matrix
- b – a 1 x n matrix
- c – a 1 x n matrix
- proof – whether or not to compute the det modulo enough times to provably compute the determinant.

OUTPUT:

- a pair of two integers.

EXAMPLES:

```
sage: from sage.matrix.matrix_integer_dense_hnf import double_det
sage: A = matrix(ZZ, 2, 3, [1,2,3, 4,-2,5])
sage: b = matrix(ZZ, 1, 3, [1,-2,5])
sage: c = matrix(ZZ, 1, 3, [8,2,10])
sage: A.stack(b).det()...
```

```
sage: double_det(A, b, c, False)
(-48, 42)
```
```python
>>> from sage.all import *

>>> from sage.matrix.matrix_integer_dense_hnf import double_det

>>> A = matrix(ZZ, Integer(2), Integer(3), [Integer(1),Integer(2),Integer(3),
                                           Integer(4),-Integer(2),Integer(5)])

>>> b = matrix(ZZ, Integer(1), Integer(3), [Integer(1),-Integer(2),Integer(5)])

>>> c = matrix(ZZ, Integer(1), Integer(3), [Integer(8),Integer(2),Integer(10)])

>>> A.stack(b).det()
-48

>>> A.stack(c).det()
42

>>> double_det(A, b, c, False)
(-48, 42)
```

`sage.matrix.matrix_integer_dense_hnf.extract_ones_data(H, pivots)`

Compute ones data and corresponding submatrices of H.

This is used to optimized the `add_row()` function.

**INPUT:**

- H – a matrix in HNF
- pivots – list of all pivot column positions of H

**OUTPUT:**

C, D, E, onecol, onerow, non_onecol, non_onerow where onecol, onerow, non_onecol, non_onerow are as for the ones function, and C, D, E are matrices:

- C – submatrix of all non-onecol columns and onecol rows
- D – all non-onecol columns and other rows
- E – inverse of D

If D is not invertible or there are 0 or more than 2 non onecols, then C, D, and E are set to None.

**EXAMPLES:**

```python
sage: H = matrix(ZZ, 3, 4, [1, 0, 0, 7, 0, 1, 5, 2, 0, 0, 6, 6])
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: matrix_integer_dense_hnf.extract_ones_data(H, [0,1,2])
([0], [5], [6], [1/6], [0, 1], [0, 1], [2], [2])
```

```python
>>> from sage.all import *

>>> H = matrix(ZZ, Integer(3), Integer(4), [Integer(1), Integer(2), Integer(0), Integer(0),
                                           Integer(7), Integer(0), Integer(1), Integer(5),
                                           Integer(2), Integer(0), Integer(0), Integer(6),
                                           Integer(5), Integer(0), Integer(6)])

>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf

>>> matrix_integer_dense_hnf.extract_ones_data(H, [Integer(0),Integer(1),
                                                  Integer(2)])
([0], [5], [6], [1/6], [0, 1], [0, 1], [2], [2])
```

Here we get None's since the (2,2) position submatrix is not invertible.

```python
sage: H = matrix(ZZ, 3, 5, [1, 0, 0, 45, -36, 0, 1, 0, 131, -107, 0, 0, 0, 178, -145]); H
[ 1 0 0 45 -36]
```

## Chapter 17. Modular algorithm to compute Hermite normal forms of integer matrices
sage.matrix.matrix_integer_dense_hnf.hnf(A, include_zero_rows=True, proof=True)

Return the Hermite Normal Form of a general integer matrix A, along with the pivot columns.

**INPUT:**

- A – an n x m matrix A over the integers.
- include_zero_rows – bool (default: True) whether or not to include zero rows in the output matrix
- proof – whether or not to prove the result correct.

**OUTPUT:**

- matrix – the Hermite normal form of A
- pivots – the pivot column positions of A

**EXAMPLES:**

```python
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: a = matrix(ZZ,3,5,[-2, -6, -3, -17, -1, 2, -1, -1, -2, -1, -2, -2, -6, 9, 2])
sage: matrix_integer_dense_hnf.hnf(a)
(\begin{bmatrix} 2 & 0 & 26 & -75 & -10 \\ 0 & 1 & 27 & -73 & -9 \\ 0 & 0 & 37 & -106 & -13 \end{bmatrix}, [0, 1, 2])
sage: matrix_integer_dense_hnf.hnf(a.transpose())
(\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, [0, 1, 2])
```

sage.matrix.matrix_integer_dense_hnf.hnf_square(A, proof)

INPUT:
• a nonsingular n x n matrix A over the integers.

OUTPUT:
• the Hermite normal form of A.

EXAMPLES:

sage: import sage.matrix.matrix_integer_dense_hnf as hnf
sage: A = matrix(ZZ, 3, [-21, -7, 5, 1,20,-7, -1,1,-1])

sage: hnf.hnf_square(A, False)

[ 0 0 46]

sage: A.echelon_form()

[ 1 6 29]
[ 0 7 28]
[ 0 0 46]

sage.matrix.matrix_integer_dense_hnf.hnf_with_transformation(A, proof=True)

Compute the HNF H of A along with a transformation matrix U such that U*A = H.

INPUT:
• A – an n x m matrix A over the integers.
• proof – whether or not to prove the result correct.

OUTPUT:
• matrix – the Hermite normal form H of A
• U – a unimodular matrix such that $U \cdot A = H$

EXAMPLES:

```python
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: A = matrix(ZZ, 2, [1, -5, -10, 1, 3, 197]); A
[ 1 -5 -10]
[ 1  3 197]
sage: H, U = matrix_integer_dense_hnf.hnf_with_transformation(A)
sage: H
[ 1  3 197]
[ 0  8 207]
sage: U
[ 0  1]
[-1  1]
sage: U*A
[ 1  3 197]
[ 0  8 207]
```

```python
>>> from sage.all import *
>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
>>> A = matrix(ZZ, Integer(2), [Integer(1), -Integer(5), -Integer(10), Integer(1),
                                 Integer(3), Integer(197)]); A
[ 1 -5 -10]
[ 1  3 197]
>>> H, U = matrix_integer_dense_hnf.hnf_with_transformation(A)
>>> H
[ 1  3 197]
[ 0  8 207]
>>> U
[ 0  1]
[-1  1]
>>> U*A
[ 1  3 197]
[ 0  8 207]
```

`sage.matrix.matrix_integer_dense_hnf.hnf_with_transformation_tests(n=10, m=5, trials=10)`

Use this to randomly test that hnf with transformation matrix is working.

EXAMPLES:

```python
sage: from sage.matrix.matrix_integer_dense_hnf import hnf_with_transformation_tests
sage: hnf_with_transformation_tests(n=15, m=10, trials=10)
0 1 2 3 4 5 6 7 8 9
```

```python
>>> from sage.all import *
>>> from sage.matrix.matrix_integer_dense_hnf import hnf_with_transformation_tests
>>> hnf_with_transformation_tests(n=Integer(15), m=Integer(10),...
                                      trials=Integer(10))
0 1 2 3 4 5 6 7 8 9
```

`sage.matrix.matrix_integer_dense_hnf.interleave_matrices(A, B, cols1, cols2)`

INPUT:

• A, B – matrices with the same number of rows
• cols1, cols2 – disjoint lists of integers
construct a new matrix $C$ by sticking the columns of $A$ at the positions specified by $\text{cols1}$ and the columns of $B$ at the positions specified by $\text{cols2}$.

**EXAMPLES:**

```python
sage: A = matrix(ZZ, 2, [1,2,3,4]); B = matrix(ZZ, 2, [-1,5,2,3])
sage: A
[1 2]
[3 4]
sage: B
[-1 5]
[ 2 3]
sage: import sage.matrix.matrix_integer_dense_hnf as hnf
sage: hnf.interleave_matrices(A, B, [1,3], [0,2])
[-1 1 5 2]
[ 2 3 3 4]
```

`sage.matrix.matrix_integer_dense_hnf.is_in_hnf_form(H, pivots)`

Return whether the matrix $H$ is in Hermite normal form with given pivot columns.

**INPUT:**

- $H$ – matrix
- pivots – sorted list of integers

**OUTPUT:**

boolean

**EXAMPLES:**

```python
sage: a = matrix(ZZ,3,5,[-2, -6, -3, -17, -1, 2, -1, -1, -2, -1, -2, -2, -6, 2])
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: matrix_integer_dense_hnf.is_in_hnf_form(a,range(3))
False
sage: e = a.hermite_form(); p = a.pivots()
sage: matrix_integer_dense_hnf.is_in_hnf_form(e, p)
True
```
sage.matrix.matrix_integer_dense_hnf.max_det_prime(n)

Return the largest prime so that it is reasonably efficient to compute modulo that prime with n x n matrices in LinBox.

INPUT:

• n – a positive integer

OUTPUT:

a prime number

EXAMPLES:

sage: from sage.matrix.matrix_integer_dense_hnf import max_det_prime
sage: max_det_prime(10000)
8388593
sage: max_det_prime(1000)
8388593
sage: max_det_prime(10)
8388593

sage.matrix.matrix_integer_dense_hnf.ones(H, pivots)

Find all 1 pivot columns of the matrix H in Hermite form, along with the corresponding rows, and also the non 1 pivot columns and non-pivot rows. Here a 1 pivot column is a pivot column so that the leading bottom entry is 1.

INPUT:

• H – matrix in Hermite form

• pivots – list of integers (all pivot positions of H).

OUTPUT:

4-tuple of integer lists: onecol, onerow, non_onecol, non_onerow

EXAMPLES:

sage: H = matrix(ZZ, 3, 5, [1, 0, 0, 45, -36, 0, 1, 0, 131, -107, 0, 0, 0, 178, -145]); H
[ 1 0 0 45 -36]
sage.matrix.matrix_integer_dense_hnf.pad_zeros(A, nrows)

Add zeros to the bottom of A so that the resulting matrix has nrows.

INPUT:

• A – a matrix

• nrows – an integer that is at least as big as the number of rows of A.

OUTPUT:

a matrix with nrows rows.

EXAMPLES:

sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: a = matrix(ZZ, 2, 4, [1, 0, 0, 7, 0, 1, 5, 2])
sage: matrix_integer_dense_hnf.pad_zeros(a, 4)
[1 0 0 7]
[0 1 5 2]
[0 0 0 0]
[0 0 0 0]
sage: matrix_integer_dense_hnf.pad_zeros(a, 2)
[1 0 0 7]
[0 1 5 2]

>>> from sage.all import *
>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
>>> a = matrix(ZZ, Integer(2), Integer(4), [Integer(1), Integer(0), Integer(0),...
←Integer(7), Integer(0), Integer(1), Integer(5), Integer(2)])
>>> matrix_integer_dense_hnf.pad_zeros(a, Integer(4))
[1 0 0 7]
[0 1 5 2]
[0 0 0 0]
[0 0 0 0]
>>> matrix_integer_dense_hnf.pad_zeros(a, Integer(2))
[1 0 0 7]
[0 1 5 2]
sage.matrix.matrix_integer_dense_hnf.pivots_of_hnf_matrix(H)
Return the pivot columns of a matrix H assumed to be in HNF.

INPUT:
• H – a matrix that must be HNF

OUTPUT:
• list – list of pivots

EXAMPLES:

```
sage: H = matrix(ZZ, 3, 5, [1, 0, 0, 45, -36, 0, 1, 0, 131, -107, 0, 0, 0, 178, -145]); H
[ 1 0 0 45 -36]
[ 0 1 0 131 -107]
[ 0 0 0 178 -145]
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: matrix_integer_dense_hnf.pivots_of_hnf_matrix(H)
[0, 1, 3]
```

```
>>> from sage.all import *

>>> H = matrix(ZZ, Integer(3), Integer(5), [Integer(1), Integer(0), Integer(0), Integer(45), -Integer(36), Integer(0), Integer(1), Integer(0), Integer(131), -Integer(107), Integer(0), Integer(0), Integer(0), Integer(178), -Integer(145)]); H
[ 1 0 0 45 -36]
[ 0 1 0 131 -107]
[ 0 0 0 178 -145]
>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf

>>> matrix_integer_dense_hnf.pivots_of_hnf_matrix(H)
[0, 1, 3]
```

sage.matrix.matrix_integer_dense_hnf.probable_hnf(A, include_zero_rows, proof)
Return the HNF of A or raise an exception if something involving the randomized nature of the algorithm goes wrong along the way.

Calling this function again a few times should result it in it working, at least if proof=True.

INPUT:
• A – a matrix
• include_zero_rows – bool
• proof – bool

OUTPUT:
the Hermite normal form of A. cols – pivot columns

EXAMPLES:

```
sage: a = matrix(ZZ, 4, 3, [-1, -1, -1, -20, 4, 1, -1, 1, 2,1,2,3])
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: matrix_integer_dense_hnf.probable_hnf(a, True, True)
[1 0 0]
[0 1 0]
[0 0 1]
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

[0 0 0], [0, 1, 2]
)
sage: matrix_integer_dense_hnf.probable_hnf(a, False, True)
{
  [1 0 0]
  [0 1 0]
  [0 0 1], [0, 1, 2]
}
sage: matrix_integer_dense_hnf.probable_hnf(a, False, False)
{
  [1 0 0]
  [0 1 0]
  [0 0 1], [0, 1, 2]
}

>>> from sage.all import *
>>> a = matrix(ZZ,Integer(4),Integer(3),
[0 -1 -1]
[0 -20 1]
[0 1 2])
>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf

sage.matrix.matrix_integer_dense_hnf.probable_pivot_columns(A)
INPUT:
  • A – a matrix

OUTPUT:
  a tuple of integers

EXAMPLES:

sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: a = matrix(ZZ,3,[0, -1, -1, 0, -20, 1, 0, 1, 2])
sage: a
[ 0 -1 -1]
[ 0 -20 1]
[ 0 1 2]
\begin{verbatim}
>>> from sage.all import *
>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf

>>> a = matrix(ZZ,Integer(3),[Integer(0), -Integer(1), -Integer(1), Integer(0), -
˓→Integer(20), Integer(1), Integer(0), Integer(1), Integer(2)])

>>> a
[ 0 -1 -1]
[ 0 -20 1]
[ 0 1 2]

>>> matrix_integer_dense_hnf.probable_pivot_columns(a)
(1, 2)
\end{verbatim}

\texttt{sage.matrix.matrix_integer_dense_hnf.probable_pivot_columns(A)}

Return rows of \( A \) that are very likely to be pivots.

This really finds the pivots of \( A \) modulo a random prime.

INPUT:

- \( A \) – a matrix

OUTPUT:

a tuple of integers

EXAMPLES:

\begin{verbatim}
>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
>>> a = matrix(ZZ,3,[0, -1, -1, 0, -20, 1, 0, 1, 2])

>>> a
[ 0 -1 -1]
[ 0 -20 1]
[ 0 1 2]

>>> matrix_integer_dense_hnf.probable_pivot_columns(a)
(0, 1)
\end{verbatim}

\texttt{sage.matrix.matrix_integer_dense_hnf.sanity_checks(times=50, n=8, m=5, proof=True, stabilize=2, check_using_magma=True)}

Run random sanity checks on the modular \( p \)-adic HNF with tall and wide matrices both dense and sparse.

INPUT:

- \( \text{times} \) – number of times to randomly try matrices with each shape
- \( \text{n} \) – number of rows
• m – number of columns
• proof – test with proof true
• stabilize – parameter to pass to hnf algorithm when proof is False
• check_using_magma – if True use Magma instead of PARI to check correctness of computed HNF’s. Since PARI’s HNF is buggy and slow (as of 2008-02-16 non-pivot entries sometimes are not normalized to be nonnegative) the default is Magma.

EXAMPLES:

```python
sage: import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf
sage: matrix_integer_dense_hnf.sanity_checks(times=5, check_using_magma=False)
small 8 x 5
0 1 2 3 4 (done)
big 8 x 5
0 1 2 3 4 (done)
small 5 x 8
0 1 2 3 4 (done)
big 5 x 8
0 1 2 3 4 (done)
sparse 8 x 5
0 1 2 3 4 (done)
sparse 5 x 8
0 1 2 3 4 (done)
ill conditioned -- 1000*A -- 8 x 5
0 1 2 3 4 (done)
ill conditioned -- 1000*A but one row -- 8 x 5
0 1 2 3 4 (done)
```

```python
>>> from sage.all import *
>>> import sage.matrix.matrix_integer_dense_hnf as matrix_integer_dense_hnf

sage.matrix.matrix_integer_dense_hnf.solve_system_with_difficult_last_row(B, a)
Solve $B \cdot x = a$ when the last row of $B$ contains huge entries using a clever trick that reduces the problem to solve $C \cdot x = a$ where $C$ is $B$ but with the last row replaced by something small, along with one easy null space computation. The latter are both solved $p$-adically.

INPUT:

• B – a square n x n nonsingular matrix with painful big bottom row.
• a – an n x 1 column matrix

OUTPUT:

• the unique solution to $B \times x = a$.

EXAMPLES:

```python
sage: from sage.matrix.matrix_integer_dense_hnf import solve_system_with_difficult_last_row
sage: B = matrix(ZZ, 3, [1,2,4, 3,-4,7, 939082,2930982,132902384098234])
sage: a = matrix(ZZ,3,1, [1,2,5])
sage: z = solve_system_with_difficult_last_row(B, a)
sage: z
[ 106321906985474/132902379815497]
[132902385037291/1329023798154970]
[ -5221794/664511899077485]
sage: B*z
[1]
[2]
[5]
```

```python
>>> from sage.all import *
>>> from sage.matrix.matrix_integer_dense_hnf import solve_system_with_difficult_last_row
>>> B = matrix(ZZ, Integer(3), [Integer(1),Integer(2),Integer(4), Integer(3),-Integer(4),Integer(7), Integer(939082),Integer(2930982),-Integer(132902384098234)])
>>> a = matrix(ZZ,Integer(3),Integer(1), [Integer(1),Integer(2),Integer(5)])
>>> z = solve_system_with_difficult_last_row(B, a)
>>> z
[ 106321906985474/132902379815497]
[132902385037291/1329023798154970]
[ -5221794/664511899077485]
>>> B*z
[1]
[2]
[5]
```
SATURATION OVER ZZ

The index of $A$ in its saturation.

INPUT:

- $A$ – matrix over $\mathbb{Z}$
- proof – boolean (True or False)

OUTPUT:

An integer

EXAMPLES:

```sage
define index_in_saturation(A, proof=True):
    # The index of A in its saturation.
    # INPUT:
    #   A -- matrix over Z
    #   proof -- boolean (True or False)
    # OUTPUT:
    #   An integer

    from sage.matrix.matrix_integer_dense_saturation import index_in_saturation
    A = matrix(ZZ, 2, 2, [3, 2, 3, 4]); B = matrix(ZZ, 2, 3, [1, 2, 3, 4, 5, 6]); C = A*B;
    C
    # →
    C
    index_in_saturation(C)
    # 18

define W = C.row_space();
define S = W.saturation();
define W.index_in(S)
# 18
```

For any zero matrix the index in its saturation is 1 (see Issue #13034):

```sage
define m = matrix(ZZ, 3)
define m
```
```
[0 0 0]
[0 0 0]
[0 0 0]
sage: m.index_in_saturation()
1
sage: m = matrix(ZZ, 2, 3)
sage: m
[0 0 0]
[0 0 0]
sage: m.index_in_saturation()
1
>>> from sage.all import *
>>> m = matrix(ZZ, Integer(3))
>>> m
[0 0 0]
[0 0 0]
[0 0 0]
>>> m.index_in_saturation()
1
>>> m = matrix(ZZ, Integer(2), Integer(3))
>>> m
[0 0 0]
[0 0 0]
>>> m.index_in_saturation()
1
```

```
sage.matrix.matrix_integer_dense_saturation.p_saturation(A, p, proof=True)

INPUT:

• A – a matrix over ZZ
• p – a prime
• proof – bool (default: True)

OUTPUT:

The p-saturation of the matrix A, i.e., a new matrix in Hermite form whose row span a ZZ-module that is p-saturated.

EXAMPLES:

```
sage: from sage.matrix.matrix_integer_dense_saturation import p_saturation
sage: A = matrix(ZZ, 2, 2, [3,2,3,4]); B = matrix(ZZ, 2,3,[1,2,3,4,5,6])
sage: A.det()
6
sage: C = A*B; C
[11 16 21]
[19 26 33]
sage: C2 = p_saturation(C, 2); C2
[ 1 8 15]
[ 0 9 18]
sage: C2.index_in_saturation()
9
sage: C3 = p_saturation(C, 3); C3
[ 1 0 -1]
[ 0 2 4]
```
```
sage: C3.index_in_saturation()
2

```python
>>> from sage.all import *
>>> from sage.matrix.matrix_integer_dense_saturation import p_saturation

A = matrix(ZZ, Integer(2), Integer(2), [Integer(3), Integer(2), Integer(3), Integer(4)]); B = matrix(ZZ, Integer(2), Integer(3), [Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(6)]);
>>> A.det()
6
>>> C = A*B; C
\[
\begin{bmatrix}
11 & 16 & 21 \\
19 & 26 & 33
\end{bmatrix}
\]
>>> C2 = p_saturation(C, Integer(2)); C2
\[
\begin{bmatrix}
1 & 8 & 15 \\
0 & 9 & 18
\end{bmatrix}
\]
>>> C2.index_in_saturation()
9
>>> C3 = p_saturation(C, Integer(3)); C3
\[
\begin{bmatrix}
1 & 0 & -1 \\
0 & 2 & 4
\end{bmatrix}
\]
>>> C3.index_in_saturation()
2
```

`sage.matrix.matrix_integer_dense_saturation.random_sublist_of_size(k, n)`

**INPUT:**
- `k` – an integer
- `n` – an integer

**OUTPUT:**

A randomly chosen sublist of range(k) of size n.

**EXAMPLES:**

```python
sage: import sage.matrix.matrix_integer_dense_saturation as s

sage: l = s.random_sublist_of_size(10, 3)
>>> l
\[1\, 4\, 8\]
>>> len(l)
3
>>> l_check = [-1] + l + [10]
>>> all(l_check[i] < l_check[i+1] for i in range(4))
True
sage: l = s.random_sublist_of_size(10, 7)
>>> l
\[1\, 4\, 6\, 8\, 9\, 10\, 7\]
>>> len(l)
7
>>> l_check = [-1] + l + [10]
>>> all(l_check[i] < l_check[i+1] for i in range(8))
True
```

```python
>>> from sage.all import *
>>> import sage.matrix.matrix_integer_dense_saturation as s

>>> l = s.random_sublist_of_size(Integer(10), Integer(3))
>>> len(l)
3
>>> l_check = [-Integer(1)] + l + [Integer(10)]
```
sage.matrix.matrix_integer_dense_saturation.ssaturation(A, proof=True, p=0, max_dets=5)

Compute a saturation matrix of A.

INPUT:

• A – a matrix over ZZ
• proof – bool (default: True)
• p – int (default: 0); if not 0 only guarantees that output is p-saturated
• max_dets – int (default: 4) max number of det of submatrices to compute.

OUTPUT:

matrix – saturation of the matrix A.

EXAMPLES:

```python
sage: from sage.matrix.matrix_integer_dense_saturation import saturation
gsage: A = matrix(ZZ, 2, 2, [3,2,3,4]); B = matrix(ZZ, 2,3,[1,2,3,4,5,6]); C = A*B
sage: C
[11 16 21]
[19 26 33]
sage: C.index_in_saturation()
18
sage: S = saturation(C); S
[11 16 21]
[-2 -3 -4]
sage: S.index_in_saturation()
1
sage: saturation(C, proof=False)
[11 16 21]
[-2 -3 -4]
sage: saturation(C, p=2)
[11 16 21]
[-2 -3 -4]
sage: saturation(C, p=2, max_dets=1)
[11 16 21]
[-2 -3 -4]
```

```python
from sage.all import *
```
Solve the matrix equation $B*Z = A$ when the last row of $B$ contains huge entries.

**INPUT:**
- $B$ – a square $n \times n$ nonsingular matrix with painful big bottom row.
- $A$ – an $n \times k$ matrix.

**OUTPUT:**
the unique solution to $B*Z = A$.

**EXAMPLES:**

```python
sage: from sage.matrix.matrix_integer_dense_saturation import solve_system_with_difficult_last_row
sage: B = matrix(ZZ, 3, [1,2,3, 3,-1,2,939239082,39202803080,2939028038402834]);
>>> A = matrix(ZZ,2,[1,2,4,3,-1,0])
sage: X = solve_system_with_difficult_last_row(B, A); X
[ 290668794698843/226075992027744 468068726971/409557956572]
[-226078357385539/1582531944194208 1228691305937/2866905696004]
[ 2365357795/1582531944194208 -17436221/2866905696004]
```

```python
>>> from sage.all import *
>>> from sage.matrix.matrix_integer_dense_saturation import solve_system_with_difficult_last_row
>>> B = matrix(ZZ, Integer(3), [Integer(1),Integer(2),Integer(3), Integer(3),-Integer(1),Integer(0)]);
>>> A = matrix(ZZ,Integer(3),Integer(2),[Integer(1),Integer(2),Integer(4),Integer(3),-Integer(1),Integer(0)])
>>> X = solve_system_with_difficult_last_row(B, A); X
[ 290668794698843/226075992027744 468068726971/409557956572]
[-226078357385539/1582531944194208 1228691305937/2866905696004]
[ 2365357795/1582531944194208 -17436221/2866905696004]
```

```python
>>> B*X == A
True
```
DENSE MATRICES OVER THE RATIONAL FIELD

EXAMPLES:

We create a 3x3 matrix with rational entries and do some operations with it.

```
sage: a = matrix(QQ, 3, 3, [1, 2/3, -4/5, 1, 1, 1, 8, 2, -3/19]); a
[ 1  2/3 -4/5]
[ 1   1   1]
[ 8   2 -3/19]
sage: a.det()
2303/285
sage: a.charpoly()
x^3 - 35/19*x^2 + 1259/285*x - 2303/285
sage: b = a**(-1); b
[-615/2303 -426/2303 418/2303]
[ 2325/2303 1779/2303 -513/2303]
[-1710/2303 950/2303  95/2303]
sage: b.det()
285/2303

class sage.matrix.matrix_rational_dense.MatrixWindow

Bases: object

class sage.matrix.matrix_rational_dense.Matrix_rational_dense

Bases: Matrix_dense

INPUT:

• parent – a matrix space over QQ
• entries – see matrix()
• copy – ignored (for backwards compatibility)
• coerce – if False, assume without checking that the entries are of type Rational.

BKZ(*args, **kwargs)

Return the result of running Block Korkin-Zolotarev reduction on self interpreted as a lattice.

The arguments *args and **kwargs are passed onto sage.matrix.matrix_integer_dense.Matrix_integer_dense.BKZ(), see there for more details.

EXAMPLES:

sage: A = Matrix(QQ, 3, 3, [1/n for n in range(1, 10)])
sage: A.BKZ()
[ 1/28  -1/40  -1/18 ]
[ 1/28  -1/40   1/18 ]
[-1/14  -1/40    0 ]

sage: A = random_matrix(QQ, 10, 10)
sage: d = lcm(a.denom() for a in A.list())
True

>>> from sage.all import *

>>> A = Matrix(QQ, Integer(3), Integer(3), [Integer(1)/n for n in range(Integer(1), Integer(10))])

>>> A.BKZ()
[ 1/28  -1/40  -1/18 ]
[ 1/28  -1/40   1/18 ]
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

\[
\begin{bmatrix}
-1/14 & -1/40 & 0 \\
\end{bmatrix}
\]

```python
>>> A = random_matrix(QQ, Integer(10), Integer(10))
>>> d = lcm(a.denom() for a in A.list())
>>> A.BKZ() == (A * d).change_ring(ZZ).BKZ() / d
True
```

LLL(*args, **kwargs)

Return an LLL reduced or approximated LLL reduced lattice for self interpreted as a lattice.

The arguments *args and **kwargs are passed onto `sage.matrix.matrix_integer_dense.Matrix_integer_dense.LLL()`, see there for more details.

**EXAMPLES:**

```python
sage: A = Matrix(QQ, 3, 3, [1/n for n in range(1, 10)])
sage: A.LLL()
\[
\begin{bmatrix}
 1/28 & -1/40 & -1/18 \\
 1/28 & -1/40 & 1/18 \\
 0 & -3/40 & 0 \\
\end{bmatrix}
\]
sage: A = random_matrix(QQ, 10, 10)
sage: d = lcm(a.denom() for a in A.list())
True
```

add_to_entry(i, j, elt)

Add elt to the entry at position (i, j)

**EXAMPLES:**

```python
sage: m = matrix(QQ, 2, 2)
sage: m.add_to_entry(0, 0, -1/3)
```

```python
>>> from sage.all import *
>>> m = matrix(QQ, Integer(2), Integer(2))
>>> m.add_to_entry(Integer(0), Integer(0), -Integer(1)/Integer(3))
```

689
antitranspose()

Returns the antitranspose of self, without changing self.

EXAMPLES:

```
sage: A = matrix(QQ,2,3,range(6))
sage: type(A)
<class 'sage.matrix.matrix_rational_dense.Matrix_rational_dense'>
sage: A.antitranspose()
[5 2]
[4 1]
[3 0]
sage: A
[0 1 2]
[3 4 5]

sage: A.subdivide(1,2); A
[0 1|2]
[---+-]
[3 4|5]
sage: A.antitranspose()
[5|2]
[-+-]
[4|1]
[3|0]
```

```
>>> from sage.all import *

>>> A = matrix(QQ,Integer(2),Integer(3),range(Integer(6)))

>>>

\textbf{charpoly}(\texttt{var='x', algorithm=None})

Return the characteristic polynomial of this matrix.

\textbf{Note:} The characteristic polynomial is defined as $\det(xI - A)$.

\begin{itemize}
\item \texttt{var} -- (optional) name of the variable as a string
\item \texttt{algorithm} -- an optional specification of an algorithm. It can be one of:
  \begin{itemize}
  \item \texttt{None}: (default) will use flint for small dimensions and linbox otherwise
  \item \texttt{'flint'}: uses flint library
  \item \texttt{'linbox'}: uses linbox library
  \item \texttt{'generic'}: uses Sage generic implementation
  \end{itemize}
\end{itemize}

\textbf{OUTPUT:} a polynomial over the rational numbers.

\textbf{EXAMPLES:}

sage: a = matrix(QQ, 3, [4/3, 2/5, 1/5, 4, -3/2, 0, 0, -2/3, 3/4])
sage: f = a.charpoly(); f
x^3 - 7/12*x^2 - 149/40*x + 97/30
sage: f(a)
[0 0 0]
[0 0 0]
[0 0 0]
column \(i, \text{from\_list=False}\)

Return the \(i\)-th column of this matrix as a dense vector.

**INPUT:**

- \(i\) – integer
- \(\text{from\_list}\) – ignored

**EXAMPLES:**

```
sage: m = matrix(QQ, 3, 2, [1/5,-2/3,3/4,4/9,-1,0])
sage: m.column(1)
(-2/3, 4/9, 0)
sage: m.column(1,from_list=True)
(-2/3, 4/9, 0)
sage: m.column(-1)
(-2/3, 4/9, 0)
sage: m.column(-2)
(1/5, 3/4, -1)
sage: m.column(2)
Traceback (most recent call last):

IndexError: column index out of range
sage: m.column(-3)
Traceback (most recent call last):
...
IndexError: column index out of range
```
decomposition\( (\texttt{is\_diagonalizable=False, dual=False, algorithm=None, height\_guess=None, proof=None}) \)

Returns the decomposition of the free module on which this matrix \( A \) acts from the right (i.e., the action is \( x \) goes to \( xA \)), along with whether this matrix acts irreducibly on each factor. The factors are guaranteed to be sorted in the same way as the corresponding factors of the characteristic polynomial.

Let \( A \) be the matrix acting from the on the vector space \( V \) of column vectors. Assume that \( A \) is square. This function computes maximal subspaces \( W_1, \ldots, W_n \) corresponding to Galois conjugacy classes of eigenvalues of \( A \). More precisely, let \( f(X) \) be the characteristic polynomial of \( A \). This function computes the subspace \( W_i = \ker(g_i(A)^n) \), where \( g_i(X) \) is an irreducible factor of \( f(X) \) and \( g_i(X) \) exactly divides \( f(X) \).

If the optional parameter \( \texttt{is\_diagonalizable} \) is True, then we let \( W_i = \ker(g(A)) \), since then we know that \( \ker(g(A)) = \ker(g(A)^n) \).

If \( \texttt{dual} \) is True, also returns the corresponding decomposition of \( V \) under the action of the transpose of \( A \). The factors are guaranteed to correspond.

**INPUT:**
- \( \texttt{is\_diagonalizable} \) – ignored
- \( \texttt{dual} \) – whether to also return decompositions for the dual
- \( \texttt{algorithm} \) – an optional specification of an algorithm
  - \( \texttt{None} \) – (default) use default algorithm for computing Echelon forms
  - \( \texttt{‘multimodular’} \) – much better if the answers factors have small height
- \( \texttt{height\_guess} \) – positive integer; only used by the multimodular algorithm
- \( \texttt{proof} \) – bool or \( \texttt{None} \) (default: \( \texttt{None} \), see \texttt{proof.linear\_algebra} or \texttt{sage.structure.proof}); only used by the multimodular algorithm. Note that the Sage global default is \( \texttt{proof=True} \).

**Note:** IMPORTANT: If you expect that the subspaces in the answer are spanned by vectors with small height coordinates, use \texttt{algorithm=‘multimodular’} and \( \texttt{height\_guess=1} \); this is potentially much faster than the default. If you know for a fact the answer will be very small, use \texttt{algorithm=‘multimodular’}, \( \texttt{height\_guess=bound on height} \), \( \texttt{proof=False} \).

You can get very very fast decomposition with \( \texttt{proof=False} \).

**EXAMPLES:**

```python
sage: a = matrix(QQ,3,[1..9])
sage: a.decomposition()

[ (Vector space of degree 3 and dimension 1 over Rational Field
  Basis matrix:
  [ 1 -2 1], True),
  (Vector space of degree 3 and dimension 2 over Rational Field
  Basis matrix:
  [ 1 0 -1]
  [ 0 1 2], True)
]```
denominator()

Return the denominator of this matrix.

OUTPUT: a Sage Integer

EXAMPLES:

```python
sage: b = matrix(QQ, 2, range(6)); b[0,0]=-5007/293; b
[-5007/293  1  2]
[   3   4   5]
sage: b.denominator()
293
```

```python
sage: matrix(QQ, 2, [1/2, 1/3, 1/4, 1/5]).denominator()
60
```

determinant(algorithm=None, proof=None)

Return the determinant of this matrix.

INPUT:

- algorithm -- an optional specification of an algorithm. It can be one of
  - None: (default) uses flint
  - 'flint': uses flint library
  - 'pari': uses PARI library
  - 'integer': removes denominator and call determinant on the corresponding integer matrix
  - 'generic': calls the generic Sage implementation
- proof -- bool or None; if None use proof.linear_algebra(); only relevant for the padic algorithm.
Note: It would be *VERY VERY* hard for det to fail even with proof=False.

EXAMPLES:

```python
sage: m = matrix(QQ, 3, [1,2/3,4/5, 2,2,2, 5,3,2/5])
sage: m.determinant()
-34/15
sage: m.charpoly()
x^3 - 17/5*x^2 - 122/15*x + 34/15

sage: m = matrix(QQ, 3, [(1/i)**j for i in range(2,5) for j in range(3)])

sage: m.determinant(algorithm="flint")
-1/288

sage: m = matrix(QQ, 4, [(-1)**n/n for n in range(1,17)])

sage: m.determinant(algorithm="pari")
2/70945875

sage: m = matrix(QQ, 5, [1/(i+j+1) for i in range(5) for j in range(5)])

sage: m.determinant(algorithm="integer")
1/266716800000

>>> from sage.all import *

>>> m = matrix(QQ,Integer(3),[Integer(1)/Integer(3),Integer(2)/Integer(3),Integer(4)/Integer(5), Integer(2), Integer(2), Integer(2), Integer(5), Integer(3), Integer(2)/Integer(5)])

>>> m.determinant()
-34/15

>>> m.charpoly()
x^3 - 17/5*x^2 - 122/15*x + 34/15

>>> m = matrix(QQ, Integer(3), [(Integer(1)/i)**j for i in range(Integer(2),Integer(5)) for j in range(Integer(3))])

>>> m.determinant(algorithm="flint")
-1/288

>>> m = matrix(QQ, Integer(4), [(-Integer(1))**n/n for n in range(Integer(1),Integer(17))])

>>> m.determinant(algorithm="pari")
2/70945875

>>> m = matrix(QQ, Integer(5), [Integer(1)/(i+j+Integer(1)) for i in range(Integer(5)) for j in range(Integer(5))])

>>> m.determinant(algorithm="integer")
1/266716800000

On non-square matrices, the method raises a ValueError:

```python
sage: matrix(QQ, 2, 3).determinant(algorithm='flint')
Traceback (most recent call last):
 ...
ValueError: non square matrix
sage: matrix(QQ, 2, 3).determinant(algorithm='pari')
Traceback (most recent call last):
 ...
ValueError: non square matrix
```
sage: matrix(QQ, 2, 3).determinant(algorithm='integer')
Traceback (most recent call last):
...

Traceback (most recent call last):
...  
ValueError: non square matrix
>>> matrix(QQ, Integer(2), Integer(3)).determinant(algorithm='generic')
Traceback (most recent call last):
...  
ValueError: non square matrix

```
from sage.all import *

t = matrix(QQ, Integer(2), Integer(3))
t[0,0] = 1/19; t[0,1] = 1/5; t
```

```
[1/19 1/5 2 3]
[ 4  5  6  7]
[ 8  9 10 11]
[12 13 14 15]
```

```
sage: t.echelon_form()
```

```
[ 1 0 0 -76/157]
[ 0 1 0 -5/157]
[ 0 0 1 238/157]
[ 0 0 0 0]
```

```
sage: t.echelon_form(algorithm='multimodular')
```

```
[ 1 0 0 -76/157]
[ 0 1 0 -5/157]
[ 0 0 1 238/157]
[ 0 0 0 0]
```

```
>>> from sage.all import *

>>> a = matrix(QQ, Integer(4), range(Integer(16))); a[Integer(0),Integer(0)] ← Integer(1)/Integer(19); a[Integer(0),Integer(1)] = Integer(1)/Integer(5); ...
```

```
sage: a.echelon_form()
```

```
[ 1 0 0 -76/157]
[ 0 1 0 -5/157]
[ 0 0 1 238/157]
[ 0 0 0 0]
```

```
sage: a.echelon_form(algorithm='multimodular')
```

```
[ 1 0 0 -76/157]
[ 0 1 0 -5/157]
[ 0 0 1 238/157]
[ 0 0 0 0]
```

For more information about using the echelon form function, please refer to the documentation for the echelonize() function.
The result is an immutable matrix, so if you want to modify the result then you need to make a copy. This checks that Issue #10543 is fixed:

```python
sage: A = matrix(QQ, 2, range(6))
sage: E = A.echelon_form()
sage: E.is_mutable()
False	sage: F = copy(E)
sage: F[0,0] = 50
tsage: F
[50 0 -1]
[ 0 1 2]
```

**echelonize** (*algorithm=None, height_guess=None, proof=None, **kwds*)

Transform the matrix self into reduced row echelon form in place.

**INPUT:**

- **algorithm** – an optional specification of an algorithm. One of
  - None: (default) uses flint for small dimension and multimodular otherwise
  - 'flint': use the flint library,
  - 'padic': an algorithm based on the IML p-adics solver,
  - 'multimodular': uses a multimodular algorithm the uses linbox modulo many primes (likely to be faster when coefficients are huge),
  - 'classical': just clear each column using Gauss elimination.
  - height_guess, **kwds** – all passed to the multimodular algorithm; ignored by other algorithms.
proof – bool or None (default: None, see proof.linear_algebra or sage.structure.proof). Passed to the multimodular algorithm. Note that the Sage global default is proof=True.

EXAMPLES:

```python
sage: a = matrix(QQ, 4, range(16)); a[0,0] = 1/19; a[0,1] = 1/5; a
[1/19  1/5  2   3]
[  4   5   6   7]
[  8   9  10  11]
[ 12  13  14  15]
sage: a.echelonize()
sage: a
[ 1  0  0  -76/157]
[ 0  1  0  -5/157]
[ 0  0  1  238/157]
[ 0  0  0   0]
```

```python
>>> from sage.all import *
>>> a = matrix(QQ, Integer(4), range(Integer(16))); a[Integer(0),Integer(0)] = Integer(1)/Integer(19); a[Integer(0),Integer(1)] = Integer(1)/Integer(5); a
[[1/19  1/5  2   3]
 [  4   5   6   7]
 [  8   9  10  11]
 [ 12  13  14  15]]
>>> a.echelonize()
>>> a
[1 0 0 -76/157]
[0 1 0 -5/157]
[0 0 1 238/157]
[0 0 0 0]
```

```python
sage: a = matrix(QQ, 4, range(16)); a[0,0] = 1/19; a[0,1] = 1/5
sage: a.echelonize(algorithm='multimodular')
sage: a
[1 0 0 -76/157]
[0 1 0 -5/157]
[0 0 1 238/157]
[0 0 0 0]
```

```python
>>> from sage.all import *
>>> a = matrix(QQ, Integer(4), range(Integer(16))); a[Integer(0),Integer(0)] = Integer(1)/Integer(19); a[Integer(0),Integer(1)] = Integer(1)/Integer(5)
>>> a.echelonize(algorithm='multimodular')
>>> a
[1 0 0 -76/157]
[0 1 0 -5/157]
[0 0 1 238/157]
[0 0 0 0]
```

height()

Return the height of this matrix, which is the maximum of the absolute values of all numerators and denominators of entries in this matrix.

OUTPUT: an Integer

EXAMPLES:
inverse\( (algorithm=None, \text{check\_invertible}=True)\)

Return the inverse of this matrix

INPUT:

\begin{itemize}
  \item algorithm – an optional specification of an algorithm. It can be one of
    \begin{itemize}
    \item None: (default) uses flint
    \item 'flint': uses flint library
    \item 'pari': uses PARI library
    \item 'iml': uses IML library
    \end{itemize}
  \item check\_invertible – only used when algorithm=iml. Whether to check that matrix is invertible
\end{itemize}

EXAMPLES:

```sage
sage: a = matrix(QQ, 3, [1, 2, 5, 3, 2, 1, 1, 1, 1])
sage: a.inverse()
[1/2 3/2 -4]
[ -1 -2 7]
[1/2 1/2 -2]
```

```sage
sage: a = matrix(QQ, 2, [1, 5, 17, 3])
sage: a.inverse(algorithm="flint")
[-3/82 5/82]
[17/82 -1/82]
sage: a.inverse(algorithm="flint") * a
[1 0]
[0 1]
```

```sage
sage: a = matrix(QQ, 2, [-1, 5, 12, -3])
sage: a.inverse(algorithm="iml")
[1/19 5/57]
[4/19 1/57]
sage: a.inverse(algorithm="iml") * a
[1 0]
[0 1]
```

```sage
sage: a = matrix(QQ, 4, primes_first_n(16))
sage: a.inverse(algorithm="pari")
[ 3/11 -12/55 -1/5 2/11]
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

[ -5/11 -2/55 3/10 -3/22]
[ -13/22 307/440 -1/10 -9/88]
[ 15/22 -37/88 0 7/88]

```python
>>> from sage.all import *
>>> a = matrix(QQ,Integer(3),[Integer(1),Integer(2),Integer(5),Integer(3),
˓→Integer(2),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),])
>>> a.inverse()
[1/2 3/2 -4]
[ -1 -2 7]
[1/2 1/2 -2]
```

```python
>>> a = matrix(QQ, Integer(2), [Integer(1), Integer(5), Integer(17),
˓→Integer(3)])
>>> a.inverse(algorithm="flint")
[-3/82 5/82]
[17/82 -1/82]
```

```python
>>> a = matrix(QQ, Integer(2), [Integer(1), Integer(1), Integer(17),
˓→Integer(1)])
>>> a.inverse(algorithm="iml")
[1/19 5/57]
[4/19 1/57]
```

```python
>>> a = matrix(QQ, Integer(4), primes_first_n(Integer(16)))
>>> a.inverse(algorithm="pari")
[ 3/11 -12/55 -1/5 2/11]
[ -5/11 -2/55 3/10 -3/22]
[ -13/22 307/440 -1/10 -9/88]
[ 15/22 -37/88 0 7/88]
```

On singular matrices this method raises a **ZeroDivisionError**:

```python
sage: a = matrix(QQ, 2)
sage: a.inverse(algorithm="flint")
Traceback (most recent call last):
...
ZeroDivisionError: input matrix must be nonsingular
sage: a.inverse(algorithm="iml")
Traceback (most recent call last):
...
ZeroDivisionError: input matrix must be nonsingular
sage: a.inverse(algorithm="pari")
Traceback (most recent call last):
...
ZeroDivisionError: input matrix must be nonsingular
```

```python
>>> from sage.all import *
>>> a = matrix(QQ, Integer(2))
>>> a.inverse(algorithm="flint")
```
Traceback (most recent call last):
...
ZeroDivisionError: input matrix must be nonsingular

>>> a.inverse(algorithm="iml")
Traceback (most recent call last):
...
ZeroDivisionError: input matrix must be nonsingular

>>> a.inverse(algorithm="pari")
Traceback (most recent call last):
...
ZeroDivisionError: input matrix must be nonsingular

is_LLL_reduced(delta=None, eta=None)

Return True if this lattice is ($\delta$, $\eta$)-LLL reduced. For a definition of LLL reduction, see sage.matrix.matrix_integer_dense.Matrix_integer_dense.LLL().

EXAMPLES:

sage: A = random_matrix(QQ, 10, 10)
sage: L = A.LLL()
sage: A.is_LLL_reduced()
False
sage: L.is_LLL_reduced()
True

>>> from sage.all import *

>>> A = random_matrix(QQ, Integer(10), Integer(10))
>>> L = A.LLL()
>>> A.is_LLL_reduced()
False
>>> L.is_LLL_reduced()
True

matrix_from_columns(columns)

Return the matrix constructed from self using columns with indices in the columns list.

EXAMPLES:

sage: A = matrix(QQ, 3, range(9))
sage: A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.matrix_from_columns([2,1])
[2 1]
[5 4]
[8 7]
sage: A.matrix_from_columns((2,1,0,2))
[2 1 0 2]
[5 4 3 5]
[8 7 6 8]

>>> from sage.all import *

>>> A = matrix(QQ, Integer(3), range(Integer(9)))
>>> A
[0 1 2]
minpoly (var='x', algorithm=None)

Return the minimal polynomial of this matrix

INPUT:

• var – (optional) the variable name as a string (default is 'x')

• algorithm – an optional specification of an algorithm. It can be one of

  - None: (default) will use linbox
  - 'linbox': uses the linbox library
  - 'generic': uses the generic Sage implementation

OUTPUT: a polynomial over the rationals

EXAMPLES:

```
sage: a = matrix(QQ, 3, [4/3, 2/5, 1/5, 4, -3/2, 0, 0, -2/3, 3/4])
sage: f = a.minpoly(); f
x^3 - 7/12*x^2 - 149/40*x + 97/30
sage: a = Mat(ZZ,4)(range(16))
sage: f = a.minpoly(); f.factor()
x * (x^2 - 30*x - 80)
sage: f(a) == Integer(0)
True
```

```
>>> from sage.all import *

>>> a = matrix(QQ, 3, [Integer(4)/Integer(3), Integer(2)/Integer(5), Integer(1)/Integer(5), Integer(4), -Integer(3)/Integer(2), Integer(0), 0, -Integer(2)/Integer(3), Integer(3)/Integer(4)])
>>> f = a.minpoly(); f
x^3 - 7/12*x^2 - 149/40*x + 97/30
>>> a = Mat(ZZ,Integer(4))(range(Integer(16)))
>>> f = a.minpoly(); f.factor()
x * (x^2 - 30*x - 80)
>>> f(a) == Integer(0)
True
```

```
sage: a = matrix(QQ, 4, [1..4^2])
sage: factor(a.minpoly())
x * (x^2 - 34*x - 80)
sage: factor(a.minpoly(y))
y * (y^2 - 34*y - 80)
sage: factor(a.charpoly())
x^2 * (x^2 - 34*x - 80)
```
sage: b = matrix(QQ, 4, [-1, 2, 2, 0, 0, 4, 2, 2, 0, 0, -1, -2, 0, -4, 0, 4])
sage: a = matrix(QQ, 4, [1, 1, 0,0, 0,1,0,0, 0,0,5,0, 0,0,0,5])
sage: c = b^(-1)*a*b
sage: factor(c.minpoly())
(x - 5) * (x - 1)^2
sage: factor(c.charpoly())
(x - 5)^2 * (x - 1)^2

>>> from sage.all import *
>>> a = matrix(QQ, Integer(4), (ellipsis_range(Integer(1),Ellipsis,
˓→Integer(4)**Integer(2))))
>>> factor(a.minpoly())
x * (x^2 - 34*x - 80)
>>> factor(a.minpoly('y'))
y * (y^2 - 34*y - 80)
>>> factor(a.charpoly())
x^2 * (x^2 - 34*x - 80)
>>> b = matrix(QQ, Integer(4), [-Integer(1), Integer(2), Integer(2),␣
˓→Integer(0), Integer(4), Integer(2), Integer(2), Integer(0),␣
˓→Integer(0), -Integer(1), -Integer(2), Integer(0), -Integer(4), Integer(0),␣
˓→Integer(4)])
>>> a = matrix(QQ, Integer(4), [Integer(1), Integer(1), Integer(0),Integer(0),␣
˓→Integer(0), Integer(1), Integer(0),Integer(0), Integer(0), Integer(0),Integer(0),␣
˓→Integer(5),Integer(0), Integer(0),Integer(0),Integer(0),Integer(5)])
>>> c = b**(-Integer(1))*a*b
>>> factor(c.minpoly())
(x - 5) * (x - 1)^2
>>> factor(c.charpoly())
(x - 5)^2 * (x - 1)^2

Check consistency:

sage: for _ in range(100):
    ...:     dim = randint(0, 10)
    ...:     m = random_matrix(QQ, dim, num_bound=8, den_bound=8)
    ...:     p_linbox = m.charpoly(algorithm='linbox'); m._clear_cache()
    ...:     p_generic = m.charpoly(algorithm='generic')
    ...:     assert p_linbox == p_generic

prod_of_row_sums (cols)

randomize (density=1, num_bound=2, den_bound=2, distribution=None, nonzero=False)

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.

If $x$ and $y$ are given, randomized entries of this matrix have numerators and denominators bounded by $x$ and $y$ and have density 1.

INPUT:
• **density**—number between 0 and 1 (default: 1)
• **num_bound**—numerator bound (default: 2)
• **den_bound**—denominator bound (default: 2)
• **distribution**—None or ‘1/n’ (default: None); if ‘1/n’ then **num_bound** and **den_bound** are ignored and numbers are chosen using the GMP function `mpq_randomize_entry_recip_uniform`

**OUTPUT:**
- None, the matrix is modified in-space

**EXAMPLES:**

The default distribution:

```python
def add_samples(distribution=None):
    global dic, total_count
    for _ in range(100):
        A = Matrix(QQ, 2, 4, 0)
        A.randomize(distribution=distribution)
        for a in A.list():
            dic[a] += 1
            total_count += 1.0
```

```python
total_count = 0
dic = defaultdict(Integer)
def add_samples(distribution=None):
    global dic, total_count
    A = Matrix(QQ, 2, 4, 0)
    A.randomize(distribution=distribution)
    for a in A.list():
        dic[a] += 1
        total_count += 1.0

total_count = 0
dic = defaultdict(Integer)
def add_samples(distribution=None):
    global dic, total_count
    A = Matrix(QQ, 2, 4, 0)
    A.randomize(distribution=distribution)
    for a in A.list():
        dic[a] += 1
        total_count += 1.0
```

The distribution '1/n':

```python
>>> from sage.all import *
>>> from collections import defaultdict
>>> total_count = Integer(0)
>>> dic = defaultdict(Integer)
>>> def add_samples(distribution=None):
...     global dic, total_count
...     for _ in range(Integer(100)):
...         A = Matrix(QQ, Integer(2), Integer(4), Integer(0))
...         A.randomize(distribution=distribution)
...         for a in A.list():
...             dic[a] += Integer(1)
...             total_count += RealNumber('1.0')

>>> expected = {-Integer(2): Integer(1)/Integer(9), -Integer(1): Integer(3)/Integer(18), -Integer(1)/Integer(2): Integer(1)/Integer(18), Integer(0):Integer(3)/Integer(18), Integer(1)/Integer(2): Integer(1)/Integer(18), Integer(2): Integer(1)/Integer(9)}
>>> add_samples()
>>> while not all(abs(dic[a]/total_count - expected[a]) < RealNumber('0.001') for a in dic):
...     add_samples()
```
```python
sage: def mpq_randomize_entry_recip_uniform():
    r = 2*random() - 1
    if r == 0: r = 1
    num = int(4/(5*r))
    r = random()
    if r == 0: r = 1
    den = int(1/random())
    return Integer(num)/Integer(den)

sage: total_count = 0
sage: dic = defaultdict(Integer)
sage: dic2 = defaultdict(Integer)
sage: add_samples(1/n)
sage: for _ in range(8):
    dic2[mpq_randomize_entry_recip_uniform()] += 1
sage: while not all(abs(dic[a] - dic2[a])/total_count < 0.005 for a in dic):
    add_samples(1/n)
    for _ in range(800):
        dic2[mpq_randomize_entry_recip_uniform()] += 1

>>> from sage.all import *
>>> def mpq_randomize_entry_recip_uniform():
...     r = Integer(2)*random() - Integer(1)
...     if r == Integer(0): r = Integer(1)
...     num = int(Integer(4)/(Integer(5)*r))
...     r = random()
...     if r == Integer(0): r = Integer(1)
...     den = int(Integer(1)/random())
...     return Integer(num)/Integer(den)

>>> total_count = Integer(0)
>>> dic = defaultdict(Integer)
>>> dic2 = defaultdict(Integer)
>>> add_samples('1/n')
>>> for _ in range(Integer(8)):
...     dic2[mpq_randomize_entry_recip_uniform()] += Integer(1)
>>> while not all(abs(dic[a] - dic2[a])/total_count < RealNumber('0.005') for a in dic):
...     add_samples('1/n')
...     for _ in range(Integer(800)):
...         dic2[mpq_randomize_entry_recip_uniform()] += Integer(1)
```

The default can be used to obtain matrices of different rank:

```python
sage: ranks = [False]*11
sage: while not all(ranks):
    for dens in (0.05, 0.1, 0.2, 0.5):
        A = Matrix(QQ, 10, 10, 0)
        A.randomize(dens)
        ranks[A.rank()] = True
```

```python
>>> from sage.all import *
>>> ranks = [False]*Integer(11)
>>> while not all(ranks):
...     for dens in (RealNumber('0.05'), RealNumber('0.1'), RealNumber('0.2'),
                  RealNumber('0.5')):
...         A = Matrix(QQ, Integer(10), Integer(10), Integer(0))
```

(continues on next page)
The default density is $6/9$:

```
sage: def add_sample(density, num_rows, num_cols):
    global density_sum, total_count
    total_count += 1.0
    A = Matrix(QQ, num_rows, num_cols, 0)
    A.randomize(density)
    density_sum += float(A.density())

sage: density_sum = 0.0
sage: total_count = 0.0
sage: expected_density = 6/9
sage: add_sample(1.0, 100, 100)
```

```
>>> from sage.all import *
>>>
>>> def add_sample(density, num_rows, num_cols):
... global density_sum, total_count
... total_count += RealNumber('1.0')
... A = Matrix(QQ, num_rows, num_cols, Integer(0))
... A.randomize(density)
... density_sum += float(A.density())

>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> expected_density = Integer(6)/Integer(9)
>>> add_sample(RealNumber('1.0'), Integer(100), Integer(100))
>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001'):
...     add_sample(RealNumber('1.0'), Integer(100), Integer(100))
```

The modified density depends on the number of columns:

```
sage: density_sum = 0.0
sage: total_count = 0.0
sage: expected_density = 6/9*0.5
sage: add_sample(0.5, 100, 2)
```

```
sage: while abs(density_sum/total_count - expected_density) > 0.001:
    add_sample(0.5, 100, 2)
```

```
sage: density_sum = 0.0
sage: total_count = 0.0
sage: expected_density = 6/9*(1.0 - (99/100)^50)
```

```
sage: expected_density
0.263...
```

```
sage: add_sample(0.5, 100, 100)
```

```
sage: while abs(density_sum/total_count - expected_density) > 0.001:
    add_sample(0.5, 100, 100)
```

```
>>> total_count = RealNumber('0.0')
>>> expected_density = Integer(6)/Integer(9)*RealNumber('0.5')
>>> add_sample(RealNumber('0.5'), Integer(100), Integer(2))

>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001 ' + '-> '):
...    add_sample(RealNumber('0.5'), Integer(100), Integer(2))

>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> expected_density = Integer(6)/Integer(9)*(RealNumber('1.0') -
-> (Integer(99)/Integer(100))**Integer(50))
>>> expected_density
0.263...

>>> add_sample(RealNumber('0.5'), Integer(100), Integer(100))

>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001 ' + '-> '):
...    add_sample(RealNumber('0.5'), Integer(100), Integer(100))

Modifying the bounds for numerator and denominator:

```
sage: num_dic = defaultdict(Integer)
sage: den_dic = defaultdict(Integer)
sage: while not (all(num_dic[i] for i in range(-200, 201))
... and all(den_dic[i] for i in range(1, 101))):
...    a = matrix(QQ, 2, 4)
...    a.randomize(num_bound=200, den_bound=100)
...    for q in a.list():
...        num_dic[q.numerator()] += 1
...        den_dic[q.denominator()] += 1
sage: len(num_dic)
401
sage: len(den_dic)
100
```

```
>>> from sage.all import *
>>> num_dic = defaultdict(Integer)
>>> den_dic = defaultdict(Integer)
>>> while not (all(num_dic[i] for i in range(-Integer(200), Integer(201)))
... and all(den_dic[i] for i in range(Integer(1), Integer(101))):
...    a = matrix(QQ, Integer(2), Integer(4))
...    a.randomize(num_bound=Integer(200), den_bound=Integer(100))
...    for q in a.list():
...        num_dic[q.numerator()] += Integer(1)
...        den_dic[q.denominator()] += Integer(1)
>>> len(num_dic)
401
>>> len(den_dic)
100
```

**rank (algorithm=None)**

Return the rank of this matrix.

**INPUT:**

- **algorithm** – an optional specification of an algorithm. One of
  - **None** (default) will use flint
- 'flint': uses the flint library
- 'pari': uses the PARI library
- 'integer': eliminate denominators and calls the rank function on the corresponding integer matrix

EXAMPLES:

```
sage: matrix(QQ,3,[1..9]).rank()
sage: matrix(QQ,100,[1..100^2]).rank()
```

```
>>> from sage.all import *
>>>
>>> matrix(QQ,Integer(3),(ellipsis_range(Integer(1),Ellipsis,Integer(9)))).rank()
>>> matrix(QQ,Integer(100),(ellipsis_range(Integer(1),Ellipsis,Integer(100)**Integer(2)))).rank()
```

```
row(i, from_list=False)
```

Return the i-th row of this matrix as a dense vector.

INPUT:

- i – integer
- from_list – ignored

EXAMPLES:

```
sage: m = matrix(QQ, 2, [1/5, -2/3, 3/4, 4/9])
sage: m.row(0)
(1/5, -2/3)
sage: m.row(1)
(3/4, 4/9)
sage: m.row(1, from_list=True)
(3/4, 4/9)
sage: m.row(-2)
(1/5, -2/3)
sage: m.row(2)
Traceback (most recent call last):
...
IndexError: row index out of range
sage: m.row(-3)
Traceback (most recent call last):
...
IndexError: row index out of range
```

```
>>> from sage.all import *
>>>
>>> m = matrix(QQ, Integer(2), [Integer(1)/Integer(5), -Integer(2)/Integer(3), Integer(3)/Integer(4), Integer(4)/Integer(9)])
>>> m.row(Integer(0))
(1/5, -2/3)
>>> m.row(Integer(1))
(3/4, 4/9)
```

(continues on next page)
set_row_to_multiple_of_row(i, j, s)

Set row i equal to s times row j.

EXAMPLES:

```
sage: a = matrix(QQ, 2, 3, range(6)); a
[0 1 2]
[3 4 5]
sage: a.set_row_to_multiple_of_row(1, 0, -3)
sage: a
[0 1 2]
[0 -3 -6]
```

transpose()

Returns the transpose of self, without changing self.

EXAMPLES:

We create a matrix, compute its transpose, and note that the original matrix is not changed.

```
sage: A = matrix(QQ, 2, 3, range(6))
sage: type(A)
<class 'sage.matrix.matrix_rational_dense.Matrix_rational_dense'>
sage: B = A.transpose()
sage: print(B)
[0 3]
[1 4]
[2 5]
sage: print(A)
[0 1 2]
[3 4 5]
```
from sage.all import *

A = matrix(QQ, Integer(2), Integer(3), range(Integer(6)))

B = A.transpose()

print(B)

[0 3]
[1 4]
[2 5]

print(A)

[0 1 2]
[3 4 5]

.T is a convenient shortcut for the transpose:

sage: print(A.T)

[0 3]
[1 4]
[2 5]

sage: A.subdivide(None, 1); A

[0 1 2]
[3 4 5]

sage: A.transpose()

[0 3]
[---]
[1 4]
[2 5]

sage: A.subdivide(None, Integer(1)); A

[0 1 2]
[3 4 5]

sage: A.transpose()

[0 3]
[---]
[1 4]
[2 5]
SPARSE RATIONAL MATRICES

AUTHORS:

• William Stein (2007-02-21)
• Soroosh Yazdani (2007-02-21)

class sage.matrix.matrix_rational_sparse.Matrix_rational_sparse

Bases: Matrix_sparse

Create a sparse matrix over the rational numbers.

INPUT:

• parent – a matrix space over \( \mathbb{Q} \)
• entries – see matrix()
• copy – ignored (for backwards compatibility)
• coerce – if False, assume without checking that the entries are of type Rational.

add_to_entry\((i, j, elt)\)

Add \( elt \) to the entry at position \((i, j)\).

EXAMPLES:

```
sage: m = matrix(QQ, 2, 2, sparse=True)
sage: m.add_to_entry(0, 0, -1/3)
sage: m
[-1/3 0]
[ 0 0]
sage: m.add_to_entry(0, 0, 1/3)
sage: m
[0 0]
[0 0]
sage: m.nonzero_positions()
[]
```

```python
>>> from sage.all import *
>>> m = matrix(QQ, Integer(2), Integer(2), sparse=True)
>>> m.add_to_entry(Integer(0), Integer(0), -Integer(1)/Integer(3))
>>> m
[-1/3 0]
[ 0 0]
>>> m.add_to_entry(Integer(0), Integer(0), Integer(1)/Integer(3))
>>> m
[0 0]
```

(continues on next page)
denominator()

Return the denominator of this matrix.

OUTPUT:

- Sage Integer

EXAMPLES:

```python
sage: b = matrix(QQ, 2, range(6)); b[0,0]=-5007/293; b
[-5007/293  1  2]
[   3   4   5]
sage: b.denominator()
293
```

```python
>>> from sage.all import *

>>> b = matrix(QQ,Integer(2),range(Integer(6))); b[Integer(0),Integer(0)]=-Integer(5007)/Integer(293); b
[-5007/293  1  2]
[   3   4   5]
>>> b.denominator()
293
```

dense_matrix()

Return dense version of this matrix.

EXAMPLES:

```python
sage: a = matrix(QQ, 2, [1..4], sparse=True); type(a)
<class 'sage.matrix.matrix_rational_sparse.Matrix_rational_sparse'>
sage: type(a.dense_matrix())
<class 'sage.matrix.matrix_rational_dense.Matrix_rational_dense'>
sage: a.dense_matrix()
[1 2]
[3 4]
```

```python
>>> from sage.all import *

>>> a = matrix(QQ,Integer(2),(ellipsis_range(Integer(1),Ellipsis,Integer(4))),
             sparse=True); type(a)
<class 'sage.matrix.matrix_rational_sparse.Matrix_rational_sparse'>
>>> type(a.dense_matrix())
<class 'sage.matrix.matrix_rational_dense.Matrix_rational_dense'>
>>> a.dense_matrix()
[1 2]
[3 4]
```

Check that subdivisions are preserved when converting between dense and sparse matrices:

```python
sage: a.subdivide([1,1], [2])
sage: b = a.dense_matrix().sparse_matrix().dense_matrix()
sage: b.subdivisions() == a.subdivisions()
True
```
>>> from sage.all import *
>>> a = a.subdivide([Integer(1), Integer(1)], [Integer(2)])
>>> b = a.dense_matrix().sparse_matrix().dense_matrix()
>>> b.subdivisions() == a.subdivisions()
True

**echelon_form** *(algorithm='default', height_guess=None, proof=True, **kwds)*

**INPUT:**

- `height_guess`, `proof`, `**kwds` all passed to the multimodular algorithm; ignored by the p-adic algorithm.

**OUTPUT:**

- `self` is no in reduced row echelon form.

**EXAMPLES:**

```python
sage: a = matrix(QQ, 4, range(16), sparse=True); a[0,0] = 1/19; a[0,1] = 1/5;
sage: a
[1/19 1/5 2 3]
[4 5 6 7]
[8 9 10 11]
[12 13 14 15]
sage: a.echelon_form()
[ 1 0 0 -76/157]
[ 0 1 0 -5/157]
[ 0 0 1 238/157]
[ 0 0 0 0]
```

```python
c>> from sage.all import *
c>> a = matrix(QQ, Integer(4), range(Integer(16)), sparse=True); a[Integer(0), Integer(0)] = Integer(1)/Integer(19); a[Integer(0),Integer(1)] = Integer(1)/
```

```python
c>> a.echelon_form()
c>>
[ 1 0 0 -76/157]
[ 0 1 0 -5/157]
[ 0 0 1 238/157]
[ 0 0 0 0]
```

**echelonize** *(height_guess=None, proof=True, **kwds)*

Transform the matrix `self` into reduced row echelon form in place.

**INPUT:**

- `height_guess`, `proof`, `**kwds` all passed to the multimodular algorithm; ignored by the p-adic algorithm.

**OUTPUT:**

- Nothing. The matrix `self` is transformed into reduced row echelon form in place.

**ALGORITHM:** a multimodular algorithm.

**EXAMPLES:**
sage: a = matrix(QQ, 4, range(16), sparse=True); a[0,0] = 1/19; a[0,1] = 1/5;...
→
a
[1/19 1/5 2 3]
[ 4 5 6 7]
[ 8 9 10 11]
[12 13 14 15]
sage: a.echelonize(); a
[ 1 0 0 -76/157]
[ 0 1 0 -5/157]
[ 0 0 1 238/157]
[ 0 0 0 0]

>>> from sage.all import *
>>> a = matrix(QQ, Integer(4), range(Integer(16)), sparse=True); a[Integer(0), Integer(0)] = Integer(1)/Integer(19); a[Integer(0),Integer(1)] = Integer(1)/Integer(5); a

[1/19 1/5 2 3]
[ 4 5 6 7]
[ 8 9 10 11]
[12 13 14 15]
>>> a.echelonize(); a

[ 1 0 0 -76/157]
[ 0 1 0 -5/157]
[ 0 0 1 238/157]
[ 0 0 0 0]

Issue #10319 has been fixed:

sage: m = Matrix(QQ, [1], sparse=True); m.echelonize()
sage: m = Matrix(QQ, [1], sparse=True); m.echelonize(); m
[1]

>>> from sage.all import *
>>> m = Matrix(QQ, [Integer(1)], sparse=True); m.echelonize(); m

[1]

height()

Return the height of this matrix, which is the least common multiple of all numerators and denominators of elements of this matrix.

OUTPUT:

– Integer

EXAMPLES:

sage: b = matrix(QQ,2,range(6), sparse=True); b[0,0]=-5007/293; b

[-5007/293 1 2]
[ 1 3 4 5]
sage: b.height()
5007

>>> from sage.all import *
>>> b = matrix(QQ,Integer(2),range(Integer(6)), sparse=True); b[Integer(0), Integer(0)]=Integer(5007)/Integer(293); b

[-5007/293 1 2]
**set_row_to_multiple_of_row***(i,j,s)*

Set row i equal to s times row j.

**EXAMPLES:**

```python
sage: a = matrix(QQ,2,3,range(6), sparse=True); a
[0 1 2]
[3 4 5]
sage: a.set_row_to_multiple_of_row(1,0,-3)
sage: a
[ 0 1 2]
[ 0 -3 -6]
```

```python
>>> from sage.all import *
>>> a = matrix(QQ,Integer(2),Integer(3),range(Integer(6)), sparse=True); a
[0 1 2]
[3 4 5]
>>> a.set_row_to_multiple_of_row(Integer(1),Integer(0),-Integer(3))
>>> a
[ 0 1 2]
[ 0 -3 -6]
```
This serves as a base class for dense matrices over Real Double Field and Complex Double Field.

AUTHORS:

- Jason Grout, Sep 2008: switch to NumPy backend, factored out the Matrix_double_dense class
- Josh Kantor
- William Stein: many bug fixes and touch ups.

EXAMPLES:

```sage
sage: b = Mat(RDF,2,3).basis()
sage: b[0,0]
[1.0 0.0 0.0]
[0.0 0.0 0.0]
```

```python
>>> from sage.all import *

>>> b = Mat(RDF,Integer(2),Integer(3)).basis()

>>> b[Integer(0),Integer(0)]
[1.0 0.0 0.0]
[0.0 0.0 0.0]
```

We deal with the case of zero rows or zero columns:

```sage
sage: m = MatrixSpace(RDF,0,3)
sage: m.zero_matrix()
[]
```

```python
>>> from sage.all import *

>>> m = MatrixSpace(RDF,Integer(0),Integer(3))

>>> m.zero_matrix()
[]
```

```python

class sage.matrix.matrix_double_dense.Matrix_double_dense
Bases: Matrix_numpy_dense

Base class for matrices over the Real Double Field and the Complex Double Field. These are supposed to be fast matrix operations using C doubles. Most operations are implemented using numpy which will call the underlying BLAS on the system.

This class cannot be instantiated on its own. The numpy matrix creation depends on several variables that are set in the subclasses.

EXAMPLES:
```
sage: m = Matrix(RDF, [[1,2],[3,4]])
sage: m**2
[ 7.0 10.0]
[15.0 22.0]
sage: m^(-1)  # rel tol 1e-15
¬→ needs scipy
[-1.9999999999999996 0.9999999999999998]
[ 1.4999999999999998 -0.4999999999999999]

>>> from sage.all import *
>>> m = Matrix(RDF, [[Integer(1),Integer(2)],[Integer(3),Integer(4)]])
>>> m**Integer(2)
[ 7.0 10.0]
[15.0 22.0]
>>> m**(-Integer(1))  # rel tol 1e-15
¬→ # needs scipy
[-1.9999999999999996 0.9999999999999998]
[ 1.4999999999999998 -0.4999999999999999]

LU()

Return a decomposition of the (row-permuted) matrix as a product of a lower-triangular matrix (“L”) and an upper-triangular matrix (“U”).

OUTPUT:

For an $m \times n$ matrix $A$ this method returns a triple of immutable matrices $P$, $L$, $U$ such that

• $A = P \cdot L \cdot U$

• $P$ is a square permutation matrix, of size $m \times m$, so is all zeroes, but with exactly a single one in each row and each column.

• $L$ is lower-triangular, square of size $m \times m$, with every diagonal entry equal to one.

• $U$ is upper-triangular with size $m \times n$, i.e. entries below the “diagonal” are all zero.

The computed decomposition is cached and returned on subsequent calls, thus requiring the results to be immutable.

Effectively, $P$ permutes the rows of $A$. Then $L$ can be viewed as a sequence of row operations on this matrix, where each operation is adding a multiple of a row to a subsequent row. There is no scaling (thus 1’s on the diagonal of $L$) and no row-swapping ($P$ does that). As a result $U$ is close to being the result of Gaussian-elimination. However, round-off errors can make it hard to determine the zero entries of $U$.

Note: The behaviour of LU() has changed in Sage version 9.1. Earlier, LU() returned $P, L, U$ such that $P \cdot A = L \cdot U$, where $P$ represents the permutation and is the matrix inverse of the $P$ returned by this method. The computation of this matrix inverse can be accomplished quickly with just a transpose as the matrix is orthogonal/unitary.

For details see Issue #18365.

EXAMPLES:

sage: m = matrix(RDF, 4, range(16))
sage: P, L, U = m.LU()
sage: P*L*U  # rel tol 2e-16
[ 0.0 1.0 2.0 3.0]
[ 4.0 5.0 6.0 7.0]
Below example illustrates the change in behaviour of LU().

```python
sage: (m - P*L*U).norm() < 1e-14
True
sage: (P*m - L*U).norm() < 1e-14
False
```

<sage: from sage.all import *
>>> m = matrix(RDF,Integer(4),range(Integer(16)))
>>> P, L, U = m.LU()
>>> P*L*U # rel tol 2e-16
[ 0.0 1.0  2.0  3.0]
[ 4.0 5.0  6.0  7.0]
[ 8.0 9.0 10.0 11.0]
[12.0 13.0 14.0 15.0]

Issue #10839 made this routine available for rectangular matrices.

```python
sage: A = matrix(RDF, 5, 6, range(30)); A
[ 0.0  1.0  2.0  3.0  4.0  5.0]

[0.0 0.0 0.0 0.0 0.0 0.0]

Trivial cases return matrices of the right size and characteristics.

sage: A = matrix(RDF, 5, 0)
sage: P, L, U = A.LU()
sage: P.parent()
Full MatrixSpace of 5 by 5 dense matrices over Real Double Field
sage: L.parent()
Full MatrixSpace of 5 by 5 dense matrices over Real Double Field
(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```
sage: U.parent()
Full MatrixSpace of 5 by 0 dense matrices over Real Double Field
sage: A-P*L*U
[]
```

```python
>>> from sage.all import *

>>> A = matrix(RDF, Integer(5), Integer(0))
>>> P, L, U = A.LU()
>>> P.parent()
Full MatrixSpace of 5 by 5 dense matrices over Real Double Field
>>> L.parent()
Full MatrixSpace of 5 by 5 dense matrices over Real Double Field
>>> U.parent()
Full MatrixSpace of 5 by 0 dense matrices over Real Double Field
>>> A-P*L*U
[]
```

The results are immutable since they are cached.

```
sage: P, L, U = matrix(RDF, 2, 2, range(4)).LU()
sage: L[0,0] = 0
Traceback (most recent call last):
  ... ValueError: matrix is immutable; please change a copy instead (i.e., use ~
copy(M) to change a copy of M).
sage: P[0,0] = 0
Traceback (most recent call last):
  ... ValueError: matrix is immutable; please change a copy instead (i.e., use ~
copy(M) to change a copy of M).
sage: U[0,0] = 0
Traceback (most recent call last):

Traceback (most recent call last):
  ... ValueError: matrix is immutable; please change a copy instead (i.e., use ~
copy(M) to change a copy of M).
```

`LU_valid()`

Return `True` if the LU form of this matrix has already been computed.
EXAMPLES:

<table>
<thead>
<tr>
<th>sage: A = random_matrix(RDF,3) ; A.LU_valid()</th>
</tr>
</thead>
<tbody>
<tr>
<td>False</td>
</tr>
<tr>
<td>sage: P, L, U = A.LU()</td>
</tr>
<tr>
<td>sage: A.LU_valid()</td>
</tr>
<tr>
<td>True</td>
</tr>
</tbody>
</table>

```python
>>> from sage.all import *
```  

```python
>>> A = random_matrix(RDF,Integer(3)) ; A.LU_valid()
False
```  

```python
>>> P, L, U = A.LU()
```  

```python
>>> A.LU_valid()
True
```  

**QR()**

Return a factorization into a unitary matrix and an upper-triangular matrix.

**INPUT:**

Any matrix over RDF or CDF.

**OUTPUT:**

$Q, R$ – a pair of matrices such that if $A$ is the original matrix, then

$$A = QR, \quad Q^*Q = I$$

where $R$ is upper-triangular. $Q^*$ is the conjugate-transpose in the complex case, and just the transpose in the real case. So $Q$ is a unitary matrix (or rather, orthogonal, in the real case), or equivalently $Q$ has orthogonal columns. For a matrix of full rank this factorization is unique up to adjustments via multiples of rows and columns by multiples with scalars having modulus 1. So in the full-rank case, $R$ is unique if the diagonal entries are required to be positive real numbers.

The resulting decomposition is cached.

**ALGORITHM:**

Calls scipy.linalg.qr() from SciPy, which is in turn an interface to LAPACK routines.

**EXAMPLES:**

Over the reals, the inverse of $Q$ is its transpose, since including a conjugate has no effect. In the real case, we say $Q$ is orthogonal.

| sage: A = matrix(RDF, [[-2, 0, -4, -1, -1],
| .....: [-2, 1, -6, -3, -1],
| .....: [1, 1, 7, 4, 5],
| .....: [3, 0, 8, 3, 3],
<table>
<thead>
<tr>
<th>.....: [-1, 1, -6, -6, 5]])</th>
</tr>
</thead>
<tbody>
<tr>
<td>sage: Q, R = A.QR()</td>
</tr>
</tbody>
</table>

```python
>>> from sage.all import *
```  

```python
>>> A = matrix(RDF, [[-Integer(2), Integer(0), -Integer(4), -Integer(1), -Integer(1)],
| ...: [-Integer(2), Integer(1), -Integer(6), -Integer(3), -Integer(1)],
| ...: [Integer(1), Integer(1), Integer(7), Integer(4), -Integer(3)],
| ...: [Integer(3), Integer(0), Integer(8), Integer(3), -Integer(5)],
| ...: [Integer(3), Integer(0), Integer(8), Integer(3), -Integer(5)]]
```  

(continues on next page)
At this point, $Q$ is only well-defined up to the signs of its columns, and similarly for $R$ and its rows, so we normalize them:

```python
sage: Qnorm = Q._normalize_columns()
sage: Rnorm = R._normalize_rows()
```

```python
sage: Qnorm.round(6).zero_at(10^-6)
```

```python
\begin{verbatim}
[ 0.458831 0.126051 0.381212 0.394574 0.68744]
[ 0.458831 -0.47269 -0.051983 -0.717294 0.220963]
[-0.229416 -0.661766 0.661923 0.180872 -0.196411]

[0.0 0.0 0.0 0.0 0.0]
[0.0 0.0 0.0 0.0 0.0]
\end{verbatim}
```

```python
>>> from sage.all import *
```

```python
>>> Qnorm = Q._normalize_columns()
```

```python
>>> Rnorm = R._normalize_rows()
```

```python
>>> Qnorm.round(Integer(6)).zero_at(Integer(10)**-Integer(6))
```

```python
\begin{verbatim}
[ 0.458831 0.126051 0.381212 0.394574 0.68744]
[ 0.458831 -0.47269 -0.051983 -0.717294 0.220963]
[-0.229416 -0.661766 0.661923 0.180872 -0.196411]
[-0.688247 -0.189076 -0.204468 -0.09663 0.662889]
[ 0.229416 -0.535715 -0.609939 0.536422 -0.024551]
\end{verbatim}
```

```python
>>> Rnorm.round(Integer(6)).zero_at(Integer(10)**-Integer(6))
```

```python
\begin{verbatim}
[ 4.358899 -0.458831 13.076697 6.194225 2.982405]
[ 0.0 1.670172 0.598741 -1.29202 6.207997]
[ 0.0 0.0 5.444402 5.468661 -0.682716]
[ 0.0 0.0 0.0 1.027626 -3.6193]
[ 0.0 0.0 0.0 0.0 0.024551]
\end{verbatim}
```

```python
>>> (Q*R.transpose()) # tol 1e-14
```

(continues on next page)
Now over the complex numbers, demonstrating that the SciPy libraries are (properly) using the Hermitian inner product, so that \( Q \) is a unitary matrix (its inverse is the conjugate-transpose).

\[
\begin{align*}
Q & = \begin{bmatrix}
0.9999999999999994 & 0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 1.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.9999999999999999 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.9999999999999998 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 & 1.0000000000000002
\end{bmatrix}\\
R & = A - \begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 & 0.0
\end{bmatrix}
\end{align*}
\]

\[
\begin{align*}
Q \cdot R & = A,
\end{align*}
\]
An example of a rectangular matrix that is also rank-deficient. If you run this example yourself, you may see a very small, nonzero entries in the third row, in the third column, even though the exact version of the matrix has rank 2. The final two columns of Q span the left kernel of A (as evidenced by the two zero rows of R). Different platforms will compute different bases for this left kernel, so we do not exhibit the actual matrix.
sage: Arat = matrix(QQ, [[2, -3, 3], 
....: [-1, 1, -1], 
....: [-1, 3, -3], 
....: [-5, 1, -1]])

sage: Arat.rank()
2

Q, R = A.QR()
>>>
Q.is_mutable()
False
>>> R.is_mutable()
False
>>> Q[Integer(0),Integer(0)] = Integer(0)
Traceback (most recent call last):
... Value Error: matrix is immutable; please change a copy instead (i.e., use \texttt{copy(M)} to change a copy of \texttt{M}).
>>> Qcopy = copy(Q)
>>> Qcopy[Integer(0),Integer(0)] = Integer(679)
>>> Qcopy[Integer(0),Integer(0)]
679.0

\textbf{SVD()}

Return the singular value decomposition of this matrix.

The \textit{U} and \textit{V} matrices are not unique and may be returned with different values in the future or on different systems. The \textit{S} matrix is unique and contains the singular values in descending order.

The computed decomposition is cached and returned on subsequent calls.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{A} – a matrix
\end{itemize}

\textbf{OUTPUT:}

\begin{itemize}
  \item \texttt{U, S, V} – immutable matrices such that \( A = U * S * V.\text{\texttt{conj}}().\text{\texttt{transpose}}() \) where \texttt{U} and \texttt{V} are orthogonal and \texttt{S} is zero off of the diagonal.
\end{itemize}

Note that if self is m-by-n, then the dimensions of the matrices that this returns are (m, m), (m, n), and (n, n).

\textbf{Note:} If all you need is the singular values of the matrix, see the more convenient \texttt{\texttt{singular\_values()}}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: m = matrix(RDF,4,range(1,17))
sage: U, S, V = m.SVD()
sage: U*S*V.transpose()  # tol 1e-14

\[
\begin{bmatrix}
[0.999999999999993 & 1.999999999999997 & 3.000000000000001 & 4.000000000000002] \\
[ 4.999999999999998 & 5.999999999999998 & 6.999999999999998 & 8.0] \\
[12.999999999999998 & 14.0 & 15.0 & 16.0]
\end{bmatrix}
\end{verbatim}
Matrices and Spaces of Matrices, Release 10.4

From `sage.all` import *

from sage.all import *

m = matrix(RDF, Integer(4), range(Integer(1), Integer(17)))

U, S, V = m.SVD()

U*S*V.transpose()  # tol 1e-14

[0.9999999999999993 1.9999999999999987 3.0000000000000001 4.0000000000000002]

[-0.566306918848 0.112382414097 -0.816496580928]

(continues on next page)
cholesky()

Return the Cholesky factorization of a matrix that is real symmetric, or complex Hermitian.

INPUT:

Any square matrix with entries from RDF that is symmetric, or with entries from CDF that is Hermitian. The matrix must be positive definite for the Cholesky decomposition to exist.

OUTPUT:

For a matrix $A$ the routine returns a lower triangular matrix $L$ such that,

$$A = LL^*$$

where $L^*$ is the conjugate-transpose in the complex case, and just the transpose in the real case. If the matrix fails to be positive definite (perhaps because it is not symmetric or Hermitian), then this function raises a ValueError.

IMPLEMENTATION:

The existence of a Cholesky decomposition and the positive definite property are equivalent. So this method and the is_positive_definite() method compute and cache both the Cholesky decomposition and the positive-definiteness. So the is_positive_definite() method or catching a ValueError from the cholesky() method are equally expensive computationally and if the decomposition exists, it is cached as a side-effect of either routine.

EXAMPLES:

A real matrix that is symmetric, Hermitian, and positive definite:
A complex matrix that is Hermitian and positive definite.

```
>>> from sage.all import *
>>> M = matrix(CDF, [[ 23, 17*I + 3, 24*I + 25, 21*I],
                   [-17*I + 3, 38, -69*I + 89, 7*I + 15],
                   [-24*I + 25, 69*I + 89, 976, 24*I + 6],
                   [-21*I, -7*I + 15, -24*I + 6, 28]])
>>> M.is_hermitian()  # needs sage.symbolic
True
>>> M.is_symmetric()  # needs sage.symbolic
True
>>> L = M.cholesky()
>>> (L*L.transpose()).round(6).zero_at(10^-10)
[ 1.0 1.0 1.0 1.0 1.0]
[ 1.0 5.0 3.1 121.0 341.0]
[ 1.0 341.0 4681.0 1555.0 1555.0]
[ 1.0 121.0 7381.0 22621.0 22621.0]
[ 1.0 341.0 4681.0 22621.0 69905.0]
```

A complex matrix that is Hermitian and positive definite.
This routine will recognize when the input matrix is not positive definite. The negative eigenvalues are an equivalent indicator. (Eigenvalues of a Hermitian matrix must be real, so there is no loss in ignoring the imprecise imaginary parts).

sage: A = matrix(RDF, [[ 3, -6, 9, 6, -9], ....: [-6, 11, -16, -11, 17], ....: [ 9, -16, 28, 16, -40], ....: [ 6, -11, 16, 9, -19], ....: [-9, 17, -40, -19, 68]])

condition (p='frob')
Return the condition number of a square nonsingular matrix.

Roughly speaking, this is a measure of how sensitive the matrix is to round-off errors in numerical computations. The minimum possible value is 1.0, and larger numbers indicate greater sensitivity.

INPUT:

- \( p \) – (default: ‘frob’); controls which norm is used to compute the condition number, allowable values are ‘frob’ (for the Frobenius norm), integers -2, -1, 1, 2, positive and negative infinity. See output discussion for specifics.

OUTPUT:

The condition number of a matrix is the product of a norm of the matrix times the norm of the inverse of the matrix. This requires that the matrix be square and invertible (nonsingular, full rank).

Returned value is a double precision floating point value in RDF, or Infinity. Row and column sums described below are sums of the absolute values of the entries, where the absolute value of the complex number \( a + bi \) is \( \sqrt{a^2 + b^2} \). Singular values are the “diagonal” entries of the “S” matrix in the singular value decomposition.

- \( p = \text{frob} \): the default norm employed in computing the condition number, the Frobenius norm, which for a matrix \( A = (a_{ij}) \) computes
  \[
  \left( \sum_{i,j} |a_{i,j}|^2 \right)^{1/2}
  \]
- \( p = \text{sv} \): the quotient of the maximal and minimal singular value.
- \( p = \text{Infinity} \) or \( p = \text{oo} \): the maximum row sum.
- \( p = \text{-Infinity} \) or \( p = \text{-oo} \): the minimum column sum.
- \( p = 1 \): the maximum column sum.
- \( p = -1 \): the minimum column sum.
- \( p = 2 \): the 2-norm, equal to the maximum singular value.
- \( p = -2 \): the minimum singular value.

ALGORITHM:

Computation is performed by the cond() function of the SciPy/NumPy library.

EXAMPLES:

First over the reals.

```
sage: A = matrix(RDF, 4, [(1/4)*x^3 for x in range(16)]); A
[ 0.0 0.25 2.0 6.75]
[ 16.0 31.25 54.0 85.75]
[128.0 182.25 250.0 332.75]
[432.0 549.25 686.0 843.75]
sage: A.condition() 9923.88955...
sage: A.condition(p='frob') 9923.88955...
sage: A.condition(p=Infinity) # tol 3e-14 22738.50000000045
sage: A.condition(p=-Infinity) # tol 2e-14
```
And over the complex numbers.

```
sage: B = matrix(CDF, 3, [x + x^2*I for x in range(9)]); B
[ 0.0  1.0 + 1.0*I  2.0 + 4.0*I]
[ 3.0 + 9.0*I  4.0 + 16.0*I  5.0 + 25.0*I]
[ 6.0 + 36.0*I  7.0 + 49.0*I  8.0 + 64.0*I]
sage: B.condition()  
203.851798...  
sage: B.condition(p='frob')
203.851798...
```
>>> from sage.all import *
>>> B = matrix(CDF, Integer(3), [x + x**Integer(2)*I for x in range(Integer(9))]); B
[ 0.0 1.0 + 1.0*I 2.0 + 4.0*I]
[ 3.0 + 9.0*I 4.0 + 16.0*I 5.0 + 25.0*I]
[6.0 + 36.0*I 7.0 + 49.0*I 8.0 + 64.0*I]
>>> B.condition()
203.851798...
>>> B.condition(p='frob')
203.851798...
>>> B.condition(p=Infinity)
369.55630...
>>> B.condition(p=-Infinity)
5.46112969...
>>> B.condition(p=integer(1))
289.251481...
>>> B.condition(p=-Integer(1))
20.4566639...
>>> B.condition(p=Integer(2))
202.653543...
>>> B.condition(p=-Integer(2))
0.00493453005...

Hilbert matrices are famously ill-conditioned, while an identity matrix can hit the minimum with the right norm.

sage: A = matrix(RDF, 10, [1/(i+j+1) for i in range(10) for j in range(10)])
sage: A.condition()  # tol 2e-4
16332197709146.014
sage: id = identity_matrix(CDF, 10)
sage: id.condition(p=1)
1.0

>>> from sage.all import *
>>> A = matrix(RDF, Integer(10), [Integer(1)/(i+j+Integer(1)) for i in range(Integer(10)) for j in range(Integer(10))])
>>> A.condition()  # tol 2e-4
16332197709146.014
>>> id = identity_matrix(CDF, Integer(10))
>>> id.condition(p=Integer(1))
1.0

Return values are in RDF.

sage: A = matrix(CDF, 2, range(1,5))
sage: A.condition() in RDF
True

>>> from sage.all import *
>>> A = matrix(CDF, Integer(2), range(Integer(1),Integer(5)))
>>> A.condition() in RDF
True

Rectangular and singular matrices raise errors if p is not ‘sv’.

sage: A = matrix(RDF, 2, 3, range(6))
sage: A.condition()
Traceback (most recent call last):
  ...
TypeError: matrix must be square if p is not 'sv', not 2 x 3

sage: A.condition('sv')
7.34...

sage: A = matrix(QQ, 5, range(25))
sage: A.is_singular()
True
sage: B = A.change_ring(CDF)
sage: B.condition()
+Infinity

>>> from sage.all import *
>>> A = matrix(RDF, Integer(2), Integer(3), range(Integer(6)))
>>> A.condition()
Traceback (most recent call last):
  ...
TypeError: matrix must be square if p is not 'sv', not 2 x 3

>>> A.condition('sv')
7.34...

>>> A = matrix(QQ, Integer(5), range(Integer(25)))
>>> A.is_singular()
True
>>> B = A.change_ring(CDF)
>>> B.condition()
+Infinity

Improper values of p are caught.

sage: A = matrix(CDF, 2, range(1,5))
sage: A.condition(p='bogus')
Traceback (most recent call last):
  ...
ValueError: condition number 'p' must be +/- infinity, 'frob', 'sv' or an--integer, not bogus
sage: A.condition(p=632)
Traceback (most recent call last):
  ...
ValueError: condition number integer values of 'p' must be -2, -1, 1 or 2,--not 632

>>> from sage.all import *
>>> A = matrix(CDF, Integer(2), range(Integer(1),Integer(5)))
>>> A.condition(p='bogus')
Traceback (most recent call last):
  ...
ValueError: condition number 'p' must be +/- infinity, 'frob', 'sv' or an--integer, not bogus
>>> A.condition(p=Integer(632))
Traceback (most recent call last):
  ...
ValueError: condition number integer values of 'p' must be -2, -1, 1 or 2,
conjugate()

Return the conjugate of this matrix, i.e. the matrix whose entries are the conjugates of the entries of self.

EXAMPLES:

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, [[1+I, 3-I], [0, 2*I]])
sage: A.conjugate()
[1.0 - 1.0*I 3.0 + 1.0*I]
[ 0.0      -2.0*I]
```

There is a shorthand notation:

```python
sage: A.conjugate() == A.C  # needs sage.symbolic
True
```

Conjugates work (trivially) for real matrices:

```python
sage: B = matrix.random(RDF, 3)
sage: B == B.conjugate()
True
```

determinant()

Return the determinant of self.

ALGORITHM:
Uses scipy.linalg.det().

EXAMPLES:

```python
sage: m = matrix(RDF, 2, range(4)); m.det()
-2.0
sage: m = matrix(RDF, 0, []); m.det()
1.0
```
sage: m = matrix(RDF, 2, range(6)); m.det()
Traceback (most recent call last):
...
ValueError: self must be a square matrix

```sage
>>> from sage.all import *
>>> m = matrix(RDF,Integer(2),range(Integer(4))); m.det()
-2.0
>>> m = matrix(RDF,Integer(0),[]); m.det()
1.0
>>> m = matrix(RDF, Integer(2), range(Integer(6))); m.det()
Traceback (most recent call last):
...
ValueError: self must be a square matrix
```

eigenvalues (other=None, algorithm='default', tol=None, homogeneous=False)

Return a list of ordinary or generalized eigenvalues.

INPUT:

• self – a square matrix
• other – a square matrix \( B \) (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved; if algorithm is 'symmetric' or 'hermitian', \( B \) must be real symmetric or hermitian positive definite, respectively
• algorithm – default: 'default'
  – 'default' – applicable to any matrix with double-precision floating point entries. Uses the eigvals() function from SciPy.
  – 'symmetric' – converts the matrix into a real matrix (i.e. with entries from RDF), then applies the algorithm for Hermitian matrices. This algorithm can be significantly faster than the 'default' algorithm.
  – 'hermitian' – uses the eigh() function from SciPy, which applies only to real symmetric or complex Hermitian matrices. Since Hermitian is defined as a matrix equaling its conjugate-transpose, for a matrix with real entries this property is equivalent to being symmetric. This algorithm can be significantly faster than the 'default' algorithm.
• tol – (default: None); if set to a value other than None, this is interpreted as a small real number used to aid in grouping eigenvalues that are numerically similar, but is ignored when homogeneous is set. See the output description for more information.
• homogeneous – boolean (default: False); if True, use homogeneous coordinates for the output (see eigenvectors_right() for details)

**Warning:** When using the 'symmetric' or 'hermitian' algorithms, no check is made on the input matrix, and only the entries below, and on, the main diagonal are employed in the computation. Methods such as is_symmetric() and is_hermitian() could be used to verify this beforehand.

OUTPUT:

Default output for a square matrix of size \( n \) is a list of \( n \) eigenvalues from the complex double field, CDF. If the 'symmetric' or 'hermitian' algorithms are chosen, the returned eigenvalues are from the real double field, RDF.
If a tolerance is specified, an attempt is made to group eigenvalues that are numerically similar. The return is then a list of pairs, where each pair is an eigenvalue followed by its multiplicity. The eigenvalue reported is the mean of the eigenvalues computed, and these eigenvalues are contained in an interval (or disk) whose radius is less than $5 \times \text{tol}$ for $n < 10,000$ in the worst case.

More precisely, for an $n \times n$ matrix, the diameter of the interval containing similar eigenvalues could be as large as the sum of the reciprocals of the first $n$ integers times $\text{tol}$.

**Warning:** Use caution when using the $\text{tol}$ parameter to group eigenvalues. See the examples below to see how this can go wrong.

EXAMPLES:

```python
sage: m = matrix(RDF, 2, 2, [1,2,3,4])
sage: ev = m.eigenvalues(); ev
[-0.372281323..., 5.37228132...]
sage: ev[0].parent()  
Complex Double Field

sage: m = matrix(RDF, 2, 2, [0,1,-1,0])
sage: m.eigenvalues(algorithm=default)
[1.0*I, -1.0*I]

sage: m = matrix(CDF, 2, 2, [1*I,1,-1*I,0])
# needs sage.symbolic
sage: m.eigenvalues()
[-0.624810533... + 1.30024259...*I, 0.624810533... - 0.30024259...*I]
```

The adjacency matrix of a graph will be symmetric, and the eigenvalues will be real.

```python
>>> from sage.all import *
>>> m = matrix(RDF, Integer(2), Integer(2), [Integer(1),Integer(2),Integer(3), Integer(4)])
>>> ev = m.eigenvalues(); ev
[-0.372281323..., 5.37228132...]
```

(continues on next page)
sage: ev[0].parent()
Real Double Field

>>> from sage.all import *
>>> # needs sage.graphs
>>> A = graphs.PetersenGraph().adjacency_matrix()
>>> A = A.change_ring(RDF)
>>> ev = A.eigenvalues(algorithm='symmetric'); ev # tol 1e-14
[-2.0, -2.0, -2.0, -2.0, 1.0, 1.0, 1.0, 1.0, 1.0, 3.0]
>>> ev[Integer(0)].parent()
Real Double Field

The matrix $A$ is “random”, but the construction of $C$ provides a positive-definite Hermitian matrix. Note that the eigenvalues of a Hermitian matrix are real, and the eigenvalues of a positive-definite matrix will be positive.

sage: # needs sage.symbolic
sage: A = matrix([[ 4*I + 5, 8*I + 1, 7*I + 5, 3*I + 5],
              [ 7*I - 2, -4*I + 7, -2*I + 4, 8*I + 8],
              [-2*I + 1, 6*I + 6, 5*I + 5, -I - 4],
              [ 5*I + 1, 6*I + 2, I - 4, -I + 3]])

sage: C = (A*A.conjugate_transpose()).change_ring(CDF)
sage: ev = C.eigenvalues(algorithm='hermitian'); ev
[2.68144025..., 49.5167998..., 274.086188..., 390.71557...]

A tolerance can be given to aid in grouping eigenvalues that are similar numerically. However, if the parameter is too small it might split too finely. Too large, and it can go wrong very badly. Use with care.

sage: # needs sage.graphs
sage: G = graphs.PetersenGraph()
sage: G.spectrum()
[3, 1, 1, 1, 1, -2, -2, -2, -2]

sage: A = G.adjacency_matrix().change_ring(RDF)
sage: A.eigenvalues(algorithm='symmetric', tol=1.0e-5) # tol 1e-15
[(-2.0, 4), (1.0, 5), (3.0, 1)]
sage: A.eigenvalues(algorithm='symmetric', tol=2.5) # tol 1e-15
[(-2.0, 4), (1.333333333333333, 6)]
An (extreme) example of properly grouping similar eigenvalues.

In this generalized eigenvalue problem, the homogeneous coordinates explain the output obtained for the eigenvalues:

See also:

* eigenvectors_left(), eigenvectors_right(), Matrix.eigenmatrix_left(), Matrix.eigenmatrix_right().

* eigenvectors_left (other=None, homogeneous=False)

Compute the ordinary or generalized left eigenvectors of a matrix of double precision real or complex numbers (i.e. RDF or CDF).
INPUT:

- **other** – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved

- **homogeneous** – boolean (default: False); if True, use homogeneous coordinates for the eigenvalues in the output

OUTPUT:

A list of triples, each of the form $(e, [v], 1)$, where $e$ is the eigenvalue, and $v$ is an associated left eigenvector such that

$$vA = ev.$$

If the matrix $A$ is of size $n$, then there are $n$ triples.

If a matrix $B$ is passed as optional argument, the output is a solution to the generalized eigenvalue problem such that

$$vA = evB.$$

If **homogeneous** is set, each eigenvalue is returned as a tuple $(\alpha, \beta)$ of homogeneous coordinates such that

$$\beta vA = \alpha vB.$$

The format of the output is designed to match the format for exact results. However, since matrices here have numerical entries, the resulting eigenvalues will also be numerical. No attempt is made to determine if two eigenvalues are equal, or if eigenvalues might actually be zero. So the algebraic multiplicity of each eigenvalue is reported as 1. Decisions about equal eigenvalues or zero eigenvalues should be addressed in the calling routine.

The SciPy routines used for these computations produce eigenvectors normalized to have length 1, but on different hardware they may vary by a complex sign. So for doctests we have normalized output by forcing their eigenvectors to have their first non-zero entry equal to one.

ALGORITHM:

Values are computed with the SciPy library using `scipy.linalg.eig()`.

EXAMPLES:

```python
sage: m = matrix(RDF, [[-5, 3, 2, 8], [10, 2, 4, -2], [-1, -10, -10, -17], [-2, 7, 6, 13]])
sage: m
[ -5.0 3.0 2.0 8.0]
[ 10.0 2.0 4.0 -2.0]
[ -1.0 -10.0 -10.0 -17.0]
[ -2.0 7.0 6.0 13.0]
sage: spectrum = m.left_eigenvectors()
sage: for i in range(len(spectrum)):
....:     spectrum[i][1][0] = matrix(RDF, spectrum[i][1]).echelon_form()[0]
sage: spectrum[0]  # tol 1e-13
(2.0, [[1.0, 1.0, 1.0, 1.0]], 1)
sage: spectrum[1]  # tol 1e-13
(1.0, [[1.0, 0.8, 0.8, 0.6]], 1)
(-2.0, [[1.0, 0.4, 0.6, 0.2]], 1)
(-1.0, [[1.0, 1.0, 2.0, 2.0]], 1)
```
```python
>>> from sage.all import *

>>> m = matrix(RDF, 
[[-Integer(5), Integer(3), Integer(2), Integer(8)],
 [Integer(10), Integer(2), Integer(4), -Integer(2)],
 [Integer(10), -Integer(10), Integer(17), -Integer(17)],
 [Integer(6), Integer(13)]])

>>> m
[-5.0 3.0 2.0 8.0]
[10.0 2.0 4.0 -2.0]
[-1.0 -10.0 -10.0 -17.0]
[-2.0 7.0 6.0 13.0]

>>> spectrum = m.left_eigenvectors()

>>> for i in range(len(spectrum)):
...     spectrum[i][1][0] = matrix(RDF, spectrum[i][1][0]).echelon_form()[0]

>>> spectrum[0]  # tol 1e-13
(2.0, [(1.0, 1.0, 1.0, 1.0)], 1)

>>> spectrum[1]  # tol 1e-13
(1.0, [(1.0, 0.8, 0.8, 0.6)], 1)

>>> spectrum[2]  # tol 1e-13
(-2.0, [(1.0, 0.4, 0.6, 0.2)], 1)

>>> spectrum[3]  # tol 1e-13
(-1.0, [(1.0, 1.0, 2.0, 2.0)], 1)

A generalized eigenvalue problem:

```python
sage: A = matrix(CDF, [[1+I, -2], [3, 4]])
sage: B = matrix(CDF, [[0, 7-I], [2, -3]])
sage: E = A.eigenvectors_left(B)
sage: all((v * A - e * v * B).norm() < 1e-14 for e, [v], _ in E)
True
```

```python
>>> from sage.all import *

>>> A = matrix(CDF, [[Integer(1)+I, -Integer(2)], [Integer(3), Integer(4)]])
>>> B = matrix(CDF, [[Integer(0), Integer(7)-I], [Integer(2), -Integer(3)]])
>>> E = A.eigenvectors_left(B)

>>> all((beta * v * A - alpha * v * B).norm() < RealNumber('1e-14') for e, [v], _ in E)
True
```

In a generalized eigenvalue problem with a singular matrix $B$, we can check the eigenvector property using homogeneous coordinates, even though the quotient $\alpha/\beta$ is not always defined:

```python
sage: A = matrix.identity(CDF, 2)
sage: B = matrix(CDF, [[2, 1+I], [4, 2+2*I]])
sage: E = A.eigenvectors_left(B, homogeneous=True)
sage: all((beta * v * A - alpha * v * B).norm() < RealNumber('1e-14') for (alpha, beta), [v], _ in E)
True
```

```python
>>> from sage.all import *

>>> A = matrix.identity(CDF, Integer(2))
>>> B = matrix(CDF, [[Integer(2), Integer(1)+I], [Integer(4), -Integer(2)+Integer(2)*I]])

>>> E = A.eigenvectors_left(B, homogeneous=True)

>>> all((beta * v * A - alpha * v * B).norm() < RealNumber('1e-14') for (alpha, beta), [v], _ in E)
True
```

eigenvalues(), eigenvectors_right(), Matrix.eigenmatrix_left().

eigenvectors_right(\text{other}=\text{None}, \text{homogeneous}=\text{False})

Compute the ordinary or generalized right eigenvectors of a matrix of double precision real or complex numbers (i.e. RDF or CDF).

INPUT:

• \text{other} – a square matrix \(B\) (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved.

• \text{homogeneous} – boolean (default: False); if True, use homogeneous coordinates for the eigenvalues in the output.

OUTPUT:

A list of triples, each of the form \((e, [v], 1)\), where \(e\) is the eigenvalue, and \(v\) is an associated right eigenvector such that

\[ Av = ev. \]

If the matrix \(A\) is of size \(n\), then there are \(n\) triples.

If a matrix \(B\) is passed as optional argument, the output is a solution to the generalized eigenvalue problem such that

\[ Av = eBv. \]

If \text{homogeneous} is set, each eigenvalue is returned as a tuple \((\alpha, \beta)\) of homogeneous coordinates such that

\[ \beta Av = \alpha Bv. \]

The format of the output is designed to match the format for exact results. However, since matrices here have numerical entries, the resulting eigenvalues will also be numerical. No attempt is made to determine if two eigenvalues are equal, or if eigenvalues might actually be zero. So the algebraic multiplicity of each eigenvalue is reported as 1. Decisions about equal eigenvalues or zero eigenvalues should be addressed in the calling routine.

The SciPy routines used for these computations produce eigenvectors normalized to have length 1, but on different hardware they may vary by a complex sign. So for doctests we have normalized output by forcing their eigenvectors to have their first non-zero entry equal to one.

ALGORITHM:

Values are computed with the SciPy library using \texttt{scipy.linalg.eig()}.

EXAMPLES:

```python
sage: m = matrix(RDF, [[-9, -14, 19, -74], [-1, 2, 4, -11], [-4, -12, 6, -32], [0, -2, -1, 1]])
sage: m
[ -9.0 -14.0 19.0 -74.0]
[ -1.0 2.0 4.0 -11.0]
[ -4.0 -12.0 6.0 -32.0]
[ 0.0 -2.0 -1.0 1.0]
sage: spectrum = m.right_eigenvectors()
sage: for i in range(len(spectrum)):
....:     spectrum[i][1][0] = matrix(RDF, spectrum[i][1]).echelon_form()[0]
sage: spectrum[0] # tol 1e-13
```

(continued from previous page)

```python
>>> from sage.all import *
>>> m = matrix(RDF, [[-Integer(9), -Integer(14), Integer(19), -Integer(74)], [-Integer(1), Integer(2), Integer(4), -Integer(11)], [-Integer(4), -Integer(12), Integer(6), -Integer(32)], [Integer(0), -Integer(2), -Integer(1), Integer(1)]]
```

```python
>>> spectrum = m.right_eigenvectors()
>>> for i in range(len(spectrum)):
...     spectrum[i][Integer(1)][Integer(0)] = matrix(RDF, _
...     spectrum[i][Integer(1)]).echelon_form()[Integer(0)]
```

```python
A generalized eigenvalue problem:
```

```python
sage: A = matrix(CDF, [[1+I, -2], [3, 4]])
sage: B = matrix(CDF, [[0, 7-I], [2, -3]])
sage: E = A.eigenvectors_right(B)
sage: all((A * v - e * B * v).norm() < 1e-14 for e, [v], _ in E)
True
```

```python
>>> from sage.all import *
>>> A = matrix(CDF, [[Integer(1)+I, -Integer(2)], [3, Integer(4)]])
>>> B = matrix(CDF, [[Integer(1) - Integer(2)], [Integer(3), Integer(4)]]))
>>> E = A.eigenvectors_right(B)
```

```python
all((A * v - e * B * v).norm() < RealNumber('1e-14') for e, [v], _ in E)
True
```

In a generalized eigenvalue problem with a singular matrix $B$, we can check the eigenvector property using homogeneous coordinates, even though the quotient $\alpha/\beta$ is not always defined:

```python
sage: A = matrix.identity(RDF, 2)
sage: B = matrix(RDF, [[3, 5], [6, 10]])
sage: E = A.eigenvectors_right(B, homogeneous=True)
sage: all((beta * A * v - alpha * B * v).norm() < 1e-14 for (alpha, beta), [v], _ in E)
True
```
>>> from sage.all import *
>>> A = matrix.identity(RDF, Integer(2))
>>> B = matrix(RDF, [[Integer(3), Integer(5)], [Integer(6), Integer(10)]]
>>> E = A.eigenvectors_right(B, homogeneous=True)
>>> all((beta * A * v - alpha * B * v).norm() < RealNumber('1e-14')
...     for (alpha, beta), [v], _ in E)
True

See also:

eigenvalues(), eigenvectors_left(), Matrix.eigenmatrix_right().

eval()

Calculate the exponential of this matrix X, which is the matrix

\[ e^X = \sum_{k=0}^{\infty} \frac{X^k}{k!}. \]

EXAMPLES:

```
sage: A = matrix(RDF, 2, [1,2,3,4]); A
[1.0 2.0]
[3.0 4.0]
sage: A.exp() # tol 1e-14
[ 51.968956198705044 74.73656456700327]

[ 1.0 2.0 + 1.0*I]
[ 3.0*I 4.0]
>>> A.exp() # tol 3e-14 # needs sage.symbolic
[-32.383580980922254 + 21.88423595789845*I 2.269633004093535 + 44.901324827684824*I]
```

is_hermitian(tol=1e-12, algorithm='naive')

Return True if the matrix is equal to its conjugate-transpose.
INPUT:

- **tol** – (default: $1e^{-12}$); the largest value of the absolute value of the difference between two matrix entries for which they will still be considered equal.

- **algorithm** – string (default: “naive”); either “naive” or “orthonormal”

OUTPUT:

True if the matrix is square and equal to the transpose with every entry conjugated, and False otherwise.

Note that if conjugation has no effect on elements of the base ring (such as for integers), then the `is_symmetric()` method is equivalent and faster.

The tolerance parameter is used to allow for numerical values to be equal if there is a slight difference due to round-off and other imprecisions.

The result is cached, on a per-tolerance and per-algorithm basis.

ALGORITHMS:

The naive algorithm simply compares corresponding entries on either side of the diagonal (and on the diagonal itself) to see if they are conjugates, with equality controlled by the tolerance parameter.

The orthonormal algorithm first computes a Schur decomposition (via the `schur()` method) and checks that the result is a diagonal matrix with real entries.

So the naive algorithm can finish quickly for a matrix that is not Hermitian, while the orthonormal algorithm will always compute a Schur decomposition before going through a similar check of the matrix entry-by-entry.

EXAMPLES:

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, [[ 1 + I, 1 - 6*I, -1 - I],
...: [-3 - I, -4*I, -2],
...: [-1 + I, -2 - 8*I, 2 + I]])
```

```python
sage: A.is_hermitian(algorithm='orthonormal')
False
```

```python
sage: A.is_hermitian(algorithm='naive')
False
```

```python
sage: B = A*A.conjugate_transpose()
```

```python
sage: B.is_hermitian(algorithm='orthonormal')
True
```

```python
sage: B.is_hermitian(algorithm='naive')
True
```

```python
>>> from sage.all import *
```

```python
>>> # needs sage.symbolic
```

```python
>>> A = matrix(CDF, [[ Integer(1) + I, Integer(1) - Integer(6)*I, -
...: Integer(1) - I],
...: [-Integer(3) - I, -Integer(4)*I, -Integer(2)],
...: [-Integer(1) + I, -Integer(2) - Integer(8)*I, Integer(2) + I]])
```

```python
>>> A.is_hermitian(algorithm='orthonormal')
False
```

```python
>>> A.is_hermitian(algorithm='naive')
False
```

```python
>>> B = A*A.conjugate_transpose()
```

```python
>>> B.is_hermitian(algorithm='orthonormal')
True
```

```python
>>> B.is_hermitian(algorithm='naive')
True
```
A matrix that is nearly Hermitian, but for one non-real diagonal entry.

\[
\begin{bmatrix}
2 & 2-I & 1+4*I \\
2+I & 3+I & 2-6*I \\
1-4*I & 2+6*I & 5
\end{bmatrix}
\]

sage: A.is_hermitian(algorithm='orthonormal')
False
sage: A[1,1] = 132
sage: A.is_hermitian(algorithm='orthonormal')
True

We get a unitary matrix from the SVD routine and use this numerical matrix to create a matrix that should be Hermitian (indeed it should be the identity matrix), but with some imprecision. We use this to illustrate that if the tolerance is set too small, then we can be too strict about the equality of entries and may achieve the wrong result (depending on the system):

\[
\begin{bmatrix}
1 + I & 1 - 6*I & -1 - I \\
-3 - I & -4*I & -2 \\
-1 + I & -2 - 8*I & 2 + I
\end{bmatrix}
\]

sage: U, _, _ = A.SVD()
sage: B = U*U.conjugate_transpose()
sage: B.is_hermitian(algorithm='naive')
True
sage: B.is_hermitian(algorithm='naive', tol=1.0e-17) # random
False
sage: B.is_hermitian(algorithm='naive', tol=1.0e-15)
True

(continues on next page)
>>> B.is_hermitian(algorithm='naive', tol=RealNumber('1.0e-15'))
True

A square, empty matrix is trivially Hermitian.

```python
sage: A = matrix(RDF, 0, 0)
sage: A.is_hermitian()
True
```

Rectangular matrices are never Hermitian, no matter which algorithm is requested.

```python
>>> from sage.all import *
>>> A = matrix(RDF, Integer(0), Integer(0))
>>> A.is_hermitian()
True
```

AUTHOR:

• Rob Beezer (2011-03-30)

is_normal (tol=1e-12, algorithm='orthonormal')

Return True if the matrix commutes with its conjugate-transpose.

INPUT:

• tol – (default: 1e-12); the largest value of the absolute value of the difference between two matrix entries for which they will still be considered equal.

• algorithm – (default: 'orthonormal'); set to 'orthonormal' for a stable procedure and set to 'naive' for a fast procedure.

OUTPUT:

True if the matrix is square and commutes with its conjugate-transpose, and False otherwise.

Normal matrices are precisely those that can be diagonalized by a unitary matrix.

The tolerance parameter is used to allow for numerical values to be equal if there is a slight difference due to round-off and other imprecisions.

The result is cached, on a per-tolerance and per-algorithm basis.

ALGORITHMS:

The naive algorithm simply compares entries of the two possible products of the matrix with its conjugate-transpose, with equality controlled by the tolerance parameter.

The orthonormal algorithm first computes a Schur decomposition (via the schur() method) and checks that the result is a diagonal matrix. An orthonormal diagonalization is equivalent to being normal.
So the naive algorithm can finish fairly quickly for a matrix that is not normal, once the products have been computed. However, the orthonormal algorithm will compute a Schur decomposition before going through a similar check of a matrix entry-by-entry.

EXAMPLES:

First over the complexes. \( \mathbb{B} \) is Hermitian, hence normal.

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, [[ 1 + I, 1 - 6*I, -1 - I],
...: [-3 - I, -4*I, -2],
...: [-1 + I, -2 - 8*I, 2 + I]])
```

```python
sage: B = A*A.conjugate_transpose()
```

```python
sage: B.is_hermitian()
True
```

```python
sage: B.is_normal(algorithm='orthonormal')
True
```

```python
sage: B.is_normal(algorithm='naive')
True
```

```python
sage: B[0,0] = I
```

```python
sage: B.is_normal(algorithm='orthonormal')
False
```

```python
sage: B.is_normal(algorithm='naive')
False
```

```python
>>> from sage.all import *
```

```python
>>> A = matrix(CDF, [[ Integer(1) + I, Integer( 1) - Integer(6)*I, Integer(1) - I],
...: [-Integer(3) - I, -Integer(4)*I, -Integer(2)],
...: [-Integer(1) + I, -Integer(2) - Integer(8)*I, Integer(2) + I]])
```

```python
>>> B = A*A.conjugate_transpose()
```

```python
>>> B.is_hermitian()
True
```

```python
>>> B.is_normal(algorithm='orthonormal')
True
```

```python
>>> B.is_normal(algorithm='naive')
True
```

```python
>>> B[0,0] = I
```

```python
>>> B.is_normal(algorithm='orthonormal')
False
```

```python
>>> B.is_normal(algorithm='naive')
False
```

Now over the reals. Circulant matrices are normal.

```python
sage: # needs sage.graphs
sage: D = digraphs.Circuit(20)
```

```python
sage: A = 3*D.adjacency_matrix() - 5*G.adjacency_matrix()
```

```python
sage: A = A.change_ring(RDF)
```

```python
sage: A.is_normal()
True
```

```python
sage: A.is_normal(algorithm='naive')
True
```

```python
sage: A[19,0] = 4.0
```

```python
sage: A.is_normal()
```

(continues on next page)
False
sage: A.is_normal(algorithm='naive')
False

>>> from sage.all import *
>>> # needs sage.graphs
>>> G = graphs.CirculantGraph(Integer(20), [Integer(3), Integer(7)])
>>> D = digraphs.Circuit(Integer(20))
>>> A = Integer(3)*D.adjacency_matrix() - Integer(5)*G.adjacency_matrix()
>>> A = A.change_ring(RDF)
>>> A.is_normal()
True
>>> A.is_normal(algorithm='naive')
True
>>> A[Integer(19),Integer(0)] = RealNumber('4.0')
>>> A.is_normal()
False
>>> A.is_normal(algorithm='naive')
False

Skew-Hermitian matrices are normal.

sage: # needs sage.symbolic
sage: A = matrix(CDF, [[ 1 + I, 1 - 6*I, -1 - I],
...: [-3 - I, -4*I, -2],
...: [-1 + I, -2 - 8*I, 2 + I]])

sage: B = A - A.conjugate_transpose()
sage: B.is_hermitian()
False
sage: B.is_normal()
True
sage: B.is_normal(algorithm='naive')
True

>>> from sage.all import *
>>> # needs sage.symbolic
>>> A = matrix(CDF, [[ Integer(1) + I, Integer(1) - Integer(6)*I, -
...: Integer(1) - I],
...: [-Integer(3) - I, -Integer(4)*I, -Integer(2)],
...: [-Integer(1) + I, -Integer(2) - Integer(8)*I, Integer(2) + I]])

>>> B = A - A.conjugate_transpose()
>>> B.is_hermitian()
False
>>> B.is_normal()
True
>>> B.is_normal(algorithm='naive')
True

A small matrix that does not fit into any of the usual categories of normal matrices.

sage: A = matrix(RDF, [[1, -1],
...: [1, 1]])

sage: A.is_normal()
True
sage: not A.is_hermitian() and not A.is_skew_symmetric()
Sage has several fields besides the entire complex numbers where conjugation is non-trivial.

```python
sage: # needs sage.rings.number_field
sage: F.<b> = QuadraticField(-7)

sage: C = matrix(F, 
                [[-2*b - 3, 7*b - 6, -b + 3],
                 [-2*b - 3, -3*b + 2, -2*b],
                 [  b + 1,     0,    -2]])

sage: C = C*C.conjugate_transpose()

sage: C.is_normal()
True
```

A square, empty matrix is trivially normal.

```python
sage: A = matrix(CDF, 0, 0)

sage: A.is_normal()
True
```

Rectangular matrices are never normal, no matter which algorithm is requested.

```python
sage: A = matrix(CDF, 3, 4)

sage: A.is_normal()
False
```

AUTHOR:
is_positive_definite()

Determines if a matrix is positive definite.

A matrix $A$ is positive definite if it is square, is Hermitian (which reduces to symmetric in the real case), and for every nonzero vector $\vec{x}$,

$$\vec{x}^* A \vec{x} > 0$$

where $\vec{x}^*$ is the conjugate-transpose in the complex case and just the transpose in the real case. Equivalently, a positive definite matrix has only positive eigenvalues and only positive determinants of leading principal submatrices.

INPUT:

Any matrix over RDF or CDF.

OUTPUT:

True if and only if the matrix is square, Hermitian, and meets the condition above on the quadratic form. The result is cached.

IMPLEMENTATION:

The existence of a Cholesky decomposition and the positive definite property are equivalent. So this method and the cholesky() method compute and cache both the Cholesky decomposition and the positive-definiteness. So the is_positive_definite() method or catching a ValueError from the cholesky() method are equally expensive computationally and if the decomposition exists, it is cached as a side-effect of either routine.

EXAMPLES:

A matrix over RDF that is positive definite.

```python
sage: M = matrix(RDF,[[ 1,  1,  1,  1,  1],
...:                    [ 1,  5,  31, 121, 341],
...:                    [ 1, 31, 341, 1555, 4681],
...:                    [ 1,121, 1555, 7381, 22621],
...:                    [ 1,341, 4681, 22621, 69905]])

sage: M.is_symmetric()
True
sage: M.eigenvalues()
[77547.66..., 82.44..., 2.41..., 0.46..., 0.011...]

sage: [round(M[:i,:i].determinant()) for i in range(1, M.nrows()+1)]
[1, 4, 460, 27936, 82944]

sage: M.is_positive_definite()
True
```

```python
>>> from sage.all import *

>>> M = matrix(RDF,[[ Integer(1), Integer(1), Integer(1), Integer(1),...

→ Integer(1)],
...:                    [ Integer(1), Integer(5), Integer(31), Integer(121),...
→ Integer(341)],
...:                    [ Integer(1), Integer(31), Integer(341), Integer(1555),...
→ Integer(4681)],
...:                    [ Integer(1),Integer(121), Integer(1555), Integer(7381),...
→Integer(22621)],
...:                    [ Integer(1),Integer(341), Integer(4681), Integer(22621),...
→Integer(69905)]]
```

(continues on next page)
A matrix over CDF that is positive definite.

```python
sage: # needs sage.symbolic
sage: C = matrix(CDF, [[ 23, 17*I + 3, 24*I + 25, 21*I],
                   [ -17*I + 3, 38, -69*I + 89, 7*I + 15],
                   [ -24*I + 25, 69*I + 89, 976, 24*I + 6],
                   [ -21*I, -7*I + 15, -24*I + 6, 28]])
sage: C.is_hermitian()
True
sage: [x.real() for x in C.eigenvalues()]
[991.46..., 55.96..., 3.69..., 13.87...]
```

A matrix over RDF that is not positive definite.

```python
sage: from sage.all import *
sage: # needs sage.symbolic
sage: C = matrix(CDF, [[ Integer( 23), Integer( 17)*I + Integer(3), ...
                     Integer(24)*I + Integer(25), Integer(21)*I],
                     [ -Integer(17)*I + Integer(3), Integer( 38), ...
                      -Integer(69)*I + Integer(89), Integer(7)*I + Integer(15)],
                     [ -Integer(24)*I + Integer(25), Integer(69)*I +...
                      Integer(89), Integer(976), Integer(24)*I + Integer(6)],
                     [ -Integer(21)*I, -Integer(7)*I + Integer(15), ...
                      -Integer(24)*I + Integer(6), Integer(28)])]
```
```python
>>> from sage.all import *

>>> A = matrix(RDF, [[ Integer(3), -Integer(6), Integer(9), Integer(6), -Integer(9)],
                  ...                   [-Integer(6), Integer(11), -Integer(16), -Integer(11), Integer(17)],
                  ...                   [ Integer(9), -Integer(16), Integer(28), Integer(16), -Integer(40)],
                  ...                   [ Integer(6), -Integer(11), Integer(16), Integer(9), -Integer(19)],
                  ...                   [-Integer(9), Integer(17), -Integer(40), -Integer(19), Integer(68)]])

>>> A.is_symmetric()
True

>>> A.eigenvalues()
[108.07..., 13.02..., -0.02..., -0.70..., -1.37...]

>>> [round(A[:i,:i].determinant()) for i in range(1, A.nrows()+1)]
[3, -3, -15, 30, -30]

>>> A.is_positive_definite()
False

A matrix over CDF that is not positive definite.

```
A large random matrix that is guaranteed by theory to be positive definite.

```
sage: R = random_matrix(CDF, 200)
sage: H = R.conjugate_transpose() * R
sage: H.is_positive_definite()
True
```

AUTHOR:

• Rob Beezer (2012-05-28)

**`is_skew_hermitian(tol=1e-12, algorithm='orthonormal')`**

Return `True` if the matrix is equal to the negative of its conjugate transpose.

**INPUT:**

- `tol` – (default: `1e-12`); the largest value of the absolute value of the difference between two matrix entries for which they will still be considered equal.
- `algorithm` – (default: `orthonormal`); set to `orthonormal` for a stable procedure and set to `naive` for a fast procedure.

**OUTPUT:**

`True` if the matrix is square and equal to the negative of its conjugate transpose, and `False` otherwise.

Note that if conjugation has no effect on elements of the base ring (such as for integers), then the `is_skew_symmetric()` method is equivalent and faster.

The tolerance parameter is used to allow for numerical values to be equal if there is a slight difference due to round-off and other imprecisions.

The result is cached, on a per-tolerance and per-algorithm basis.

**ALGORITHMS:**

The naive algorithm simply compares corresponding entries on either side of the diagonal (and on the diagonal itself) to see if they are conjugates, with equality controlled by the tolerance parameter.

The orthonormal algorithm first computes a Schur decomposition (via the `schur()` method) and checks that the result is a diagonal matrix with real entries.

So the naive algorithm can finish quickly for a matrix that is not Hermitian, while the orthonormal algorithm will always compute a Schur decomposition before going through a similar check of the matrix entry-by-entry.

**EXAMPLES:**

```
sage: A = matrix(CDF, [[0, -1], [1, 0]])
sage: A.is_skew_hermitian(algorithm='orthonormal')
True
```
```python
sage: A.is_skew_hermitian(algorithm='naive')
True
```

```python
>>> from sage.all import *

>>> A = matrix(CDF, [[Integer(0), -Integer(1)], ...
... [Integer(1), Integer(0)]])

>>> A.is_skew_hermitian(algorithm='orthonormal')
True

>>> A.is_skew_hermitian(algorithm='naive')
True
```

A matrix that is nearly skew-Hermitian, but for a non-real diagonal entry.

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, [[ -I, -1, 1-I], ...
... [ 1, 1, -1], ...
... [-1-I, 1, -I]])

sage: A.is_skew_hermitian()
False

sage: A[1,1] = -I

sage: A.is_skew_hermitian()
True
```

We get a unitary matrix from the SVD routine and use this numerical matrix to create a matrix that should be skew-Hermitian (indeed it should be the identity matrix multiplied by $I$), but with some imprecision. We use this to illustrate that if the tolerance is set too small, then we can be too strict about the equality of entries and may achieve the wrong result (depending on the system):

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, [[ 1 + I, 1 - 6*I, -1 - I], ...
... [-3 - I, -4*I, -2], ...
... [-1 + I, -2 - 8*I, 2 + I]])

sage: U, _, _ = A.SVD()

sage: B = 1j*U*U.conjugate_transpose()

sage: B.is_skew_hermitian(algorithm='naive')
True

sage: B.is_skew_hermitian(algorithm='naive', tol=1.0e-17)  # random
False

sage: B.is_skew_hermitian(algorithm='naive', tol=1.0e-15)
True
```

```python
>>> from sage.all import *

>>> # needs sage.symbolic

>>> A = matrix(CDF, [[ Integer(1) + I, Integer(1) - Integer(6)*I, -...
```

AUTHOR:

• Rob Beezer (2011-03-30)

\texttt{is\_unitary}(\texttt{tol}=1\texttt{e}\texttt{-}12, \texttt{algorithm}=\texttt{\textquoteleft orthonormal\textquoteright})

Return True if the columns of the matrix are an orthonormal basis.

For a matrix with real entries this determines if a matrix is “orthogonal” and for a matrix with complex entries this determines if the matrix is “unitary.”

INPUT:

• \texttt{tol} = (default: 1\texttt{e}\texttt{-}12); the largest value of the absolute value of the difference between two matrix entries for which they will still be considered equal.

• \texttt{algorithm} = (default: ‘orthonormal’); set to ‘orthonormal’ for a stable procedure and set to ‘naive’ for a fast procedure.

OUTPUT:

True if the matrix is square and its conjugate-transpose is its inverse, and False otherwise. In other words, a matrix is orthogonal or unitary if the product of its conjugate-transpose times the matrix is the identity matrix.
The tolerance parameter is used to allow for numerical values to be equal if there is a slight difference due to round-off and other imprecisions.

The result is cached, on a per-tolerance and per-algorithm basis.

**ALGORITHMS:**

The naive algorithm simply computes the product of the conjugate-transpose with the matrix and compares the entries to the identity matrix, with equality controlled by the tolerance parameter.

The orthonormal algorithm first computes a Schur decomposition (via the `schur()` method) and checks that the result is a diagonal matrix with entries of modulus 1, which is equivalent to being unitary.

So the naive algorithm might finish fairly quickly for a matrix that is not unitary, once the product has been computed. However, the orthonormal algorithm will compute a Schur decomposition before going through a similar check of a matrix entry-by-entry.

**EXAMPLES:**

A matrix that is far from unitary.

```python
sage: A = matrix(RDF, 4, range(16))
sage: A.conjugate().transpose()*A
[224.0 248.0 272.0 296.0]
[248.0 276.0 304.0 332.0]
[272.0 304.0 336.0 368.0]
[296.0 332.0 368.0 404.0]
sage: A.is_unitary()
False
sage: A.is_unitary(algorithm='naive')
False
sage: A.is_unitary(algorithm='orthonormal')
False
```

```python
>>> from sage.all import *

>>> A = matrix(RDF, Integer(4), range(Integer(16)))

>>> A.conjugate().transpose()*A
[224.0 248.0 272.0 296.0]
[248.0 276.0 304.0 332.0]
[272.0 304.0 336.0 368.0]
[296.0 332.0 368.0 404.0]

>>> A.is_unitary()
False

>>> A.is_unitary(algorithm='naive')
False

>>> A.is_unitary(algorithm='orthonormal')
False
```

The QR decomposition will produce a unitary matrix as Q and the SVD decomposition will create two unitary matrices, U and V.

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, 
[ 1 - I, -3*I, -2 + I, 1, -2 + 3*I],
[ 1 - I, -2 + I, 1 + 4*I, 0, 2 + I],
[-1, -5 + I, -2 + I, 1 + I, -5 - 4*I],
[-2 + 4*I, 2 - I, 8 - 4*I, 1 - 8*I, 3 - 2*I])

sage: Q, R = A.QR()
sage: Q.is_unitary()
True
sage: U, S, V = A.SVD()
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
sage: U.is_unitary(algorithm='naive')
True
sage: U.is_unitary(algorithm='orthonormal')
True
sage: V.is_unitary(algorithm='naive')
True
```

```python
>>> from sage.all import *
>>> # needs sage.symbolic
>>> A = matrix(CDF, [[ Integer(1) - I, -Integer(3)*I, -Integer(2) + I, ...
˓→ Integer(1), -Integer(2) + Integer(3)*I],
˓→ Integer(4)*I, Integer(0), Integer(2) + I],
˓→ Integer(1) + I, -Integer(5) - Integer(4)*I],
˓→ Integer(4)*I, Integer(1) - Integer(8)*I, Integer(3) - Integer(2)*I])
>>> Q, R = A.QR()
>>> Q.is_unitary(algorithm='naive')
True
>>> U, S, V = A.SVD()
>>> U.is_unitary(algorithm='naive')
True
>>> V.is_unitary(algorithm='naive')
True
```

If we make the tolerance too strict we can get misleading results.

```python
sage: A = matrix(RDF, 10, 10, [1/(i+j+1) for i in range(10) for j in range(10)])
```

```python
sage: Q, R = A.QR()
```

```python
sage: Q.is_unitary(algorithm='naive', tol=1e-16)
False
sage: Q.is_unitary(algorithm='orthonormal', tol=1e-17)
False
```

Rectangular matrices are not unitary/orthogonal, even if their columns form an orthonormal set.

```python
sage: A = matrix(CDF, [[1,0], [0,0], [0,1]])
```

```python
sage: A.is_unitary()
False
```

```python
>>> from sage.all import *
>>> A = matrix(CDF, [[Integer(1), Integer(0)], [Integer(0), Integer(0)], ...
˓→ [0,0]])
```

(continues on next page)
The smallest cases:

```python
>>> A = matrix(CDF, [Integer(0), Integer(1)])
>>> A.is_unitary()
False
```

```python
>>> from sage.all import *
>>> P = matrix(CDF, Integer(0), Integer(0))
>>> P.is_unitary(algorithm='naive')
True
>>> P = matrix(CDF, Integer(1), Integer(1), [Integer(1)])
>>> P.is_unitary(algorithm='orthonormal')
True
```

`left_eigenvectors (other=None, homogeneous=False)`

Compute the ordinary or generalized left eigenvectors of a matrix of double precision real or complex numbers (i.e. RDF or CDF).

**INPUT:**

- `other` – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved
- `homogeneous` – boolean (default: False); if True, use homogeneous coordinates for the eigenvalues in the output

**OUTPUT:**

A list of triples, each of the form $(e, [v], 1)$, where $e$ is the eigenvalue, and $v$ is an associated left eigenvector such that

$$vA = ev.$$

If the matrix $A$ is of size $n$, then there are $n$ triples.

If a matrix $B$ is passed as optional argument, the output is a solution to the generalized eigenvalue problem such that

$$vA = evB.$$
If `homogeneous` is set, each eigenvalue is returned as a tuple \((\alpha, \beta)\) of homogeneous coordinates such that

\[
\beta v A = \alpha v B.
\]

The format of the output is designed to match the format for exact results. However, since matrices here have numerical entries, the resulting eigenvalues will also be numerical. No attempt is made to determine if two eigenvalues are equal, or if eigenvalues might actually be zero. So the algebraic multiplicity of each eigenvalue is reported as 1. Decisions about equal eigenvalues or zero eigenvalues should be addressed in the calling routine.

The SciPy routines used for these computations produce eigenvectors normalized to have length 1, but on different hardware they may vary by a complex sign. So for doctests we have normalized output by forcing their eigenvectors to have their first non-zero entry equal to one.

**ALGORITHM:**

Values are computed with the SciPy library using `scipy.linalg.eig()`.

**EXAMPLES:**

```python
sage: m = matrix(RDF, [[-5, 3, 2, 8], [10, 2, 4, -2], [-1, -10, -10, -17], [-2, -7, 6, 13]])
sage: m

[ -5.0 3.0 2.0 8.0]
[ 10.0 2.0 4.0 -2.0]
[ -1.0 -10.0 -10.0 -17.0]
[ -2.0 -7.0 6.0 13.0]
sage: spectrum = m.left_eigenvectors()
sage: for i in range(len(spectrum)):
    spectrum[i][1][0] = matrix(RDF, spectrum[i][1]).echelon_form()[0]

sage: spectrum[0]  # tol 1e-13
(2.0, [(1.0, 1.0, 1.0, 1.0)], 1)
sage: spectrum[1]  # tol 1e-13
(1.0, [(1.0, 0.8, 0.8, 0.6)], 1)
(-2.0, [(1.0, 0.4, 0.6, 0.2)], 1)
(-1.0, [(1.0, 1.0, 2.0, 2.0)], 1)
```

```python
>>> from sage.all import *

>>> m = matrix(RDF, [[-Integer(5), Integer(3), Integer(2), Integer(8)],
[Integer(10), Integer(2), Integer(4), -Integer(2)], [-Integer(1),
-Integer(10), -Integer(10), -Integer(17)], [-Integer(2), Integer(7),
Integer(6), Integer(13)]]

>>> m

[ -5.0 3.0 2.0 8.0]
[ 10.0 2.0 4.0 -2.0]
[ -1.0 -10.0 -10.0 -17.0]
[ -2.0 -7.0 6.0 13.0]

>>> spectrum = m.left_eigenvectors()

>>> for i in range(len(spectrum)):
    spectrum[i][Integer(1)][Integer(0)] = matrix(RDF,_
    spectrum[i][Integer(1)]).echelon_form()[Integer(0)]

>>> spectrum[Integer(0)]  # tol 1e-13
(2.0, [(1.0, 1.0, 1.0, 1.0)], 1)

>>> spectrum[Integer(1)]  # tol 1e-13
(1.0, [(1.0, 0.8, 0.8, 0.6)], 1)

>>> spectrum[Integer(2)]  # tol 1e-13
(-2.0, [(1.0, 0.4, 0.6, 0.2)], 1)
```

(continues on next page)
A generalized eigenvalue problem:

```python
sage: A = matrix(CDF, [[1+I, -2], [3, 4]])
sage: B = matrix(CDF, [[0, 7-I], [2, -3]])
sage: E = A.eigenvectors_left(B)
sage: all((v * A - e * v * B).norm() < 1e-14 for e, [v], _ in E)
True
```

In a generalized eigenvalue problem with a singular matrix $B$, we can check the eigenvector property using homogeneous coordinates, even though the quotient $\alpha/\beta$ is not always defined:

```python
sage: A = matrix.identity(CDF, 2)
sage: B = matrix(CDF, [[2, 1+I], [4, 2+2*I]])
sage: E = A.eigenvectors_left(B, homogeneous=True)
sage: all((beta * v * A - alpha * v * B).norm() < 1e-14 for (alpha, beta), [v], _ in E)
True
```

See also:
- `eigenvalues()`
- `eigenvectors_right()`
- `Matrix.eigenmatrix_left()`
- `log_determinant()`

Compute the log of the absolute value of the determinant using LU decomposition.

**Note:** This is useful if the usual determinant overflows.

**EXAMPLES:**

```python
sage: m = matrix(RDF, 2, 2, range(4)); m
[0.0 1.0]
[2.0 3.0]
sage: RDF(log(abs(m.det()))))
0.6931471805599453
sage: m.log_determinant()
0.6931471805599453
```
sage: m = matrix(RDF,0,0,[]); m
[]
sage: m.log_determinant()
0.0
sage: m = matrix(CDF,2,2,range(4)); m
[0.0 1.0]
[2.0 3.0]
sage: RDF(log(abs(m.determinant())))
0.6931471805599453
sage: m.log_determinant()
0.6931471805599453
sage: m = matrix(CDF,0,0,[]); m
[]
sage: m.log_determinant()
0.0

>>> from sage.all import *

>>> m = matrix(RDF,Integer(2),Integer(2),range(Integer(4))); m
[0.0 1.0]
[2.0 3.0]
>>> RDF(log(abs(m.determinant())))
0.6931471805599453
>>> m.log_determinant()
0.6931471805599453
>>> m = matrix(RDF,Integer(0),Integer(0),[]); m
[]
>>> m.log_determinant()
0.0
>>> m = matrix(CDF,Integer(2),Integer(2),range(Integer(4))); m
[0.0 1.0]
[2.0 3.0]
>>> RDF(log(abs(m.determinant())))
0.6931471805599453
>>> m.log_determinant()
0.6931471805599453
>>> m = matrix(CDF,Integer(0),Integer(0),[]); m
[]
>>> m.log_determinant()
0.0

**norm** *(p=2)*

Return the norm of the matrix.

**INPUT:**

- p – (default: 2); controls which norm is computed, allowable values are ‘frob’ (for the Frobenius norm), integers -2, -1, 1, 2, positive and negative infinity. See output discussion for specifics.

**OUTPUT:**

Returned value is a double precision floating point value in RDF. Row and column sums described below are sums of the absolute values of the entries, where the absolute value of the complex number \(a + bi\) is \(\sqrt{a^2 + b^2}\). Singular values are the “diagonal” entries of the “S” matrix in the singular value decomposition.
• \( p = \text{'frob'} \): the Frobenius norm, which for a matrix \( A = (a_{ij}) \) computes
\[
\left( \sum_{i,j} |a_{ij}|^2 \right)^{1/2}
\]
• \( p = \text{Infinity} \) or \( p = \infty \): the maximum row sum.
• \( p = -\text{Infinity} \) or \( p = -\infty \): the minimum column sum.
• \( p = 1 \): the maximum column sum.
• \( p = -1 \): the minimum column sum.
• \( p = 2 \): the induced 2-norm, equal to the maximum singular value.
• \( p = -2 \): the minimum singular value.

**ALGORITHM:**
Computation is performed by the `norm()` function of the SciPy/NumPy library.

**EXAMPLES:**
First over the reals.

```sage
sage: A = matrix(RDF, 3, range(-3, 6)); A
[-3.0 -2.0 -1.0]
[ 0.0 1.0 2.0]
[ 3.0 4.0 5.0]
sage: A.norm()
7.99575670...
sage: A.norm(p='frob')
8.30662386...
sage: A.norm(p=Infinity)
12.0
sage: A.norm(p=-Infinity)
3.0
sage: A.norm(p=1)
8.0
sage: A.norm(p=-1)
6.0
sage: A.norm(p=2)
7.99575670...
sage: A.norm(p=-2) < 10^-15
True
```

```python
>>> from sage.all import *
>>> A = matrix(RDF, Integer(3), range(-Integer(3), Integer(6)))); A
[-3.0 -2.0 -1.0]
[ 0.0 1.0 2.0]
[ 3.0 4.0 5.0]
>>> A.norm()
7.99575670...
>>> A.norm(p='frob')
8.30662386...
>>> A.norm(p=Infinity)
12.0
>>> A.norm(p=-Infinity)
3.0
```

(continues on next page)
>>> A.norm(p=Integer(1))
8.0
>>> A.norm(p=-Integer(1))
6.0
>>> A.norm(p=Integer(2))
7.99575670...
>>> A.norm(p=-Integer(2)) < Integer(10)**-Integer(15)
True

And over the complex numbers.

```python
sage: # needs sage.symbolic
sage: B = matrix(CDF, 2, [[1+I, 2+3*I], [3+4*I, 3*I]]); B
[[1.0 + 1.0*I 2.0 + 3.0*I]
 [3.0 + 4.0*I 3.0*I]]
sage: B.norm()
6.66189877...
sage: B.norm(p='frob')
7.0

6.1421356...
>>> B.norm(p=Integer(2))
6.66189877...
>>> B.norm(p=-Integer(2))
2.14921023...
```

Since it is invariant under unitary multiplication, the Frobenius norm is equal to the square root of the sum of squares of the singular values.
Matrices and Spaces of Matrices, Release 10.4

```python
sage: A = matrix(RDF, 5, range(1,26))
sage: f = A.norm(p='frob')
sage: U, S, V = A.SVD()
sage: s = sqrt(sum([S[i,i]**2 for i in range(5)]))
sage: abs(f-s) < 1.0e-12
True

>>> from sage.all import *
>>> A = matrix(RDF, Integer(5), range(Integer(1),Integer(26)))
>>> f = A.norm(p='frob')
>>> U, S, V = A.SVD()
>>> s = sqrt(sum([S[i,i]**2 for i in range(Integer(5))]))
>>> abs(f-s) < RealNumber('1.0e-12')
True
```

Return values are in RDF.

```python
sage: A = matrix(CDF, 2, range(4))
sage: A.norm() in RDF
True

>>> from sage.all import *
>>> A = matrix(CDF, Integer(2), range(Integer(4)))
>>> A.norm() in RDF
True
```

Improper values of $p$ are caught.

```python
sage: A.norm(p='bogus')
Traceback (most recent call last):
... ValueError: matrix norm p must be +/- infinity, 'frob' or an integer, not... →bogus
sage: A.norm(p=632)
Traceback (most recent call last):
... ValueError: matrix norm integer values of p must be -2, -1, 1 or 2, not 632
```

```python
>>> from sage.all import *
>>> A.norm(p='bogus')
Traceback (most recent call last):
... ValueError: matrix norm p must be +/- infinity, 'frob' or an integer, not... →bogus
>>> A.norm(p=Integer(632))
Traceback (most recent call last):
... ValueError: matrix norm integer values of p must be -2, -1, 1 or 2, not 632
```

**right_eigenvectors** *(other=None, homogeneous=False)*

Compute the ordinary or generalized right eigenvectors of a matrix of double precision real or complex numbers (i.e. RDF or CDF).

**INPUT:**

- **other** – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved
• homogeneous – boolean (default: False); if True, use homogeneous coordinates for the eigenvalues in the output

OUTPUT:
A list of triples, each of the form \((e, [v], 1)\), where \(e\) is the eigenvalue, and \(v\) is an associated right eigenvector such that

\[ A v = e v. \]

If the matrix \(A\) is of size \(n\), then there are \(n\) triples.

If a matrix \(B\) is passed as optional argument, the output is a solution to the generalized eigenvalue problem such that

\[ A v = e B v. \]

If homogeneous is set, each eigenvalue is returned as a tuple \((\alpha, \beta)\) of homogeneous coordinates such that

\[ \beta A v = \alpha B v. \]

The format of the output is designed to match the format for exact results. However, since matrices here have numerical entries, the resulting eigenvalues will also be numerical. No attempt is made to determine if two eigenvalues are equal, or if eigenvalues might actually be zero. So the algebraic multiplicity of each eigenvalue is reported as 1. Decisions about equal eigenvalues or zero eigenvalues should be addressed in the calling routine.

The SciPy routines used for these computations produce eigenvectors normalized to have length 1, but on different hardware they may vary by a complex sign. So for doctests we have normalized output by forcing their eigenvectors to have their first non-zero entry equal to one.

ALGORITHM:
Values are computed with the SciPy library using \texttt{scipy.linalg.eig()}. 

EXAMPLES:

```python
sage: m = matrix(RDF, \[
[-9, -14, 19, -74],
[-1, 2, 4, -11],
[-4, -12, 6, -32],
[0, -2, -1, 1]\])
sage: m
\[
\begin{pmatrix}
-9.0 & -14.0 & 19.0 & -74.0 \\
-1.0 & 2.0 & 4.0 & -11.0 \\
-4.0 & -12.0 & 6.0 & -32.0 \\
0.0 & -2.0 & -1.0 & 1.0
\end{pmatrix}
\]
sage: spectrum = m.right_eigenvectors()
sage: for i in range(len(spectrum)):
    spectrum[i][1][0] = matrix(RDF, spectrum[i][1]).echelon_form()[0]
sage: spectrum[0]  # tol 1e-13
(2.0, [(1.0, -2.0, 3.0, 1.0)], 1)
sage: spectrum[1]  # tol 1e-13
(1.0, [(1.0, -0.666666666666633, 1.3333333333333155, 0.3333333333333155)], 1)
(-2.0, [(1.0, -0.2, 1.0, 0.2)], 1)
sage: spectrum[3]  # tol 1e-12
(-1.0, [(1.0, -0.5, 2.0, 0.5)], 1)
```

```python
>>> from sage.all import *
```

```python
>>> m = matrix(RDF, \[
[-\text{Integer}(9), -\text{Integer}(14), \text{Integer}(19), -\text{Integer}(74)],
-\text{Integer}(1), \text{Integer}(2), \text{Integer}(4), -\text{Integer}(11), -\text{Integer}(4), -
\]
```
A generalized eigenvalue problem:

```python
sage: A = matrix(CDF, [[1+I, -2], [3, 4]])
sage: B = matrix(CDF, [[0, 7-I], [2, -3]])
sage: E = A.eigenvectors_right(B)
sage: all((A * v - e * B * v).norm() < 1e-14 for e, [v], _ in E)
True
```

In a generalized eigenvalue problem with a singular matrix $B$, we can check the eigenvector property using homogeneous coordinates, even though the quotient $\alpha/\beta$ is not always defined:

```python
sage: A = matrix.identity(RDF, 2)
sage: B = matrix(RDF, [[3, 5], [6, 10]])
sage: E = A.eigenvectors_right(B, homogeneous=True)
sage: all((beta * A * v - alpha * B * v).norm() < RealNumber('1e-14') for e, [v], _ in E)
True
```

See also:

`eigenvalues()`, `eigenvectors_left()`, `Matrix.eigenmatrix_right()`.

769
round \((\texttt{ndigits}=0)\)

Return a copy of the matrix where all entries have been rounded to a given precision in decimal digits (default 0 digits).

INPUT:

- \(\texttt{ndigits}\) – The precision in number of decimal digits

OUTPUT:

A modified copy of the matrix

EXAMPLES:

```
\begin{verbatim}
sage: M = matrix(CDF, \[[10.234r + 34.2343jr, 34e10r]\])
sage: M
[10.234 + 34.2343*I 340000000000.0]
sage: M.round(2)
[10.23 + 34.23*I 340000000000.0]
sage: M.round()
[ 10.0 + 34.0*I 340000000000.0]
\end{verbatim}
```

schur \((\texttt{base\_ring}=\texttt{None})\)

Return the Schur decomposition of the matrix.

INPUT:

- \(\texttt{base\_ring}\) – optional, defaults to the base ring of \(\texttt{self}\). Use this to request the base ring of the returned matrices, which will affect the format of the results.

OUTPUT:

A pair of immutable matrices. The first is a unitary matrix \(Q\). The second, \(T\), is upper-triangular when returned over the complex numbers, while it is almost upper-triangular over the reals. In the latter case, there can be some \(2 \times 2\) blocks on the diagonal which represent a pair of conjugate complex eigenvalues of \(\texttt{self}\).

If \(\texttt{self}\) is the matrix \(A\), then

\[
A = QT(Q)\text{f}
\]

where the latter matrix is the conjugate-transpose of \(Q\), which is also the inverse of \(Q\), since \(Q\) is unitary.

Note that in the case of a normal matrix (Hermitian, symmetric, and others), the upper-triangular matrix is a diagonal matrix with eigenvalues of \(\texttt{self}\) on the diagonal, and the unitary matrix has columns that form an orthonormal basis composed of eigenvectors of \(\texttt{self}\). This is known as “orthonormal diagonalization”.

Warning: The Schur decomposition is not unique, as there may be numerous choices for the vectors of the orthonormal basis, and consequently different possibilities for the upper-triangular matrix. However, the diagonal of the upper-triangular matrix will always contain the eigenvalues of the matrix (in the
complex version), or $2 \times 2$ block matrices in the real version representing pairs of conjugate complex eigenvalues.

In particular, results may vary across systems and processors.

**EXAMPLES:**

First over the complexes. The similar matrix is always upper-triangular in this case.

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, 4, 4, range(16)) + matrix(CDF, 4, 4, [x^3*I for x in range(0, 16)])

 -0.025... - 0.642...*I]
```

(continues on next page)
We begin with a real matrix but ask for a decomposition over the complexes. The result will yield an upper-triangular matrix over the complex numbers for $T$.

```python
sage: A = matrix(RDF, 4, 4, [x^3 for x in range(16)])

sage: Q, T = A.schur(base_ring=CDF)

sage: (Q*Q.conjugate().transpose()).zero_at(1e-12) # tol 1e-12

[0.9999999999999987 0.0 0.0 0.0]
[ 0.0 0.9999999999999999 0.0 0.0]
[ 0.0 0.0 1.0000000000000013 0.0]
[ 0.0 0.0 0.0 1.0000000000000007]

sage: T.parent()
Full MatrixSpace of 4 by 4 dense matrices over Complex Double Field

sage: all(T.zero_at(1.0e-12)[i,j] == Integer(0) for i in range(4) for j in range(i))
True
```

Now totally over the reals. But with complex eigenvalues, the similar matrix may not be upper-triangular. But “at worst” there may be some $2 \times 2$ blocks on the diagonal which represent a pair of conjugate complex eigenvalues. These blocks will then just interrupt the zeros below the main diagonal. This example has a pair of these of the blocks.

```python
sage: A = matrix(RDF, 4, 4, [[1, 0, -3, -1],
.....: [4, -16, -7, 0],
.....: [1, 21, 1, -2],
.....: [26, -1, -2, 1]])

sage: Q, T = A.schur()
```

True
Starting with complex numbers and requesting a result over the reals will never happen.

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, 2, 2, [[2+I, -1+3*I], [5-4*I, 2-7*I]])
sage: A.schur(base_ring=RDF)
Traceback (most recent call last):
  ...  
TypeError: unable to convert input matrix over CDF to a matrix over RDF

>>> from sage.all import *
>>> # needs sage.symbolic
>>> A = matrix(CDF, Integer(2), Integer(2), [[Integer(2)+I, -
˓→Integer(1)+Integer(3)*I], [Integer(5)-Integer(4)*I, Integer(2)-
˓→Integer(7)*I]])
>>> A.schur(base_ring=RDF)
Traceback (most recent call last):
  ...  
TypeError: unable to convert input matrix over CDF to a matrix over RDF
```

If theory predicts your matrix is real, but it contains some very small imaginary parts, you can specify the cutoff for “small” imaginary parts, then request the output as real matrices, and let the routine do the rest.

```python
sage: A = matrix(RDF, 2, 2, [1, 1, -1, 0]) + matrix(CDF, 2, 2, [1.0e-14*I]*4)
sage: B = A.zero_at(1.0e-12)
sage: B.parent()

>>> T.round(Integer(6))
```

(continues on next page)
A Hermitian matrix has real eigenvalues, so the similar matrix will be upper-triangular. Furthermore, a Hermitian matrix is diagonalizable with respect to an orthonormal basis, composed of eigenvectors of the matrix. Here that basis is the set of columns of the unitary matrix.

```python
sage: # needs sage.symbolic
sage: A = matrix(CDF, [[ 52, -9*I - 8, 6*I - 187, -188*I + 2],
                    [ 9*I - 8, 12, -58*I + 59, 30*I + 42],
                    [-6*I - 187, 58*I + 59, 2677, 2264*I + 65],
                    [ 188*I + 2, -30*I + 42, -2264*I + 65, 2080]])
```

```python
sage: Q, T = A.schur()
```

```python
sage: T = T.zero_at(1.0e-12).change_ring(RDF)
```

```python
sage: T.round(6)
```

```python
sage: (Q*T*Q.conjugate().transpose() - A).zero_at(1.0e-11)
```

```python
from sage.all import *
```

```python
sage: # needs sage.symbolic
```

```python
>>> from sage.all import *
```
Similarly, a real symmetric matrix has only real eigenvalues, and there is an orthonormal basis composed of eigenvectors of the matrix.

```python
sage: A = matrix(RDF, [[ 1, -2, 5, -3],
                    [-2, 9, 1, 5],
                    [ 5, 1, 3, 7],
                    [-3, 5, 7, -8]])

sage: Q, T = A.schur()

sage: Q.round(4)

>>> (Q*T*Q.transpose() - A).zero_at(RealNumber('1.0e-11'))
```
The results are cached, both as a real factorization and also as a complex factorization. This means the returned matrices are immutable.

```sage
A = matrix(RDF, 2, 2, [[0, -1], [1, 0]])
Qr, Tr = A.schur(base_ring=RDF)
Qc, Tc = A.schur(base_ring=CDF)
all(M.is_immutable() for M in [Qr, Tr, Qc, Tc])
True
Tr.round(6) != Tc.round(6)
True
```

- Rob Beezer (2011-03-31)

`singular_values (eps=None)`

Return a sorted list of the singular values of the matrix.

INPUT:

- `eps` – (default: None); the largest number which will be considered to be zero. May also be set to the string 'auto'. See the discussion below.

OUTPUT:

A sorted list of the singular values of the matrix, which are the diagonal entries of the “S” matrix in the SVD decomposition. As such, the values are real and are returned as elements of RDF. The list is sorted with larger values first, and since theory predicts these values are always positive, for a rank-deficient matrix the list should end in zeros (but in practice may not). The length of the list is the minimum of the row count and column count for the matrix.

The number of non-zero singular values will be the rank of the matrix. However, as a numerical matrix, it is impossible to control the difference between zero entries and very small non-zero entries. As an informed consumer it is up to you to use the output responsibly. We will do our best, and give you the tools to work with the output, but we cannot give you a guarantee.

With `eps` set to None you will get the raw singular values and can manage them as you see fit. You may also set `eps` to any positive floating point value you wish. If you set `eps` to ‘auto’ this routine will compute a reasonable cutoff value, based on the size of the matrix, the largest singular value and the smallest nonzero value representable by the 53-bit precision values used. See the discussion at page 268 of [Wat2010].

See the examples for a way to use the “verbose” facility to easily watch the zero cutoffs in action.

ALGORITHM:
The singular values come from the SVD decomposition computed by SciPy/NumPy using \texttt{scipy.linalg.svd}.

**EXAMPLES:**

Singular values close to zero have trailing digits that may vary on different hardware. For exact matrices, the number of non-zero singular values will equal the rank of the matrix. So for some of the doctests we round the small singular values that ideally would be zero, to control the variability across hardware.

This matrix has a determinant of one. A chain of two or three theorems implies the product of the singular values must also be one.

```python
sage: A = matrix(QQ, [[ 1, 0, 0, 0, 0, 1, 3],
                    [-2, 1, 1, -2, 0, -4, 0],
                    [-2, 2, 1, 1, 7, 1, -1],
                    [-1, 0, -1, 5, 8, 4, -6],
                    [ 4, -2, -2, 1, 0, 8],
                    [-2, 1, 0, 2, 7, 3, -4]])

sage: A.determinant()
1

sage: B = A.change_ring(RDF)
sage: sv = B.singular_values(); sv # tol 1e-12
[20.523980658874265, 8.486837028536643, 5.86168134845073, 2.4429165899286978, 0.5831970144724045, 0.26933287286576313, 0.0025524488076110402]
sage: prod(sv) # tol 1e-12
0.9999999999999525
```

An exact matrix that is obviously not of full rank, and then a computation of the singular values after conversion to an approximate matrix.

```python
>>> from sage.all import *
>>> A = matrix(QQ, [[ Integer(1), Integer(0), Integer(0), Integer(0), ...
                       Integer(0), Integer(1), Integer(3)],
                    [-Integer(2), Integer(1), Integer(1), -Integer(2), ...
                       Integer(0), -Integer(4), Integer(0)],
                    [-Integer(1), Integer(1), Integer(1), -Integer(4), ...
                       Integer(0), Integer(0), Integer(1), -Integer(4)],
                    [-Integer(2), Integer(2), Integer(1), Integer(1), ...
                       Integer(7)],
                    [-Integer(1), Integer(1), -Integer(1)],
                    [-Integer(1), Integer(0), -Integer(1), Integer(5), ...
                       Integer(4), -Integer(6)],
                    [ Integer(4), -Integer(2), -Integer(2), Integer(1), ...
                       Integer(3), Integer(0), Integer(8)],
                    [-Integer(2), Integer(1), Integer(0), Integer(2), ...

>>> sv[Integer(2)] < 10^-14
True
```

(continues on next page)
A full-rank matrix that is ill-conditioned. We use this to illustrate ways of using the various possibilities for \(\varepsilon\), including one that is ill-advised. Notice that the automatically computed cutoff gets this (difficult) example slightly wrong. This illustrates the impossibility of any automated process always getting this right. Use with caution and judgement.

```
sage: entries = [1/(i+j+1) for i in range(12) for j in range(12)]
sage: B = matrix(QQ, 12, 12, entries)
sage: B.rank()
12

With Sage’s “verbose” facility, you can compactly see the cutoff at work. In any application of this routine, or those that build upon it, it would be a good idea to conduct this exercise on samples. We also test here that all the values are returned in RDF since singular values are always real.

sage: A = matrix(CDF, 4, range(16))
sage: from sage.misc.verbose import set_verbose
sage: set_verbose(1)
sage: sv = A.singular_values(eps='auto'); sv
verbose 1 (<module>) singular values,
smallest-non-zero:cutoff:largest-zero,
2.2766...:6.2421...e-14:...
[35.13996365902..., 2.27661020871472..., 0.0, 0.0]
sage: set_verbose(0)

sage: all(s in RDF for s in sv)
True

>> from sage.all import *

>> A = matrix(CDF, 4, range(Integer(16)))
>> from sage.misc.verbose import set_verbose
>> set_verbose(Integer(1))
>> sv = A.singular_values(eps='auto'); sv
verbose 1 (<module>) singular values,
smallest-non-zero:cutoff:largest-zero,
2.2766...:6.2421...e-14:...
[35.13996365902..., 2.27661020871472..., 0.0, 0.0]
>> set_verbose(Integer(0))

>> all(s in RDF for s in sv)
True

AUTHOR:

• Rob Beezer - (2011-02-18)

zero_at (eps)

Return a copy of the matrix where elements smaller than or equal to eps are replaced with zeroes. For complex matrices, the real and imaginary parts are considered individually.

This is useful for modifying output from algorithms which have large relative errors when producing zero elements, e.g. to create reliable doctests.

INPUT:

• eps – Cutoff value

OUTPUT:

A modified copy of the matrix.
EXAMPLES:

```python
sage: # needs sage.symbolic
sage: a = matrix(CDF, [[1, 1e-4r, 1+1e-100jr], [1e-8+3j, 0, 1e-58r]])
```

```python
sage: a
[ 1.0 0.0001 1.0 + 1e-100*I]
[ 1e-08 + 3.0*I 0.0 1e-58]
```

```python
sage: a.zero_at(1e-50)
[ 1.0 0.0001 1.0]
[1e-08 + 3.0*I 0.0 0.0]
```

```python
sage: a.zero_at(1e-4)
[ 1.0 0.0 1.0]
[3.0*I 0.0 0.0]
```

```python
>>> from sage.all import *
```

```python
>>> # needs sage.symbolic
```

```python
>>> a = matrix(CDF, [[Integer(1), 1e-4, Integer(1)+1e-100J], [RealNumber('1e-8') + ComplexNumber(0, '3'), Integer(0), 1e-58]])
```

```python
>>> a
[ 1.0 0.0001 1.0 + 1e-100*I]
[ 1e-08 + 3.0*I 0.0 1e-58]
```

```python
>>> a.zero_at(RealNumber('1e-50'))
[ 1.0 0.0001 1.0]
[1e-08 + 3.0*I 0.0 0.0]
```

```python
>>> a.zero_at(RealNumber('1e-4'))
[ 1.0 0.0 1.0]
[3.0*I 0.0 0.0]
```
DENSE MATRICES OVER THE REAL DOUBLE FIELD USING NUMPY

EXAMPLES:

```python
sage: b = Mat(RDF,2,3).basis()
sage: b[0,0]
[1.0 0.0 0.0]
[0.0 0.0 0.0]
```

```python
>>> from sage.all import *
>>> b = Mat(RDF,Integer(2),Integer(3)).basis()
>>> b[Integer(0),Integer(0)]
[1.0 0.0 0.0]
[0.0 0.0 0.0]
```

We deal with the case of zero rows or zero columns:

```python
sage: m = MatrixSpace(RDF,0,3)
sage: m.zero_matrix()
[]
```

```python
>>> from sage.all import *
>>> m = MatrixSpace(RDF,Integer(0),Integer(3))
>>> m.zero_matrix()
[]
```

AUTHORS:

- Jason Grout (2008-09): switch to NumPy backend, factored out the Matrix_double_dense class
- Josh Kantor
- William Stein: many bug fixes and touch ups.

```python
class sage.matrix.matrix_real_double_dense.Matrix_real_double_dense
    Bases: Matrix_double_dense

    Class that implements matrices over the real double field. These are supposed to be fast matrix operations using C doubles. Most operations are implemented using numpy which will call the underlying BLAS on the system.

    EXAMPLES:
```

```python
sage: m = Matrix(RDF, [[1,2],[3,4]])
sage: m**2
[ 7.0 10.0]
[15.0 22.0]
sage: n = m^(-1); n  # rel tol 1e-15
```

(continues on next page)
needs scipy

\[
\begin{bmatrix}
-1.9999999999999996 & 0.9999999999999998 \\
1.4999999999999998 & -0.4999999999999999
\end{bmatrix}
\]

```
>>> from sage.all import *

>>> m = Matrix(RDF, [[Integer(1), Integer(2)], [Integer(3), Integer(4)]])
>>> m**Integer(2)
[ 7.0 10.0]
[15.0 22.0]

>>> n = m**(-Integer(1)); n

# rel tol 1e-15

# needs scipy

\[
\begin{bmatrix}
-1.9999999999999996 & 0.9999999999999998 \\
1.4999999999999998 & -0.4999999999999999
\end{bmatrix}
\]
```

To compute eigenvalues, use the method `left_eigenvectors()` or `right_eigenvectors()`.

```
sage: p, e = m.right_eigenvectors()

# rel tol 1e-15

# needs scipy
```

The result is a pair \((p, e)\), where \(p\) is a diagonal matrix of eigenvalues and \(e\) is a matrix whose columns are the eigenvectors.

To solve a linear system \(Ax = b\) where \(A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}\) and \(b = \begin{bmatrix} 5 \\ 6 \end{bmatrix}\):

```
sage: b = vector(RDF, [5, 6])
sage: m.solve_right(b)  # rel tol 1e-15
-3.9999999999999987, 4.499999999999999
```

```
>>> from sage.all import *

>>> p, e = m.right_eigenvectors()

# rel tol 1e-15

# needs scipy
```

```
>>> from sage.all import *

>>> p, e = m.right_eigenvectors()

# rel tol 1e-15

# needs scipy
```

See the methods `QR()`, `LU()`, and `SVD()` for QR, LU, and singular value decomposition.

```
Todo:

- make LinBox frontend and use it
  - charpoly?
  - minpoly?
- make Matrix_modn_frontend and use it (?)

```
class sage.matrix.matrix_mod2_dense.Matrix_mod2_dense
Bases: Matrix_dense
Dense matrix over GF(2).

augment (right, subdivide=False)
   Augments self with right.
```

```sage
sage: MS = MatrixSpace(GF(2),3,3)
sage: A = MS([0, 1, 0, 1, 1, 0, 1, 1, 1]); A
[0 1 0]
[1 1 0]
[1 1 1]
sage: B = A.augment(MS(1)); B
[0 1 0 1 0 0]
[1 1 0 0 1 0]
[1 1 1 0 0 1]
sage: B.echelonize(); B
[1 0 0 1 1 0]
[0 1 0 1 0 0]
[0 0 1 0 1 1]
sage: C = B.matrix_from_columns([3,4,5]); C
[1 1 0]
[1 0 0]
[0 1 1]
sage: C == ~A
True
sage: C*A == MS(1)
True
```

```python
>>> from sage.all import *

>>> MS = MatrixSpace(GF(Integer(2)),Integer(3),Integer(3))
>>> A = MS([Integer(0), Integer(1), Integer(0), Integer(1), Integer(1),
       Integer(0), Integer(1), Integer(1), Integer(1)]); A
[0 1 0]
[1 1 0]
[1 1 1]
>>> B = A.augment(MS(Integer(1))); B
[0 1 0 1 0 0]
[1 1 0 0 1 0]
[1 1 1 0 0 1]
>>> B.echelonize(); B
[1 0 0 1 1 0]
[0 1 0 1 0 0]
[0 0 1 0 1 1]
>>> C = B.matrix_from_columns([Integer(3),Integer(4),Integer(5)]); C
```

Matrix and Spaces of Matrices, Release 10.4

[1 1 0]
[1 0 0]
[0 1 1]

>>> C == ~A
True
>>> C*A == MS(Integer(1))
True

A vector may be augmented to a matrix.

sage: A = matrix(GF(2), 3, 4, range(12))
sage: v = vector(GF(2), 3, range(3))
sage: A.augment(v)

[0 1 0 1 0]
[0 1 0 1 1]
[0 1 0 1 0]

The `subdivide` option will add a natural subdivision between `self` and `right`. For more details about how subdivisions are managed when augmenting, see `sage.matrix.matrix1.Matrix.augment()`.

sage: A = matrix(GF(2), 3, 5, range(15))
sage: B = matrix(GF(2), 3, 3, range(9))
sage: A.augment(B, subdivide=True)

[0 1 0 1 0|0 1 0]
[1 0 1 0 1|1 0 1]
[0 1 0 1 0|0 1 0]

```
columns (copy=True)
Return list of the columns of self.

INPUT:

- `copy` – (default: True) if True, return a copy so you can modify it safely

EXAMPLES:

An example with a small 3x3 matrix:
```
sage: M2 = Matrix(GF(2), [[1, 0, 0], [0, 1, 0], [0, 1, 1]])
sage: M2.columns()

[(1, 0, 0), (0, 1, 1), (0, 0, 1)]

(continued from previous page)
density (approx=False)

Return the density of this matrix.

By density we understand the ratio of the number of nonzero positions and the self.nrows() * self.ncols(), i.e. the number of possible nonzero positions.

INPUT:

• approx – return floating point approximation (default: False)

EXAMPLES:

```python
sage: A = random_matrix(GF(2), 1000, 1000)
sage: d = A.density()
sage: float(d) == A.density(approx=True)
True
sage: len(A.nonzero_positions())/1000^2 == d
True
sage: total = 1.0
sage: density_sum = A.density()
sage: while abs(density_sum/total - 0.5) > 0.001:
    A = random_matrix(GF(2), 1000, 1000)
    total += 1
    density_sum += A.density()
```

determinant ()

Return the determinant of this matrix over GF(2).

EXAMPLES:

```python
sage: matrix(GF(2), 2, [1,1,0,1]).determinant()
1
sage: matrix(GF(2), 2, [1,1,1,1]).determinant()
0
```
Matrices and Spaces of Matrices, Release 10.4

>>> from sage.all import *
>>>
>>> matrix(GF(Integer(2)), Integer(2), [Integer(1), Integer(1), Integer(0),
   → Integer(1)]).determinant()
1
>>> matrix(GF(Integer(2)), Integer(2), [Integer(1), Integer(1), Integer(1),
   → Integer(1)]).determinant()
0

```
randomize (density=1, nonzero=False)
```

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.

**INPUT:**

- density – float; proportion (roughly) to be considered for changes

**REFERENCES:**

- [Bar2006]
• nonzero – `Bool` (default: `False`); whether the new entries are forced to be non-zero

**OUTPUT:**

• None, the matrix is modified in-space

**EXAMPLES:**

```python
sage: A = matrix(GF(2), 5, 5, 0)
sage: A.randomize(0.5)
sage: A.density() < 0.5
True
sage: expected = 0.5
sage: A = matrix(GF(2), 5, 5, 0)
sage: A.randomize()
>>> density_sum = float(A.density())
>>> total = 1
>>> while abs(density_sum/total - expected) > 0.001:
>>>     A = matrix(GF(2), 5, 5, 0)
>>>     A.randomize()
>>>     density_sum += float(A.density())
>>>     total += 1
```

```python
>>> from sage.all import *
>>> A = matrix(GF(Integer(2)), Integer(5), Integer(5), Integer(0))
>>> A.randomize(RealNumber(0.5))
>>> A.density() < RealNumber(0.5)
True
>>> expected = RealNumber('0.5')
>>> A = matrix(GF(Integer(2)), Integer(5), Integer(5), Integer(0))
>>> A.randomize()
>>> density_sum = float(A.density())
>>> total = Integer(1)
>>> while abs(density_sum/total - expected) > RealNumber('0.001'):
...     A = matrix(GF(Integer(2)), Integer(5), Integer(5), Integer(0))
...     A.randomize()
...     density_sum += float(A.density())
...     total += Integer(1)
```

**rank** *(algorithm='ple')*

Return the rank of this matrix.

On average 'ple' should be faster than 'm4ri' and hence it is the default choice. However, for small - i.e. quite few thousand rows & columns - and sparse matrices 'm4ri' might be a better choice.

**INPUT:**

• `algorithm` – either “ple” or “m4ri”

**EXAMPLES:**

```python
sage: while random_matrix(GF(2), 1000, 1000).rank() != 999:
    pass
sage: A = matrix(GF(2),10, 0)
sage: A.rank()
0
```
```python
>>> from sage.all import *
>>> while random_matrix(GF(Integer(2)), Integer(1000), Integer(1000)).rank() !← Integer(999):
...    pass

>>> A = matrix(GF(Integer(2)), Integer(10), Integer(0))

>>> A.rank()
0
```

**`row(i, from_list=False)`**

Return the i’th row of this matrix as a vector.

This row is a dense vector if and only if the matrix is a dense matrix.

**INPUT:**

- `i` — integer
- `from_list` — bool (default: False); if True, returns the i’th element of `self.rows()` (see `rows()`), which may be faster, but requires building a list of all rows the first time it is called after an entry of the matrix is changed.

**EXAMPLES:**

```python
sage: l = [GF(2).random_element() for _ in range(100)]
sage: A = matrix(GF(2), 10, 10, l)
sage: list(A.row(0)) == l[:10]
True
sage: list(A.row(-1)) == l[-10:]
True
sage: list(A.row(2, from_list=True)) == l[20:30]
True
sage: A = Matrix(GF(2), 1, 0)

sage: A.row(0)
()```

```python
>>> from sage.all import *

>>> l = [GF(Integer(2)).random_element() for _ in range(Integer(100))]

>>> A = matrix(GF(Integer(2)), Integer(10), Integer(10), l)

>>> list(A.row(Integer(0))) == l[:Integer(10)]
True

>>> list(A.row(-Integer(1))) == l[-Integer(10):]
True

>>> list(A.row(Integer(2), from_list=True)) == l[20:30]
True

>>> A = Matrix(GF(Integer(2)), Integer(1), Integer(0))

>>> A.row(Integer(0))
()```

**`str(rep_mapping=None, zero=None, plus_one=None, minus_one=None, unicode=False, shape=None, character_art=False, left_border=None, right_border=None, top_border=None, bottom_border=None)`**

Return a nice string representation of the matrix.

**INPUT:**
• **rep_mapping** – a dictionary or callable used to override the usual representation of elements. For a dictionary, keys should be elements of the base ring and values the desired string representation.

• **zero** – string (default: None); if not None use the value of zero as the representation of the zero element.

• **plus_one** – string (default: None); if not None use the value of plus_one as the representation of the one element.

• **minus_one** – Ignored. Only for compatibility with generic matrices.

• **unicode** – boolean (default: False). Whether to use Unicode symbols instead of ASCII symbols for brackets and subdivision lines.

• **shape** – one of "square" or "round" (default: None). Switches between round and square brackets. The default depends on the setting of the **unicode** keyword argument. For Unicode symbols, the default is round brackets in accordance with the TeX rendering, while the ASCII rendering defaults to square brackets.

• **character_art** – boolean (default: False); if True, the result will be of type **AsciiArt** or **UnicodeArt** which support line breaking of wide matrices that exceed the window width

• **left_border, right_border** – sequence (default: None); if not None, call `str()` on the elements and use the results as labels for the rows of the matrix. The labels appear outside of the parentheses.

• **top_border, bottom_border** – sequence (default: None); if not None, call `str()` on the elements and use the results as labels for the columns of the matrix. The labels appear outside of the parentheses.

**EXAMPLES:**

```sage
sage: B = matrix(GF(2), 3, 3, [0, 1, 0, 0, 1, 1, 0, 0, 0])
sage: B # indirect doctest
[0 1 0]
[0 1 1]
[0 0 0]
sage: block_matrix([[B, 1], [0, B]])
[0 1 0|1 0 0]
[0 1 1|0 1 0]
[0 0 0|0 0 1]
[------]
[0 0 0|0 1 0]
[0 0 0|0 1 1]
[0 0 0|0 0 0]
sage: B.str(zero='.')
'[, . |n [, . |n . .]'

sage: M = matrix.identity(GF(2), 3)
sage: M.subdivide(None, 2)
sage: print(M.str(unicode=True, shape='square'))
[1 0 0]
[0 1 0]
[0 0 1]
sage: print(unicode_art(M)) # indirect doctest
[1 0 0]
[0 1 0]
[0 0 1]
```

793
```python
>>> from sage.all import *

>>> B = matrix(GF(Integer(2)), Integer(3), Integer(3), [Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(1), Integer(0), Integer(0)])
>>> B  # indirect doctest
[0 1 0]
[0 1 1]
[0 0 0]

>>> B = block_matrix([[B, Integer(1)], [Integer(0), B]])
[0 1 0|1 0 0]
[0 1 1|0 1 0]
[0 0 0|0 0 1]
[-------+-------]
[0 0 0|0 1 0]
[0 0 0|0 1 1]
[0 0 0|0 0 0]

>>> B.str(zero='.')
'[
 . 1 .
 . 1 1
 . . .
]'

>>> M = matrix.identity(GF(Integer(2)), Integer(3))
>>> M.subdivide(None, Integer(2))

>>> print(M.str(unicode=True, shape='square'))
[1 0 0]
[0 1 0]
[0 0 1]

>>> print(unicode_art(M))  # indirect doctest
⎛1 0 0
0 1 0
0 0 1⎞

submatrix (row=0, col=0, nrows=-1, ncols=-1)

Return submatrix from the index row, col (inclusive) with dimension nrows x ncols.

INPUT:

• row – index of start row
• col – index of start column
• nrows – number of rows of submatrix
• ncols – number of columns of submatrix

EXAMPLES:

sage: A = random_matrix(GF(2), 200, 200)
sage: A[0:2,0:2] == A.submatrix(0,0,2,2)
True
sage: A[0:100,0:100] == A.submatrix(0,0,100,100)
True
sage: A == A.submatrix(0,0,200,200)
True
sage: A[1:3,1:3] == A.submatrix(1,1,2,2)
True
True
True
```

submatrix (row=0, col=0, nrows=-1, ncols=-1)

Return submatrix from the index row, col (inclusive) with dimension nrows x ncols.

INPUT:

• row – index of start row
• col – index of start column
• nrows – number of rows of submatrix
• ncols – number of columns of submatrix

EXAMPLES:

```python
def submatrix(A, row, col, nrows, ncols):
    if nrows == -1:
        nrows = A.nrows() - row
    if ncols == -1:
        ncols = A.ncols() - col

g = random_matrix(GF(2), 5, 5)
g.submatrix(1, 1, 3, 3)
[
 . 1 .
 . 1 1
 . . .
]
```
>>> from sage.all import *

A = random_matrix(GF(Integer(2)),Integer(200),Integer(200))
A[Integer(0):Integer(2),Integer(0):Integer(2)] == A.submatrix(Integer(0),
   Integer(0),Integer(2),Integer(2))
True

A[Integer(0):Integer(100),Integer(0):Integer(100)] == A.
   submatrix(Integer(0),Integer(0),Integer(100),Integer(100))
True

A == A.submatrix(Integer(0),Integer(0),Integer(200),Integer(200))
True

   Integer(1),Integer(2),Integer(2))
True

A[Integer(1):Integer(100),Integer(1):Integer(100)] == A.
   submatrix(Integer(1),Integer(1),Integer(199),Integer(199))
True

TESTS for handling of default arguments (Issue #18761):

sage: A.submatrix(17,15) == A.submatrix(17,15,183,185)
True

sage: A.submatrix(row=Integer(100),col=Integer(37),nrows=Integer(1),
   ncols=Integer(3)) == A.submatrix(Integer(100),Integer(37),Integer(1),
   Integer(3))
True

transpose()

Returns transpose of self and leaves self untouched.

EXAMPLES:

sage: A = Matrix(GF(2),3,5,[1, 0, 1, 0, 0, 0, 1, 1, 0, 0, 1, 1, 0, 1, 0])
sage: A

[1 0 1 0 0]
[0 1 1 0 0]
[1 1 0 1 0]

sage: B = A.transpose(); B

[1 0 1]
[0 1 1]
[1 1 0]
[0 0 1]
[0 0 0]

sage: B.transpose() == A
True
>>> from sage.all import *
>>> A = Matrix(GF(Integer(2)), Integer(3), Integer(5), [Integer(1), Integer(0),
˓→Integer(1), Integer(0), Integer(0), Integer(0), Integer(1), Integer(1),
˓→Integer(0), Integer(0), Integer(1), Integer(1), Integer(0), Integer(1),
˓→Integer(0))
>>> A
[1 0 1 0 0]
[0 1 1 0 0]
[1 1 0 1 0]
>>> B = A.transpose(); B
[1 0 1]
[0 1 1]
[1 1 0]
[0 0 1]
[0 0 0]
>>> B.transpose() == A
True

.T is a convenient shortcut for the transpose:

sage: A.T
[1 0 1]
[0 1 1]
[1 1 0]
[0 0 1]
[0 0 0]

sage.matrix.matrix_mod2_dense.from_png(filename)

Returns a dense matrix over GF(2) from a 1-bit PNG image read from filename. No attempt is made to verify that the filename string actually points to a PNG image.

INPUT:

• filename – a string

EXAMPLES:

sage: from sage.matrix.matrix_mod2_dense import from_png, to_png
sage: A = random_matrix(GF(2), 10, 10)
sage: fn = tmp_filename()
sage: to_png(A, fn)
sage: B = from_png(fn)
sage: A == B
True

(continues on next page)
sage.matrix.matrix_mod2_dense.parity(a)

Return the parity of the number of bits in a.

EXAMPLES:

```python
sage: from sage.matrix.matrix_mod2_dense import parity
sage: parity(1)
1
sage: parity(3)
0
sage: parity(0x10000101011)
1
```

sage.matrix.matrix_mod2_dense.ple(A, algorithm='standard', param=0)

Return PLE factorization of A.

INPUT:

- A – matrix
- algorithm
  - 'standard' asymptotically fast (default)
  - 'russian' M4RI inspired
  - 'naive' naive cubic
- param – either k for 'mmpf' is chosen or matrix multiplication cutoff for 'standard' (default: 0)

EXAMPLES:

```python
sage: from sage.matrix.matrix_mod2_dense import ple
sage: A = matrix(GF(2), 4, 4, [0, 1, 0, 1, 0, 1, 1, 0, 0, 0, 0, 1, 0, 1, 1, 0])
sage: A
[0 1 0 1]
[0 1 1 1]
[0 0 0 1]
[0 1 1 0]
sage: LU, P, Q = ple(A)
sage: LU
[1 0 0 1]
[1 1 0 0]
(continues on next page)```
\begin{verbatim}
[0 0 1 0]
[1 1 1 0]

sage: P
[0, 1, 2, 3]

sage: Q
[1, 2, 3, 3]

sage: A = random_matrix(GF(2),1000,1000)

sage: ple(A) == ple(A,'russian') == ple(A,'naive')
True

>>> from sage.all import *

>>> from sage.matrix.matrix_mod2_dense import ple

>>> A = matrix(GF(Integer(2)), Integer(4), Integer(4),
[Integer(0), Integer(1), Integer(0), Integer(1),
→Integer(0), Integer(1), Integer(0), Integer(1),
→Integer(0), Integer(0), Integer(0), Integer(1),
→Integer(1), Integer(0)])

>>> A
[0 1 0 1]
[0 1 1 1]
[0 0 0 1]
[0 1 1 0]

>>> LU, P, Q = ple(A)

>>> LU
[1 0 0 1]
[1 1 0 0]
[0 0 1 0]
[1 1 1 0]

>>> P
[0, 1, 2, 3]

>>> Q
[1, 2, 3, 3]

>>> A = random_matrix(GF(Integer(2)),Integer(1000),Integer(1000))

>>> ple(A) == ple(A,'russian') == ple(A,'naive')
True

sage.matrix.matrix_mod2_dense.pluq(A, algorithm='standard', param=0)

Return PLUQ factorization of A.

INPUT:

• A – matrix

• algorithm

  – ‘standard’ asymptotically fast (default)

  – ‘mmpf’ M4RI inspired

  – ‘naive’ naive cubic

• param – either k for ‘mmpf’ is chosen or matrix multiplication cutoff for ‘standard’ (default: 0)
\end{verbatim}
EXAMPLES:

```python
sage: from sage.matrix.matrix_mod2_dense import pluq
sage: A = matrix(GF(2), 4, 4, [0, 1, 0, 1, 0, 1, 1, 0, 0, 0, 1, 0, 1, 1, 0])
sage: A
[0 1 0 1]
[0 1 1 1]
[0 0 0 1]
[0 1 1 0]
sage: LU, P, Q = pluq(A)
sage: LU
[1 0 1 0]
[1 1 0 0]
[0 0 1 0]
[1 1 1 0]
sage: P
[0, 1, 2, 3]
sage: Q
[1, 2, 3, 3]
```
Deserializes a matrix encoded in the string $s$.

**INPUT:**

- $r$ – number of rows of matrix
- $c$ – number of columns of matrix
- $s$ – a string
- $\text{size}$ – length of the string $s$
- $\text{immutable}$ – (default: False) whether the matrix is immutable or not

**EXAMPLES:**

```python
defpickle_matrix_mod2_dense_v2(r, c, data, size, immutable=False):
    # Deserializes a matrix encoded in the string $s$
```
The M4RIE library offers two matrix representations:

1) **mzed_t**

m x n matrices over $\mathbb{F}_{2^E}$ are internally represented roughly as m x (en) matrices over $\mathbb{F}_2$. Several elements are packed into words such that each element is filled with zeroes until the next power of two. Thus, for example, elements of $\mathbb{F}_{2^3}$ are represented as $[0xxx|0xxx|0xxx|0xxx|...]$. This representation is wrapped as `Matrix_gf2e_dense` in Sage.

Multiplication and elimination both use “Newton-John” tables. These tables are simply all possible multiples of a given row in a matrix such that a scale+add operation is reduced to a table lookup + add. On top of Newton-John multiplication M4RIE implements asymptotically fast Strassen-Winograd multiplication. Elimination uses simple Gaussian elimination which requires $O(n^3)$ additions but only $O(n^2 \cdot 2^E)$ multiplications.

2) **mzd_slice_t**

m x n matrices over $\mathbb{F}_{2^E}$ are internally represented as slices of m x n matrices over $\mathbb{F}_2$. This representation allows for very fast matrix times matrix products using Karatsuba’s polynomial multiplication for polynomials over matrices. However, it is not feature complete yet and hence not wrapped in Sage for now.

See [http://m4ri.sagemath.org](http://m4ri.sagemath.org) for more details on the M4RIE library.

**EXAMPLES:**

```python
>>> from sage.all import *

>>> K = GF(Integer(2)**Integer(8), names=('a',)); (a,) = K._first_ngens(1)

>>> A = random_matrix(K, Integer(3),Integer(4))

>>> E = A.echelon_form()

>>> all(r[r.nonzero_positions()[Integer(0)]] == Integer(1) for r in E.rows() if r)
True
```

**AUTHOR:**

- Martin Albrecht <martinralbrecht@googlemail.com>
Todo: Wrap `mzd_slice_t`.

REFERENCES:

- [BB2009]

class `sage.matrix.matrix_GF2e_dense.M4RIE_finite_field`

Bases: `object`

A thin wrapper around the M4RIE finite field class such that we can put it in a hash table. This class is not meant for public consumption.

class `sage.matrix.matrix_GF2e_dense.Matrix_GF2e_dense`

Bases: `Matrix_dense`

Create new matrix over $GF(2^e)$ for $2 \leq e \leq 16$.

INPUT:

- `parent` – a matrix space over $GF(2^e)$
- `entries` – see `matrix()`
- `copy` – ignored (for backwards compatibility)
- `coerce` – if False, assume without checking that the entries lie in the base ring

EXAMPLES:

```
sage: K.<a> = GF(2^4)
sage: l = [K.random_element() for _ in range(3*4)]
sage: A = Matrix(K, 3, 4, l)
sage: l == A.list()
True
sage: l[0] == A[0,0]
True
sage: A = Matrix(K, 3, 3, a); A
[a 0 0]
[0 a 0]
[0 0 a]
```

```python
>>> from sage.all import *
>>> K = GF(Integer(2)**Integer(4), names=('a',)); (a,) = K._first_ngens(1)
>>> l = [K.random_element() for _ in range(Integer(3)*Integer(4))]
>>> A = Matrix(K, Integer(3), Integer(4), l)
>>> l == A.list()
True
>>> l[Integer(0)] == A[Integer(0),Integer(0)]
True
>>> A = Matrix(K, Integer(3), Integer(3), a); A
[a 0 0]
[0 a 0]
[0 0 a]
```
**augment** *(right)*

Augments self with right.

**INPUT:**

- right – a matrix

**EXAMPLES:**

```sage
sage: K.<a> = GF(2^4)
sage: MS = MatrixSpace(K,3,3)
sage: A = random_matrix(K,3,3)
sage: B = A.augment(MS([1]))
sage: B.echelonize()
sage: C = B.matrix_from_columns([3,4,5])
sage: A.rank() < 3 or C == ~A
True
sage: A.rank() < 3 or C*A == MS(1)
True
```

**cling** *(C)*

Pack the matrices over \( \mathbb{F}_2 \) into this matrix over \( \mathbb{F}_{2^n} \).

Elements in \( \mathbb{F}_{2^n} \) can be represented as \( \sum c_i a^i \) where \( a \) is a root the minimal polynomial. If this matrix is \( A \) then this function writes \( c_i a^i \) to the entry \( A[x, y] \) where \( c_i \) is the entry \( C_i[x, y] \).

**INPUT:**

- C – a list of matrices over GF(2)

**EXAMPLES:**

```sage
sage: K.<a> = GF(2^2)
sage: A = matrix(K, 5, 5)
sage: A0 = random_matrix(GF(2), 5, 5)
sage: A1 = random_matrix(GF(2), 5, 5)
sage: A.cling(A0, A1)
sage: all(A.list()[i] == A0.list()[i] + a*A1.list()[i] for i in range(25))
True
```

```python
>>> from sage.all import *
>>> K = GF(Integer(2)**Integer(2), names=('a',)); (a,) = K._first_ngens(1)
>>> MS = MatrixSpace(K, Integer(5), Integer(5))
>>> A = matrix(K, Integer(5), Integer(5))
>>> A0 = random_matrix(GF(Integer(2)), Integer(5), Integer(5))
>>> A1 = random_matrix(GF(Integer(2)), Integer(5), Integer(5))
>>> A.cling(A0, A1)
```

(continues on next page)
Slicing and clinging are inverse operations:

```python
sage: B0, B1 = A.slice()
sage: B0 == A0 and B1 == A1
True
```

```python
>>> from sage.all import *
>>> B0, B1 = A.slice()
>>> B0 == A0 and B1 == A1
True
```

**echelonize**(algorithm='heuristic', reduced=True, **kwds)

Compute the row echelon form of self in place.

**INPUT:**

- `algorithm` – one of the following - `heuristic` - let M4RIE decide (default) - `newton_john` - use newton_john table based algorithm - `ple` - use PLE decomposition - `naive` - use naive cubic Gaussian elimination (M4RIE implementation) - `builtin` - use naive cubic Gaussian elimination (Sage implementation)

- `reduced` – if True return reduced echelon form. No guarantee is given that the matrix is not reduced if False (default: True)

**EXAMPLES:**

```python
sage: K.<a> = GF(2^4)
sage: m, n = 3, 5
sage: A = random_matrix(K, 3, 5)
sage: R = A.row_space()
sage: A.echelonize()
sage: all(r[r.nonzero_positions()[0]] == 1 for r in A.rows() if r)
True
sage: A.row_space() == R
True
```

```python
sage: K.<a> = GF(2^3)
sage: m, n = 3, 5
sage: MS = MatrixSpace(K,m,n)
sage: A = random_matrix(K, 3, 5)
sage: B = copy(A).echelon_form('newton_john')
sage: C = copy(A).echelon_form('naive')
sage: D = copy(A).echelon_form('builtin')
sage: B == C == D
True
sage: all(r[r.nonzero_positions()[0]] == 1 for r in B.rows() if r)
True
```

```python
>>> from sage.all import *
>>> K = GF(Integer(2)**Integer(4), names=('a',)); (a,) = K._first_ngens(1)
>>> m, n = Integer(3), Integer(5)
>>> A = random_matrix(K, Integer(3), Integer(5))
>>> R = A.row_space()
>>> A.echelonize()
```
all(r[r.nonzero_positions()][Integer(0)] == Integer(1) for r in A.rows() if r)
True
>>> A.row_space() == R
True

K = GF(Integer(2)**Integer(3), names=('a',)); (a,) = K._first_ngens(1)

m, n = Integer(3), Integer(5)

MS = MatrixSpace(K, m, n)

A = random_matrix(K, Integer(3), Integer(5))

B = copy(A).echelon_form('newton_john')

C = copy(A).echelon_form('naive')

D = copy(A).echelon_form('builtin')

B == C == D
True

randomize(density=1, nonzero=False, *args, **kwds)

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.

INPUT:

• density – float; proportion (roughly) to be considered for changes

• nonzero – Bool (default: False); whether the new entries are forced to be non-zero

OUTPUT:

• None, the matrix is modified in-place

EXAMPLES:

sage: K.<a> = GF(2^4)
sage: total_count = 0
dsage: from collections import defaultdict
dsage: dic = defaultdict(Integer)
dsage: def add_samples():
    ....:     global dic, total_count
    ....:     for _ in range(100):
    ....:         A = Matrix(K, 3, 3)
    ....:         A.randomize()
    ....:         for a in A.list():
    ....:             dic[a] += 1
    ....:             total_count += 1.0
sage: add_samples()
sage: while not all(abs(dic[a]/total_count - 1/16) < 0.01 for a in dic):
    ....:     add_samples()

sage: def add_sample(density):
    ....:     global density_sum, total_count
    ....:     total_count += 1.0
    ....:     density_sum += random_matrix(K, 1000, 1000, density=density).density()

sage: density_sum = 0.0
sage: total_count = 0.0

(continues on next page)
sage: add_sample(0.1)
sage: while abs(density_sum/total_count - 0.1) > 0.001:
  ....:    add_sample(0.1)

density_sum = 0.0
total_count = 0.0

add_sample(1.0)
sage: while abs(density_sum/total_count - 1.0) > 0.001:
  ....:    add_sample(1.0)

density_sum = 0.0
total_count = 0.0

add_sample(0.5)
sage: while abs(density_sum/total_count - 0.5) > 0.001:
  ....:    add_sample(0.5)

from sage.all import *
K = GF(Integer(2)**Integer(4), names=('a',)); (a,) = K._first_ngens(1)
total_count = Integer(0)

from collections import defaultdict
dic = defaultdict(Integer)
def add_samples():
  global dic, total_count
  for _ in range(Integer(100)):
    A = Matrix(K,Integer(3),Integer(3))
    A.randomize()
    for a in A.list():
      dic[a] += Integer(1)
    total_count += RealNumber('1.0')
add_samples()

while not all(abs(dic[a]/total_count - Integer(1)/Integer(16)) < RealNumber('0.01') for a in dic):
  add_samples()

def add_sample(density):
  global density_sum, total_count
  total_count += RealNumber('1.0')
  density_sum += random_matrix(K, Integer(1000), Integer(1000), density=density).density()

density_sum = RealNumber('0.0')
total_count = RealNumber('0.0')
add_sample(RealNumber('0.1'))

while abs(density_sum/total_count - RealNumber('0.1')) > RealNumber('0.001'):
  add_sample(RealNumber('0.1'))

density_sum = RealNumber('0.0')
total_count = RealNumber('0.0')
add_sample(RealNumber('1.0'))

while abs(density_sum/total_count - RealNumber('1.0')) > RealNumber('0.001'):
  add_sample(RealNumber('1.0'))
```python
>>> add_sample(RealNumber('0.5'))
>>> while abs(density_sum/total_count - RealNumber('0.5')) > RealNumber('0.001'):
... add_sample(RealNumber('0.5'))

Note, that the matrix is updated and not zero-ed out before being randomized:

```python
def add_sample(density, nonzero):
    global density_sum, total_count
    total_count += 1.0
    A = matrix(K, 1000, 1000)
    A.randomize(nonzero=nonzero, density=density)
    density_sum += A.density()
```

```python
def add_sample(density, nonzero):
    global density_sum, total_count
    total_count += RealNumber(1.0)
    A = matrix(K, Integer(1000), Integer(1000))
    A.randomize(nonzero=nonzero, density=density)
    density_sum += A.density()
```

```python
>>> from sage.all import *
>>> def add_sample(density, nonzero):
... global density_sum, total_count
... total_count += RealNumber('1.0')
... A = matrix(K, Integer(1000), Integer(1000))
... A.randomize(nonzero=nonzero, density=density)
... density_sum += A.density()
```

```python
>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> add_sample(RealNumber('0.1'), True)
>>> while abs(density_sum/total_count - (Integer(1) - RealNumber('0.9')**Integer(2))) > RealNumber('0.001'):
... add_sample(RealNumber('0.1'), True)
```

```python
>>> density_sum = RealNumber('0.0')
```
>>> total_count = RealNumber('0.0')
>>> add_sample(RealNumber('0.1'), False)
>>> while abs(density_sum/total_count - (Integer(1) - RealNumber('0.9**Integer(2)))*Integer(15)/Integer(16)) > RealNumber('0.001'):
...   add_sample(RealNumber('0.1'), False)

>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> add_sample(RealNumber('0.05'), True)
>>> while abs(density_sum/total_count - (Integer(1) - RealNumber('0.95**Integer(2)))*Integer(17)/Integer(16)) > RealNumber('0.001'):
...   add_sample(RealNumber('0.05'), True)

>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> add_sample(RealNumber('0.5'), True)
>>> while abs(density_sum/total_count - (Integer(1) - RealNumber('0.5**Integer(2)))*Integer(16)/Integer(16)) > RealNumber('0.001'):
...   add_sample(RealNumber('0.5'), True)

rank()

Return the rank of this matrix (cached).

EXAMPLES:

```
sage: K.<a> = GF(2^4)
sage: A = random_matrix(K, 10, 10, algorithm="unimodular")
sage: A.rank()
10
sage: A = matrix(K, 10, 0)
sage: A.rank()
0
```

```
from sage.all import *

>>> K = GF(Integer(2)**Integer(4), names=('a',)); (a,) = K._first_ngens(1)
>>> A = random_matrix(K, Integer(10), Integer(10), algorithm="unimodular")
>>> A.rank()
10
>>> A = matrix(K, Integer(10), Integer(0))
>>> A.rank()
0
```

slice()

Unpack this matrix into matrices over \( \mathbb{F}_2 \).

Elements in \( \mathbb{F}_{2^e} \) can be represented as \( \sum c_i a^i \) where \( a \) is a root the minimal polynomial. This function returns a tuple of matrices \( C \) whose entry \( C_i[x,y] \) is the coefficient of \( c_i \) in \( A[x,y] \) if this matrix is \( A \).

EXAMPLES:

```
sage: K.<a> = GF(2^2)
sage: A = random_matrix(K, 5, 5)
sage: A0, A1 = A.slice()
sage: all(A.list()[i] == A0.list()[i] + a*A1.list()[i] for i in range(25))
True

sage: K.<a> = GF(2^3)
```

(continues on next page)
Slicing and clinging are inverse operations:

```python
sage: B = matrix(K, 5, 5)
sage: B.cling(A0, A1, A2)
sage: B == A
True
```

**submatrix** *(row=0, col=0, nrows=-1, ncols=-1)*

Return submatrix from the index *row, col* (inclusive) with dimension *nrows x ncols*.

**INPUT:**

- *row* – index of start row
- *col* – index of start column
- *nrows* – number of rows of submatrix
- *ncols* – number of columns of submatrix

**EXAMPLES:**

```python
sage: K.<a> = GF(2^10)
sage: A = random_matrix(K, 200, 200)
sage: A[0:2,0:2] == A.submatrix(0,0,2,2)
True
sage: A[0:100,0:100] == A.submatrix(0,0,100,100)
True
sage: A == A.submatrix(0,0,200,200)
True
```
Matrices and Spaces of Matrices, Release 10.4

sage: A[1:3,1:3] == A.submatrix(1,1,2,2)
True
True
True

>>> from sage.all import *

>>> K = GF(Integer(2)**Integer(10), names=('a',)); (a,) = K._first_ngens(1)
>>> A = random_matrix(K,200,200)

>>> A[Integer(0):Integer(2),Integer(0):Integer(2)] == A.submatrix(Integer(0),Integer(0),Integer(2),Integer(2))
True

>>> A[Integer(0):Integer(100),Integer(0):Integer(100)] == A.submatrix(Integer(0),Integer(0),Integer(100),Integer(100))
True

>>> A == A.submatrix(Integer(0),Integer(0),Integer(200),Integer(200))
True

True

>>> A[Integer(1):Integer(100),Integer(1):Integer(100)] == A.submatrix(Integer(1),Integer(1),Integer(99),Integer(99))
True

TESTS for handling of default arguments (Issue #18761):

sage: A.submatrix(17,15) == A.submatrix(17,15,183,185)
True
sage: A.submatrix(row=100,col=37,nrows=1,ncols=3) == A.submatrix(100,37,1,3)
True

>>> from sage.all import *

>>> A.submatrix(Integer(17),Integer(15)) == A.submatrix(Integer(17),Integer(15),Integer(183),Integer(185))
True

>>> A.submatrix(row=Integer(100),col=Integer(37),nrows=Integer(1),ncols=Integer(3)) == A.submatrix(Integer(100),Integer(37),Integer(1),Integer(3))
True

sage.matrix.matrix_gf2e_dense.unpickle_matrix_gf2e_dense_v0(a, base_ring, nrows, ncols)

EXAMPLES:

sage: K.<a> = GF(2^2)
sage: A = random_matrix(K,10,10)
sage: f, s = A._reduce_()
sage: from sage.matrix.matrix_gf2e_dense import unpickle_matrix_gf2e_dense_v0
sage: f == unpickle_matrix_gf2e_dense_v0
True
sage: f(*s) == A
True

Chapter 24. Dense matrices over $\mathbb{F}_2^e$ for $2 \leq e \leq 16$ using the M4RIE library
We can still unpickle pickles from before Issue #19240:

```
from sage.all import
K = GF(Integer(2)**Integer(2), names=('a',)); (a,) = K._first_ngens(1)
A = random_matrix(K,Integer(10),Integer(10))
>>> from sage.matrix.matrix_gf2e_dense import 

... f, s = A.__reduce__()
>>> K = GF(Integer(2)**Integer(2), names=(a,)); (a,) = K._first_ngens(1)
```

(continues on next page)

DENSE MATRICES OVER $\mathbb{Z}/N\mathbb{Z}$ FOR $N < 94906266$ USING LINBOX’S MODULAR<DOUBLE>

AUTHORS:

- Burcin Erocal
- Martin Albrecht

class sage.matrix.matrix_modn_dense_double.Matrix_modn_dense_double

Bases: Matrix_modn_dense_template

Dense matrices over $\mathbb{Z}/n\mathbb{Z}$ for $n < 94906266$ using LinBox’s Modular<double>

These are matrices with integer entries mod $n$ represented as floating-point numbers in a 64-bit word for use with LinBox routines. This allows for $n$ up to 94906266. By default, the analogous Matrix_modn_dense_float class is used for smaller moduli, specifically for $n$ up to $2^8$.

Routines here are for the most basic access, see the matrix_modn_dense_template.pxi file for higher-level routines.

class sage.matrix.matrix_modn_dense_double.Matrix_modn_dense_template

Bases: Matrix_dense

Create a new matrix.

INPUT:

- parent – a matrix space
- entries – see matrix()
- copy – ignored (for backwards compatibility)
- coerce – perform modular reduction first?

EXAMPLES:

```python
sage: A = random_matrix(GF(3),1000,1000)
sage: type(A)
<class 'sage.matrix.matrix_modn_dense_float.Matrix_modn_dense_float'>
sage: A = random_matrix(Integers(10),1000,1000)
sage: type(A)
<class 'sage.matrix.matrix_modn_dense_float.Matrix_modn_dense_float'>
sage: A = random_matrix(Integers(2^16),1000,1000)
sage: type(A)
<class 'sage.matrix.matrix_modn_dense_double.Matrix_modn_dense_double'>
```
```python
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(3)), Integer(1000), Integer(1000))
>>> type(A)
<class 'sage.matrix.matrix_modn_dense_float.Matrix_modn_dense_float'>
>>> A = random_matrix(Integers(Integer(10)), Integer(1000), Integer(1000))
>>> type(A)
<class 'sage.matrix.matrix_modn_dense_float.Matrix_modn_dense_float'>
>>> A = random_matrix(Integers(Integer(2)**Integer(16)), Integer(1000), Integer(1000))
>>> type(A)
<class 'sage.matrix.matrix_modn_dense_double.Matrix_modn_dense_double'>
```

```
charpoly
( var='x', algorithm='linbox')

Return the characteristic polynomial of self.

INPUT:

- var -- a variable name
- algorithm -- 'generic', 'linbox' or 'all' (default: linbox)

EXAMPLES:

```
sage: min_p.divides(char_p)
True

sage: A = Mat(Integers(6),3,3)(range(9))
sage: A.charpoly()
x^3

>>> from sage.all import *
>>>
A = random_matrix(GF(Integer(2916337)), Integer(7), Integer(7))  # needs sage.rings.finite_rings
>>> B = copy(A)
>>> char_p = A.characteristic_polynomial()
>>> char_p(A) == Integer(0)
True
>>> B == A  # A is not modified
True

>>> min_p = A.minimal_polynomial(proof=True)
>>> min_p.divides(char_p)
True

>>> A = Mat(Integers(Integer(6)),Integer(3),Integer(3))(range(Integer(9)))
>>> A.charpoly()
x^3

ALGORITHM: Uses LinBox if self.base_ring() is a field, otherwise use Hessenberg form algorithm.

determinant()

Return the determinant of this matrix.

EXAMPLES:

sage: s = set()
sage: while s != set(GF(7)):
.....:     A = random_matrix(GF(7), 10, 10)
.....:     s.add(A.determinant())

>>> from sage.all import *
>>> s = set()
>>> while s != set(GF(Integer(7))):
...     A = random_matrix(GF(Integer(7)), Integer(10), Integer(10))
...     s.add(A.determinant())

sage: A = random_matrix(GF(7), 100, 100)
sage: A.determinant() == A.transpose().determinant()
True

sage: B = random_matrix(GF(7), 100, 100)
sage: (A*B).determinant() == A.determinant() * B.determinant()
True

>>> from sage.all import *
>>> A = random_matrix(GF(Integer(7)), Integer(100), Integer(100))
>>> A.determinant() == A.transpose().determinant()
True
Matrices and Spaces of Matrices, Release 10.4

>>> B = random_matrix(GF(Integer(7)), Integer(100), Integer(100))
>>> (A*B).determinant() == A.determinant() * B.determinant()
True

sage: # needs sage.rings.finite_rings
sage: A = random_matrix(GF(16007), 10, 10)
sage: A.determinant().parent() is GF(16007)
True

>>> from sage.all import *

# needs sage.rings.finite_rings
A = random_matrix(GF(Integer(16007)), Integer(10), Integer(10))
A.determinant().parent() is GF(Integer(16007))
True

sage: # needs sage.rings.finite_rings
sage: A = random_matrix(GF(16007), 100, 100)
A.determinant().parent() is GF(16007)
True

sage: A.determinant() == A.transpose().determinant()
True

A = random_matrix(GF(16007), 100, 100)
(A*B).determinant() == A.determinant() * B.determinant()
True

Parallel computation:

sage: # needs sage.rings.finite_rings
sage: A = random_matrix(GF(65521),200)
B = copy(A)
Parallelism().set('linbox', nproc=2)
d = A.determinant()
Parallelism().set('linbox', nproc=1) # switch off parallelization
e = B.determinant()
d==e
True

>>> from sage.all import *

# needs sage.rings.finite_rings
A = random_matrix(GF(Integer(65521)),Integer(200))
B = copy(A)
Parallelism().set('linbox', nproc=Integer(2))
d = A.determinant()
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> Parallelism().set('linbox', nproc=Integer(1)) # switch off parallelization
>>> e = B.determinant()
>>> d==e
True
```

echelonize(algorithm='linbox_noefd', **kwds)

Put self in reduced row echelon form.

**INPUT:**

- **self** – a mutable matrix
- **algorithm**
  - `linbox` – uses the LinBox library (wrapping fflas-ffpack)
  - `linbox_noefd` – uses the FFPACK directly, less memory and faster (default)
  - `gauss` – uses a custom slower $O(n^3)$ Gauss elimination implemented in Sage.
  - `all` – compute using both algorithms and verify that the results are the same.
- **kwds** – these are all ignored

**OUTPUT:**

- self is put in reduced row echelon form.
- the rank of self is computed and cached
- the pivot columns of self are computed and cached.
- the fact that self is now in echelon form is recorded and cached so future calls to echelonize return immediately.

**EXAMPLES:**

```python
sage: A = random_matrix(GF(7), 10, 20)
sage: E = A.echelon_form()
sage: A.row_space() == E.row_space()
True
sage: all(r[r.nonzero_positions()[0]] == 1 for r in E.rows() if r)
True
```

```python
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(7)), Integer(10), Integer(20))
>>> E = A.echelon_form()
>>> A.row_space() == E.row_space()
True
>>> all(r[r.nonzero_positions()[Integer(0)]] == Integer(1) for r in E.rows() if r)
True
```

```python
sage: A = random_matrix(GF(13), 10, 10)
sage: while A.rank() != 10:
....:     A = random_matrix(GF(13), 10, 10)
sage: MS = parent(A)
sage: B = A.augment(MS(1))
sage: B.echelonize()
sage: A.rank()
```

(continues on next page)
sage: C = B.submatrix(0,10,10,10)
sage: ~A == C
True

>>> from sage.all import *
>>> A = random_matrix(GF(Integer(13)), Integer(10), Integer(10))
>>> while A.rank() != Integer(10):
...     A = random_matrix(GF(Integer(13)), Integer(10), Integer(10))
>>> MS = parent(A)
>>> B = A.augment(MS(Integer(1)))
>>> B.echelonize()
>>> A.rank()

Parallel computation:

```python
sage: # needs sage.rings.finite_rings
sage: A = random_matrix(GF(65521),100,200)

sage: Parallelism().set('linbox', nproc=2)

sage: E = A.echelon_form()

sage: Parallelism().set('linbox', nproc=1) # switch off parallelization

sage: F = A.echelon_form()

sage: E==F
True
```

```python
>>> from sage.all import *

>>> # needs sage.rings.finite_rings

>>> A = random_matrix(GF(Integer(65521)),Integer(100),Integer(200))

>>> Parallelism().set('linbox', nproc=Integer(2))

>>> E = A.echelon_form()

>>> Parallelism().set('linbox', nproc=Integer(1)) # switch off parallelization

>>> F = A.echelon_form()

>>> E==F
True
```

hessenbergize()

Transforms self in place to its Hessenberg form.

EXAMPLES:

```python
sage: A = random_matrix(GF(17), 10, 10, density=0.1)

sage: B = copy(A)

sage: A.hessenbergize()

sage: all(A[i,j] == 0 for j in range(10) for i in range(j+2, 10))
True

sage: A.charpoly() == B.charpoly()
True
```

```python
>>> from sage.all import *

>>> A = random_matrix(GF(Integer(17)), Integer(10), Integer(10), density=RealNumber(0.1))

>>> B = copy(A)

>>> A.hessenbergize()

>>> all(A[i,j] == Integer(0) for j in range(Integer(10)) for i in range(j+Integer(2), Integer(10)))
True

>>> A.charpoly() == B.charpoly()
True
```
**lift()**

Return the lift of this matrix to the integers.

**EXAMPLES:**

```python
sage: A = matrix(GF(7), 2, 3, [1..6])
sage: A.lift()
[1 2 3]
[4 5 6]
sage: A.lift().parent()
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring
```

```python
# needs sage.rings.finite_rings
sage: A = matrix(GF(16007), 2, 3, [1..6])
sage: A.lift()
[1 2 3]
[4 5 6]
sage: A.lift().parent()
Full MatrixSpace of 2 by 3 dense matrices over Integer Ring
```

```python
>>> from sage.all import *

A = matrix(GF(Integer(7)), Integer(2), Integer(3), (ellipsis_˓→range(Integer(1), Ellipsis, Integer(6))))
A.subdivide([], [1, 1]); A
[1||2 3]
[4||5 6]
A.lift()
[1||2 3]
[4||5 6]
```

Subdivisions are preserved when lifting:

```python
sage: A.subdivide([], [1, 1]); A
[1||2 3]
[4||5 6]
sage: A.lift()
[1||2 3]
[4||5 6]
```

```python
>>> from sage.all import *

A.subdivide([], [Integer(1), Integer(1)]); A
[1||2 3]
[4||5 6]
```

**matrix_from_columns(columns)**

Return the matrix constructed from self using columns with indices in the columns list.
**EXAMPLES:**

```python
sage: M = MatrixSpace(Integers(8), 3, 3)
sage: A = M(range(9)); A
\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 0
\end{bmatrix}
\]
sage: A.matrix_from_columns([2, 1])
\[
\begin{bmatrix}
2 & 1 \\
5 & 4 \\
0 & 7
\end{bmatrix}
\]
```

```python
from sage.all import *
M = MatrixSpace(Integers(Integer(8)), Integer(3), Integer(3))
A = M(range(Integer(9))); A
```

```python
A.matrix_from_columns([Integer(2), Integer(1)])
\[
\begin{bmatrix}
6 & 7 & 0 \\
3 & 4 & 5
\end{bmatrix}
\]
```

**matrix_from_rows** *(rows)*

Return the matrix constructed from self using rows with indices in the rows list.

**EXAMPLES:**

```python
sage: M = MatrixSpace(Integers(8), 3, 3)
sage: A = M(range(9)); A
\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 0
\end{bmatrix}
\]
sage: A.matrix_from_rows([2, 1])
\[
\begin{bmatrix}
6 & 7 & 0 \\
3 & 4 & 5
\end{bmatrix}
\]
```

```python
from sage.all import *
M = MatrixSpace(Integers(Integer(8)), Integer(3), Integer(3))
A = M(range(Integer(9))); A
```

```python
A.matrix_from_rows([Integer(2), Integer(1)])
\[
\begin{bmatrix}
6 & 7 & 0 \\
3 & 4 & 5
\end{bmatrix}
\]
```

**matrix_from_rows_and_columns** *(rows, columns)*

Return the matrix constructed from self from the given rows and columns.

**EXAMPLES:**

```python
sage: M = MatrixSpace(Integers(8), 3, 3)
sage: A = M(range(9)); A
\[
\begin{bmatrix}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 0
\end{bmatrix}
\]
```

(continues on next page)
```python
sage: A.matrix_from_rows_and_columns([1], [0, 2])
[3 5]
sage: A.matrix_from_rows_and_columns([1, 2], [1, 2])
[4 5]
[7 0]
```

```python
>>> from sage.all import *

>>> M = MatrixSpace(Integers(Integer(8)), Integer(3), Integer(3))

>>> A = M(range(Integer(9))); A

[[0 1 2]
 [3 4 5]
 [6 7 0]]

```

```python
>>> A.matrix_from_rows_and_columns([Integer(1)], [Integer(0), Integer(2)])
[3 5]

>>> A.matrix_from_rows_and_columns([Integer(1), Integer(2)], [Integer(1), Integer(2)])
[4 5]
[7 0]
```

Note that row and column indices can be reordered or repeated:

```python
sage: A.matrix_from_rows_and_columns([2, 1], [2, 1])

[0 7]
[5 4]
```

```python
>>> from sage.all import *

>>> A.matrix_from_rows_and_columns([Integer(2), Integer(1)], [Integer(2), Integer(1)])

[0 7]
[5 4]
```

For example here we take from row 1 columns 2 then 0 twice, and do this 3 times:

```python
sage: A.matrix_from_rows_and_columns([1, 1, 1], [2, 0, 0])

[[5 3 3]
 [5 3 3]
 [5 3 3]]
```

```python
>>> from sage.all import *

>>> A.matrix_from_rows_and_columns([Integer(1), Integer(1), Integer(1)], [Integer(2), Integer(0), Integer(0)])

[[5 3 3]
 [5 3 3]
 [5 3 3]]
```

**AUTHORS:**

### minpoly

```python
minpoly(var='x', algorithm='linbox', proof=None)
```

Returns the minimal polynomial of "self".

**INPUT:**

- `var` – a variable name
• algorithm – generic or linbox (default: linbox)

• proof – (default: True); whether to provably return the true minimal polynomial; if False, we only guarantee to return a divisor of the minimal polynomial. There are also certainly cases where the computed results is frequently not exactly equal to the minimal polynomial (but is instead merely a divisor of it).

**Warning:** If proof=True, minpoly is insanely slow compared to proof=False. This matters since proof=True is the default, unless you first type proof.linear_algebra(False).

**EXAMPLES:**

```sage
sage: A = random_matrix(GF(17), 10, 10)
sage: B = copy(A)
sage: min_p = A.minimal_polynomial(proof=True)
sage: min_p(A) == 0
True
sage: B == A
True

sage: char_p = A.characteristic_polynomial()
sage: min_p.divides(char_p)
True
```

```python
from sage.all import *

A = random_matrix(GF(Integer(17)), Integer(10), Integer(10))
B = copy(A)
min_p = A.minimal_polynomial(proof=True)
min_p(A) == Integer(0)
B == A
char_p = A.characteristic_polynomial()
min_p.divides(char_p)
```

```sage
sage: A = random_matrix(GF(1214471), 10, 10)  # needs sage.rings.finite_rings
sage: B = copy(A)
sage: min_p = A.minimal_polynomial(proof=True)
sage: min_p(A) == Integer(0)
True
sage: B == A
True

sage: char_p = A.characteristic_polynomial()
sage: min_p.divides(char_p)
True
```

```python
from sage.all import *

A = random_matrix(GF(Integer(1214471)), Integer(10), Integer(10))  # needs sage.rings.finite_rings
```
>>> B = copy(A)
>>> min_p = A.minimal_polynomial(proof=True)
>>> min_p(A) == Integer(0)
True
>>> B == A
True

>>> char_p = A.characteristic_polynomial()
>>> min_p.divides(char_p)
True

EXAMPLES:

\[
\text{sage: } R.<x>=GF(3)[x]
\text{sage: } A = matrix(GF(3), 2, [0, 0, 1, 2])
\text{sage: } A.minpoly()
\text{x^2} + x
\]

\[
\text{sage: } A.minpoly(proof=False) \text{ in } [x, x+1, x^2+x]
\]

\[
\text{randomize (density=1, nonzero=False)}
\]
Randomize\n
\[
\text{density} \text{ proportion of the entries of this matrix, leaving the rest unchanged.}
\]

\[
\text{INPUT:}
\]

\[
\cdot \text{ density – Integer; proportion (roughly) to be considered for changes}
\]

\[
\cdot \text{ nonzero – Bool (default: False); whether the new entries are forced to be non-zero}
\]

\[
\text{OUTPUT:}
\]

\[
\cdot \text{ None, the matrix is modified in-space}
\]

EXAMPLES:

\[
\text{sage: } A = matrix(GF(5), 5, 5, 0)
\text{sage: } total_count = 0
\text{sage: } from collections import defaultdict
\text{sage: } dic = defaultdict(Integer)
\text{sage: } def add_samples(density):
\text{....: } global dic, total_count
\text{....: } for _ in range(100):
\text{....: } A = Matrix(GF(5), 5, 5, 0)
\text{....: } A.randomize(density)
\text{....: } for a in A.list():
\]

(continues on next page)
```python
....:    dic[a] += 1
....:    total_count += 1.0

sage: add_samples(1.0)
sage: while not all(abs(dic[a]/total_count - 1/5) < 0.01 for a in dic):
....:    add_samples(1.0)

sage: def add_sample(density):
....:    global density_sum, total_count
....:    total_count += 1.0
....:    density_sum += random_matrix(GF(5), 1000, 1000, density=density).density()

density_sum = 0.0
total_count = 0.0
add_sample(0.5)

sage: expected_density = 1.0 - (999/1000)^500
expected_density
0.3936...
sage: while abs(density_sum/total_count - expected_density) > 0.001:
....:    add_sample(0.5)

>>> from sage.all import *
>>> A = matrix(GF(Integer(5)), Integer(5), Integer(5), Integer(0))
>>> total_count = Integer(0)
>>> from collections import defaultdict
>>> dic = defaultdict(Integer)
>>> def add_samples(density):
...    global dic, total_count
...    for _ in range(Integer(100)):
...        A = Matrix(GF(Integer(5)), Integer(5), Integer(5), Integer(0))
...        A.randomize(density)
...        for a in A.list():
...            dic[a] += Integer(1)
...            total_count += RealNumber(1.0)

>>> add_samples(RealNumber('1.0'))
>>> while not all(abs(dic[a]/total_count - Integer(1)/Integer(5)) <
...    RealNumber('0.01') for a in dic):
...    add_samples(RealNumber('1.0'))

>>> def add_sample(density):
...    global density_sum, total_count
...    total_count += RealNumber('1.0')
...    density_sum += random_matrix(GF(Integer(5)), Integer(1000),
...    Integer(1000), density=density).density()

density_sum = RealNumber('0.0')
total_count = RealNumber('0.0')
add_sample(RealNumber('0.5'))
expected_density = RealNumber('1.0') - (Integer(999)/Integer(1000))**Integer(500)
expected_density
0.3936...
>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001'):
...    add_sample(RealNumber('0.5'))
```
The matrix is updated instead of overwritten:

```python
sage: def add_sample(density):
....:     global density_sum, total_count
....:     total_count += 1.0
....:     A = random_matrix(GF(5), 1000, 1000, density=density)
....:     A.randomize(density=density, nonzero=True)
....:     density_sum += A.density()

sage: density_sum = 0.0
sage: total_count = 0.0
sage: add_sample(0.5)

sage: expected_density = 1.0 - (999/1000)^1000
sage: expected_density
0.6323...

sage: while abs(density_sum/total_count - expected_density) > 0.001:
....:     add_sample(0.5)

sage: density_sum = 0.0
sage: total_count = 0.0
sage: add_sample(0.1)

sage: expected_density = 1.0 - (999/1000)^200
sage: expected_density
0.1813...

sage: while abs(density_sum/total_count - expected_density) > 0.001:
....:     add_sample(0.1)
```

```
>>> from sage.all import *
>>> def add_sample(density):
...     global density_sum, total_count
...     total_count += RealNumber('1.0')
...     A = random_matrix(GF(Integer(5)), Integer(1000), Integer(1000),
...     density=density)
...     A.randomize(density=density, nonzero=True)
...     density_sum += A.density()

>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> add_sample(RealNumber('0.5'))

>>> expected_density = RealNumber('1.0') - (Integer(999)/
... Integer(1000))**Integer(1000)
>>> expected_density
0.6323...

>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001'):
...     add_sample(RealNumber('0.5'))

>>> density_sum = RealNumber('0.0')
>>> total_count = RealNumber('0.0')
>>> add_sample(RealNumber('0.1'))

>>> expected_density = RealNumber('1.0') - (Integer(999)/
... Integer(1000))**Integer(200)
>>> expected_density
0.1813...

>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001'):
...     add_sample(RealNumber('0.1'))
```

... rank ()
Return the rank of this matrix.

EXAMPLES:

```sage
def A = random_matrix(GF(3), 100, 100)
def B = copy(A)
def _ = A.rank()
def B == A
True

def A = random_matrix(GF(3), 100, 100, density=0.01)
def A.transpose().rank() == A.rank()
True

def A = matrix(GF(3), 100, 100)
def A.rank()
0

>>> from sage.all import *

>>> A = random_matrix(GF(Integer(3)), Integer(100), Integer(100))
>>> B = copy(A)
>>> _ = A.rank()
>>> B == A
True

>>> A = random_matrix(GF(Integer(3)), Integer(100), Integer(100),
˓→density=RealNumber('0.01'))
>>> A.transpose().rank() == A.rank()
True

>>> A = matrix(GF(Integer(3)), Integer(100), Integer(100))

>>> A.rank()
0

Rank is not implemented over the integers modulo a composite yet.:

```sage
def M = matrix(Integers(4), 2, [2,2,2,2])
def M.rank()
Traceback (most recent call last): ...
NotImplementedError: Echelon form not implemented over 'Ring of integers...
˓→modulo 4'.

```sage
>>> from sage.all import *

>>> M = matrix(Integers(Integer(4)), Integer(2), [Integer(2),Integer(2), ...
˓→Integer(2),Integer(2)])
>>> M.rank()
Traceback (most recent call last): ...
NotImplementedError: Echelon form not implemented over 'Ring of integers...
˓→modulo 4'.

```sage
def # needs sage.rings.finite_rings

def A = random_matrix(GF(16007), 100, 100)
def B = copy(A)
def A.rank()
```
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
sage: B == A
True
sage: MS = A.parent()
sage: MS(1) == -A*A
True
```

```python
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> A = random_matrix(GF(Integer(16007)), Integer(100), Integer(100))
>>> B = copy(A)
>>> A.rank()
100
>>> B == A
True
>>> MS = A.parent()
>>> MS(Integer(1)) == -A*A
True
```

**right_kernel_matrix** *(algorithm='linbox', basis='echelon')*

Returns a matrix whose rows form a basis for the right kernel of `self`.

If the base ring is the ring of integers modulo a composite, the keyword arguments are ignored and the computation is delegated to `Matrix_dense.right_kernel_matrix()`.

**INPUT:**

- `algorithm` – (default: 'linbox') a parameter that is passed on to `self.echelon_form`, if computation of an echelon form is required; see that routine for allowable values
- `basis` – (default: 'echelon') a keyword that describes the format of the basis returned, allowable values are:
  - 'echelon': the basis matrix is in echelon form
  - 'pivot': the basis matrix is such that the submatrix obtained by taking the columns that in `self` contain no pivots, is the identity matrix
  - 'computed': no work is done to transform the basis; in the current implementation the result is the negative of that returned by 'pivot'

**OUTPUT:**

A matrix `X` whose rows are a basis for the right kernel of `self`. This means that `self * X.transpose()` is a zero matrix.

The result is not cached, but the routine benefits when `self` is known to be in echelon form already.

**EXAMPLES:**

```python
sage: M = matrix(GF(5),6,6,range(36))
sage: M.right_kernel_matrix(basis='computed')
[4 2 4 0 0 0]
[3 3 0 4 0 0]
[2 4 0 0 4 0]
[1 0 0 0 0 4]
sage: M.right_kernel_matrix(basis='pivot')
[1 3 1 0 0 0]
[2 2 0 1 0 0]
```

(continues on next page)
\begin{verbatim}
[3 1 0 0 1 0]
[4 0 0 0 0 1]
sage: M.right_kernel_matrix()
[1 0 0 0 0 4]
[0 1 0 1 3]
[0 0 1 0 2 2]
[0 0 0 1 3 1]
sage: M * M.right_kernel_matrix().transpose()
[0 0 0 0]
[0 0 0 0]
[0 0 0 0]
[0 0 0 0]
[0 0 0 0]
[0 0 0 0]

>>> from sage.all import *
>>> M = matrix(GF(Integer(5)),Integer(6),Integer(6),range(Integer(36)))
>>> M.right_kernel_matrix(basis='computed')
[4 2 4 0 0 0]
[3 3 0 4 0 0]
[2 4 0 0 4 0]
[1 0 0 0 0 4]
>>> M.right_kernel_matrix(basis='pivot')
[1 3 1 0 0 0]
[2 2 0 1 0 0]
[3 1 0 0 1 0]
[4 0 0 0 0 1]

submatrix (row=0, col=0, nrows=-1, ncols=-1)
Return the matrix constructed from self using the specified range of rows and columns.

INPUT:

- row, col — index of the starting row and column. Indices start at zero
- nrows, ncols — (optional) number of rows and columns to take. If not provided, take all rows below
  and all columns to the right of the starting entry

See also:
The functions matrix_from_rows(), matrix_from_columns(), and matrix_from_rows_and_columns() allow one to select arbitrary subsets of rows and/or columns.

EXAMPLES:
Take the 3 × 3 submatrix starting from entry (1, 1) in a 4 × 4 matrix:
\end{verbatim}
Matrices and Spaces of Matrices, Release 10.4

```python
sage: m = matrix(GF(17), 4, [1..16])
sage: m.submatrix(1, 1)
[ 6  7  8]
[10 11 12]
[14 15 16]
```

```python
>>> from sage.all import *
>>> m = matrix(GF(Integer(17)), Integer(4), (ellipsis_range(Integer(1), Ellipsis,Integer(16))))
>>> m.submatrix(Integer(1), Integer(1))
[ 6  7  8]
[10 11 12]
[14 15 16]
```

Same thing, except take only two rows:

```python
sage: m.submatrix(1, 1, 2)
[ 6  7  8]
[10 11 12]
```

```python
>>> from sage.all import *
>>> m.submatrix(Integer(1), Integer(1), Integer(2))
[ 6  7  8]
[10 11 12]
```

And now take only one column:

```python
sage: m.submatrix(1, 1, 2, 1)
[ 6]
[10]
```

```python
>>> from sage.all import *
>>> m.submatrix(Integer(1), Integer(1), Integer(2), Integer(1))
[ 6]
[10]
```

You can take zero rows or columns if you want:

```python
sage: m.submatrix(0, 0, 0)
[]
sage: parent(m.submatrix(0, 0, 0))
Full MatrixSpace of 0 by 4 dense matrices over Finite Field of size 17
```

```python
>>> from sage.all import *
>>> m.submatrix(Integer(0), Integer(0), Integer(0))
[]
>>> parent(m.submatrix(Integer(0), Integer(0), Integer(0)))
Full MatrixSpace of 0 by 4 dense matrices over Finite Field of size 17
```

```python
transpose()
```

Return the transpose of `self`, without changing `self`.

EXEPMLES:

We create a matrix, compute its transpose, and note that the original matrix is not changed.
```python
sage: M = MatrixSpace(GF(41), 2)
sage: A = M([1,2,3,4])
sage: B = A.transpose()
sage: B
[1 3]
[2 4]
sage: A
[1 2]
[3 4]

>>> from sage.all import *
>>> M = MatrixSpace(GF(Integer(41)), Integer(2))
>>> A = M([Integer(1),Integer(2),Integer(3),Integer(4)])
>>> B = A.transpose()
>>> B
[1 3]
[2 4]
>>> A
[1 2]
[3 4]

.T is a convenient shortcut for the transpose:

sage: A.T
[1 3]
[2 4]

>>> from sage.all import *
>>> A.T
[1 3]
[2 4]

sage: A.subdivide(None, 1); A
[1|2]
[3|4]
sage: A.transpose()
[1 3]
[---]
[2 4]

>>> from sage.all import *
>>> A.subdivide(None, Integer(1)); A
[1|2]
[3|4]
>>> A.transpose()
[1 3]
[---]
[2 4]
```
Chapter 25. Dense matrices over $\mathbb{Z}/n\mathbb{Z}$ for $n < 94906266$ using LinBox's Modular<double>
DENSE MATRICES OVER $\mathbb{Z}/N\mathbb{Z}$ FOR $N < 2^8$ USING LINBOX'S MODULAR<FLOAT>
charpoly \(\text{var='x', algorithm='linbox'}\)

Return the characteristic polynomial of self.

INPUT:

- \text{var} – a variable name
- \text{algorithm} – ‘generic’, ‘linbox’ or ‘all’ (default: linbox)

EXAMPLES:

```python
sage: A = random_matrix(GF(19), 10, 10)
sage: B = copy(A)
sage: char_p = A.characteristic_polynomial()
sage: char_p(A) == 0
True
sage: B == A  # A is not modified
True
sage: min_p = A.minimal_polynomial(proof=True)
sage: min_p.divides(char_p)
True
```

```python
from sage.all import *
```

```python
sage: A = random_matrix(GF(Integer(19)), Integer(10), Integer(10))
sage: B = copy(A)
sage: char_p = A.characteristic_polynomial()
sage: char_p(A) == Integer(0)
True
sage: B == A  # A is not modified
True
sage: min_p = A.minimal_polynomial(proof=True)
sage: min_p.divides(char_p)
True
```

```python
sage: A = random_matrix(GF(2916337), 7, 7)  # needs sage.rings.finite_rings
sage: B = copy(A)
sage: char_p = A.characteristic_polynomial()
sage: char_p(A) == 0
True
sage: B == A  # A is not modified
True
sage: min_p = A.minimal_polynomial(proof=True)
sage: min_p.divides(char_p)
True
```

(continues on next page)
sage: A = Mat(Integers(6), 3, 3)(range(9))
sage: A.charpoly()
x^3

>>> from sage.all import *
>>> A = random_matrix(GF(Integer(2916337)), Integer(7), Integer(7))  # needs sage.rings.finite_rings

>>>

>>> B = copy(A)

>>> E = A.characteristic_polynomial()

>>> E(A) == Integer(0)
True

>>> B == A  # A is not modified
True

>>> min_p = A.minimal_polynomial(proof=True)

>>> min_p.divides(char_p)
True

ALGORITHM: Uses LinBox if self.base_ring() is a field, otherwise use Hessenberg form algorithm.

determinant()

Return the determinant of this matrix.

EXAMPLES:

sage: s = set()
sage: while s != set(GF(7)):
    A = random_matrix(GF(7), 10, 10)
    s.add(A.determinant())

sage: A = random_matrix(GF(7), 100, 100)

sage: A.determinant() == A.transpose().determinant()
True

sage: B = random_matrix(GF(7), 100, 100)

sage: (A*B).determinant() == A.determinant() * B.determinant()
True

>>> from sage.all import *

>>> A = random_matrix(GF(Integer(7)), Integer(100), Integer(100))

>>> A.determinant() == A.transpose().determinant()
True

>>> B = random_matrix(GF(Integer(7)), Integer(100), Integer(100))

>>> (A*B).determinant() == A.determinant() * B.determinant()
True
Matrices and Spaces of Matrices, Release 10.4

sage: # needs sage.rings.finite_rings
sage: A = random_matrix(GF(16007), 10, 10)
sage: A.determinant().parent() is GF(16007)

>>> d = A.determinant()
>>> Parallelism().set('linbox', nproc=Integer(1)) # switch off parallelization
>>> e = B.determinant()
>>> d==e
True

echelonize(algorithm='linbox_noefd', **kwds)
Put **self** in reduced row echelon form.

**INPUT:**

- **self** - a mutable matrix
- **algorithm**
  - **linbox** - uses the LinBox library (wrapping fflas-ffpack)
  - **linbox_noefd** - uses the FFPACK directly, less memory and faster (default)
  - **gauss** - uses a custom slower \(O(n^3)\) Gauss elimination implemented in Sage.
  - **all** - compute using both algorithms and verify that the results are the same.
- **kwds** - these are all ignored

**OUTPUT:**

- **self** is put in reduced row echelon form.
- the rank of **self** is computed and cached
- the pivot columns of **self** are computed and cached.
- the fact that **self** is now in echelon form is recorded and cached so future calls to echelonize return immediately.

**EXAMPLES:**

```python
sage: A = random_matrix(GF(7), 10, 20)
sage: E = A.echelon_form()
sage: A.row_space() == E.row_space()
True
sage: all(r[r.nonzero_positions()[0]] == 1 for r in E.rows() if r)
True
```

```python
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(7)), Integer(10), Integer(20))
>>> E = A.echelon_form()
>>> A.row_space() == E.row_space()
True
>>> all(r[r.nonzero_positions()[Integer(0)]] == Integer(1) for r in E.rows() if r)
True
```

```python
sage: A = random_matrix(GF(13), 10, 10)
sage: while A.rank() != 10:
    ....:     A = random_matrix(GF(13), 10, 10)
    sage: MS = parent(A)
sage: B = A.augment(MS(1))
sage: B.echelonize()
sage: A.rank()
10
sage: C = B.submatrix(0,10,10,10)
sage: ~A == C
True
```

```python
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(13)), Integer(10), Integer(10))
>>> while A.rank() != Integer(10):
    ....:     A = random_matrix(GF(Integer(13)), Integer(10), Integer(10))
```

(continues on next page)
... A = random_matrix(GF(Integer(13)), Integer(10), Integer(10))

>>> A.echelon_form()
Traceback (most recent call last):
NotImplementedError: Echelon form not implemented over 'Ring of integers modulo 10000'.

Parallel computation:

```python
sage: # needs sage.rings.finite_rings
sage: A = random_matrix(GF(65521),100,200)
true: Parallelism().set('linbox', nproc=2)
true: E = A.echelon_form()
true: Parallelism().set('linbox', nproc=1) # switch off parallelization
true: F = A.echelon_form()
true: E==F
True
```

```python
>>> from sage.all import *
true: # needs sage.rings.finite_rings
true: A = random_matrix(GF(Integer(65521)),Integer(100),Integer(200))
true: Parallelism().set('linbox', nproc=Integer(2))
true: E = A.echelon_form()
true: Parallelism().set('linbox', nproc=Integer(1)) # switch off parallelization
true: F = A.echelon_form()
true: E==F
True
```

**hessenbergize()**

Transforms self in place to its Hessenberg form.

**EXAMPLES:**

```python
sage: A = random_matrix(GF(17), 10, 10, density=0.1)
true: B = copy(A)
true: A.hessenbergize()
true: all(A[i,j] == 0 for j in range(10) for i in range(j+2, 10))
true: A.charpoly() == B.charpoly()
true
```

```python
>>> from sage.all import *
true: # needs sage.rings.finite_rings
true: A = random_matrix(GF(Integer(17)), Integer(10), Integer(10),
true: density=RealNumber('0.1'))
true: B = copy(A)
true: A.hessenbergize()
true: all(A[i,j] == Integer(0) for j in range(Integer(10)) for i in
true: range(j+Integer(2), Integer(10)))
true: A.charpoly() == B.charpoly()
true
```

**lift()**

Return the lift of this matrix to the integers.

**EXAMPLES:**

```python
sage: A = matrix(GF(7),2,3,[1..6])
true: A.lift()
```

(continues on next page)
Subdivisions are preserved when lifting:

\begin{verbatim}
sage: A.subdivide([], [1,1]); A
\end{verbatim}
\begin{verbatim}
\[
\begin{array}{ccc}
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{array}
\end{verbatim}
\begin{verbatim}
sage: A.lift()
\end{verbatim}
\begin{verbatim}
\[
\begin{array}{ccc}
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{array}
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> A.subdivide([], [Integer(1),Integer(1)]); A
\end{verbatim}
\begin{verbatim}
\[
\begin{array}{ccc}
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{array}
\end{verbatim}
\begin{verbatim}
>>> A.lift()
\end{verbatim}
\begin{verbatim}
\[
\begin{array}{ccc}
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{array}
\end{verbatim}

\texttt{matrix\_from\_columns}(\texttt{columns})

Return the matrix constructed from self using columns with indices in the columns list.

EXAMPLES:

\begin{verbatim}
sage: M = MatrixSpace(Integers(8), 3, 3)
sage: A = M(range(9)); A
\end{verbatim}
\begin{verbatim}
\[
\begin{array}{ccc}
0 & 1 & 2 \\
3 & 4 & 5 \\
6 & 7 & 8 \\
\end{array}
\end{verbatim}

(continues on next page)
matrix_from_rows\((rows)\)

Return the matrix constructed from self using rows with indices in the rows list.

EXAMPLES:

```
sage: M = MatrixSpace(Integers(8),3,3)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 0]
sage: A.matrix_from_rows([2,1])
[6 7 0]
[3 4 5]
```

matrix_from_rows_and_columns\((rows, columns)\)

Return the matrix constructed from self from the given rows and columns.

EXAMPLES:

```
sage: M = MatrixSpace(Integers(8),3,3)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 0]
sage: A.matrix_from_rows_and_columns([1], [0,2])
[3 5]
sage: A.matrix_from_rows_and_columns([1,2], [1,2])
```
>>> from sage.all import *
>>> M = MatrixSpace(Integers(Integer(8)), Integer(3), Integer(3))
>>> A = M(range(Integer(9))); A
[0 1 2]
[3 4 5]
[6 7 0]
>>> A.matrix_from_rows_and_columns([Integer(1)], [Integer(0), Integer(2)])
[3 5]
>>> A.matrix_from_rows_and_columns([Integer(1), Integer(2)], [Integer(1), Integer(2)])
[4 5]
[7 0]

Note that row and column indices can be reordered or repeated:

sage: A.matrix_from_rows_and_columns([2, 1], [2, 1])
[0 7]
[5 4]

For example here we take from row 1 columns 2 then 0 twice, and do this 3 times:

sage: A.matrix_from_rows_and_columns([1, 1, 1], [2, 0, 0])
[5 3 3]
[5 3 3]
[5 3 3]

sage: A.matrix_from_rows_and_columns([Integer(1), Integer(1), Integer(1)],
                                  [Integer(2), Integer(0), Integer(0)])
[5 3 3]
[5 3 3]
[5 3 3]

• Didier Deshommes: some Pyrex speedups implemented

minpoly (var='x', algorithm='linbox', proof=None)

Returns the minimal polynomial of “self”.

INPUT:

• var — a variable name
• algorithm — generic or linbox (default: linbox)
• proof – (default: True); whether to provably return the true minimal polynomial; if False, we only guarantee to return a divisor of the minimal polynomial. There are also certainly cases where the computed results is frequently not exactly equal to the minimal polynomial (but is instead merely a divisor of it).

**Warning:** If proof=True, minpoly is insanely slow compared to proof=False. This matters since proof=True is the default, unless you first type `proof.linear_algebra(False)`.

**EXAMPLES:**

```
sage: A = random_matrix(GF(17), 10, 10)
sage: B = copy(A)
sage: min_p = A.minimal_polynomial(proof=True)
sage: min_p(A) == 0
True
sage: B == A
True

sage: char_p = A.characteristic_polynomial()
sage: min_p.divides(char_p)
True
```

```python
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(17)), Integer(10), Integer(10))
>>> B = copy(A)
>>> min_p = A.minimal_polynomial(proof=True)
>>> min_p(A) == Integer(0)
True
>>> B == A
True

>>> char_p = A.characteristic_polynomial()
>>> min_p.divides(char_p)
True
```

```python
sage: A = random_matrix(GF(1214471), 10, 10) # needs sage.rings.finite_rings
sage: B = copy(A)
sage: min_p = A.minimal_polynomial(proof=True)
sage: min_p(A) == 0
True
sage: B == A
True

sage: char_p = A.characteristic_polynomial()
sage: min_p.divides(char_p)
True
```

```python
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(1214471)), Integer(10), Integer(10)) # needs sage.rings.finite_rings
>>> B = copy(A)
>>> min_p = A.minimal_polynomial(proof=True)
```
EXAMPLES:

```python
sage: R.<x>=GF(3)[]
sage: A = matrix(GF(3), 2, [0, 0, 1, 2])
sage: A.minpoly()
x^2 + x
sage: A.minpoly(proof=True) in [x, x+1, x^2+x]
True
```

```python
>>> from sage.all import *

>>> R = GF(Integer(3))[x]; (x,) = R._first_ngens(1)

>>> A = matrix(GF(Integer(3)), Integer(2), [Integer(0), Integer(0), Integer(1), Integer(2)])

>>> A.minpoly()
x^2 + x

>>> A.minpoly(proof=False) in [x, x+Integer(1), x**Integer(2)+x]
True
```

`randomize(density=1, nonzero=False)`

Randomize density proportion of the entries of this matrix, leaving the rest unchanged.

**INPUT:**

- `density` – Integer; proportion (roughly) to be considered for changes
- `nonzero` – Bool (default: False); whether the new entries are forced to be non-zero

**OUTPUT:**

- None, the matrix is modified in-space

**EXAMPLES:**

```python
sage: A = matrix(GF(5), 5, 5, 0)
sage: total_count = 0
sage: from collections import defaultdict
sage: dic = defaultdict(Integer)
sage: def add_samples(density):
.....: global dic, total_count
.....: for _ in range(100):
.....:     A = Matrix(GF(5), 5, 5, 0)
.....:     A.randomize(density)
.....:     for a in A.list():
.....:         dic[a] += 1
.....:     total_count += 1.0
```

(continues on next page)
The matrix is updated instead of overwritten:
Matrices and Spaces of Matrices, Release 10.4

```python
sage: def add_sample(density):
.....:   global density_sum, total_count
.....:   total_count += 1.0
.....:   A = random_matrix(GF(5), 1000, 1000, density=density)
.....:   A.randomize(density=density, nonzero=True)
.....:   density_sum += A.density()

sage: density_sum = 0.0
sage: total_count = 0.0
sage: add_sample(0.5)
sage: expected_density = 1.0 - (999/1000)^1000
sage: expected_density
0.6323...

sage: while abs(density_sum/total_count - expected_density) > 0.001:
.....:   add_sample(0.5)

sage: density_sum = 0.0
sage: total_count = 0.0
sage: add_sample(0.1)
sage: expected_density = 1.0 - (999/1000)^200
sage: expected_density
0.1813...

sage: while abs(density_sum/total_count - expected_density) > 0.001:
.....:   add_sample(0.1)

>>> from sage.all import *
>>> def add_sample(density):
...   global density_sum, total_count
...   total_count = RealNumber('1.0')
...   A = random_matrix(GF(Integer(5)), Integer(1000), Integer(1000),
...   density=density)
...   A.randomize(density=density, nonzero=True)
...   density_sum += A.density()

... density_sum = RealNumber('0.0')
... total_count = RealNumber('0.0')
... add_sample(RealNumber('0.5'))
... expected_density = RealNumber('1.0') - (Integer(999)/
... Integer(1000))**Integer(1000)
... expected_density
0.6323...

>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001'):
...   add_sample(RealNumber('0.5'))

... density_sum = RealNumber('0.0')
... total_count = RealNumber('0.0')
... add_sample(RealNumber('0.1'))
... expected_density = RealNumber('1.0') - (Integer(999)/
... Integer(1000))**Integer(200)
... expected_density
0.1813...

>>> while abs(density_sum/total_count - expected_density) > RealNumber('0.001'):
...   add_sample(RealNumber('0.1'))

rank()
```
Return the rank of this matrix.

EXAMPLES:

```
sage: A = random_matrix(GF(3), 100, 100)
sage: B = copy(A)
sage: _ = A.rank()
sage: B == A
True

sage: A = random_matrix(GF(3), 100, 100, density=0.01)
sage: A.transpose().rank() == A.rank()
True

sage: A = matrix(GF(3), 100, 100)
sage: A.rank()
0
```

Rank is not implemented over the integers modulo a composite yet:

```
sage: M = matrix(Integers(4), 2, [2,2,2,2])
sage: M.rank()
Traceback (most recent call last):
...                     
NotImplementedError: Echelon form not implemented over 'Ring of integers modulo 4'.
```

```
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(4)), Integer(100), Integer(100))
>>> B = copy(A)
>>> _ = A.rank()
>>> B == A
True

>>> A = random_matrix(GF(Integer(4)), Integer(100), Integer(100),
˓→ density=RealNumber('0.01'))
>>> A.transpose().rank() == A.rank()
True

>>> A = matrix(GF(Integer(4)), Integer(100), Integer(100))
>>> A.rank()
0
```

(continues on next page)
right_kernel_matrix \( (\text{algorithm}='\text{linbox}', \text{basis}=\text{\textquotesingle echelon\textquotesingle}) \)

Returns a matrix whose rows form a basis for the right kernel of \( \text{self} \).

If the base ring is the ring of integers modulo a composite, the keyword arguments are ignored and the computation is delegated to \text{Matrix\_dense.right\_kernel\_matrix()}.

**INPUT:**

• \text{algorithm} – (default: \text{\textquotesingle linbox\textquotesingle}) a parameter that is passed on to \text{self.echelon\_form}, if computation of an echelon form is required; see that routine for allowable values

• \text{basis} – (default: \text{\textquotesingle echelon\textquotesingle}) a keyword that describes the format of the basis returned, allowable values are:
  
  – \text{\textquotesingle echelon\textquotesingle}: the basis matrix is in echelon form

  – \text{\textquotesingle pivot\textquotesingle}: the basis matrix is such that the submatrix obtained by taking the columns that in \text{self} contain no pivots, is the identity matrix

  – \text{\textquotesingle computed\textquotesingle}: no work is done to transform the basis; in the current implementation the result is the negative of that returned by \text{\textquotesingle pivot\textquotesingle}

**OUTPUT:**

A matrix \( \text{X} \) whose rows are a basis for the right kernel of \( \text{self} \). This means that \( \text{self} \ast \text{X}.\text{transpose()} \) is a zero matrix.

The result is not cached, but the routine benefits when \( \text{self} \) is known to be in echelon form already.

**EXAMPLES:**

\begin{verbatim}
 sage: M = matrix(GF(5),6,6,range(36))
sage: M.right_kernel_matrix(basis='computed')
[4 2 4 0 0 0]
[3 3 0 4 0 0]
[2 4 0 0 4 0]
[1 0 0 0 0 4]
sage: M.right_kernel_matrix(basis='pivot')
[1 3 1 0 0 0]
[2 0 1 0 0]
[3 1 0 0 1 0]
\end{verbatim}

0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\end{bmatrix}
```

**submatrix** (row=0, col=0, nrows=-1, ncols=-1)

Return the matrix constructed from self using the specified range of rows and columns.

**INPUT:**

- row, col – index of the starting row and column. Indices start at zero
- nrows, ncols – (optional) number of rows and columns to take. If not provided, take all rows below and all columns to the right of the starting entry

**See also:**

The functions `matrix_from_rows()`, `matrix_from_columns()`, and `matrix_from_rows_and_columns()` allow one to select arbitrary subsets of rows and/or columns.

**EXAMPLES:**

Take the 3 × 3 submatrix starting from entry (1, 1) in a 4 × 4 matrix:
Matrices and Spaces of Matrices, Release 10.4

```python
sage: m = matrix(GF(17), 4, [1..16])
sage: m.submatrix(1, 1)
[ 6  7  8]
[10 11 12]
[14 15 16]
```

```python
>>> from sage.all import *

>>> m = matrix(GF(Integer(17)), Integer(4), (ellipsis_range(Integer(1), Ellipsis, Integer(16))))

>>> m.submatrix(Integer(1), Integer(1))
[ 6  7  8]
[10 11 12]
[14 15 16]
```

Same thing, except take only two rows:

```python
sage: m.submatrix(1, 1, 2)
[ 6  7  8]
[10 11 12]
```

```python
>>> from sage.all import *

>>> m.submatrix(Integer(1), Integer(1), Integer(2))
[ 6  7  8]
[10 11 12]
```

And now take only one column:

```python
sage: m.submatrix(1, 1, 2, 1)
[ 6]
[10]
```

```python
>>> from sage.all import *

>>> m.submatrix(Integer(1), Integer(1), Integer(2), Integer(1))
[ 6]
[10]
```

You can take zero rows or columns if you want:

```python
sage: m.submatrix(0, 0, 0)
[]
sage: parent(m.submatrix(0, 0, 0))
Full MatrixSpace of 0 by 4 dense matrices over Finite Field of size 17
```

```python
>>> from sage.all import *

>>> m.submatrix(Integer(0), Integer(0), Integer(0))
[]
>>> parent(m.submatrix(Integer(0), Integer(0), Integer(0)))
Full MatrixSpace of 0 by 4 dense matrices over Finite Field of size 17
```

`transpose()`

Return the transpose of `self`, without changing `self`.

**EXAMPLES:**

We create a matrix, compute its transpose, and note that the original matrix is not changed.
sage: M = MatrixSpace(GF(41), 2)
sage: A = M([1,2,3,4])
sage: B = A.transpose()
sage: B
[1 3]
[2 4]
sage: A
[1 2]
[3 4]

>>> from sage.all import *
>>> M = MatrixSpace(GF(Integer(41)), Integer(2))
>>> A = M([Integer(1),Integer(2),Integer(3),Integer(4)])
>>> B = A.transpose()
>>> B
[1 3]
[2 4]

.T is a convenient shortcut for the transpose:

sage: A.T
[1 3]
[2 4]

>>> from sage.all import *
>>> A.T
[1 3]
[2 4]

sage: A.subdivide(None, 1); A
[1|2]
[3|4]
sage: A.transpose()
[1 3]
[---]
[2 4]

>>> from sage.all import *
>>> A.subdivide(None, Integer(1)); A
[1|2]
[3|4]
>>> A.transpose()
[1 3]
[---]
[2 4]
Chapter 26. Dense matrices over $\mathbb{Z}/n\mathbb{Z}$ for $n < 2^8$ using LinBox's Modular<float>
CHAPTER TWENTYSEVEN

SPARSE MATRICES OVER $\mathbb{Z}/n\mathbb{Z}$ FOR $n$ SMALL

This is a compiled implementation of sparse matrices over $\mathbb{Z}/n\mathbb{Z}$ for $n$ small.

Todo: move vectors into a Cython vector class - add _add_ and _mul_ methods.

EXAMPLES:

```
sage: a = matrix(Integers(37),3,3,range(9),sparse=True); a
[0 1 2]
[3 4 5]
[6 7 8]
sage: type(a)
<class 'sage.matrix.matrix_modn_sparse.Matrix_modn_sparse'>
sage: parent(a)
Full MatrixSpace of 3 by 3 sparse matrices over Ring of integers modulo 37
sage: a^2
[15 18 21]
[5 17 29]
[32 16 0]
sage: a+a
[ 0 2 4]
[ 6 8 10]
[12 14 16]
sage: b = a.new_matrix(2,3,range(6)); b
[0 1 2]
[3 4 5]
sage: a*b
Traceback (most recent call last):
...TypeError: unsupported operand parent(s) for *: 'Full MatrixSpace of 3 by 3 sparse...
...matrices over Ring of integers modulo 37' and 'Full MatrixSpace of 2 by 3 sparse...
...matrices over Ring of integers modulo 37'
sage: b*a
[15 18 21]
[ 5 17 29]
```

```python
>>> from sage.all import *
>>> a = matrix(Integers(Integer(37)),Integer(3),Integer(3),range(Integer(9)),
... sparse=True); a
[0 1 2]
[3 4 5]
[6 7 8]
>>> type(a)
```
<class 'sage.matrix.matrix_modn_sparse.Matrix_modn_sparse'>

sage: parent(a)
Full MatrixSpace of 3 by 3 sparse matrices over Ring of integers modulo 37

sage: a**Integer(2)
[15 18 21]

[ 1 0 36]
[ 0 1 2]
[ 0 0 0]

(continues on next page)
class sage.matrix.matrix_modn_sparse.Matrix_modn_sparse

Bases: Matrix_sparse

Create a sparse matrix over the integers modulo n.

INPUT:

- parent – a matrix space over the integers modulo n
- entries – see matrix()
- copy – ignored (for backwards compatibility)
- coerce – if False, assume without checking that the entries lie in the base ring

density()

Return the density of self, i.e., the ratio of the number of nonzero entries of self to the total size of self.

EXAMPLES:

```python
sage: A = matrix(QQ, 3, 3, [0, 1, 2, 3, 0, 0, 6, 7, 8], sparse=True)
sage: A.density()
2/3
```

Notice that the density parameter does not ensure the density of a matrix; it is only an upper bound.

```python
sage: A = random_matrix(GF(127), 200, 200, density=0.3, sparse=True)
sage: density_sum = float(A.density())
sage: total = 1
sage: expected_density = 1.0 - (199/200)^60
sage: expected_density
0.2597...
sage: while abs(density_sum/total - expected_density) > 0.001:
    ....:     A = random_matrix(GF(127), 200, 200, density=0.3, sparse=True)
    ....:     density_sum += float(A.density())
    ....:     total += 1
```
Matrices and Spaces of Matrices, Release 10.4

```python
>>> from sage.all import *
>>> A = random_matrix(GF(Integer(127)), Integer(200), Integer(200),
                   density=RealNumber('0.3'), sparse=True)
>>> density_sum = float(A.density())
>>> total = Integer(1)
>>> expected_density = RealNumber('1.0') - (Integer(199)/
                           Integer(200))**Integer(60)
>>> expected_density
0.2597...
>>> while abs(density_sum/total - expected_density) > RealNumber('0.001'):
...     A = random_matrix(GF(Integer(127)), Integer(200), Integer(200),
                       density=RealNumber('0.3'), sparse=True)
...     density_sum += float(A.density())
...     total += Integer(1)
```

determinant (algorithm=None)

Return the determinant of this matrix.

**INPUT:**

- **algorithm**—either "linbox" (default) or "generic".

**EXAMPLES:**

```python
sage: A = matrix(GF(3), 4, range(16), sparse=True)
sage: B = identity_matrix(GF(3), 4, sparse=True)
sage: (A + B).det()
2
sage: (A + B).det(algorithm="linbox")
2
sage: (A + B).det(algorithm="generic")
2
sage: (A + B).det(algorithm="hey")
Traceback (most recent call last):
  ... ValueError: no algorithm 'hey'

sage: matrix(GF(11), 1, 2, sparse=True).det()
Traceback (most recent call last):
  ... ValueError: self must be a square matrix
```
... 
ValueError: self must be a square matrix

**matrix_from_columns** *(cols)*

Return the matrix constructed from self using columns with indices in the columns list.

**EXAMPLES:**

```sage
M = MatrixSpace(GF(127), 3, 3, sparse=True)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.matrix_from_columns([2, 1])
[2 1]
[5 4]
[8 7]
```

```python
from sage.all import *
>>> M = MatrixSpace(GF(Integer(127)), Integer(3), Integer(3), sparse=True)
>>> A = M(range(Integer(9))); A
[0 1 2]
[3 4 5]
[6 7 8]
>>> A.matrix_from_columns([Integer(2), Integer(1)])
[2 1]
[5 4]
[8 7]
```

**matrix_from_rows** *(rows)*

Return the matrix constructed from self using rows with indices in the rows list.

**INPUT:**

- **rows** – list or tuple of row indices

**EXAMPLES:**

```sage
M = MatrixSpace(GF(127), 3, 3, sparse=True)
sage: A = M(range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: A.matrix_from_rows([2, 1])
[6 7 8]
[3 4 5]
```

```python
from sage.all import *
>>> M = MatrixSpace(GF(Integer(127)), Integer(3), Integer(3), sparse=True)
>>> A = M(range(Integer(9))); A
[0 1 2]
[3 4 5]
[6 7 8]
>>> A.matrix_from_rows([Integer(2), Integer(1)])
[6 7 8]
[3 4 5]
```
\[ P \]

**rank** *(algorithm=None)*

Return the rank of this matrix.

**INPUT:**

- algorithm – either "linbox" (only available for matrices over prime fields) or "generic"

**EXAMPLES:**

```python
sage: A = matrix(GF(127), 2, 2, sparse=True)
sage: A[0,0] = 34
sage: A[0,1] = 102
sage: A[1,0] = 55
sage: A[1,1] = 74
sage: A.rank()
2

sage: A._clear_cache()

sage: A.rank(algorithm="generic")
2

sage: A._clear_cache()

sage: A.rank(algorithm="hey")
Traceback (most recent call last):
... ValueError: no algorithm 'hey'
```

```python
>>> from sage.all import *

>>> A = matrix(GF(Integer(127)), Integer(2), Integer(2), sparse=True)

>>> A[Integer(0),Integer(0)] = Integer(34)

>>> A[Integer(0),Integer(1)] = Integer(102)

>>> A[Integer(1),Integer(0)] = Integer(55)

>>> A[Integer(1),Integer(1)] = Integer(74)

>>> A.rank()
2

>>> A._clear_cache()

>>> A.rank(algorithm="generic")
2

>>> A._clear_cache()

>>> A.rank(algorithm="hey")
Traceback (most recent call last):
... ValueError: no algorithm 'hey'
```

**REFERENCES:**

**Note:** For very sparse matrices Gaussian elimination is faster because it barely has anything to do. If the fill in needs to be considered, ‘Symbolic Reordering’ is usually much faster.

```python
swap_rows(r1, r2)
```
**transpose()**

Return the transpose of self.

**EXAMPLES:**

```python
sage: A = matrix(GF(127),3,3,[0,1,0,2,0,0,3,0,0],sparse=True)
sage: A
[0 1 0]
[2 0 0]
[3 0 0]
sage: A.transpose()
[0 2 3]
[1 0 0]
[0 0 0]
```

```python
>>> from sage.all import *

>>> A = matrix(GF(Integer(127)),Integer(3),Integer(3),[Integer(0),Integer(1),...
   Integer(0),Integer(2),Integer(0),Integer(0),Integer(3),Integer(0),...
   Integer(0)],sparse=True)

>>> A
[0 1 0]
[2 0 0]
[3 0 0]

>>> A.transpose()
[0 2 3]
[1 0 0]
[0 0 0]
```

.T is a convenient shortcut for the transpose:

```python
sage: A.T
[0 2 3]
[1 0 0]
[0 0 0]
```

```python
>>> from sage.all import *

>>> A.T
[0 2 3]
[1 0 0]
[0 0 0]
```
SYMBOLIC DENSE MATRICES

EXAMPLES:

```python
sage: matrix(SR, 2, 2, range(4))
[[0 1]
 [2 3]]
sage: matrix(SR, 2, 2, var('t'))
[[t 0]
 [0 t]]
```

```python
>>> from sage.all import *

>>> matrix(SR, Integer(2), Integer(2), range(Integer(4)))
[[0 1]
 [2 3]]

>>> matrix(SR, Integer(2), Integer(2), var('t'))
[[t 0]
 [0 t]]
```

Arithmetic:

```python
sage: -matrix(SR, 2, range(4))
[[ 0 -1]
 [-2 -3]]
sage: m = matrix(SR, 2, [1..4]); sqrt(2)*m
[[ sqrt(2) 2*sqrt(2)]
 [3*sqrt(2) 4*sqrt(2)]]
sage: m = matrix(SR, 4, [1..4^2])
sage: m * m
[[ 90 100 110 120]
 [202 228 254 280]
 [314 356 398 440]
 [426 484 542 600]]

diff: m = matrix(SR, 3, [1, 2, 3]); m
[[1]
 [2]
 [3]]
sage: m.transpose() * m
[[14]]
```

```python
>>> from sage.all import *

>>> -matrix(SR, Integer(2), range(Integer(4)))
[[ 0 -1]
 [-2 -3]]
```

(continues on next page)
Computing inverses:

```
sage: M = matrix(SR, 2, var('a,b,c,d'))
sage: ~M
[1/a - b*c/(a^2*(b*c/a - d))  b/(a*(b*c/a - d))]
[ c/(a*(b*c/a - d)) -1/(b*c/a - d)]
sage: (~M*M).simplify_rational()
[1 0]
[0 1]
sage: M = matrix(SR, 3, 3, range(9)) - var('t')
sage: (~M * M).simplify_rational()
[1 0 0]
[0 1 0]
[0 0 1]
sage: matrix(SR, 1, 1, 1).inverse()
[1]
sage: matrix(SR, 0, 0).inverse()
[]
sage: matrix(SR, 3, 0).inverse()
Traceback (most recent call last):
  ... ArithmeticError: self must be a square matrix
```
Transposition:

\[
\begin{bmatrix}
\sqrt{2} & \pi \\
-1 & e^2
\end{bmatrix}
\]

. T is a convenient shortcut for the transpose:

\[
\begin{bmatrix}
\sqrt{2} & \pi \\
-1 & e^2
\end{bmatrix}
\]

Test pickling:

\[
\begin{bmatrix}
\sqrt{2} & 3 \\
\pi & e
\end{bmatrix}
\]

Comparison:

\[
\begin{bmatrix}
\sqrt{2} & [1..4]
\end{bmatrix}
\]

\[
\begin{bmatrix}
1
\end{bmatrix}
\]

True

True

\[
\begin{bmatrix}
1
\end{bmatrix}
\]

\[
\begin{bmatrix}
1
\end{bmatrix}
\]

(continues on next page)
Determinant:

```python
sage: M = matrix(SR, 2, 2, [x, 2, 3, 4])
sage: M.determinant()
4*x - 6
sage: M = matrix(SR, 3, 3, range(9))
sage: M.det()
0
sage: t = var('t')
sage: M = matrix(SR, 2, 2, [cos(t), sin(t), -sin(t), cos(t)])
sage: M.det()
cos(t)^2 + sin(t)^2
sage: M = matrix([[sqrt(x), 0, 0, 0], [0, 1, 0, 0], [0, 0, 1, 0], [0, 0, 0, 1]])
sage: det(M)
sqrt(x)
```

Permanents:

```python
sage: M = matrix(SR, 2, 2, [x, 2, 3, 4])
sage: M.permanent()
4*x + 6
```
Matrices and Spaces of Matrices, Release 10.4

>>> M.permanent()
4*x + 6

Rank:

```python
sage: M = matrix(SR, 5, 5, range(25))
sage: M.rank()
2
sage: M = matrix(SR, 5, 5, range(25)) - var('t')
sage: M.rank()
5
```

.. warning::

   :meth:`rank` may return the wrong answer if it cannot determine that a matrix element that is equivalent to zero is indeed so.

```python
>>> from sage.all import *
```

```python
>>> M = matrix(SR, Integer(5), Integer(5), range(Integer(25)))
```

```python
>>> M.rank()
2
```

```python
>>> M = matrix(SR, Integer(5), Integer(5), range(Integer(25))) - var('t')
```

```python
>>> M.rank()
5
```

.. warning::

   :meth:`rank` may return the wrong answer if it cannot determine that a matrix element that is equivalent to zero is indeed so.

Copying symbolic matrices:

```python
sage: m = matrix(SR, 2, [sqrt(2), 3, pi, e])
sage: n = copy(m)
sage: n[0,0] = sin(1)
```

```python
sage: m
[    sqrt(2)   3]
[   pi      e]
sage: n
[sin(1)   3]
[   pi      e]
```

```python
>>> from sage.all import *
```

```python
>>> m = matrix(SR, Integer(2), [sqrt(Integer(2)), Integer(3), pi, e])
```

```python
>>> n = copy(m)
```

```python
>>> n[Integer(0),Integer(0)] = sin(Integer(1))
```

```python
>>> m
[    sqrt(2)   3]
[   pi      e]
```

```python
>>> n
[sin(1)   3]
[   pi      e]
```

Conversion to Maxima:
sage: m = matrix(SR, 2, [sqrt(2), 3, pi, e])
sage: m._maxima_()
matrix([sqrt(2), 3], [%pi, %e])

>>> from sage.all import *
>>> m = matrix(SR, Integer(2), [sqrt(Integer(2)), Integer(3), pi, e])

>>>

class sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense

    Bases: Matrix_generic_dense

    arguments()

    Return a tuple of the arguments that self can take.

    EXAMPLES:

sage: var('x,y,z')
(x, y, z)
sage: M = MatrixSpace(SR, 2, 2)
sage: M(x).arguments()
(x,)
sage: M(x+sin(x)).arguments()
(x,)

>>> from sage.all import *
>>> var('x,y,z')
(x, y, z)
>>>
>>>
    canonicalize_radical()

    Choose a canonical branch of each entry of self by calling Expression.
    canonicalize_radical() componentwise.

    EXAMPLES:

sage: var('x','y')
(x, y)
sage: l1 = [sqrt(2)*sqrt(3)*sqrt(6) , log(x*y)]
sage: l2 = [sin(x/(x^2 + x)) , 1]
sage: m = matrix([l1, l2])
sage: m
does not display

<table>
<thead>
<tr>
<th>sqrt(6)*sqrt(3)*sqrt(2)</th>
<th>log(x*y)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sin(x/(x^2 + x))</td>
<td>1</td>
</tr>
</tbody>
</table>

sage: m.canonicalize_radical()
does not display

<table>
<thead>
<tr>
<th>6 log(x) + log(y)</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>sin(1/(x + 1))</td>
<td></td>
</tr>
</tbody>
</table>

>>> from sage.all import *
>>> var('x','y')
(x, y)
>>>
>>>
(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> l2 = [sin(x/(x**2 + x)) , Integer(1)]
>>> m = matrix([l1, l2])
>>> m

[[sqrt(6)*sqrt(3)*sqrt(2) log(x*y)]
 [ sin(x/(x^2 + x)) 1]]
>>> m.canonicalize_radical()

[[ 6 log(x) + log(y)]
 [ sin(1/(x + 1)) 1]]
```

**charpoly** *(var='x', algorithm=None)*

Compute the characteristic polynomial of `self`, using maxima.

Note: The characteristic polynomial is defined as $\det(xI - A)$.

**INPUT:**

- `var` – (default: `'x'`) name of variable of charpoly

**EXAMPLES:**

```python
sage: M = matrix(SR, 2, 2, var('a,b,c,d'))
sage: M.charpoly(t)
t^2 + (-a - d)*t - b*c + a*d
sage: matrix(SR, 5, [1..5^2]).charpoly()
x^5 - 65*x^4 - 250*x^3
```

```python
>>> from sage.all import *
```

```python
>>> M = matrix(SR, Integer(2), Integer(2), var('a,b,c,d'))
```

```python
>>> M.charpoly(t)
t^2 + (-a - d)*t - b*c + a*d
```

```python
>>> matrix(SR, Integer(5), (ellipsis_range(Integer(1),Ellipsis, Integer(5)**Integer(2)))).charpoly()
x^5 - 65*x^4 - 250*x^3
```

**echelonize** (**kwds**)

Echelonize using the classical algorithm.

**eigenvalues** *(extend=True)*

Compute the eigenvalues by solving the characteristic polynomial in maxima.

The argument `extend` is ignored but kept for compatibility with other matrix classes.

**EXAMPLES:**

```python
sage: a=matrix(SR,[[1,2],[3,4]])
sage: a.eigenvalues()
[-1/2*sqrt(33) + 5/2, 1/2*sqrt(33) + 5/2]
```

```python
>>> from sage.all import *
```

```python
>>> a=matrix(SR,[[Integer(1),Integer(2)],[Integer(3),Integer(4)]]))
```

```python
>>> a.eigenvalues()
[-1/2*sqrt(33) + 5/2, 1/2*sqrt(33) + 5/2]
```

**eigenvectors_left** *(other=None)*

Compute the left eigenvectors of a matrix.
Matrices and Spaces of Matrices, Release 10.4

INPUT:

• other – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved (currently supported only if the base ring of self is RDF or CDF)

OUTPUT:

For each distinct eigenvalue, returns a list of the form $(e, V, n)$ where $e$ is the eigenvalue, $V$ is a list of eigenvectors forming a basis for the corresponding left eigenspace, and $n$ is the algebraic multiplicity of the eigenvalue.

EXAMPLES:

```
sage: A = matrix(SR,3,3,range(9)); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenvectors_left(); es

>>> abs(abs(delta)).n() < RealNumber('1e-10')
True
```

(continues on next page)
This routine calls Maxima and can struggle with even small matrices with a few variables, such as a $3 \times 3$ matrix with three variables. However, if the entries are integers or rationals it can produce exact values in a reasonable time. These examples create 0-1 matrices from the adjacency matrices of graphs and illustrate how the format and type of the results differ when the base ring changes. First for matrices over the rational numbers, then the same matrix but viewed as a symbolic matrix.

```sage
g = graphs.CycleGraph(5)
g = am = G.adjacency_matrix() g = spectrum = am.eigenvectors_left() g = qbar_evalue = spectrum[2][0] g = type(qbar_evalue) <class 'sage.rings.qqbar.AlgebraicNumber'> g = qbar_evalue 0.618033988749895?
g = am = G.adjacency_matrix().change_ring(SR) g = spectrum = am.eigenvectors_left() g = symbolic_evalue = spectrum[2][0] g = type(symbolic_evalue) <class 'sage.symbolic.expression.Expression'> g = symbolic_evalue 1/2*sqrt(5) - 1/2 g = bool(qbar_evalue == symbolic_evalue) True
```
A slightly larger matrix with a “nice” spectrum.

```python
sage: G = graphs.CycleGraph(6)
sage: am = G.adjacency_matrix().change_ring(SR)
sage: am.eigenvectors_left()
[(-1, [(1, 0, -1, 1, 0, -1), (0, 1, -1, 0, 1, -1)], 2), (1, [(1, 0, -1, -1, 0, 1), (0, 1, 1, 0, -1, -1)], 2), (-2, [(1, -1, 1, -1, 1, -1)], 1), (2, [(1, -1, 1, 1, 1)], 1)]
```

```
>>> from sage.all import *

>>> G = graphs.CycleGraph(Integer(6))

>>> am = G.adjacency_matrix().change_ring(SR)

>>> am.eigenvectors_left()
[(-1, [(1, 0, -1, 1, 0, -1), (0, 1, -1, 0, 1, -1)], 2), (1, [(1, 0, -1, -1, 0, 1), (0, 1, 1, 0, -1, -1)], 2), (-2, [(1, -1, 1, -1, 1, -1)], 1), (2, [(1, -1, 1, 1, 1)], 1)]
```

**eigenvectors_right (other=None)**

Compute the right eigenvectors of a matrix.

**INPUT:**

- other – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved (currently supported only if the base ring of self is RDF or CDF)

**OUTPUT:**

For each distinct eigenvalue, returns a list of the form $(e,V,n)$ where $e$ is the eigenvalue, $V$ is a list of eigenvectors forming a basis for the corresponding right eigenspace, and $n$ is the algebraic multiplicity of the eigenvalue.

**EXAMPLES:**

```python
sage: A = matrix(SR,2,2,range(4)); A
[0 1]
[2 3]
sage: right = A.eigenvectors_right(); right
[(-1/2*sqrt(17) + 3/2, [(1, -1/2*sqrt(17) + 3/2)], 1), (1/2*sqrt(17) + 3/2, [(1, 1/2*sqrt(17) + 3/2)], 1)]
```
The right eigenvectors are nothing but the left eigenvectors of the transpose matrix:

```python
sage: left = A.transpose().eigenvectors_left(); left
[(-1/2*sqrt(17) + 3/2, [(1, -1/2*sqrt(17) + 3/2)], 1), (1/2*sqrt(17) + 3/2, (1, 1/2*sqrt(17) + 3/2)], 1)]
```

```python
sage: right[0][1] == left[0][1]
True
```

```python
>>> from sage.all import *

>>> m = matrix(SR, Integer(2), [Integer(0), x, x, Integer(0)]); m
[0 x]
[x 0]
```

```python
>>> m.exp()
[1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x)]
[1/2*(e^(2*x) - 1)*e^(-x) 1/2*(e^(2*x) + 1)*e^(-x)]
```

```python
>>> m.exp()
[1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x)]
[1/2*(e^(2*x) - 1)*e^(-x) 1/2*(e^(2*x) + 1)*e^(-x)]
```

Exponentiation works on 0x0 and 1x1 matrices, but the 1x1 example requires a patched version of maxima (Issue #32898) for now:
Commuting matrices $m, n$ have the property that $e^{m+n} = e^m e^n$ (but non-commuting matrices need not):

```
sage: m = matrix(SR,2,[1..4]); n = m^2
sage: m*n
[ 37  54]
[ 81 118]
sage: n*m
[ 37  54]
[ 81 118]
sage: a = exp(m+n) - exp(m)*exp(n)
sage: a.simplify_rational() == 0
True
```

The input matrix must be square:

```
sage: m = matrix(SR,2,3,[1..6]); exp(m)
Traceback (most recent call last):
...
ValueError: exp only defined on square matrices
```

(continues on next page)
In this example we take the symbolic answer and make it numerical at the end:

```python
sage: exp(matrix(SR, [[1.2, 5.6], [3,4]])).change_ring(RDF)  # rel tol 1e-15
[ 346.5574872980695 661.7345909344504]
[354.50067371488416 677.4247827652946]
```

Another example involving the reversed identity matrix, which we clumsily create:

```python
sage: m = identity_matrix(SR,4); m = matrix(list(reversed(m.rows()))) * x
sage: exp(m)
[1/2*(e^(2*x) + 1)*e^(-x) 0 0 1/2*(e^(2*x) - 1)*e^(-x)]
[0 1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x) 0]
[0 0 1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x) 0]
[1/2*(e^(2*x) - 1)*e^(-x) 0 0 1/2*(e^(2*x) + 1)*e^(-x)]
```

Another version:

```python
sage: m = identity_matrix(SR,Integer(4)); m = matrix(list(reversed(m.rows()))) * x
```

**expand()**

Operate point-wise on each element.

**EXAMPLES:**

```python
sage: M = matrix(2, 2, range(4)) - var('x')
sage: M*M
[x^2 + 2 -2*x + 3]
[-4*x + 6 (x - 3)^2 + 2]
sage: (M*M).expand()
[x^2 + 2 -2*x + 3]
[-4*x + 6 x^2 - 6*x + 11]
```
>>> from sage.all import *
>>> M = matrix(Integer(2), Integer(2), range(Integer(4))) - var('x')
>>> M*M
\[ x^2 + 2 -2*x + 3 \]
\[ -4*x + 6 (x - 3)^2 + 2 \]
>>> (M*M).expand()
\[ x^2 + 2 -2*x + 3 \]
\[ -4*x + 6 x^2 - 6*x + 11 \]

factor()

Operate point-wise on each element.

EXAMPLES:

sage: M = matrix(SR, 2, 2, x^2 - 2*x + 1); M
\[x^2 - 2*x + 1 0 \]
\[ 0 x^2 - 2*x + 1 \]
sage: M.factor()
\[(x - 1)^2 0 \]
\[ 0 (x - 1)^2 \]

fcp(var='x')

Return the factorization of the characteristic polynomial of self.

INPUT:

• var – (default: 'x') name of variable of charpoly

EXAMPLES:

sage: a = matrix(SR,[[1,2],[3,4]])
sage: a.fcp()
x^2 - 5*x - 2
sage: [i for i in a.fcp()]
[(x^2 - 5*x - 2, 1)]
sage: a = matrix(SR,[[1,0],[0,2]])
sage: a.fcp()
(x - 2) * (x - 1)
sage: [i for i in a.fcp()]
[(x - 2, 1), (x - 1, 1)]
sage: a = matrix(SR, 5, [1.5^2])
sage: a.fcp()
(x^2 - 65*x - 250) * x^3
sage: list(a.fcp())
[(x^2 - 65*x - 250, 1), (x, 3)]
function (*args)

Return a matrix over a callable symbolic expression ring.

EXAMPLES:

```python
sage: x, y = var('x, y')
sage: v = matrix([[x,y],[x*sin(y), 0]])
sage: w = v.function([x,y]); w
[  (x, y) |--> x          (x, y) |--> y]
[  (x, y) |--> x*sin(y)    (x, y) |--> 0]
sage: w.parent()
Full MatrixSpace of 2 by 2 dense matrices over Callable function ring with... arguments (x, y)
```

```python
>>> from sage.all import *

>>> x, y = var('x, y')

>>> v = matrix([[x,y],[x*sin(y), Integer(0)]])

```
EXAMPLES:

We start with some examples of diagonalisable matrices:

```python
sage: a, b, c, d = var('a, b, c, d')
sage: matrix([a]).jordan_form()
[a]
sage: matrix([[a, 0], [1, d]]).jordan_form(subdivide=True)
[d|0]  
[-+-]
[0|a]
sage: matrix([[a, 0], [1, d]]).jordan_form(subdivide=False)
[d 0]
[0 a]
sage: matrix([[a, x, x], [0, b, x], [0, 0, c]]).jordan_form()
[c|0 0]
[-+-]
[0|b 0]
[-+-]
[0|0 a]
```

In the following examples, we compute Jordan forms of some non-diagonalisable matrices:

```python
>>> from sage.all import *
>>> a, b, c, d = var('a, b, c, d')
>>> matrix([a]).jordan_form()
[a]
>>> matrix([[a, Integer(0)], [Integer(1), d]]).jordan_form(subdivide=True)
[d|0]  
[-+-]
[0|a]
>>> matrix([[a, Integer(0)], [Integer(1), d]]).jordan_form(subdivide=False)
[d 0]
[0 a]
```

(continues on next page)
The following examples illustrate the transformation flag. Note that symbolic expressions may need to be simplified to make consistency checks succeed:

```
sage: A = matrix([[x - a*c, a^2], [-c^2, x + a*c]])
sage: J, P = A.jordan_form(transformation=True)
sage: J, P
([x 1]     [-1*a*c 1]
[0 x], [-c^2 0])
sage: A1 = P * J * ~P; A1
([-1*a*c + x (a*c - x)*a/c + a*x/c]
[-c^2 0])
sage: A1.simplify_rational() == A
True

sage: B = matrix([[a, b, c], [0, a, d], [0, 0, a]])
sage: J, T = B.jordan_form(transformation=True)
sage: J, T
([a 1 0]     [b*d c 0]
[b 1 0]     [0 a 1]
[0 0 a], [0 0 1])
```
sage: matrix([[a, -b], [b, a]]).jordan_form()
\[
\begin{pmatrix}
a - I*b & 0 \\
\hline
0 | a + I*b
\end{pmatrix}
\]
sage: matrix([[a, b], [c, d]]).jordan_form(subdivide=False)
\[
\begin{pmatrix}
1/2*a + 1/2*d - 1/2*sqrt(a^2 + 4*b*c - 2*a*d + d^2) & \rightarrow 0 \\
\hline
0 & 1/2*a + 1/2*d + 1/
\end{pmatrix}
\rightarrow 2*sqrt(a^2 + 4*b*c - 2*a*d + d^2)
\]

>>> from sage.all import *

```python
>>> matrix([[a, -b], [b, a]]).jordan_form()
\[
\begin{pmatrix}
a - I*b & 0 \\
\hline
0 | a + I*b
\end{pmatrix}
\]
```

```python
>>> matrix([[a, b], [c, d]]).jordan_form(subdivide=False)
\[
\begin{pmatrix}
1/2*a + 1/2*d - 1/2*sqrt(a^2 + 4*b*c - 2*a*d + d^2) & \rightarrow 0 \\
\hline
0 & 1/2*a + 1/2*d + 1/
\end{pmatrix}
\rightarrow 2*sqrt(a^2 + 4*b*c - 2*a*d + d^2)
\]
```

minpoly (var='x')

Return the minimal polynomial of self.

**EXAMPLES:**

```python
sage: M = Matrix.identity(SR, 2)
sage: M.minpoly()
x - 1

sage: t = var('t')
sage: m = matrix(2, [1, 2, 4, t])
sage: m.minimal_polynomial()
x^2 + (-t - 1)*x + t - 8
```

```python
>>> from sage.all import *

>>> M = Matrix.identity(SR, Integer(2))

>>> M.minpoly()
x - 1

>>> t = var('t')

>>> m = matrix(Integer(2), [Integer(1), Integer(2), Integer(4), t])

>>> m.minimal_polynomial()
x^2 + (-t - 1)*x + t - 8
```

number_of_arguments()

Return the number of arguments that self can take.

**EXAMPLES:**

```python
sage: var('a,b,c,x,y')
\(a, b, c, x, y\)
sage: m = matrix([[a, (x+y)/(x+y)], [x^2, y^2+2]]); m
\[
\begin{pmatrix}
a & 1 \\
x^2 & y^2 + 2
\end{pmatrix}
\]
sage: m.number_of_arguments()
3
```
```python
>>> from sage.all import *
>>> var('a,b,c,x,y')
(a, b, c, x, y)
>>> m = matrix([[a, (x+y)/(x+y)], [x**Integer(2), y**Integer(2)+Integer(2)]]);
˓→ m
[ a 1
[ x^2 y^2 + 2
>>> m.number_of_arguments()
3
```

**simplify()**

Simplify self.

EXAMPLES:

```python
sage: var('x,y,z')
(x, y, z)
sage: m = matrix([[z, (x+y)/(x+y)], [x^2, y^2+2]]); m
[ z 1
[ x^2 y^2 + 2
sage: m.simplify()
[ z 1
[ x^2 y^2 + 2
```

```python
>>> from sage.all import *
>>> var('x,y,z')
(x, y, z)
>>> m = matrix([[z, (x+y)/(x+y)], [x**Integer(2), y**Integer(2)+Integer(2)]]);
˓→ m
[ z 1
[ x^2 y^2 + 2
```

**simplify_full()**

Simplify a symbolic matrix by calling `Expression.simplify_full()` componentwise.

INPUT:

- **self** – the matrix whose entries we should simplify.

OUTPUT:

A copy of `self` with all of its entries simplified.

EXAMPLES:

Symbolic matrices will have their entries simplified:

```python
sage: a,n,k = SR.var('a,n,k')
sage: f1 = sin(x)^2 + cos(x)^2
sage: f2 = sin(x/(x^2 + x))
sage: f3 = binomial(n,k)*factorial(k)*factorial(n-k)
sage: f4 = x*sin(2)/(x^a)
sage: A = matrix(SR, [[f1,f2],[f3,f4]])
sage: A.simplify_full()
[ 1 sin(1/(x + 1))
[ factorial(n) x^(-a + 1)*sin(2)]
```
from sage.all import *
a,n,k = SR.var('a,n,k')
f1 = sin(x)**Integer(2) + cos(x)**Integer(2)
f2 = sin(x/(x**Integer(2) + x))
f3 = binomial(n,k)*factorial(k)*factorial(n-k)
f4 = x*sin(Integer(2))/(x**a)
A = matrix(SR, [[f1,f2],[f3,f4]])
A.simplify_full()
[ 1 sin(1/(x + 1))]
[ factorial(n) x^(-a + 1)*sin(2)]
simplify_rational()

EXAMPLES:
sage: M = matrix(SR, 3, 3, range(9)) - var(t)
sage: (-M*M)[0,0]
t*(3*(2/t + (6/t + 7)/(t - 3/t - 4)*t))\frac{(2/t + (6/t + 5)/(t - 3/t - 4) + 1/t + 3/(t - 3/t - 4)*t^2) - 6*(2/t + (6/t + 5)/(t - 3/t - 4)*t)/((t - (6/t + 7)*(6/t + 5)/(t - 3/t - 4) - 4) - 12/t - 8) - 3*(6/t + 7)*(2/t + (6/t + 5)/(t - 3/t - 4)*t))/((t - (6/t + 7)*(6/t + 5)/(t - 3/t - 4) - 4) - 12/t - 8)*((t - 3/t - 4)) - 3/((t - 3/t - 4)*t)
sage: expand((-M*M)[0,0])
1
sage: (-M * M).simplify_rational()
[1 0 0]
[0 1 0]
[0 0 1]
simplify_trig()

EXAMPLES:
sage: theta = var('theta')
sage: M = matrix(SR, 2, 2, [cos(theta), sin(theta), -sin(theta), cos(theta)])
sage: ~M
\begin{bmatrix} 1/cos(theta) & -sin(theta)^2/(sin(theta)^2/cos(theta) + \infty) \\
-cos(theta)*cos(theta) & -sin(theta)/((sin(theta)^2/cos(theta) + \infty)
[ -cos(theta) + cos(theta)*cos(theta)]
[ sin(theta)/((sin(theta)^2/cos(theta) + \infty)
[ -cos(theta)*cos(theta))
1/

(continues on next page)
\[
\begin{pmatrix}
\cos(\theta) & \sin(\theta) \\
\sin(\theta) & \cos(\theta)
\end{pmatrix}
\]

```
sage: (sin(theta)^2/cos(theta) + cos(theta))
sage: (~M).simplify_trig()
[ cos(theta) -sin(theta)]
[ sin(theta)  cos(theta)]
```

```python
from sage.all import *

theta = var('theta')

M = matrix(SR, Integer(2), Integer(2), [cos(theta), sin(theta), -sin(theta), cos(theta)])

~M
[1/cos(theta) - sin(theta)^2/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta)^2) -sin(theta)/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta))]
[ sin(theta)/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta)) 1/(sin(theta)^2/cos(theta) + cos(theta))]
```

```
>>> from sage.all import *

>>> theta = var('theta')

>>> M = matrix(SR, Integer(2), Integer(2), [cos(theta), sin(theta), -sin(theta), cos(theta)])

>>> ~M

[ cos(theta) -sin(theta)]
[ sin(theta)  cos(theta)]
```

variables() method

Return the variables of self.

EXAMPLES:

```
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: m = matrix([[x, x+2], [x^2, x^2+2]]); m
[ x  x + 2]
[ x^2 x^2 + 2]
sage: m.variables()
(x,)
sage: m = matrix([[a, b+c], [x^2, y^2+2]]); m
[ a   b + c]
[ x^2 y^2 + 2]
sage: m.variables()
(a, b, c, x, y)
```

```python
from sage.all import *

>>> var('a,b,c,x,y')
(a, b, c, x, y)

>>> m = matrix([[x, x+Integer(2)], [x**Integer(2), -x**Integer(2)+Integer(2)]]); m
[ x  x + 2]
[ x^2 x^2 + 2]

>>> m.variables()
(x,)

>>> m = matrix([[a, b+c], [x**Integer(2), y**Integer(2)+Integer(2)]]); m
[ a   b + c]
[ x^2 y^2 + 2]

>>> m.variables()
(a, b, c, x, y)
```
### SYMBOLIC SPARSE MATRICES

#### EXAMPLES:

```python
sage: matrix(SR, 2, 2, range(4), sparse=True)
  [0 1]
  [2 3]
sage: matrix(SR, 2, 2, var('t'), sparse=True)
  [t 0]
  [0 t]

>>> from sage.all import *

>>> matrix(SR, Integer(2), Integer(2), range(Integer(4)), sparse=True)
  [0 1]
  [2 3]

>>> matrix(SR, Integer(2), Integer(2), var('t'), sparse=True)
  [t 0]
  [0 t]
```

#### Arithmetic:

```python
sage: -matrix(SR, 2, range(4), sparse=True)
  [ 0 -1]
  [-2 -3]
sage: m = matrix(SR, 2, [1..4], sparse=True); sqrt(2)*m
  [ sqrt(2) 2*sqrt(2)]
  [3*sqrt(2) 4*sqrt(2)]
sage: m = matrix(SR, 4, [1..4^2], sparse=True)

sage: m * m
  [ 90 100 110 120]
  [202 228 254 280]
  [314 356 398 440]
  [426 484 542 600]

sage: m = matrix(SR, 3, [1, 2, 3], sparse=True); m
  [1]
  [2]
  [3]
sage: m.transpose() * m
  [14]
```

```python
>>> from sage.all import *

>>> -matrix(SR, Integer(2), range(Integer(4)), sparse=True)
  [ 0 -1]
  [-2 -3]
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> m = matrix(SR, Integer(2), (ellipsis_range(Integer(1),Ellipsis,Integer(4))),
        sparse=True); sqrt(Integer(2))*m
[  sqrt(2) 2*sqrt(2)]
[3*sqrt(2) 4*sqrt(2)]

>>> m = matrix(SR, Integer(4), (ellipsis_range(Integer(1),Ellipsis,
        Integer(4)**Integer(2))), sparse=True)

>>> m * m
[ 90 100 110 120]
[202 228 254 280]
[314 356 398 440]
[426 484 542 600]

>>> m = matrix(SR, Integer(3), [Integer(1), Integer(2), Integer(3)], sparse=True); m
[1]
[2]
[3]

>>> m.transpose() * m
[14]
```

Computing inverses:

```python
sage: M = matrix(SR, 2, var('a,b,c,d'), sparse=True)
sage: ~M
[1/a - b*c/(a^2*(b*c/a - d)) b/(a*(b*c/a - d))]
[ c/(a*(b*c/a - d)) -1/(b*c/a - d)]

sage: (~M*M).simplify_rational()
[1 0]
[0 1]

sage: M = matrix(SR, 3, 3, range(9), sparse=True) - var('t')

sage: (~M * M).simplify_rational()
[1 0 0]
[0 1 0]
[0 0 1]
```

```
Traceback (most recent call last):
...
ArithmeticError: self must be a square matrix
```

```python
>>> from sage.all import *

>>> M = matrix(SR, Integer(2), var('a,b,c,d'), sparse=True)

>>> ~M
[1/a - b*c/(a^2*(b*c/a - d)) b/(a*(b*c/a - d))]
[ c/(a*(b*c/a - d)) -1/(b*c/a - d)]

>>> (~M*M).simplify_rational()
[1 0]
[0 1]

>>> M = matrix(SR, Integer(3), Integer(3), range(Integer(9)), sparse=True) - var('t')

ArithmeticError: self must be a square matrix

Transposition:

```python
sage: m = matrix(SR, 2, [sqrt(2), -1, pi, e^2], sparse=True)
sage: m.transpose()
[sqrt(2)  pi]
[-1    e^2]
```

. T is a convenient shortcut for the transpose:

```python
sage: m.T
[sqrt(2)  pi]
[-1    e^2]
```

Test pickling:

```python
sage: m = matrix(SR, 2, [sqrt(2), 3, pi, e], sparse=True); m
[sqrt(2)  3]
[  pi    e]
sage: TestSuite(m).run()
```

Comparison:

```python
sage: m = matrix(SR, 2, [sqrt(2), 3, pi, e], sparse=True)
sage: m == m
True
sage: m != 3
True
```
sage: m = matrix(SR, 2, [1..4], sparse=True); n = m^2
sage: (exp(m+n) - exp(m)*exp(n)).simplify_rational() == 0  # indirect test
True

>>> from sage.all import *
>>> m = matrix(SR, Integer(2), [sqrt(Integer(2)), Integer(3), pi, e], sparse=True)
>>> m == m
True

>>> m != Integer(3)
True

>>> m = matrix(SR, Integer(2), (ellipsis_range(Integer(1), Ellipsis, Integer(4))), sparse=True);
>>> n = m**Integer(2)
>>> (exp(m+n) - exp(m)*exp(n)).simplify_rational() == Integer(0)  # indirect test
True

Determinant:

sage: M = matrix(SR, 2, 2, [x,2,3,4], sparse=True)
sage: M.determinant()
4*x - 6

sage: M = matrix(SR, 3,3,range(9), sparse=True)
sage: M.det()
0

sage: t = var('t')
sage: M = matrix(SR, 2, 2, [cos(t), sin(t), -sin(t), cos(t)], sparse=True)
sage: M.det()
cos(t)^2 + sin(t)^2

sage: M = matrix([[sqrt(x),0,0,0], [0,1,0,0], [0,0,1,0], [0,0,0,1]], sparse=True)
sage: det(M)
sqrt(x)

Permanents:

sage: M = matrix(SR, 2, 2, [x,2,3,4], sparse=True)
sage: M.permanent()
4*x + 6
Matrices and Spaces of Matrices, Release 10.4

```python
>>> from sage.all import *

>>> M = matrix(SR, Integer(2), Integer(2), [x,Integer(2),Integer(3),Integer(4)], sparse=True)
>>> M.permanent()
4*x + 6
```

Rank:

```python
sage: M = matrix(SR, 5, 5, range(25), sparse=True)
sage: M.rank()
2
sage: M = matrix(SR, 5, 5, range(25), sparse=True) - var('t')
sage: M.rank()
5
```

.. warning::

   :meth:`rank` may return the wrong answer if it cannot determine that a matrix element that is equivalent to zero is indeed so.

```python
>>> from sage.all import *

>>> M = matrix(SR, Integer(5), Integer(5), range(Integer(25)), sparse=True)

>>> M.rank()
2

>>> M = matrix(SR, Integer(5), Integer(5), range(Integer(25)), sparse=True) - var('t')

>>> M.rank()
5
```

.. warning::

   :meth:`rank` may return the wrong answer if it cannot determine that a matrix element that is equivalent to zero is indeed so.

Copying symbolic matrices:

```python
sage: m = matrix(SR, 2, [sqrt(2), 3, pi, e], sparse=True)
sage: n = copy(m)
sage: n[0,0] = sin(1)
sage: m
[ sqrt(2)  3]
[   pi   e]

sage: n
[ sin(1)  3]
[   pi   e]
```

```python
>>> from sage.all import *

>>> m = matrix(SR, Integer(2), [sqrt(Integer(2)), Integer(3), pi, e], sparse=True)

>>> n = copy(m)

>>> n[Integer(0),Integer(0)] = sin(Integer(1))

>>> m
[ sqrt(2)  3]
[   pi   e]

>>> n
[ sin(1)  3]
[   pi   e]
```

Conversion to Maxima:
Matrices and Spaces of Matrices, Release 10.4

```python
sage: m = matrix(SR, 2, [sqrt(2), 3, pi, e], sparse=True)
sage: m._maxima_()
matrix([sqrt(2), 3], [%pi, %e])
```

```python
>>> from sage.all import *

>>> m = matrix(SR, Integer(2), [sqrt(Integer(2)), Integer(3), pi, e], sparse=True)

>>> m._maxima_()
matrix([sqrt(2), 3], [%pi, %e])
```

```python
class sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse
    Bases: Matrix_generic_sparse

    arguments()

    Return a tuple of the arguments that self can take.

    EXAMPLES:

    sage: var('x,y,z')
    (x, y, z)
    sage: M = MatrixSpace(SR, 2, 2, sparse=True)
    sage: M(x).arguments()
    (x,
    sage: M(x+sin(x)).arguments()
    (x,

    >>> from sage.all import *
    >>> var('x,y,z')
    (x, y, z)
    >>> M = MatrixSpace(SR, Integer(2), Integer(2), sparse=True)
    >>> M(x).arguments()
    (x,
    >>> M(x+sin(x)).arguments()
    (x,
```

```python
canonicalize_radical()

    Choose a canonical branch of each entry of self by calling Expression.
    canonicalize_radical() componentwise.

    EXAMPLES:

    sage: var('x','y')
    (x, y)
    sage: l1 = [sqrt(2)*sqrt(3)*sqrt(6) , log(x*y)]
    sage: l2 = [sin(x/(x^2 + x)) , 1]
    sage: m = matrix([l1, l2], sparse=True)
    sage: m
    [sqrt(6)*sqrt(3)*sqrt(2) log(x*y)]
    [ sin(x/(x^2 + x)) 1]
    sage: m.canonicalize_radical()
    [ 6 log(x) + log(y)]
    [ sin(1/(x + 1)) 1]
    >>> from sage.all import *
    >>> var('x','y')
    (x, y)
    >>> l1 = [sqrt(Integer(2))*sqrt(Integer(3))*sqrt(Integer(6)) , log(x*y)]
```

(continues on next page)
>>> l2 = [sin(x/(x^2 + x)), Integer(1)]
>>> m = matrix([l1, l2], sparse=True)
>>> m

<table>
<thead>
<tr>
<th>sqrt(6)*sqrt(3)<em>sqrt(2) log(x</em>y)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sin(x/(x^2 + x)) 1</td>
</tr>
</tbody>
</table>

>>> m.canonicalize_radical()

<table>
<thead>
<tr>
<th>6 log(x) + log(y)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sin(1/(x + 1)) 1</td>
</tr>
</tbody>
</table>

`charpoly` *(var='x', algorithm=None)*

Compute the characteristic polynomial of `self`, using maxima.

**Note:** The characteristic polynomial is defined as \( \det(xI - A) \).

**INPUT:**

* var – (default: 'x') name of variable of charpoly

**EXAMPLES:**

```
sage: M = matrix(SR, 2, 2, var('a,b,c,d'), sparse=True)
sage: M.charpoly(t)
t^2 + (-a - d)*t - b*c + a*d
```

```
sage: matrix(SR, 5, [1..5^2], sparse=True).charpoly()
x^5 - 65*x^4 - 250*x^3
```

```from sage.all import * ```

```
>>> from sage.all import *
```  

```
>>> M = matrix(SR, [Integer(1),Integer(2)], [Integer(3),Integer(4)], sparse=True)
>>> M.eigenvalues()
[-1/2*sqrt(33) + 5/2, 1/2*sqrt(33) + 5/2]
```

`echelonize(**kwds)`

Echelonize using the classical algorithm.

`eigenvalues`(extend=True)

Compute the eigenvalues by solving the characteristic polynomial in maxima.

The argument `extend` is ignored but kept for compatibility with other matrix classes.

**EXAMPLES:**

```
sage: a=matrix(SR,[[1,2],[3,4]], sparse=True)
sage: a.eigenvalues()
[-1/2*sqrt(33) + 5/2, 1/2*sqrt(33) + 5/2]
```

```from sage.all import * ```

```
>>> from sage.all import *
```  

```
>>> a=matrix(SR, [[Integer(1),Integer(2)],[Integer(3),Integer(4)]],...
             sparse=True)
```  

```
>>> a.eigenvalues()
[-1/2*sqrt(33) + 5/2, 1/2*sqrt(33) + 5/2]
```
**eigenvectors_left** *(other=None)*

Compute the left eigenvectors of a matrix.

**INPUT:**

- `other` – a square matrix \( B \) (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved (currently supported only if the base ring of `self` is RDF or CDF)

**OUTPUT:**

For each distinct eigenvalue, returns a list of the form \((e,V,n)\) where \(e\) is the eigenvalue, \(V\) is a list of eigenvectors forming a basis for the corresponding left eigenspace, and \(n\) is the algebraic multiplicity of the eigenvalue.

**EXAMPLES:**

```python
sage: A = matrix(SR,3,3,range(9), sparse=True); A
[0 1 2]
[3 4 5]
[6 7 8]
sage: es = A.eigenvectors_left(); es
[(-3*sqrt(6) + 6, [(1, -1/5*sqrt(6) + 4/5, -2/5*sqrt(6) + 3/5)], 1),
 (3*sqrt(6) + 6, [(1, 1/5*sqrt(6) + 4/5, 2/5*sqrt(6) + 3/5)], 1),
 (0, [(1, -2, 1)], 1)]
sage: eval, [evec], mult = es[0]
sage: delta = eval*evec - evec*A
sage: abs(abs(delta)) < 1e-10
3/5*sqrt(((2*sqrt(6) - 3)*(sqrt(6) - 2) + 7*sqrt(6) - 18)^2 + ((sqrt(6) - 2)*(sqrt(6) - 4) + 6*sqrt(6) - 14)^2) < (1.00000000000000e-10)
sage: abs(abs(delta)).n() < 1e-10
True
```

```python
>>> from sage.all import *
>>> A = matrix(SR,Integer(3),Integer(3),range(Integer(9)), sparse=True); A
[0 1 2]
[3 4 5]
[6 7 8]
>>> es = A.eigenvectors_left(); es
[(-3*sqrt(6) + 6, [(1, -1/5*sqrt(6) + 4/5, -2/5*sqrt(6) + 3/5)], 1),
 (3*sqrt(6) + 6, [(1, 1/5*sqrt(6) + 4/5, 2/5*sqrt(6) + 3/5)], 1),
 (0, [(1, -2, 1)], 1)]
>>> eval, [evec], mult = es[Integer(0)]
>>> delta = eval*evec - evec*A
>>> abs(abs(delta)) < RealNumber('1e-10')
3/5*sqrt(((2*sqrt(6) - 3)*(sqrt(6) - 2) + 7*sqrt(6) - 18)^2 + ((sqrt(6) - 2)*(sqrt(6) - 4) + 6*sqrt(6) - 14)^2) < (1.00000000000000e-10)
>>> abs(abs(delta)).n() < RealNumber('1e-10')
True
```

```python
sage: A = matrix(SR, 2, 2, var('a,b,c,d'), sparse=True)
sage: A.eigenvectors_left()
[(1/2*a + 1/2*d + 1/2*sqrt(-a^2 + 2*a*d + d^2) + 1/2*sqrt(a^2 + 2*a*d + d^2)),
 ((1, -1/2*(a - d + sqrt(a^2 + 2*a*d + d^2)))/c)],
 (1/2*a + 1/2*d - 1/2*sqrt(-a^2 + 2*a*d + d^2)),
 ((1, -1/2*(a - d - sqrt(a^2 + 2*a*d + d^2)))/c)],
 (1/2*a + 1/2*d),
 ((1, -1/2*(a - d + sqrt(a^2 + 2*a*d + d^2)))/c)]
```

```python
sage: es = A.eigenvectors_left(); es
[(1/2*a + 1/2*d + 1/2*sqrt(-a^2 + 2*a*d + d^2) + 1/2*sqrt(a^2 + 2*a*d + d^2)),
 ((1, -1/2*(a - d + sqrt(a^2 + 2*a*d + d^2)))/c)],
 (1/2*a + 1/2*d - 1/2*sqrt(a^2 + 2*a*d + d^2)),
 ((1, -1/2*(a - d - sqrt(a^2 + 2*a*d + d^2)))/c)],
 (1/2*a + 1/2*d),
 ((1, -1/2*(a - d + sqrt(a^2 + 2*a*d + d^2)))/c)]
```

(continues on next page)
This routine calls Maxima and can struggle with even small matrices with a few variables, such as a $3 \times 3$ matrix with three variables. However, if the entries are integers or rationals it can produce exact values in a reasonable time. These examples create 0-1 matrices from the adjacency matrices of graphs and illustrate how the format and type of the results differ when the base ring changes. First for matrices over the rational numbers, then the same matrix but viewed as a symbolic matrix.

This routine calls Maxima and can struggle with even small matrices with a few variables, such as a $3 \times 3$ matrix with three variables. However, if the entries are integers or rationals it can produce exact values in a reasonable time. These examples create 0-1 matrices from the adjacency matrices of graphs and illustrate how the format and type of the results differ when the base ring changes. First for matrices over the rational numbers, then the same matrix but viewed as a symbolic matrix.
0.618033988749895?

```python
>>> am = G.adjacency_matrix(sparse=True).change_ring(SR)
>>> spectrum = am.eigenvectors_left()
>>> symbolic_evalue = spectrum[Integer(2)][Integer(0)]
>>> type(symbolic_evalue)
<class 'sage.symbolic.expression.Expression'>
>>> symbolic_evalue
1/2*sqrt(5) - 1/2
>>> bool(qqbar_evalue == symbolic_evalue)
True
```

A slightly larger matrix with a "nice" spectrum.

```python
sage: G = graphs.CycleGraph(6)
sage: am = G.adjacency_matrix(sparse=True).change_ring(SR)
sage: am.eigenvectors_left()
[(-1, [(1, 0, -1, 1, 0, -1), (0, 1, -1, 0, 1, -1)], 2),
 (1, [(1, 0, -1, -1, 0, 1), (0, 1, 1, 0, -1, -1)], 2),
 (-2, [(1, -1, 1, -1, 1, -1)], 1),
 (2, [(1, 1, 1, 1, 1)], 1)]
```

**eigenvectors_right**(other=None)

Compute the right eigenvectors of a matrix.

**INPUT:**

- other – a square matrix $B$ (default: None) in a generalized eigenvalue problem; if None, an ordinary eigenvalue problem is solved (currently supported only if the base ring of self is RDF or CDF)

**OUTPUT:**

For each distinct eigenvalue, returns a list of the form $(e, V, n)$ where $e$ is the eigenvalue, $V$ is a list of eigenvectors forming a basis for the corresponding right eigenspace, and $n$ is the algebraic multiplicity of the eigenvalue.

**EXAMPLES:**

```python
sage: A = matrix(SR,2,2,range(4), sparse=True); A
[0 1]
[2 3]
sage: right = A.eigenvectors_right(); right
[(-1/2*sqrt(17) + 3/2, [(1, -1/2*sqrt(17) + 3/2)], 1),
 (1/2*sqrt(17) + 3/2, [(1, 1/2*sqrt(17) + 3/2)], 1)]
```
The right eigenvectors are nothing but the left eigenvectors of the transpose matrix:

```python
sage: left = A.transpose().eigenvectors_left(); left
[((-1/2*sqrt(17) + 3/2, [(1, -1/2*sqrt(17) + 3/2)], 1), (1/2*sqrt(17) + 3/2, [(1, 1/2*sqrt(17) + 3/2)], 1))]
sage: right[0][1] == left[0][1]
True
```

**exp()**

Return the matrix exponential of this matrix \(X\), which is the matrix

\[
e^X = \sum_{k=0}^{\infty} \frac{X^k}{k!}.
\]

This function depends on maxima's matrix exponentiation function, which does not deal well with floating point numbers. If the matrix has floating point numbers, they will be rounded automatically to rational numbers during the computation.

**EXAMPLES:**

```python
sage: m = matrix(SR,2, [0,x,x,0], sparse=True); m
[0 x]
[x 0]
sage: m.exp()
[1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x)]
[1/2*(e^(2*x) - 1)*e^(-x) 1/2*(e^(2*x) + 1)*e^(-x)]

sage: exp(m)
[1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x)]
[1/2*(e^(2*x) - 1)*e^(-x) 1/2*(e^(2*x) + 1)*e^(-x)]
```

Exponentiation works on 0x0 and 1x1 matrices, but the 1x1 example requires a patched version of maxima (Issue #32898) for now:
Commuting matrices $m, n$ have the property that $e^{m+n} = e^m e^n$ (but non-commuting matrices need not):

```
sage: m = matrix(SR, 2, [1..4], sparse=True); n = m^2
sage: m*n
[ 37  54]
[ 81 118]
sage: n*m
[ 37  54]
[ 81 118]
sage: a = exp(m+n) - exp(m)*exp(n)
sage: a.simplify_rational() == 0
True
```

The input matrix must be square:

```
sage: m = matrix(SR, 2, 3, [1..6], sparse=True); exp(m)
Traceback (most recent call last):
...
ValueError: exp only defined on square matrices
```

```
In this example we take the symbolic answer and make it numerical at the end:

```
sage: exp(matrix(SR, [[1.2, 5.6], [3,4]], sparse=True)).change_ring(RDF) # rel tol 1e-15
[ 346.5574872980695 661.734590344504]
[354.50067371488416 677.4247827652946]
```

Another example involving the reversed identity matrix, which we clumsily create:

```
sage: m = identity_matrix(SR,4, sparse=True)
sage: m = matrix(list(reversed(m.rows())), sparse=True) * x
sage: exp(m)
[1/2*(e^(2*x) + 1)*e^(-x) 0 0 1/2*(e^(2*x) - 1)*e^(-x)]
[0 1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x) 0]
[0 0 1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x) 0]
[1/2*(e^(2*x) - 1)*e^(-x) 0 0 1/2*(e^(2*x) + 1)*e^(-x)]
```

```
>>> from sage.all import *

>>> m = identity_matrix(SR,Integer(4), sparse=True)
>>> m = matrix(list(reversed(m.rows())), sparse=True) * x
>>> exp(m)
[1/2*(e^(2*x) + 1)*e^(-x) 0 0 1/2*(e^(2*x) - 1)*e^(-x)]
[0 1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x) 0]
[0 0 1/2*(e^(2*x) + 1)*e^(-x) 1/2*(e^(2*x) - 1)*e^(-x) 0]
[1/2*(e^(2*x) - 1)*e^(-x) 0 0 1/2*(e^(2*x) + 1)*e^(-x)]
```

```
expand()

Operate point-wise on each element.

EXAMPLES:

```
sage: M = matrix(2, 2, range(4)) - var('x')
sage: M*M
[x^2 + 2 -2*x + 3]
[-4*x + 6 (x - 3)^2 + 2]
sage: (M*M).expand()
```

(continues on next page)
\[
\begin{bmatrix}
  x^2 + 2 & -2x + 3 \\
  -4x + 6 & x^2 - 6x + 11
\end{bmatrix}
\]

>>> from sage.all import *

>>> M = matrix(Integer(2), Integer(2), range(Integer(4))) - var('x')

>>> M*M
\[
\begin{bmatrix}
  x^2 + 2 & -2x + 3 \\
  -4x + 6 & (x - 3)^2 + 2
\end{bmatrix}
\]

>>> (M*M).expand()
\[
\begin{bmatrix}
  x^2 + 2 & -2x + 3 \\
  -4x + 6 & x^2 - 6x + 11
\end{bmatrix}
\]

factor()
Operate point-wise on each element.

EXAMPLES:

sage: M = matrix(SR, 2, 2, x^2 - 2*x + 1, sparse=True); M
\[
\begin{bmatrix}
  x^2 - 2x + 1 & 0 \\
  0 & x^2 - 2x + 1
\end{bmatrix}
\]
sage: M.factor()
\[
\begin{bmatrix}
  (x - 1)^2 & 0 \\
  0 & (x - 1)^2
\end{bmatrix}
\]

fcp(var='x')
Return the factorization of the characteristic polynomial of self.

INPUT:

- var – (default: 'x') name of variable of charpoly

EXAMPLES:

sage: a = matrix(SR, [[1,2],[3,4]], sparse=True)
sage: a.fcp()
x^2 - 5x - 2
sage: [i for i in a.fcp()]
[(x^2 - 5*x - 2, 1)]
sage: a = matrix(SR, [[1,0],[0,2]], sparse=True)
sage: a.fcp()
(x - 2) * (x - 1)
sage: [i for i in a.fcp()]
[(x - 2, 1), (x - 1, 1)]
sage: a = matrix(SR, 5, [1..5^2], sparse=True)
sage: a.fcp()
(x^2 - 65*x - 250) * x^3
sage: list(a.fcp())
[(x^2 - 65*x - 250, 1), (x, 3)]
```python
>>> from sage.all import *
>>> a = matrix(SR,[[Integer(1),Integer(2)], [Integer(3),Integer(4)]],
         sparse=True)
>>> a.fcp()
x^2 - 5*x - 2
>>> [i for i in a.fcp()]
[(x^2 - 5*x - 2, 1)]
>>> a = matrix(SR,[[Integer(1),Integer(0)], [Integer(0),Integer(2)]],
         sparse=True)
>>> a.fcp()
(x - 2) * (x - 1)
>>> [i for i in a.fcp()]
[(x - 2, 1), (x - 1, 1)]
>>> a = matrix(SR, Integer(5), (ellipsis_range(Integer(1),Ellipsis,
         Integer(5)**Integer(2))), sparse=True)
>>> a.fcp()
(x^2 - 65*x - 250) * x^3
>>> list(a.fcp())
[(x^2 - 65*x - 250, 1), (x, 3)]

function (*args)

Return a matrix over a callable symbolic expression ring.

EXAMPLES:

```python
sage: x, y = var('x,y')
sage: v = matrix([[x,y],[x*sin(y), 0]], sparse=True)
sage: w = v.function([x,y]); w
(x, y) |--> x
(x, y) |--> y
[(x, y) |--> x*sin(y) (x, y) |--> 0]
sage: w.parent()
Full MatrixSpace of 2 by 2 sparse matrices over Callable function ring with...
       arguments (x, y)
```

```python
>>> from sage.all import *

>>> x, y = var('x,y')

>>> v = matrix([[x,y],[x*sin(y), Integer(0)]], sparse=True)

>>> w = v.function([x,y]); w
(x, y) |--> x
(x, y) |--> y
[(x, y) |--> x*sin(y) (x, y) |--> 0]

>>> w.parent()
Full MatrixSpace of 2 by 2 sparse matrices over Callable function ring with...
       arguments (x, y)
```

jordan_form (subdivide=True, transformation=False)

Return a Jordan normal form of self.

INPUT:

- `self` - a square matrix
- `subdivide` - boolean (default: True)
- `transformation` - boolean (default: False)

OUTPUT:

If transformation is False, only a Jordan normal form (unique up to the ordering of the Jordan blocks) is returned. Otherwise, a pair \((J, P)\) is returned, where \(J\) is a Jordan normal form and \(P\) is an invertible matrix such that \(self = P \cdot J \cdot P^{-1}\).
If `subdivide` is `True`, the Jordan blocks in the returned matrix $J$ are indicated by a subdivision in the sense of `subdivide()`.

**EXAMPLES:**

We start with some examples of diagonalisable matrices:

```python
sage: a, b, c, d = var('a, b, c, d')

sage: matrix([a], sparse=True).jordan_form()
[a]

sage: matrix([[a, 0], [1, d]], sparse=True).jordan_form(subdivide=True)
[d|0]

sage: matrix([[a, 0], [1, d]], sparse=True).jordan_form(subdivide=False)
[d 0]

sage: matrix([[a, x, x], [0, b, x], [0, 0, c]], sparse=True).jordan_form()
[c|0|0]
[---|--]
[0|b|0]
[---|--]
[0|0|a]
```

```python
>>> from sage.all import *

>>> a, b, c, d = var('a, b, c, d')

>>> matrix([a], sparse=True).jordan_form()
[a]

>>> matrix([[a, Integer(0)], [Integer(1), d]], sparse=True).jordan_form(subdivide=True)
[d|0]

>>> matrix([[a, Integer(0)], [Integer(1), d]], sparse=True).jordan_form(subdivide=False)
[d 0]

>>> matrix([[a, x, x], [Integer(0), b, x], [Integer(0), Integer(0), c]], sparse=True).jordan_form()
[c|0|0]
[---|--]
[0|b|0]
[---|--]
[0|0|a]
```

In the following examples, we compute Jordan forms of some non-diagonalisable matrices:

```python
sage: matrix([[a, a], [0, a]], sparse=True).jordan_form()
[a 1]
[0 a]

sage: matrix([[a, 0, b], [0, c, 0], [0, 0, a]], sparse=True).jordan_form()
[c|0|0]
[---|--]
[0|b|0]
[---|--]
[0|0|a]
```

```python
>>> from sage.all import *

>>> matrix([[a, a], [Integer(0), a]], sparse=True).jordan_form()
```

(continues on next page)
The following examples illustrate the transformation flag. Note that symbolic expressions may need to be simplified to make consistency checks succeed:

```python
sage: A = matrix([[x - a*c, a^2], [-c^2, x + a*c]], sparse=True)
sage: J, P = A.jordan_form(transformation=True)
sage: J, P
([x 1] [-a*c 1]
[0 x], [-c^2 0])
sage: A1 = P * J * ~P; A1
[-a*c + x (a*c - x)*a/c + a*x/c]
[-c^2 a*c + x]
sage: A1.simplify_rational() == A
True

sage: B = matrix([[a, b, c], [0, a, d], [0, 0, a]], sparse=True)
sage: J, T = B.jordan_form(transformation=True)
sage: J, T
([a 1 0] [b*d c 0]
[b 1 0] [0 1 0])
```

(continues on next page)
Finally, some examples involving square roots:

```python
sage: matrix([[a, -b], [b, a]], sparse=True).jordan_form()
[a - I*b | 0]
[-------+-------]
[ 0|a + I*b]

sage: matrix([[a, b], [c, d]], sparse=True).jordan_form(subdivide=False)
[1/2*a + 1/2*d - 1/2*sqrt(a^2 + 4*b*c - 2*a*d + d^2) 0]
[0 1/2*a + 1/2*d + 1/2*sqrt(a^2 + 4*b*c - 2*a*d + d^2)]
```

```python
>>> from sage.all import *

>>> matrix([[a, -b], [b, a]], sparse=True).jordan_form()
[a - I*b | 0]
[-------+-------]
[ 0|a + I*b]

>>> matrix([[a, b], [c, d]], sparse=True).jordan_form(subdivide=False)
[1/2*a + 1/2*d - 1/2*sqrt(a^2 + 4*b*c - 2*a*d + d^2) 0]
[0 1/2*a + 1/2*d + 1/2*sqrt(a^2 + 4*b*c - 2*a*d + d^2)]
```

**minpoly** *(var='x')*

Return the minimal polynomial of self.

**EXAMPLES:**

```python
sage: M = Matrix.identity(SR, 2, sparse=True)
sage: M.minpoly()
x - 1

sage: t = var('t')
sage: m = matrix(2, [1, 2, 4, t], sparse=True)
sage: m.minimal_polynomial()
x^2 + (-t - 1)*x + t - 8
```

```python
>>> from sage.all import *

>>> M = Matrix.identity(SR, Integer(2), sparse=True)

>>> M.minpoly()
x - 1

>>> t = var('t')

>>> m = matrix(Integer(2), [Integer(1), Integer(2), Integer(4), t],
...             sparse=True)

>>> m.minimal_polynomial()
x^2 + (-t - 1)*x + t - 8
```

**number_of_arguments** ()
Return the number of arguments that self can take.

EXAMPLES:

```python
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: m = matrix([[a, (x+y)/(x+y)], [x^2, y^2+2]], sparse=True); m
[    a     1]
[  x^2 y^2 + 2]
sage: m.number_of_arguments()
3
```

```python
>>> from sage.all import *

>>> var('a,b,c,x,y')
(a, b, c, x, y)

>>> m = matrix([[a, (x+y)/(x+y)], [x**Integer(2), y**Integer(2)+Integer(2)],...
˓→sparse=True); m
[    a     1]
[  x^2 y^2 + 2]

>>> m.number_of_arguments()
3
```

**simplify()**

Simplify self.

EXAMPLES:

```python
sage: var('x,y,z')
(x, y, z)
sage: m = matrix([[z, (x+y)/(x+y)], [x^2, y^2+2]], sparse=True); m
[    z     1]
[  x^2 y^2 + 2]
sage: m.simplify()
[    z     1]
[  x^2 y^2 + 2]
```

```python
>>> from sage.all import *

>>> var('x,y,z')
(x, y, z)

>>> m = matrix([[z, (x+y)/(x+y)], [x**Integer(2), y**Integer(2)+Integer(2)],...
˓→sparse=True); m
[    z     1]
[  x^2 y^2 + 2]

>>> m.simplify()
[    z     1]
[  x^2 y^2 + 2]
```

**simplify_full()**

Simplify a symbolic matrix by calling `Expression.simplify_full()` componentwise.

INPUT:

- *self* – the matrix whose entries we should simplify.

OUTPUT:

A copy of *self* with all of its entries simplified.

EXAMPLES:
Symbolic matrices will have their entries simplified:

\begin{verbatim}
 sage: a,n,k = SR.var('a,n,k')
sage: f1 = sin(x)**2 + cos(x)**2
sage: f2 = sin(x)/(x**2 + x)
sage: f3 = binomial(n,k)*factorial(k)*factorial(n-k)
sage: f4 = x*sin(2)/(x^a)
sage: A = matrix(SR, [[f1,f2],[f3,f4]], sparse=True)
sage: A.simplify_full()
[ 1 sin(1/(x + 1))]
[ factorial(n) x^(-a + 1)*sin(2)]
\end{verbatim}

```python
>>> from sage.all import *
>>> a,n,k = SR.var('a,n,k')
>>> f1 = sin(x)**Integer(2) + cos(x)**Integer(2)
>>> f2 = sin(x/(x**Integer(2) + x))
>>> f3 = binomial(n,k)*factorial(k)*factorial(n-k)
>>> f4 = x*sin(Integer(2))/(x**a)
>>> A = matrix(SR, [[f1,f2],[f3,f4]], sparse=True)
>>> A.simplify_full()
[ 1 sin(1/(x + 1))]
[ factorial(n) x^(-a + 1)*sin(2)]
```

`simplify_rational()`

**EXAMPLES:**

```python
sage: M = matrix(SR, 3, 3, range(9), sparse=True) - var('t')
sage: (~M*M)[0,0]
t*(3*(2/t + (6/t + 7)/((t - 3/t - 4)*t))*(2/t + (6/t + 5)/((t - 3/t - 4)*t)) + 6*(2/t + (6/t + 5)/((t - 3/t - 4)*t))/(t - (6/t + 7)*(6/t + 5)/(t - 3/t - 4) - 12/t - 8) - 36*(6/t + 7)/(t - 3/t - 4)*t)
sage: expand((~M*M)[0,0])
1
sage: (~M * M).simplify_rational()
\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}
```

```python
>>> from sage.all import *
>>> M = matrix(SR, Integer(3), Integer(3), range(Integer(9)), sparse=True) - var('t')
>>> (~M*M)[Integer(0),Integer(0)]
t*(3*(2/t + (6/t + 7)/((t - 3/t - 4)*t))*(2/t + (6/t + 5)/((t - 3/t - 4)*t)) + 6*(2/t + (6/t + 5)/((t - 3/t - 4)*t))/(t - (6/t + 7)*(6/t + 5)/(t - 3/t - 4) - 12/t - 8) - 36*(6/t + 7)/(t - 3/t - 4)*t)
>>> expand((~M*M)[Integer(0),Integer(0)])
1
>>> (~M * M).simplify_rational()
\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}
```
simplify_trig()

EXAMPLES:

```
sage: theta = var('theta')
sage: M = matrix(SR, 2, 2, [cos(theta), sin(theta), -sin(theta), cos(theta)], sparse=True)
sage: ~M
[1/cos(theta) - sin(theta)^2/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta)^2) -sin(theta)/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta))]
[ sin(theta)/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta)) 1/
[ (sin(theta)^2/cos(theta) + cos(theta))

>>> from sage.all import *
>>>
>>> theta = var('theta')
>>>
>>> M = matrix(SR, Integer(2), Integer(2), [cos(theta), sin(theta), -sin(theta), cos(theta)], sparse=True)
>>>
>>> ~M
[1/cos(theta) - sin(theta)^2/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta)^2) -sin(theta)/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta))]
[ sin(theta)/((sin(theta)^2/cos(theta) + cos(theta))*cos(theta)) 1/
[ (sin(theta)^2/cos(theta) + cos(theta))

>>> (-M).simplify_trig()
[ cos(theta) -sin(theta)]
[ sin(theta) cos(theta)]```

variables()

Return the variables of self.

EXAMPLES:

```
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: m = matrix([[x, x+2], [x^2, x^2+2]], sparse=True); m
[ x x + 2]
[ x^2 x^2 + 2]
sage: m.variables()
(x,)
sage: m = matrix([[a, b+c], [x^2, y^2+2]], sparse=True); m
[ a b + c]
[ x^2 y^2 + 2]
sage: m.variables()
(a, b, c, x, y)

>>> from sage.all import *
>>> var('a,b,c,x,y')
(a, b, c, x, y)
>>> m = matrix([[x, x+Integer(2)], [x**Integer(2), x**Integer(2)+Integer(2)]], sparse=True); m
[ x x + 2]
[ x^2 x^2 + 2]
```

(continues on next page)
>>> m.variables()
(x,)

>>> m = matrix([[a, b+c], [x**Integer(2), y**Integer(2)+Integer(2)]],
             sparse=True); m
[    a   b + c]
[  x^2 y^2 + 2]

>>> m.variables()
(a, b, c, x, y)
DENSE MATRICES OVER THE COMPLEX DOUBLE FIELD USING NUMPY

EXAMPLES:

```python
sage: b = Mat(CDF,2,3).basis()
sage: b[0,0]
[1.0 0.0 0.0]
[0.0 0.0 0.0]

>>> from sage.all import *

>>> b = Mat(CDF,Integer(2),Integer(3)).basis()

>>> b[Integer(0),Integer(0)]
[1.0 0.0 0.0]
[0.0 0.0 0.0]
```

We deal with the case of zero rows or zero columns:

```python
sage: m = MatrixSpace(CDF,0,3)
sage: m.zero_matrix()
[]

>>> from sage.all import *

>>> m = MatrixSpace(CDF,Integer(0),Integer(3))

>>> m.zero_matrix()
[]
```

AUTHORS:

- Jason Grout (2008-09): switch to NumPy backend
- Josh Kantor
- William Stein: many bug fixes and touch ups.

```python
class sage.matrix.matrix_complex_double_dense.Matrix_complex_double_dense
    Bases: Matrix_double_dense

Class that implements matrices over the real double field. These are supposed to be fast matrix operations using C doubles. Most operations are implemented using numpy which will call the underlying BLAS on the system.
```

EXAMPLES:

```python
sage: # needs sage.symbolic
sage: m = Matrix(CDF, [[1,2*I],[3+I,4]])
sage: m**2
```
(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

[[-1.0 + 6.0*I 10.0*I]
 [15.0 + 5.0*I 14.0 + 6.0*I]

sage: n = m^(-1); n
# abs tol 1e-15
 [ 0.3333333333333333 + 0.3333333333333333*I 0.16666666666666669 - 0.
 →16666666666666666*I]
[-0.16666666666666666 - 0.3333333333333333*I 0.08333333333333331 + 0.
 →08333333333333333*I]

>>> from sage.all import *

>>> m = Matrix(CDF, [[Integer(1),Integer(2)*I],[Integer(3)+I,Integer(4)]])

>>> m**Integer(2)
[-1.0 + 6.0*I 10.0*I]
[15.0 + 5.0*I 14.0 + 6.0*I]

>>> n = m**(-Integer(1)); n
# abs tol 1e-15
 [ 0.3333333333333333 + 0.3333333333333333*I 0.16666666666666669 - 0.
 →16666666666666666*I]
[-0.16666666666666666 - 0.3333333333333333*I 0.08333333333333331 + 0.
 →08333333333333333*I]

To compute eigenvalues, use the methods `left_eigenvectors()` or `right_eigenvectors()`:

sage: p, e = m.right_eigenvectors()
# needs sage.symbolic

>>> from sage.all import *

>>> p, e = m.right_eigenvectors()
# needs sage.symbolic

The result is a pair \((p, e)\), where \(p\) is a diagonal matrix of eigenvalues and \(e\) is a matrix whose columns are the eigenvectors.

To solve a linear system \(Ax = b\) where \(A = [[1, 2*I], [3+I, 4]]\) and \(b = [5, 6]\):

sage: b = vector(CDF, [5, 6])
# needs sage.symbolic

sage: m.solve_right(b)  # abs tol 1e-14
# needs sage.symbolic
(2.6666666666666665 + 0.6666666666666669*I, -0.33333333333333333 - 1.
 →16666666666666667*I)

See the methods `QR()`, `LU()`, and `SVD()` for QR, LU, and singular value decomposition.
ARBITRARY PRECISION COMPLEX BALL MATRICES

AUTHORS:

This is an incomplete interface to the acb_mat module of FLINT; it may be useful to refer to its documentation for more details.

```python
class sage.matrix.matrix_complex_ball_dense.Matrix_complex_ball_dense
    Bases: Matrix_dense

    Matrix over a complex ball field. Implemented using the acb_mat type of the FLINT library.

    EXAMPLES:

    sage: MatrixSpace(CBF, 3)(2)
    [2.000000000000000 0 0]
    [ 0 2.000000000000000 0]
    [ 0 0 2.000000000000000]
    sage: matrix(CBF, 1, 3, [1, 2, -3])
    [ 1.000000000000000 2.000000000000000 -3.000000000000000]
```

```python
>>> from sage.all import *
>>> MatrixSpace(CBF, Integer(3))(Integer(2))
[2.000000000000000 0 0]
[ 0 2.000000000000000 0]
[ 0 0 2.000000000000000]
>>> matrix(CBF, Integer(1), Integer(3), [Integer(1), Integer(2), -Integer(3)])
[ 1.000000000000000 2.000000000000000 -3.000000000000000]
```

```python
charpoly (var='x', algorithm=None)

    Compute the characteristic polynomial of this matrix.

    EXAMPLES:

    >>> from sage.matrix.benchmark import hilbert_matrix
    >>> mat = hilbert_matrix(5).change_ring(ComplexBallField(10))
    >>> mat.charpoly()
    x^5 + (-1.8 +/- 0.0258)*x^4 + (0.3 +/- 0.05...)*x^3 + (+/- 0.0...)*x^2 + (+/- 0.0...)*x + (+/- 0.0...)
```

```python
>>> from sage.all import *
>>> from sage.matrix.benchmark import hilbert_matrix
>>> mat = hilbert_matrix(Integer(5)).change_ring(ComplexBallField(Integer(10)))
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

>>> mat.charpoly()
x^5 + (\[-1.8 +/- 0.0258\])*x^4 + (\[0.3 +/- 0.05\...)*x^3 +
\((+/- 0.0...)]*x^2 + ( [+/- 0.0...])x + [+/- 0.0...]

contains (other)
Test if the set of complex matrices represented by self is contained in that represented by other.

EXAMPLES:

sage: b = CBF(0, RBF(0, rad=.1)); b
[+/- 0.101]*I
sage: matrix(CBF, [0, b]).contains(matrix(CBF, [0, 0]))
True
sage: matrix(CBF, [0, b]).contains(matrix(CBF, [b, 0]))
False
sage: matrix(CBF, [b, b]).contains(matrix(CBF, [b, 0]))
True

>>> from sage.all import *

b = CBF(Integer(0), RBF(Integer(0), rad=.1)); b
[+/- 0.101]*I
>>>
>>> matrix(CBF, [Integer(0), b]).contains(matrix(CBF, [Integer(0),
˓→Integer(0)]))
True
>>> matrix(CBF, [Integer(0), b]).contains(matrix(CBF, [b, Integer(0)]))
False
>>> matrix(CBF, [b, b]).contains(matrix(CBF, [b, Integer(0)]))
True

determinant ()
Compute the determinant of this matrix.

EXAMPLES:

sage: matrix(CBF, [[1/2, 1/3], [1, 1]]).determinant()
[0.1666666666666667 +/- ...e-17]
sage: matrix(CBF, [[1/2, 1/3], [1, 1]]).det()
[0.1666666666666667 +/- ...e-17]
sage: matrix(CBF, [[1/2, 1/3]]).determinant()
Traceback (most recent call last):
...
ValueError: self must be a square matrix

>>> from sage.all import *

>>> matrix(CBF, [[Integer(1)/Integer(2), Integer(1)/Integer(3)], [Integer(1),˓→Integer(1)]]).determinant()
[0.1666666666666667 +/- ...e-17]
>>> matrix(CBF, [[Integer(1)/Integer(2), Integer(1)/Integer(3)], [Integer(1),˓→Integer(1)]]).det()
[0.1666666666666667 +/- ...e-17]
>>> matrix(CBF, [[Integer(1)/Integer(2), Integer(1)/Integer(3)]]).˓→determinant()
Traceback (most recent call last):
...
ValueError: self must be a square matrix
**eigenvalues** (*other=None, extend=None*)

(Experimental.) Compute rigorous enclosures of the eigenvalues of this matrix.

**INPUT:**

- `self` – an \( n \times n \) matrix
- `other` – unsupported (generalized eigenvalue problem), should be `None`
- `extend` – ignored

**OUTPUT:**

A sequence of complex balls of length equal to the size of the matrix.

Each element represents one eigenvalue with the correct multiplicities in case of overlap. The output intervals are either disjoint or identical, and identical intervals are guaranteed to be grouped consecutively. Each complete run of \( k \) identical balls thus represents a cluster of exactly \( k \) eigenvalues which could not be separated from each other at the current precision, but which could be isolated from the other eigenvalues.

There is currently no guarantee that the algorithm converges as the working precision is increased.

See the FLINT documentation for more information.

**EXAMPLES:**

```
sage: from sage.matrix.benchmark import hilbert_matrix
sage: mat = hilbert_matrix(5).change_ring(CBF)
sage: mat.eigenvalues()

eigenvectors_right()

eigenvectors_left (other=None, extend=True)

(Experimental.) Compute rigorous enclosures of the eigenvalues and left eigenvectors of this matrix.

INPUT:

• self – an \( n \times n \) matrix
• other – unsupported (generalized eigenvalue problem), should be None
• extend – ignored

OUTPUT:

A list of triples of the form (eigenvalue, [eigenvector], 1).

Unlike eigenvalues() and eigenvectors_left_approx(), this method currently fails in the presence of multiple eigenvalues.

Additionally, there is currently no guarantee that the algorithm converges as the working precision is increased.

See the FLINT documentation for more information.

EXAMPLES:

sage: mat = matrix(CBF, 3, [2, 3, 5, 7, 11, 13, 17, 19, 23])
sage: eigval, eigvec, _ = mat.eigenvectors_left()[0]
sage: eigval
[1.1052996349...] + [+/- ...]*I
sage: eigvec[0]
[0.69817246751...] + [+/- ...]*I, [-0.67419514369...] + [+/- ...]*I, [0.
-> 240865343781...] + [+/- ...]*I)
sage: eigvec[0] * (mat - eigval)
[(+/- ...) + [+/- ...]*I, [+/- ...] + [+/- ...]*I, [+/- ...] + [+/- ...]*I]

\]

\textbf{eigenvectors_left_approx (other=\text{None}, extend=\text{None})}

(Experimental.) Compute non-rigorous approximations of the left eigenvalues and eigenvectors of this matrix.

INPUT:

- \texttt{self} – an \( n \times n \) matrix
- \texttt{other} – unsupported (generalized eigenvalue problem), should be \texttt{None}
- \texttt{extend} – ignored

OUTPUT:

A list of triples of the form \((\text{eigenvalue}, [\text{eigenvector}], 1)\). The eigenvalue and the entries of the eigenvector are complex balls with zero radius.

No guarantees are made about the accuracy of the output.

See the FLINT documentation for more information.

\textbf{EXAMPLES:}

\begin{verbatim}
>>> from sage.all import *

>>> mat = matrix(CBF, 3, [2, 3, 5, 7, 11, 13, 17, 19, 23])

>>> eigval, eigvec, _ = mat.eigenvectors_left_approx()[0]

>>> eigvec[0] * (mat - eigval)

[(+/- ...), (+/- ...), (+/- ...)]
\end{verbatim}
**eigenvectors_right**(other=None, extend=None)

(Experimental.) Compute rigorous enclosures of the eigenvalues and eigenvectors of this matrix.

**INPUT:**

- **self** – an \( n \times n \) matrix
- **other** – unsupported (generalized eigenvalue problem), should be *None*
- **extend** – ignored

**OUTPUT:**

A list of triples of the form \((\text{eigenvalue}, \text{[eigenvector]}, 1)\).

Unlike `eigenvalues()` and `eigenvectors_right_approx()`, this method currently fails in the presence of multiple eigenvalues.

Additionally, there is currently no guarantee that the algorithm converges as the working precision is increased.

See the FLINT documentation for more information.

**EXAMPLES:**

```python
sage: from sage.matrix.benchmark import hilbert_matrix
sage: mat = hilbert_matrix(3).change_ring(CBF)
sage: eigval, eigvec, _ = mat.eigenvectors_right()[0]
doctest:...: FutureWarning: This class/method/function is marked as

>>> (mat - eigval)*eigvec[Integer(0)]
([1e-15 +/- ...], [2e-15 +/- ...], [+/- ...])
```

See also:
eigenvectors_right()

exp()

Compute the exponential of this matrix.

EXAMPLES:

```python
sage: matrix(CBF, [[i*pi, 1], [0, i*pi]]).exp()  #˓→needs sage.symbolic
[[-1.00000000000000 +/- ...e-16] + [+/- ...e-16]*I
˓→e-16] + [+/- ...e-16]*I
[ 0 [-1.00000000000000 +/- ...]
```
identical (other)

Test if the corresponding entries of two complex ball matrices represent the same balls.

EXAMPLES:

```python
sage: a = matrix(CBF, [[1/3, 2], [3, 4]])
sage: b = matrix(CBF, [[1/3, 2], [3, 4]])
sage: a == b
False
sage: a.identical(b)
True
```

overlaps (other)

Test if two matrices with complex ball entries represent overlapping sets of complex matrices.

EXAMPLES:

```python
sage: b = CBF(0, RBF(0, rad=0.1)); b
[+/- 0.101]*I
sage: matrix(CBF, [0, b]).overlaps(matrix(CBF, [b, 0]))
True
sage: matrix(CBF, [1, 0]).overlaps(matrix(CBF, [b, 0]))
False
```

(continues on next page)
trace()

Compute the trace of this matrix.

EXAMPLES:

```python
sage: matrix(CBF, [[1/3, 1/3], [1, 1]]).trace()
[1.3333333333333333 +/- ...e-16]
sage: matrix(CBF, [[1/2, 1/3]]).trace()
Traceback (most recent call last):
  ... ValueError: self must be a square matrix
```

transpose()

Return the transpose of self.

EXAMPLES:

```python
sage: m = matrix(CBF, 2, 3, [1, 2, 3, 4, 5, 6])
sage: m.transpose()
[1.000000000000000 4.000000000000000

- Vincent Neiger (2024-02-13): added basis_completion(), _is_basis_completion(), _basis_completion_via_reversed_approx().

class sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense

Bases: Matrix_generic_dense

Dense matrix over a univariate polynomial ring over a field.

For a field $K$, we consider matrices over the univariate polynomial ring $K[x]$.

They are often used to represent bases of some $K[x]$-modules. In this context, there are two possible representations which are both commonly used in the literature.

- Working column-wise: each column of the matrix is a vector in the basis; then, a $K[x]$-submodule of $K[x]^m$ of rank $n$ is represented by an $m \times n$ matrix, whose columns span the module (via $K[x]$-linear combinations). This matrix has full rank, and $n \leq m$.

- Working row-wise: each row of the matrix is a vector in the basis; then, a $K[x]$-submodule of $K[x]^n$ of rank $m$ is represented by an $m \times n$ matrix, whose rows span the module (via $K[x]$-linear combinations). This matrix has full rank, and $m \leq n$.

For the rest of this class description, we assume that one is working row-wise. For a given such module, all its bases are equivalent under left-multiplication by a unimodular matrix, that is, a square matrix which has determinant in $K \setminus \{0\}$. 
There are bases which are called reduced or minimal: their rows have the minimal degree possible among all bases of this module; here the degree of a row is the maximum of the degrees of the entries of the row. An equivalent condition is that the leading matrix of this basis has full rank (see leading_matrix(), reduced_form(), is_reduced()). There is a unique minimal basis, called the Popov basis of the module, which satisfies some additional normalization condition (see popov_form(), is_popov()).

These notions can be extended via a more general degree measure, involving a tuple of integers which is called shift and acts as column degree shifts in the definition of row degree. Precisely, for given $s_1, \ldots, s_n \in \mathbb{Z}$ and a row vector $[p_1 \cdots p_n] \in K[x]^{1 \times n}$, its shifted row degree is the maximum of $\deg(p_j) + s_j$ for $1 \leq j \leq n$ (see row_degrees()). Then, reduced bases and Popov bases are defined similarly, with respect to this notion of degree.

Another important canonical basis is the Hermite basis, which is an upper triangular matrix satisfying a normalization condition similar to that for the Popov basis. In fact, if $d$ is the largest degree appearing in the Hermite basis, then the Hermite basis coincides with the shifted Popov basis with the shifts $((n-1)d, \ldots, 2d, d, 0)$.

**basis_completion(row_wise=True, algorithm='approximant')**

Return a Smith form-preserving nonsingular completion of a basis of this matrix: row-wise completing a row basis if row_wise is True; column-wise completing a column basis if it is False.

For a more detailed description, consider the row-wise case (the column-wise case is the same up to matrix transposition). Let $A$ be the input matrix, $m \times n$ over univariate polynomials $K[x]$, for some field $K$, and let $r$ be the rank of $A$, which is unknown a priori. This computes a matrix $C$ of dimensions $(n-r) \times n$ such that stacking both matrices one above the other, say $[[A], [C]]$, gives a matrix of maximal rank $n$ and with the same nontrivial Smith factors as $A$. In particular, $C$ has full row rank, and the rank of the input matrix may be recovered from the number of rows of $C$.

As a consequence, if $B$ is a basis of the module generated by the rows of $A$ (for example $B = A$ if $A$ has full row rank), then $[[B], [C]]$ is nonsingular, and its determinant is the product of the nonzero Smith factors of $A$ up to multiplication by a nonzero element of $K$.

In particular, for $A$ with full row rank: if the rows $A$ can be completed into a basis of $K[x]^n$ (or equivalently, $A$ has unimodular column bases, or also, if the rows of $A$ generate all polynomial vectors in the rational row space of $A$), then $C$ provides such a completion. In this case, $[[A], [C]]$ is unimodular: it is invertible over $K[x]$, and $\det([[A], [C]])$ is a nonzero element of the base field $K$.

**INPUT:**

- **row_wise** – (default: True) boolean, if True then compute a row-wise completion, else compute a column-wise completion.
- **algorithm** – (default: "approximant") selects the approach for computing the completion; currently supported: "approximant" and "smith".

**OUTPUT:** a matrix over the same base ring as the input matrix, which forms a completion as defined above.

**ALGORITHM:**

- **approximant:** the approximant-based algorithm follows the ideas in [ZL2014], based on polynomial reversals combined with the computation of a minimal kernel basis and a minimal approximant basis.
- **smith:** the Smith form-based algorithm computes the Smith form of this matrix along with corresponding unimodular transformations, from which a completion is readily obtained.

**EXAMPLES:**

Three polynomials whose GCD is 1 can be completed into a unimodular matrix:

```python
sage: ring.<x> = GF(7)[[]
    sage: mat = matrix([[x*(x-1)*(x-2), (x-2)*(x-3)*(x-4), (x-4)*(x-5)*(x-6)]]
    sage: mat
```
Matrices and Spaces of Matrices, Release 10.4

The following matrix has rank 2 and trivial Smith form. It can be completed row-wise into a $3 \times 3$ unimodular matrix (column-wise, there is nothing to complete):

```
sage: mat = matrix(ring, 2, 3, 
                 [[x^2 + 5*x + 5, 3*x^2 + x + 3, 4*x^2 + 5*x + 4], 
                  [5*x^2 + 4*x + 1, 3*x^2 + 4*x + 5, 5*x^2 + 5*x + 3]])
sage: rcomp = mat.basis_completion(); rcomp
[ 5*x^2 + 4*x + 1 5*x^2 + 2*x 5*x^2]
[ 2*x^3 + 4*x^2 2*x^3 + 6*x^2 + 2*x + 1 2*x^3 + x^2 + 3*x]

sage: basis = mat.stack(rcomp); basis
[[ x^3 + 4*x^2 + 2*x x^3 + 5*x^2 + 5*x + 4 x^3 + 6*x^2 + 4*x + 6]
 [ 5*x^2 + 4*x + 1 5*x^2 + 2*x 5*x^2]
 [ 2*x^3 + 4*x^2 2*x^3 + 6*x^2 + 2*x + 1 2*x^3 + x^2 + 3*x]]
```

```
sage: basis.determinant()
6
```

The following matrix has rank 1 and its nonzero Smith factor is $x + 3$. A row-wise completion has a single nonzero row, whereas a column-wise completion has two columns; in both cases, the Smith form is preserved:

```
sage: mat = matrix(ring, 3, 2, 
                 [[ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4],
                  [ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4]])
sage: rcomp = mat.basis_completion(); rcomp
[ 5*x^2 + 5*x + 1 5*x^2 + 2*x 5*x^2]
[ 2*x^3 + 4*x^2 2*x^3 + 6*x^2 + 2*x + 1 2*x^3 + x^2 + 3*x]

sage: basis = mat.stack(rcomp); basis

sage: basis.determinant()
3
```

```
sage: mat = matrix(ring, 3, 2, 
                 [[ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4],
                  [ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4]])
```

```
sage: rcomp = mat.basis_completion(); rcomp
[ 5*x^2 + 5*x + 1 5*x^2 + 2*x 5*x^2]
[ 2*x^3 + 4*x^2 2*x^3 + 6*x^2 + 2*x + 1 2*x^3 + x^2 + 3*x]
```

```
sage: rcomp = mat.basis_completion(); rcomp
[ 5*x^2 + 5*x + 1 5*x^2 + 2*x 5*x^2]
[ 2*x^3 + 4*x^2 2*x^3 + 6*x^2 + 2*x + 1 2*x^3 + x^2 + 3*x]
```

```
sage: basis = mat.stack(rcomp); basis

sage: basis.determinant()
3
```

```
sage: mat = matrix(ring, 3, 2, 
                 [[ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4],
                  [ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4]])
sage: mat = matrix(ring, 3, 2, 
                 [[ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4],
                  [ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4]])
```

```
sage: mat = matrix(ring, 3, 2, 
                 [[ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4],
                  [ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4]])
```

```
sage: mat = matrix(ring, 3, 2, 
                 [[ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4],
                  [ x^3 + x^2 + 5*x + 5, 2*x^3 + 2*x + 4]])
```
Here are a few more examples, similar to the above but over fields other than GF(7):

```python
sage: ring.<x> = QQ[]
sage: mat = matrix([[(x^3 + 3*x^2 + x + 3, 6*x^3 + 5*x^2 + x + 1), \n    [2*x^3 + 5*x^2 + 3*x + 4, 4*x^3 + 6*x^2 + 5*x + 6]])
```

```python
sage: mat.smith_form(transformation=False)
[ ]
[x + 3 0]
[ 0 0]
[ 0 0]
```

```python
sage: rcomp = mat.basis_completion(algorithm="smith"); rcomp
[ ]
[x + 1 2*x]
```

```python
sage: ccomp = mat.basis_completion(row_wise=False); ccomp
[ ]
[3*x + 1 4*x + 4]
[ 2*x 5*x + 1]
[ 6*x x]
```

```python
sage: rcomp.stack(mat).smith_form(transformation=False)
[ ]
[1 0]
[0 x + 3]
[0 0]
```

```python
sage: ccomp.augment(mat).smith_form(transformation=False)
[ ]
[1 0 0 0]
[0 1 0 0]
[0 0 x + 3 0]
```

(continued from previous page)

```python
[3*x^3 + 2*x^2 + x + 3, 6*x^3 + 5*x^2 + x + 1], \n[2*x^3 + 5*x^2 + 3*x + 4, 4*x^3 + 6*x^2 + 5*x + 6])
sage: mat.smith_form(transformation=False)
[x + 3 0]
[0 0]
[0 0]
sage: rcomp = mat.basis_completion(); rcomp
[x + 1 2*x]
sage: ccomp = mat.basis_completion(row_wise=False); ccomp
[3*x + 1 4*x + 4]
[2*x 5*x + 1]
[6*x x]
sage: rcomp.stack(mat).smith_form(transformation=False)
[1 0]
[0 x + 3]
[0 0]
sage: ccomp.augment(mat).smith_form(transformation=False)
[1 0 0 0]
[0 1 0 0]
[0 0 x + 3 0]
```

Here are a few more examples, similar to the above but over fields other than GF(7):

```python
>>> from sage.all import *
```

```python

>>> ccomp.augment(mat).smith_form(transformation=False)
[ 1 0 0]
```

(continues on next page)
coefficient_matrix\( (d, \text{row\_wise=True}) \)

Return the constant matrix which is obtained from this matrix by taking the coefficient of its entries with degree specified by \(d\).

- if \(d\) is an integer, this selects the coefficient of \(d\) for all entries;
- if \(d\) is a list \( (d_1, \ldots, d_m) \) and \(\text{row\_wise}\) is True, this selects the coefficient of degree \(d_i\) for all entries of the \(i\)th foreach \(i\);
- if \(d\) is a list \( (d_1, \ldots, d_n) \) and \(\text{row\_wise}\) is False, this selects the coefficient of degree \(d_j\) for all entries of the \(j\)th column foreach \(j\).

INPUT:

- \(d\) – a list of integers, or an integer,
- \( \text{row\_wise} \) – (default: True) boolean, if True (resp. False) then \(d\) should be a list of length equal to the row (resp. column) dimension of this matrix.

OUTPUT: a matrix over the base field.

EXAMPLES:

```
sage: pR.<x> = GF(7)[]
sage: M = Matrix([  
....:     [ x^3+5*x^2+5*x+1, 5, 6*x+4, 0],  
....:     [ 6*x^2+3*x+1, 1, 2, 0],  
....:     [2*x^3+4*x^2+6*x+4, 5*x+1, 2*x^2+5*x+5, x^2+5*x+6]  
....:     ])
sage: M.coefficient_matrix(2)  
[5 0 0 0]  
[6 0 0 0]  
[4 0 2 1]  
sage: M.coefficient_matrix(0) == M.constant_matrix()  
True
```

```python
>>> from sage.all import *  
>>> pR = GF(Integer(7))['x']; (x,) = pR._first_ngens(1)  
>>> M = Matrix([  
...     [ x**Integer(3)+Integer(5)*x**Integer(2)+Integer(5)*x+Integer(1),  
...       Integer(5),  
...     [ Integer(6)*x+Integer(4),  
...       Integer(0)],  
...     [ Integer(6)*x**Integer(2)+Integer(3)*x+Integer(1),  
...       Integer(1),  
...       Integer(2),  
...       Integer(0)],  
...     ])
```
Row-wise and column-wise coefficient extraction are available:

```sage
sage: M.coefficient_matrix([3,2,1])
[1 0 0 0]
[6 0 0 0]
[6 5 5 5]
sage: M.coefficient_matrix([2,0,1,3], row_wise=False)
[5 5 6 0]
[6 1 0 0]
[4 1 5 0]
```

Negative degrees give zero coefficients:

```sage
sage: M.coefficient_matrix([-1,0,1,3], row_wise=False)
[0 5 6 0]
[0 1 0 0]
[0 1 5 0]
```

Length of list of degrees is checked:

```sage
sage: M.coefficient_matrix([2,1,1,2])
Traceback (most recent call last):
  ...
ValueError: length of input degree list should be the row
```

(continues on next page)
dimension of the input matrix
sage: M.coefficient_matrix([3,2,1], row_wise=False)
Traceback (most recent call last):
...
ValueError: length of input degree list should be the column
dimension of the input matrix

>>> from sage.all import *

>>> M.coefficient_matrix([Integer(2),Integer(1),Integer(1),Integer(2)])
Traceback (most recent call last):
...
ValueError: length of input degree list should be the row
dimension of the input matrix

>>> M.coefficient_matrix([Integer(3),Integer(2),Integer(1)], row_wise=False)
Traceback (most recent call last):
...
ValueError: length of input degree list should be the column
dimension of the input matrix

column_degrees(shifts=None)

Return the (shifted) column degrees of this matrix.

For a given polynomial matrix \( M = (M_{i,j})_{i,j} \) with \( m \) rows and \( n \) columns, its column degrees is the tuple
\( (d_1, \ldots, d_n) \) where
\[
d_j = \max_i(\deg(M_{i,j})) \quad \text{for} \quad 1 \leq j \leq n.
\]
Thus, \( d_j = -1 \) if the \( j \)-th column of \( M \) is zero,
and \( d_j \geq 0 \) otherwise.

For given shifts \( s_1, \ldots, s_m \in \mathbb{Z} \), the shifted column degrees of \( M \) is
\( (d_1, \ldots, d_n) \) where
\[
d_j = \max_i(\deg(M_{i,j}) + s_i). \quad \text{Here, if the} \quad j\text{-th column of} \quad M \quad \text{is zero then} \quad d_j = \min(s_1, \ldots, s_m) - 1; \text{otherwise} \quad d_j \quad \text{is larger than this value.}
\]

INPUT:

- shifts – (default: None) list of integers; None is interpreted as shifts=[0,...,0].

OUTPUT: a list of integers.

EXAMPLES:

sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[3*x+1, 0, 1], [x^3+3, 0, 0]])
sage: M.column_degrees()
[3, -1, 0]
sage: M.column_degrees(shifts=[Integer(0),Integer(2)])
[5, -1, 0]
A zero column in a polynomial matrix can be identified in the (shifted) column degrees as the entries equal to \( \min(shifts) - 1 \):

```
sage: M.column_degrees(shifts=[-2,1])
[4, -3, -2]
```

```python
>>> from sage.all import *

>>> M.column_degrees(shifts=[-Integer(2),Integer(1)])
[4, -3, -2]
```

The column degrees of an empty matrix \((0 \times n)\) or \((m \times 0)\) is not defined:

```
sage: M = Matrix(pR, 0, 3)
sage: M.column_degrees()
Traceback (most recent call last):
...
ValueError: empty matrix does not have column degrees
```

```
sage: M = Matrix(pR, 3, 0)
sage: M.column_degrees()
Traceback (most recent call last):
...
ValueError: empty matrix does not have column degrees
```

```python
>>> from sage.all import *

>>> M = Matrix(pR, Integer(0), Integer(3))

>>> M.column_degrees()
Traceback (most recent call last):
...
ValueError: empty matrix does not have column degrees
```

```python
>>> M = Matrix(pR, Integer(3), Integer(0))

>>> M.column_degrees()
Traceback (most recent call last):
...
ValueError: empty matrix does not have column degrees
```

See also:

The documentation of \(\text{row\_degrees()}\).

\textbf{constant\_matrix()}

Return the constant coefficient of this matrix seen as a polynomial with matrix coefficients; this is also this matrix evaluated at zero.

\textbf{OUTPUT:} a matrix over the base field.

\textbf{EXAMPLES:}

```
sage: pR.<x> = GF(7)[]

sage: M = Matrix(
....: [ x^3+5*x^2+5*x+1, 5, 6*x+4, 0],
....: [ 6*x^2+3*x+1, 1, 2, 0],
....: [2*x^3+4*x^2+6*x+4, 5*x + 1, 2*x^2+5*x+5, x^2+5*x+6]
....: )

sage: M.constant_matrix()

[1 5 4 0]
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

```
>>> from sage.all import *

>>> pR = GF(Integer(7))['x'] ; (x,) = pR._first_ngens(1)

>>> M = Matrix([...
    [ x**Integer(3)+Integer(5)*x**Integer(2)+Integer(5)*x+Integer(1), ...
      → Integer(5), Integer(6)*x+Integer(4), Integer(0)],
    [ Integer(6)*x**Integer(2)+Integer(3)*x+Integer(1), ...
      → Integer(1), Integer(2), Integer(0)],
    ...
    → [Integer(2)*x**Integer(3)+Integer(4)*x**Integer(2)+Integer(6)*x+Integer(4),...
      → Integer(5)*x + Integer(1), Integer(2)*x**Integer(2)+Integer(5)*x+Integer(5),
      → x**Integer(2)+Integer(5)*x+Integer(6)] ...
])

>>> M.constant_matrix()

[1 5 4 0]
[1 1 2 0]
[4 1 5 6]
```

degree()

Return the degree of this matrix.

For a given polynomial matrix, its degree is the maximum of the degrees of all its entries. If the matrix is nonzero, this is a nonnegative integer; here, the degree of the zero matrix is -1.

OUTPUT: an integer.

EXAMPLES:

```
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[3*x+1, 0, 1], [x^3+3, 0, 0]])
sage: M.degree()
3
```

```
>>> from sage.all import *

>>> pR = GF(Integer(7))['x'] ; (x,) = pR._first_ngens(1)

>>> M = Matrix(pR, [[Integer(3)*x+Integer(1), Integer(0), Integer(1)],...
                → [x**Integer(3)+Integer(1), Integer(0), Integer(1)]])

>>> M.degree()
3
```

The zero matrix has degree -1:

```
sage: M = Matrix(pR, 2, 3)
sage: M.degree()
-1
```

```
>>> from sage.all import *

>>> M = Matrix(pR, Integer(2), Integer(3))

>>> M.degree()
-1
```

For an empty matrix, the degree is not defined:
Matrices and Spaces of Matrices, Release 10.4

```python
sage: M = Matrix(pR, 3, 0)
sage: M.degree()
Traceback (most recent call last):
...
ValueError: empty matrix does not have a degree

>>> from sage.all import *
>>> M = Matrix(pR, Integer(3), Integer(0))
>>> M.degree()
Traceback (most recent call last):
...
ValueError: empty matrix does not have a degree
```

**degree_matrix** *(shifts=None, row_wise=True)*

Return the matrix of the (shifted) degrees in this matrix.

For a given polynomial matrix $M = (M_{i,j})_{i,j}$, its degree matrix is the matrix $(\deg(M_{i,j}))_{i,j}$ formed by the degrees of its entries. Here, the degree of the zero polynomial is $-1$.

For given shifts $s_1, \ldots, s_m \in \mathbb{Z}$, the shifted degree matrix of $M$ is either $(\deg(M_{i,j}) + s_j)_{i,j}$ if working row-wise, or $(\deg(M_{i,j}) + s_i)_{i,j}$ if working column-wise. In the former case, $m$ has to be the number of columns of $M$; in the latter case, the number of its rows. Here, if $M_{i,j} = 0$ then the corresponding entry in the shifted degree matrix is $\min(s_1, \ldots, s_m) - 1$. For more on shifts and working row-wise versus column-wise, see the class documentation.

**INPUT:**
- `shifts` *(default: None)* list of integers; None is interpreted as $shifts=[0, \ldots, 0]$.
- `row_wise` *(default: True)* boolean, if True then shifts apply to the columns of the matrix and otherwise to its rows (see the class description for more details).

**OUTPUT:** an integer matrix.

**EXAMPLES:**

```python
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[3*x+1, 0, 1], [x^3+3, 0, 0]])
sage: M.degree_matrix()
[ 1 -1 0]
[ 3 -1 -1]
sage: M.degree_matrix(shifts=[0,1,2])
[ 1 -1 2]
[ 3 -1 -1]
```

```python
>>> from sage.all import *
>>> pR = GF(Integer(7))[x]; (x,) = pR._first_ngens(1)
>>> M = Matrix(pR, [[Integer(3)*x+Integer(1), Integer(0), Integer(1)],
[x**Integer(3)+Integer(3), Integer(0), Integer(0)]]).
>>> M.degree_matrix()
[ 1 -1 0]
[ 3 -1 -1]
```

```python
>>> M.degree_matrix(shifts=[Integer(0),Integer(1),Integer(2)])
[ 1 -1 2]
[ 3 -1 -1]
```
The zero entries in the polynomial matrix can be identified in the (shifted) degree matrix as the entries equal to \( \min(\text{shifts}) - 1 \):

```python
sage: M.degree_matrix(shifts=[-2,1,2])
[-1 -3  2]
[ 1 -3 -3]
```

Using `row_wise=False`, the function supports shifts applied to the rows of the matrix (which, in terms of modules, means that we are working column-wise, see the class documentation):

```python
sage: M.degree_matrix(shifts=[-1,2], row_wise=False)
[ 0 -2 -1]
[ 5 -2 -2]
```

**hermite_form** (`include_zero_rows=True, transformation=False`)

Returns the Hermite form of this matrix.

See `is_hermite()` for a definition of Hermite forms. If the input is a matrix \( A \), then its Hermite form is the unique matrix \( H \) in Hermite form such that \( UA = H \) for some unimodular matrix \( U \).

**INPUT:**

- `include_zero_rows` – boolean (default: `True`); if `False`, the zero rows in the output matrix are deleted.
- `transformation` – boolean (default: `False`); if `True`, return the transformation matrix.

**OUTPUT:**

- the Hermite normal form \( H \) of this matrix \( A \).
- (optional) transformation matrix \( U \) such that \( UA = H \).

**EXAMPLES:**

```python
sage: M.<x> = GF(7)[]
sage: A = matrix(M, 2, 3, [x, 1, 2*x, x, 1+x, 2])
sage: A.hermite_form()
[ x  1  2*x]
[ 0  x  5*x + 2]
sage: A = matrix(M, 2, 3, [x, 1, 2*x, 2*x, 2, 4*x])
sage: A.hermite_form(transformation=True, include_zero_rows=False)
[[ x  1  2*x] [1 0]]
[ 0  x  5*x + 2], [6 1]]
```

(continues on next page)
See also:

- `is_hermite()`
- `popov_form()`

**inverse_series_trunc**(d)

Return a matrix polynomial approximation of precision d of the inverse series of this matrix polynomial.

Here matrix polynomial means that self is seen as a univariate polynomial with matrix coefficients, meaning that this method has the same output as if one: 1) converts this matrix to a univariate polynomial with matrix coefficients, 2) calls

```python
sage.rings.polynomial.polynomial_element.Polynomial.inverse_series_trunc()
```
on that univariate polynomial, and 3) converts back to a matrix of polynomials.

Raises a `ZeroDivisionError` if the constant matrix of `self` is not invertible (i.e. has zero determinant); raises an `ArithmeticError` if `self` is nonsquare; and raises a `ValueError` if the precision `d` is not positive.

INPUT: a positive integer `d`.

OUTPUT: the unique polynomial matrix `B` of degree less than `d` such that `AB` and `BA` are the identity matrix modulo `x^d`, where `A` is `self`.

**ALGORITHM:** This uses Newton iteration, performing about `log(d)` polynomial matrix multiplications in size `m x m` and in degree less than `2d`, where `m` is the row dimension of `self`.

**EXAMPLES:**

```sage
pR.<x> = GF(7)
sage: A = Matrix(pR, 3, 3,
....: [4*x+5, 5*x^2 + x + 1, 4*x^2 + 4],
....: [6*x^2 + 6*x + 6, 4*x^2 + 5*x, 4*x^2 + x + 3],
....: [3*x^2 + 2, 4*x + 1, x^2 + 3*x])
sage: B = A.inverse_series_trunc(4); B
[ x^3 + 5*x^2 + x + 4  x^3 + 5*x^2 + 6*x + 4  6*x^2 + 5*x + 3
[ 4*x^2 + 5*x + 6  6*x^3 + x^2 + x + 6  3*x^2 + 2*x^2 + 2]
[5*x^3 + 5*x^2 + 6*x + 6 4*x^3 + 2*x^2 + 6*x + 4  6*x^3 + x^2 + 6*x + 1]
sage: (B*A).truncate(4) == 1
True

sage: A.inverse_series_trunc(0)
Traceback (most recent call last):
... ValueError: the precision must be positive

sage: A[:2,:].inverse_series_trunc(4)
Traceback (most recent call last):
... ArithmeticError: the input matrix must be square

sage: A.inverse_series_trunc(4)
Traceback (most recent call last):
... ZeroDivisionError: the constant matrix term self(0) must be invertible
```

```python
>>> from sage.all import *

>>> pR = GF(Integer(7))[x]; (x,) = pR._first_ngens(1)
>>> A = Matrix(pR, Integer(3), Integer(3),
....: [[Integer(4)*x+Integer(5), Integer(5)*x**Integer(2)+x + Integer(2)],
....: [Integer(4)*x**Integer(2)+x + Integer(1), Integer(4)*x**Integer(2) + Integer(4)],
....: [Integer(6)*x**Integer(2) + Integer(6)*x + Integer(6), Integer(4)*x**Integer(2) + x + Integer(3)],
....: [Integer(3)*x**Integer(2) + Integer(2), Integer(4)*x + Integer(3)*x])

>>> B = A.inverse_series_trunc(Integer(4)); B

[ x^3 + 5*x^2 + x + 4  x^3 + 5*x^2 + 6*x + 4  6*x^2 + 5*x + 3
[ 4*x^2 + 5*x + 6  6*x^3 + x^2 + x + 6  3*x^2 + 2*x^2 + 2]
[5*x^3 + 5*x^2 + 6*x + 6 4*x^3 + 2*x^2 + 6*x + 4  6*x^3 + x^2 + 6*x + 1]

>>> (B*A).truncate(Integer(4)) == Integer(1)
```

(continues on next page)
True

```python
>>> A.inverse_series_trunc(Integer(0))
Traceback (most recent call last):
...  ValueError: the precision must be positive
```

```python
>>> A[:Integer(2),:].inverse_series_trunc(Integer(4))
Traceback (most recent call last):
...  ArithmeticError: the input matrix must be square
```

```python
>>> A[Integer(0),:] = A[Integer(0),:] - A[Integer(0),:](Integer(0)) +
...   A[Integer(1),:](Integer(0)) + A[Integer(2),:](Integer(0))
```

```python
>>> A.inverse_series_trunc(Integer(4))
Traceback (most recent call last):
...  ZeroDivisionError: the constant matrix term self(0) must be invertible
```

See also:

Todo: in the current state of polynomial matrix multiplication (July 2021), it would be highly beneficial to use conversions and rely on polynomials with matrix coefficients when the matrix size is “large” and the degree “small”, see Issue #31472#comment:3.

### is_constant()

Return whether this polynomial matrix is constant, that is, all its entries are constant.

OUTPUT: a boolean.

EXAMPLES:

```python
sage: pR.<x> = GF(7)[]
sage: M = Matrix(
...    [ x^3+5*x^2+5*x+1, 5, 6*x+4, 0],
...    [ 6*x^2+3*x+1, 1, 2, 0],
...    [2*x^3+4*x^2+6*x+4, 5*x + 1, 2*x^2+5*x+5, x^2+5*x+6]
...    )
sage: M.is_constant()
False
sage: M = Matrix(pR, [[1,5,2], [3,1,5]]); M.is_constant()
True
sage: M = Matrix.zero(pR, 3, 5); M.is_constant()
True
```

```python
>>> from sage.all import *
```

(continues on previous page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

... ...
→ [Integer(2) * x**Integer(3) + Integer(4) * x**Integer(2) + Integer(6) * x + Integer(4),...
→ Integer(5) * x + Integer(1), Integer(2) * x**Integer(2) + Integer(5) * x + Integer(5),
→ x**Integer(2) + Integer(5) * x + Integer(6)]
...

False

>>> M = Matrix(pR, [[Integer(1), Integer(5), Integer(2)],
→ Integer(1), Integer(5)]); M.is_constant()
True

>>> M = Matrix.zero(pR, Integer(3), Integer(5)); M.is_constant()
True

See also:
sage.rings.polynomial.polynomial_element.Polynomial.is_constant()

is_hermite (row_wise=True, lower_echelon=False, include_zero_vectors=True)

Return a boolean indicating whether this matrix is in Hermite form.

If working row-wise, a polynomial matrix is said to be in Hermite form if it is in row echelon form with all pivot entries monic and such that all entries above a pivot have degree less than this pivot. Being in row echelon form means that all zero rows are gathered at the bottom of the matrix, and in each nonzero row the pivot (leftmost nonzero entry) is strictly to the right of the pivot of the row just above this row.

Note that, for any integer \( d \) strictly greater than all degrees appearing in the Hermite form, then the Hermite form coincides with the shifted Popov form with the shifts \((n - 1)d, \ldots, 2d, d, 0)\), where \( n \) is the column dimension.

If working column-wise, a polynomial matrix is said to be in Hermite form if it is in column echelon form with all pivot entries monic and such that all entries to the left of a pivot have degree less than this pivot. Being in column echelon form means that all zero columns are gathered at the right-hand side of the matrix, and in each nonzero column the pivot (topmost nonzero entry) is strictly below the pivot of the column just to the left of this row.

Optional arguments provide support of alternative definitions, concerning the choice of upper or lower echelon forms and concerning whether zero rows (resp. columns) are allowed.

INPUT:

- **row_wise** – (default: True) boolean, True if working row-wise (see the class description).
- **lower_echelon** – (default: False) boolean, False if working with upper triangular Hermite forms, True if working with lower triangular Hermite forms.
- **include_zero_vectors** – (default: True) boolean, False if one does not allow zero rows (resp. zero columns) in Hermite forms.

OUTPUT: a boolean.

EXAMPLES:

```
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[x^4+6*x^3+4*x+4, 3*x+6, 3],
...: [0, x^2+5*x+5, 2],
...: [0, 0, x+5]])

sage: M.is_hermite()
True
sage: M.is_hermite(row_wise=False)
```

(continues on next page)
sage: M.is_hermite(row_wise=False, lower_echelon=True)
False

sage: N = Matrix(pR, [[x+5, 0, 0],
                  ..., [2, x^4+6*x^3+4*x+4, 0],
                  ..., [3, 3*x^3+6, x^2+5*x+5]])

sage: N.is_hermite()
False

sage: N.is_hermite(lower_echelon=True)
True

sage: N.is_hermite(row_wise=False)
False

sage: N.is_hermite(row_wise=False, lower_echelon=True)
False

>>> from sage.all import *

>>> pR = GF(Integer(7))['x']; (x,) = pR._first_ngens(1)

sage: M = Matrix(pR, 
                     [[x**Integer(4)+Integer(6)*x**Integer(3)+Integer(4)*x+Integer(4),
                      Integer(3)*x+Integer(6), Integer(3)],
                      ... [Integer(0),
                      ... x**Integer(2)+Integer(5)*x+Integer(5), Integer(2)],
                      ... [Integer(0),
                      ... x+Integer(5)]])

sage: M.is_hermite()
True

sage: M.is_hermite(row_wise=False)
True

sage: M.is_hermite(row_wise=False, lower_echelon=True)
False

sage: N = Matrix(pR, [[x+Integer(5), Integer(0), Integer(0)],
                  ..., [x**Integer(4)+Integer(6)*x**Integer(3)+Integer(4)*x+Integer(4),
                  Integer(0)],
                  ... [Integer(3),
                  ... x**Integer(2)+Integer(5)*x+Integer(5)])

sage: N.is_hermite()
False

sage: N.is_hermite(lower_echelon=True)
True

sage: N.is_hermite(row_wise=False)
False

sage: N.is_hermite(row_wise=False, lower_echelon=True)
False

Rectangular matrices with zero rows are supported. Zero rows (resp. columns) can be forbidden, and other- wise they should be at the bottom (resp. the right-hand side) of the matrix:

sage: N[:,1:].is_hermite(lower_echelon=True)
False

False
>>> N[[Integer(1),Integer(2),Integer(0)],Integer(1):].is_hermite(lower_echelon=True)
True
>>> N[:,Integer(2),:].is_hermite(row_wise=False, lower_echolon=True)
False
```

See also:

*hermite_form()*.

**is_minimal_approximant_basis** *(pmat, order, shifts=None, row_wise=True, normal_form=False)*

Return whether this matrix is an approximant basis in shifts-ordered weak Popov form for the polynomial matrix pmat at order order.

If normal_form is True, then the polynomial matrix must furthermore be in shifts-Popov form. An error is raised if the input dimensions are not sound. If a single integer is provided for order, then it is interpreted as a list of repeated integers with this value. (See *minimal_approximant_basis()* for definitions and more details.)

**INPUT:**

- pmat – a polynomial matrix.
- order – a list of positive integers, or a positive integer.
- shifts – (default: None) list of integers; None is interpreted as shifts=[0,...,0].
- row_wise – (default: True) boolean, if True then the basis considered row-wise and operates on the left of pmat; otherwise it is column-wise and operates on the right of pmat.
- normal_form – (default: False) boolean, if True then checks for a basis in shifts-Popov form.

**OUTPUT:** a boolean.

**ALGORITHM:**

Verification that the matrix is formed by approximants is done via a truncated matrix product; verification that the matrix is square, nonsingular and in shifted weak Popov form is done via *is_weak_popov()*; verification that the matrix generates the module of approximants is done via the characterization in Theorem 2.1 of [GN2018].

**EXAMPLES:**

```python
sage: pR.<x> = GF(97) []
```
We consider the following example from [Arne Storjohann, Notes on computing minimal approximant bases, 2006]:

```python
>>> from sage.all import *
>>> pR = GF(Integer(97))['x']; (x,) = pR._first_ngens(1)

We consider the following example from [Arne Storjohann, Notes on computing minimal approximant bases, 2006]:

```sage```
order = 8; shifts = [1,1,0,0,0]
sage: pmat = Matrix(pR, 5, 1, [  
....: pR([35, 0, 41, 87, 3, 42, 22, 90]),  
....: pR([80, 15, 62, 87, 14, 93, 24, 0]),  
....: pR([42, 57, 90, 87, 22, 80, 71, 53]),  
....: pR([37, 72, 74, 6, 5, 75, 23, 47]),  
....: pR([36, 10, 74, 1, 29, 44, 87, 74])]  
sage: appbas = Matrix(pR, [  
....: [x+47, 57, 58*x+44, 9*x+23, 93*x+76],  
....: [15, x+18, 52*x+23, 15*x+58, 93*x+88],  
....: [17, 86, x^2+77*x+16, 76*x+29, 90*x+78],  
....: [44, 36, 3*x+42, x^2+50*x+26, 85*x+44],  
....: [2, 22, 54*x+94, 73*x+24, x^2+2+2*x+25]])  
sage: appbas.is_minimal_approximant_basis(  
# ˓→needs sage.libs.pari  
....: pmat, order, shifts, row_wise=True, normal_form=True)  
True
```

The matrix $x^8\text{Id}_5$ is square, nonsingular, in Popov form, and its rows are approximants for $\text{pmat}$ at order 8. However, it is not an approximant basis since its rows generate a module strictly contained in the set of
approximants for \( pmat \) at order 8:

\[
\text{sage: } M = x^8 \ast \text{Matrix.identity}(pR, 5) \\
\text{sage: } M.\text{is_minimal_approximant_basis}(pmat, 8) \quad \# \text{ needs sage.libs.pari} \\
\to False
\]

\[
\text{from sage.all import } * \\
\text{M = x**Integer(8) \ast \text{Matrix.identity}(pR, Integer(5))} \\
\text{M.\text{is_minimal_approximant_basis}(pmat, Integer(8)) \quad \# \text{ needs sage.libs.pari} \\
\to False
\]

Since \( pmat \) is a single column, with nonzero constant coefficient, its column-wise approximant bases at order 8 are all \( 1 \times 1 \) matrices \([c x^n]\) for some nonzero field element \( c \):

\[
\text{sage: } M = \text{Matrix}(pR, [x^8]) \\
\text{sage: } M.\text{is_minimal_approximant_basis}( \quad \text{...: } \text{pmat, 8, row_wise=False, normal_form=True} ) \\
\to True
\]

\[
\text{from sage.all import } * \\
\text{M = Matrix(pR, [x**Integer(8)])} \\
\text{M.\text{is_minimal_approximant_basis}( \quad \text{... } \text{pmat, Integer(8), row_wise=False, normal_form=True} )} \\
\to True
\]

Exceptions are raised if input dimensions are not sound:

\[
\text{sage: } \text{appbas.}\text{is_minimal_approximant_basis}(pmat, [8,8], \text{shifts}) \\
\text{Traceback (most recent call last):} \\
\text{... \text{ValueError: order length should be the column dimension of the input matrix}}
\]

\[
\text{sage: } \text{appbas.}\text{is_minimal_approximant_basis}( \quad \text{...: } \text{pmat, order, shifts, row_wise=False} ) \\
\text{Traceback (most recent call last):} \\
\text{... \text{ValueError: shifts length should be the column dimension of the input matrix}}
\]

\[
\text{sage: } \text{Matrix(pR, [x^8]).}\text{is_minimal_approximant_basis}(pmat, 8) \\
\text{Traceback (most recent call last):} \\
\text{... \text{ValueError: column dimension should be the row dimension of the input matrix}}
\]

\[
\text{from sage.all import } * \\
\text{appbas.}\text{is_minimal_approximant_basis}(pmat, [Integer(8),Integer(8)], \text{shifts}) \\
\text{Traceback (most recent call last):} \\
\text{... \text{ValueError: order length should be the column dimension of the input matrix}}
\]

\[
\text{appbas.}\text{is_minimal_approximant_basis}( \quad \text{... } \text{pmat, order, shifts, row_wise=False})
\]

(continues on next page)
Traceback (most recent call last):

minimal_approximant_basis()

is_minimal_kernel_basis(pmat, shifts=None, row_wise=True, normal_form=False)

Return whether this matrix is a left kernel basis in shifts-ordered weak Popov form for the polynomial matrix pmat.

If normal_form is True, then the kernel basis must furthermore be in shifts-Popov form. An error is raised if the input dimensions are not sound.

INPUT:

• pmat – a polynomial matrix.

• shifts – (default: None) list of integers; None is interpreted as shifts=[0,...,0].

• row_wise – (default: True) boolean, if True then the basis is considered row-wise and operates on the left of pmat; otherwise it is column-wise and operates on the right of pmat.

• normal_form – (default: False) boolean, if True then checks for a basis in shifts-Popov form.

OUTPUT: a boolean.

ALGORITHM:

Verification that the matrix has full rank and is in shifted weak Popov form is done via is_weak_popov(); verification that the matrix is a left kernel basis is done by checking that the rank is correct, that the product is indeed zero, and that the matrix is saturated, i.e. it has unimodular column bases (see Lemma 6.10 of https://arxiv.org/pdf/1807.01272.pdf for details).

EXAMPLES:

sage: pR.<x> = GF(97)[]
sage: pmat = Matrix(pR, [[1], [x], [x**2]])
sage: kerbas = Matrix(pR, [[x,-1,0], [0,x,-1]])
sage: kerbas.is_minimal_kernel_basis(pmat)
True

>>> from sage.all import *
>>> pR = GF(Integer(97))['x']; (x,) = pR._first_ngens(1)
>>> pmat = Matrix(pR, [[Integer(1)], [x], [x**Integer(2)]])

>>> kerbas = Matrix(pR, [[x,-Integer(1),Integer(0)], [Integer(0),x,-Integer(1)]])
>>> kerbas.is_minimal_kernel_basis(pmat)
True
A matrix in Popov form which has the right rank, all rows in the kernel, but does not generate the kernel:

```python
sage: kerbas = Matrix(pR, [[x**2,0,-1], [0,x,-1]])
sage: kerbas.is_minimal_kernel_basis(pmat)
False
```

Shifts and right kernel bases are supported (with `row_wise`), and one can test whether the kernel basis is normalized in shifted-Popov form (with `normal_form`):

```python
sage: kerbas = Matrix(pR, [[x**Integer(2),Integer(0),-Integer(1)], [Integer(0), -x,-Integer(1)]]))
>>> kerbas.is_minimal_kernel_basis(pmat)
False
```

```python
>>> from sage.all import *
>>> kerbas = Matrix(pR, [[-x,-x**2], [1,0], [0,1]])
>>> kerbas.is_minimal_kernel_basis(pmat, row_wise=False, normal_form=True, shifts=[0,1,2])
True
```

```python
>>> from sage.all import *
>>> kerbas = Matrix(pR, [[-x,-x**Integer(2)], [Integer(1),Integer(0)], [Integer(0),Integer(1)],[Integer(0),Integer(1),Integer(2)])
>>> kerbas.is_minimal_kernel_basis(pmat, row_wise=False, normal_form=True, shifts=[0,1,2])
True
```

**is_popov** *(shifts=None, row_wise=True, up_to_permutation=False, include_zero_vectors=True)*

Return a boolean indicating whether this matrix is in (shifted) Popov form.

If working row-wise (resp. column-wise), a polynomial matrix is said to be in Popov form if it has no zero row above a nonzero row (resp. no zero column to the left of a nonzero column), the leading positions of its nonzero rows (resp. columns) are strictly increasing, and for each row (resp. column) the pivot entry is monic and has degree strictly larger than the other entries in its column (resp. row).

Since other conventions concerning the ordering of the rows (resp. columns) are sometimes useful, an optional argument allows one to test whether the matrix is in Popov form up to row (resp. column) permutation. For example, there is an alternative definition which replaces “leading positions strictly increasing” by “row (resp. column) degree nondecreasing, and for rows (resp. columns) of same degree, leading positions increasing”.

**INPUT:**

- `shifts` – (default: None) list of integers; None is interpreted as `shifts=[0, ..., 0]`.
- `row_wise` – (default: True) boolean, True if working row-wise (see the class description).
- `up_to_permutation` – (option, default: False) boolean, True if testing Popov form up to row permutation (if working row-wise).
- `include_zero_vectors` – (default: True) boolean, False if one does not allow zero rows (resp. zero columns) in Popov forms.

**OUTPUT:** a boolean.

**REFERENCES:**

For the square case, without shifts: [Pop1972] and [Kai1980] (Section 6.7.2). For the general case: [BLV2006].
EXAMPLES:

```
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[x^4+6*x^3+4*x+4, 3*x+6, 3 ],
       ....: [x^2+6*x+6, x^2+5*x+5, 2 ],
       ....: [3*x, 6*x+5, x+5]])
sage: M.is_popov()
True
sage: M.is_popov(shifts=[0,1,2])
True
sage: M[:,2].is_popov()
False
sage: M[:2,:].is_popov(shifts=[0,1,2])
True
sage: M = Matrix(pR, [[x^4+3*x^3+x^2+2*x+6, x^3+5*x^2+5*x+1],
       ....: [6*x+1, x^2+4*x+1 ],
       ....: [6, 6 ]])
sage: M.is_popov(row_wise=False)
False
sage: M.is_popov(shifts=[0,2,3], row_wise=False)
True
>>> from sage.all import *
>>> pR = GF(Integer(7))['x']; (x,) = pR._first_ngens(1)
>>> M = Matrix(pR, 
   →[[x**Integer(4)+Integer(6)*x**Integer(3)+Integer(4)*x+Integer(4),
   →Integer(3)*x+Integer(6), Integer(3) ],
   ... [x**Integer(2)+Integer(6)*x+Integer(6),
   →x**Integer(2)+Integer(5)*x+Integer(5), Integer(2) ],
   ... [Integer(3)*x, Integer(6)*x+Integer(5), ...
   →x+Integer(5)])])
>>> M.is_popov()
True
>>> M.is_popov(shifts=[Integer(0),Integer(1),Integer(2)])
True
>>> M[:Integer(2)].is_popov()
False
>>> M[:Integer(2),:].is_popov(shifts=[Integer(0),Integer(1),Integer(2)])
True
>>> M = Matrix(pR, 
   →[[x**Integer(4)+Integer(3)*x**Integer(3)+x**Integer(2)+Integer(2)*x+Integer(6),
   →x**Integer(3)+Integer(5)*x**Integer(2)+Integer(5)*x+Integer(1)],
   ... [Integer(6)*x+Integer(1), ...
   →x**Integer(2)+Integer(4)*x+Integer(1) ],
   ... [Integer(6), Integer(6) ]])
>>> M.is_popov(row_wise=False)
False
>>> M.is_popov(shifts=[Integer(0),Integer(2),Integer(3)], row_wise=False)
(continues on next page)
One can forbid zero rows (or columns if not working row-wise):

```
sage: N = Matrix(pR, [[x^4+3*x^3+x^2+2*x+6, 6*x+1],
                    [5*x^2+5*x+1, x^2+4*x+1],
                    [0, 0]])
sage: N.is_popov()
True
sage: N.is_popov(include_zero_vectors=False)
False
```

One can verify Popov form up to row permutation (or column permutation if not working row-wise):

```
>>> from sage.all import *
>>> M = Matrix(pR, ...
→[[x**Integer(4)+Integer(3)*x**Integer(3)+x**Integer(2)+Integer(2)*x+Integer(6),
→ Integer(6)*x+Integer(1) ],
... [Integer(5)*x**Integer(2)+Integer(5)*x+Integer(1), ...
→ x**Integer(2)+Integer(4)*x+Integer(1) ],
... [Integer(0), Integer(0)]])
>>> M.is_popov()
True
>>> M.is_popov(include_zero_vectors=False)
False
```

```
is_reduced (shifts=None, row_wise=True, include_zero_vectors=True)

Return a boolean indicating whether this matrix is in (shifted) reduced form.

An $m \times n$ univariate polynomial matrix $M$ is said to be in shifted row reduced form if it has $k$ nonzero rows with $k \leq n$ and its shifted leading matrix has rank $k$. Equivalently, when considering all the matrices obtained by left-multiplying $M$ by a unimodular matrix, then the shifted row degrees of $M$ – once sorted in nondecreasing order – is lexicographically minimal.

Similarly, $M$ is said to be in shifted column reduced form if it has $k$ nonzero columns with $k \leq m$ and its shifted leading matrix has rank $k$.

Sometimes, one forbids $M$ to have zero rows (resp. columns) in the above definitions; an optional parameter allows one to adopt this more restrictive setting.

INPUT:

- shifts – (default: None) list of integers; None is interpreted as shifts=[0,...,0].
- row_wise – (default: True) boolean, True if working row-wise (see the class description).
- include_zero_vectors – (default: True) boolean, False if one does not allow zero rows in row reduced forms (resp. zero columns in column reduced forms).

OUTPUT: a boolean value.

REFERENCES:

[Wol1974] (Section 2.5, without shifts) and [VBB1992] (Section 3).

EXAMPLES:

```
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[[3*x+1, 0, 1], [x^3+3, 0, 0]]])
sage: M.is_reduced()
False
sage: M.is_reduced(shifts=[0,1,2])
True
sage: M.is_reduced(shifts=[2,0], row_wise=False)
True
sage: M.is_reduced(shifts=[2,0], row_wise=False, include_zero_vectors=False)
False
sage: M = Matrix(pR, [[[3*x+1, 0, 1], [x^3+3, 0, 0], [0, 1, 0]]])
sage: M.is_reduced(shifts=[2,0,0], row_wise=False)
True
```

```
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> M = Matrix(pR, [[Integer(3)*x+Integer(1), Integer(0), Integer(1)],
               [x**Integer(3)+Integer(3), Integer(0), Integer(0)]])
```

```python
>>> M.is_reduced()
False
```

```python
>>> M.is_reduced(shifts=[Integer(0),Integer(1),Integer(2)])
True
```

```python
>>> M.is_reduced(shifts=[Integer(2),Integer(0)], row_wise=False)
True
```

```python
>>> M.is_reduced(shifts=[Integer(2),Integer(0)], row_wise=False,
               include_zero_vectors=False)
False
```

```python
>>> M = Matrix(pR, [[Integer(3)*x+Integer(1), Integer(0), Integer(1)],
               [x**Integer(3)+Integer(3), Integer(0), Integer(0)],
               [Integer(0), Integer(1), Integer(0)]])
```

```python
>>> M.is_reduced(shifts=[Integer(2),Integer(0),Integer(0)], row_wise=False)
True
```

See also:

`leading_matrix()`, `reduced_form()`.

**is_weak_popov** (shifts=None, row_wise=True, ordered=False, include_zero_vectors=True)

Return a boolean indicating whether this matrix is in (shifted) (ordered) weak Popov form.

If working row-wise (resp. column-wise), a polynomial matrix is said to be in weak Popov form if the leading positions of its nonzero rows (resp. columns) are pairwise distinct. For the ordered weak Popov form, these positions must be strictly increasing, except for the possibly repeated -1 entries which are at the end. For the shifted variants, see the class description for an introduction to shifts.

**INPUT:**

- `shifts` – (default: None) list of integers; `None` is interpreted as `shifts=[0,...,0]`.
- `row_wise` – (default: True) boolean, True if working row-wise (see the class description).
- `ordered` – (default: False) boolean, True if checking for an ordered weak Popov form.
- `include_zero_vectors` – (default: True) boolean, False if one does not allow zero rows (resp. zero columns) in (ordered) weak Popov forms.

**OUTPUT:** a boolean.

**REFERENCES:**

[Kai1980] (Section 6.7.2, square case without shifts), [MS2003] (without shifts), [BLV1999].

**EXAMPLES:**

```python
sage: pR.<x> = GF(7)[]
sage: M = Matrix([ [x^3+3*x^2+6*x+6, 3*x^2+3*x+6, 4*x^2+x+3],
               [5, 1, 0],
               [2*x^2+2, 2*x+5, x^2+4*x+6] ])  
```

```python
sage: M.is_weak_popov()  
True
```
One can check whether the leading positions, in addition to being pairwise distinct, are actually in increasing order:

```python
sage: M.is_weak_popov(ordered=True)
True
sage: N = M.with_swapped_rows(1, 2)
sage: N.is_weak_popov()
True
sage: N.is_weak_popov(ordered=True)
False
```

Shifts and orientation (row-wise or column-wise) are supported:

```python
sage: M.is_weak_popov(shifts=[2, 3, 1])
False
sage: M.is_weak_popov(shifts=[0, 2, 0], row_wise=False, ordered=True)
True
```

Rectangular matrices are supported:

```python
sage: M = Matrix(
....: [ x^3+5*x^2+5*x+1, 5, 6*x+4, 0],
....: [Integer(5), Integer(1), Integer(0), ]
```
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

....: [ 6*x^2+3*x+1, 1, 2, 0],
....: [2*x^3+4*x^2+6*x+4, 5*x + 1, 2*x^2+5*x+5, x^2+5*x+6]
....: ]
)
sage: M.is_weak_popov(shifts=[0,2,1,3])
True

sage: M.is_weak_popov(shifts=[0,2,1,3], ordered=True)
True

>>> from sage.all import *
>>> M = Matrix([... [ x**Integer(3)+Integer(5)*x**Integer(2)+Integer(5)*x+Integer(1), ...
\rightarrow Integer(5), Integer(6)*x+Integer(4), Integer(0)], ...
\rightarrow Integer(1), Integer(2), Integer(0)], ...
\rightarrow[Integer(2)*x**Integer(3)+Integer(4)*x**Integer(2)+Integer(5)*x+Integer(4), ...
\rightarrow Integer(5)*x + Integer(1), Integer(2)*x**Integer(2)+Integer(5)*x+Integer(5), ...
\rightarrow x**Integer(2)+Integer(5)*x+Integer(6)]
})

sage: M.is_weak_popov(shifts=[Integer(0),Integer(2),Integer(1),Integer(3)])
True

sage: M.is_weak_popov(shifts=[Integer(0),Integer(2),Integer(1),Integer(3)], ordered=True)
True

Zero rows (resp. columns) can be forbidden:

sage: M = Matrix([...
....: [ 6*x+4, 0, 5*x+1, 0],
....: [ 2, 5*x + 1, 6*x^2+3*x+1, 0],
....: [2*x^2+5*x+5, 1, 2*x^3+4*x^2+6*x+4, 0]
....: ])

sage: M.is_weak_popov(shifts=[2,1,0], row_wise=False, ordered=True)
True

sage: M.is_weak_popov(shifts=[2,1,0], row_wise=False, include_zero_vectors=False)
False

>>> from sage.all import *
>>> M = Matrix([...
....: [ Integer(6)*x+Integer(4), Integer(0)], ...
\rightarrow Integer(5)*x+Integer(1), Integer(0)], ...
\rightarrow Integer(2), Integer(5)*x + Integer(1), ...
\rightarrow Integer(6)*x**Integer(2)+Integer(3)*x+Integer(1), Integer(0)], ...
\rightarrow Integer(2)*x**Integer(2)+Integer(5)*x+Integer(5), Integer(1), ...
\rightarrow Integer(2)*x**Integer(3)+Integer(4)*x**Integer(2)+Integer(6)*x+Integer(4), ...
\rightarrow Integer(0)]
})

sage: M.is_weak_popov(shifts=[Integer(2),Integer(1),Integer(0)], row_wise=False, ordered=True)
True

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

>>> M.is_weak_popov(shifts=[Integer(2),Integer(1),Integer(0)], row_wise=False, include_zero_vectors=False)
False

See also:

weak_popov_form().

**leading_matrix**(shifts=None, row_wise=True)

Return the (shifted) leading matrix of this matrix.

Let $M$ be a univariate polynomial matrix in $\mathbb{K}[x]^{m \times n}$. Working row-wise and without shifts, its leading matrix is the matrix in $\mathbb{K}^{m \times n}$ formed by the leading coefficients of the entries of $M$ which reach the degree of the corresponding row.

More precisely, if working row-wise, let $s_1, \ldots, s_n \in \mathbb{Z}$ be a shift, and let $(d_1, \ldots, d_m)$ denote the shifted row degrees of $M$. Then, the shifted leading matrix of $M$ is the matrix in $\mathbb{K}^{m \times n}$ whose entry $i,j$ is the coefficient of degree $d_i - s_j$ of the entry $i,j$ of $M$.

If working column-wise, let $s_1, \ldots, s_m \in \mathbb{Z}$ be a shift, and let $(d_1, \ldots, d_n)$ denote the shifted column degrees of $M$. Then, the shifted leading matrix of $M$ is the matrix in $\mathbb{K}^{m \times n}$ whose entry $i,j$ is the coefficient of degree $d_j - s_i$ of the entry $i,j$ of $M$.

**INPUT:**

- shifts – (default: None) list of integers; None is interpreted as shifts=[0, \ldots, 0].
- row_wise – (default: True) boolean, True if working row-wise (see the class description).

**OUTPUT:** a matrix over the base field.

**REFERENCES:**

[Wol1974] (Section 2.5, without shifts) and [VBB1992] (Section 3).

**EXAMPLES:**

```
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[3*x+1, 0, 1], [x^3+3, 0, 0]])
sage: M.leading_matrix()
[3 0 0]
[1 0 0]
sage: M.leading_matrix().base_ring()
Finite Field of size 7
sage: M.leading_matrix(shifts=[0,1,2])
[0 0 1]
[1 0 0]
sage: M.leading_matrix(row_wise=False)
[0 0 1]
[1 0 0]
sage: M.leading_matrix(shifts=[-2,1], row_wise=False)
[0 0 1]
[1 0 0]
sage: M.leading_matrix(shifts=[2,0], row_wise=False)
```

[3 0 1]
[1 0 0]
```

**leading_positions (shifts=None, row_wise=True, return_degree=False)**

Return the (shifted) leading positions (also known as the pivot indices), and optionally the (shifted) pivot degrees of this matrix.

If working row-wise, for a given shift $s_1, \ldots, s_n \in \mathbb{Z}$, taken as $(0, \ldots, 0)$ by default, and a row vector of univariate polynomials $[p_1, \ldots, p_n]$, the leading position of this vector is the index $j$ of the rightmost nonzero entry $p_j$ such that $\deg(p_j) + s_j$ is equal to the shifted row degree of the vector. Then the pivot degree of the vector is the degree $\deg(p_j)$.

For the zero row, both the leading positions and degree are $-1$. For a $m \times n$ polynomial matrix, the leading positions and pivot degrees are the two lists containing the leading positions and the pivot degrees of its rows.

The definition is similar if working column-wise (instead of rightmost nonzero entry, we choose the bottom-most nonzero entry).

**INPUT:**

- **shifts** – (default: None) list of integers; None is interpreted as shifts=[0, ..., 0].
- **row_wise** – (default: True) boolean, True if working row-wise (see the class description).
- **return_degree** – (default: False) boolean, True implies that the pivot degrees are returned.

**OUTPUT:** a list of integers if return_degree=False; a pair of lists of integers otherwise.

**REFERENCES:**

[Kai1980] (Section 6.7.2, without shifts).

**EXAMPLES:**
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[3*x+1, 0, 1], [x^3+3, 0, 0]])
sage: M.leading_positions()
[0, 0]
sage: M.leading_positions(return_degree=True)
([0, 0], [1, 3])
sage: M.leading_positions(shifts=[0,5,2], return_degree=True)
([2, 0], [0, 3])
sage: M.leading_positions(row_wise=False, return_degree=True)
([[1, -1, 0], [3, -1, 0]])
sage: M.leading_positions(shifts=[1,2], row_wise=False, ...:
return_degree=True)
([[1, -1, 0], [3, -1, 0]])

```python
>>> from sage.all import *
```
```python
>>> pR = GF(Integer(7))['x']; (x,) = pR._first_ngens(1)
```
```python
>>> M = Matrix(pR, [[Integer(3)*x+Integer(1), Integer(0), Integer(1)],
                   [x**Integer(3)+Integer(3), Integer(0), Integer(0)]])
```
```python
>>> M.leading_positions()  
[0, 0]
```
```python
>>> M.leading_positions(return_degree=True)
([0, 0], [1, 3])
```
```python
>>> M.leading_positions(shifts=[Integer(0),Integer(5),Integer(2)], return_...
return_degree=True)
([2, 0], [0, 3])
```
```python
>>> M.leading_positions(row_wise=False, return_degree=True)
([[1, -1, 0], [3, -1, 0]])
```
```python
>>> M.leading_positions(shifts=[Integer(1),Integer(2)], row_wise=False, ...
return_degree=True)
([[1, -1, 0], [3, -1, 0]])
```

In case several entries in the row (resp. column) reach the shifted row (resp. column) degree, the leading position is chosen as the rightmost (resp. bottommost) such entry:

```python
sage: M.leading_positions(shifts=[0,5,1], return_degree=True)
([2, 0], [0, 3])
```
```python
sage: M.leading_positions(shifts=[2,0], row_wise=False, ...
return_degree=True)
([[1, -1, 0], [3, -1, 0]])
```

```python
>>> from sage.all import *
```
```python
>>> M.leading_positions(shifts=[Integer(0),Integer(5),Integer(1)], return_...
return_degree=True)
([2, 0], [0, 3])
```
```python
>>> M.leading_positions(shifts=[Integer(2),Integer(0)], row_wise=False, ...
return_degree=True)
([[1, -1, 0], [3, -1, 0]])
```
The leading positions and pivot degrees of an empty matrix \((0 \times n)\) or \((m \times 0)\) is not defined:

```
sage: M = Matrix(pR, 0, 3)
sage: M.leading_positions()
Traceback (most recent call last):
...  
ValueError: empty matrix does not have leading positions
sage: M.leading_positions(row_wise=False)
Traceback (most recent call last):
...  
ValueError: empty matrix does not have leading positions
```

```
>>> from sage.all import *
>>> M = Matrix(pR, Integer(0), Integer(3))
>>> M.leading_positions()
Traceback (most recent call last):
...  
ValueError: empty matrix does not have leading positions
>>> M.leading_positions(row_wise=False)
Traceback (most recent call last):
...  
ValueError: empty matrix does not have leading positions
```

```
left_quo_rem\(B\)
```

Return, if it exists, the quotient and remainder \((Q, R)\) such that \(\text{self} = BQ + R\), where \(R\) has row degrees less than those of \(B\) entrywise.

This method directly calls \(right_quo_rem()\) on transposed matrices, and transposes the result. See \(right_quo_rem()\) for a complete documentation and more examples.

EXAMPLES:

```
sage: pR.<x> = GF(7)[]
sage: A = Matrix(pR, 3, 2,  
...:     [[ 3*x^3 + 3*x, 2*x^3 + 4], 
...:     [ 3*x^3 + 6*x + 5, 6*x^3 + 5*x^2 + 1], 
...:     [ 2*x^3 + 2*x + 6, 3*x^2 + 2*x + 2]])

sage: B = Matrix(pR, 3, 3,  
...:     [[ 3*x^3 + 3*x + 1, 4*x^2 + 3*x, 6*x^3 + x + 4], 
...:     [ 4*x^2 + x + 4, 3*x^2 + 4*x, 3*x^2 + 3*x + 2]])

sage: Q, R = A.left_quo_rem(B); Q, R
([2*x^2 + 4*x + 6 6*x^2 + 4*x + 1] [ 3 1]  
(continues on next page)

minimal_approximant_basis(order, shifts=None, row_wise=True, normal_form=False)

Return an approximant basis in shifts-ordered weak Popov form for this polynomial matrix at order or-
der.

Assuming we work row-wise, if $F$ is an $m \times n$ polynomial matrix and $(d_0,\ldots,d_{n-1})$ are positive integers, 
then an approximant basis for $F$ at order $(d_0,\ldots,d_{n-1})$ is a polynomial matrix whose rows form a basis 
of the module of approximants for $F$ at order $(d_0,\ldots,d_{n-1})$. The latter approximants are the polynomial 

vectors $p$ of size $m$ such that the column $j$ of $pF$ has valuation at least $d_j$, for all $0 \leq j \leq n-1$.

If \texttt{normal_form} is \texttt{True}, then the output basis $P$ is furthermore in shifts-Popov form. By default, $P$ 
is considered row-wise, that is, its rows are left-approximants for \texttt{self}; if \texttt{row_wise} is \texttt{False} then its 
columns are right-approximants for \texttt{self}. It is guaranteed that the degree of the output basis is at most the 
maximum of the entries of \texttt{order}, independently of \texttt{shifts}.

An error is raised if the input dimensions are not sound: if working row-wise (resp. column-wise), the length 
of \texttt{order} must be the number of columns (resp. rows) of \texttt{self}, while the length of \texttt{shifts} must be the 
number of rows (resp. columns) of \texttt{self}.

If a single integer is provided for \texttt{order}, then it is converted into a list of repeated integers with this value.

INPUT:

• \texttt{order} – a list of positive integers, or a positive integer.
• shifts – (default: None) list of integers; None is interpreted as shifts=[0,...,0].
• row_wise – (default: True) boolean, if True then the output basis is considered row-wise and operates on the left of self; otherwise it is column-wise and operates on the right of self.
• normal_form – (default: False) boolean, if True then the output basis is in shifts-Popov form.

OUTPUT: a polynomial matrix.

ALGORITHM:
The implementation is inspired from the iterative algorithms described in [VBB1992] and [BL1994]; for obtaining the normal form, it relies directly on Lemmas 3.3 and 4.1 in [JNSV2016].

EXAMPLES:

```sage
sage: pR.<x> = GF(7)[]
sage: order = [4, 3]; shifts = [-1, 2, 0]
sage: F = Matrix(pR, [[5*x^3 + 4*x^2 + 4*x + 6, 5*x^2 + 4*x + 1],
                   [2*x^2 + 2*x + 3, 6*x^2 + 6*x + 3],
                   [4*x^3 + x + 1, 4*x^2 + 2*x + 3]])
sage: P = F.minimal_approximant_basis(order, shifts)
sage: P.is_minimal_approximant_basis(F, order, shifts)
True
```

By default, the computed basis is not required to be in normal form (and will not be except in rare special cases):

```sage
sage: P.is_minimal_approximant_basis(F, order, shifts,
                   normal_form=True)
False
sage: P = F.minimal_approximant_basis(order, shifts,
                   normal_form=True)
```

(continues on next page)
... normal_form=True)
>>> P.is_minimal_approximant_basis(F, order, shifts,
... normal_form=True)
True

If shifts are not specified, they are chosen as uniform \([0, \ldots, 0]\) by default. Besides, if the orders are all the same, one can rather give a single integer:

\[
sage: (F.minimal_approximant_basis(3) ==
....: F.minimal_approximant_basis([3,3], shifts=None))
True
\]

\[
>>> from sage.all import *

>>> (F.minimal_approximant_basis(Integer(3)) ==
... F.minimal_approximant_basis([Integer(3),Integer(3)], shifts=None))
True
\]

One can work column-wise by specifying \(\text{row-wise=False}\):

\[
sage: P = F.minimal_approximant_basis([5,2,2], [0,1],
....: row_wise=False)

sage: P.is_minimal_approximant_basis(F, [5,2,2], shifts=[0,1],
....: row_wise=False)
True

sage: (F.minimal_approximant_basis(3, row_wise=True) ==
....: F.transpose().minimal_approximant_basis(3, row_wise=False).transpose())
True
\]

\[
>>> from sage.all import *

>>> P = F.minimal_approximant_basis([Integer(5),Integer(2),Integer(2)],
˓→[Integer(0),Integer(1)],
...
row_wise=False)

>>> P.is_minimal_approximant_basis(F, [Integer(5),Integer(2),Integer(2)],
˓→shifts=[Integer(0),Integer(1)],
...
row_wise=False)
True

>>> (F.minimal_approximant_basis(Integer(3), row_wise=True) ==
...
F.transpose().minimal_approximant_basis(
...
Integer(3), row_wise=False).transpose())
True
\]

Errors are raised if the input dimensions are not sound:

\[
sage: P = F.minimal_approximant_basis([4], shifts)
Traceback (most recent call last):
...
ValueError: order length should be the column dimension
\]

\[
sage: P = F.minimal_approximant_basis(order, [0,0,0,0])
Traceback (most recent call last):
...
ValueError: shifts length should be the row dimension
\]
An error is raised if order does not contain only positive integers:

```
sage: P = F.minimal_approximant_basis([1,0], shifts)
Traceback (most recent call last):
  ... ValueError: order should consist of positive integers
```

```
>>> from sage.all import *

>>> P = F.minimal_approximant_basis(order, [Integer(0),Integer(0),Integer(0),
˓→Integer(0)])
Traceback (most recent call last):
  ... ValueError: shifts length should be the row dimension
```

`minimal_kernel_basis`(shifts=None, row_wise=True, normal_form=False)

Return a left kernel basis in shifts-ordered weak Popov form for this polynomial matrix.

Assuming we work row-wise, if F is an \( m \times n \) polynomial matrix, then a left kernel basis for F is a polynomial matrix whose rows form a basis of the left kernel of F, which is the module of polynomial vectors p of size m such that \( pF \) is zero.

If normal_form is True, then the output basis \( P \) is furthermore in shifts-Popov form. By default, \( P \) is considered row-wise, that is, its rows are left kernel vectors for self; if row_wise is False then its columns are right kernel vectors for self.

An error is raised if the input dimensions are not sound: if working row-wise (resp. column-wise), the length of shifts must be the number of rows (resp. columns) of self.

INPUT:

- shifts- (default: None) list of integers; None is interpreted as shifts=[0, ..., 0].
- row_wise- (default: True) boolean, if True then the output basis considered row-wise and operates on the left of self; otherwise it is column-wise and operates on the right of self.
- normal_form- (default: False) boolean, if True then the output basis is in shifts-Popov form.

OUTPUT: a polynomial matrix.

ALGORITHM: uses minimal approximant basis computation at a sufficiently large order so that the approximant basis contains a kernel basis as a submatrix.

EXAMPLES:

```
sage: pR.<x> = GF(7)[]
sage: pmat = Matrix([[x+1]*(x+3)], [(x+1)*(x+3)+1]])
sage: pmat.minimal_kernel_basis()
[6*x^2 + 3*x + 3  x^2 + 4*x + 3]
```
Matrices and Spaces of Matrices, Release 10.4

[6 x 0]
[6 6 1]

**popov_form** *(transformation=False, shifts=None, row_wise=True, include_zero_vectors=True)*

Return the (shifted) Popov form of this matrix.

See **is_popov()** for a definition of Popov forms. If the input matrix is $A$, the (shifted) Popov form of $A$ is the unique matrix $P$ in (shifted) Popov form and such that $UA = P$ for some unimodular matrix $U$. The latter matrix is called the transformation, and the first optional argument allows one to specify whether to return this transformation. We refer to the description of **weak_popov_form()** for an explanation of the option **include_zero_vectors**.

**INPUT:**

- **transformation** – (default: False). If this is True, the transformation matrix $U$ will be returned as well.
- **shifts** – (default: None) list of integers; None is interpreted as shifts=[0, ... , 0].
- **row_wise** – (default: True) boolean, True if working row-wise (see the class description).
- **include_zero_vectors** – (default: True) boolean, False if zero rows (resp. zero columns) should be discarded from the Popov forms.

**OUTPUT:**

- A polynomial matrix which is the Popov form of **self** if **transformation** is False; otherwise
two polynomial matrices which are the Popov form of self and the corresponding unimodular transformation.

ALGORITHM:

This method implements the Mulders-Storjohann algorithm of [MS2003] for transforming a weak Popov form into Popov form, straightforwardly extended to the case of shifted forms.

EXAMPLES:

```
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [ 
    ...: 6*x+4, 5*x^3+5*x, 6*x^2+2*x+2], 
    ...: [4*x^2+5*x+2, x^4+5*x^2+2*x+4, 4*x^3+6*x^2+6*x+5])

sage: # needs sage.combinat
sage: P, U = M.popov_form(transformation=True)

sage: P
\begin{bmatrix}
4 & x^2 + 4*x + 1 & 3 \\
0 & 4*x + 1 & x^2 + 6*x + 1
\end{bmatrix}

sage: U
\begin{bmatrix}
 x & 2 \\
5*x^2 + x + 6 & 3*x + 2
\end{bmatrix}

sage: P.is_popov() and U.is_invertible() and U*M == P
True
```

Demonstrating shifts and specific case of Hermite form:

```
sage: # needs sage.combinat
sage: P = M.popov_form(shifts=[0,2,4]); P
\begin{bmatrix}
4*x^2 + 3*x + 4 & x^4 + 3*x^3 + 5*x^2 + 5*x + 5 \\
0 & 6 & 5*x^2 + 6*x + 5
\end{bmatrix}

sage: P.is_popov(shifts=[0,2,4])
True

sage: P == M.popov_form(shifts=[-6,-4,-2])
True
```

(continues on next page)
Column-wise form is the row-wise form of the transpose:

```sage
M.popov_form() == M.T.popov_form(row_wise=False).T
True
```

Zero vectors can be discarded:

```sage
M.popov_form(row_wise=False)
[[x + 2 6 0]
 [0 1 0]]

# needs sage.combinat
P, U = M.popov_form(transformation=True,
....: row_wise=False,
....: include_zero_vectors=False)
P
[[x + 2 6]
 [0 1]]
U
[[3*x^2 + 6*x + 3 5*x^2 + 4*x + 4 3*x^3 + 3*x^2 + 2*x + 4]
 [3 1 2*x + 1]
 [5*x + 2 2 6]]
M*U[:,2] == P and (M*U[:,2]).is_zero()
True
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

... row_wise=False,
... include_zero_vectors=False)

>>> P
[x + 2 6]
[ 0 1]

>>> U
[3*x^2 + 6*x + 3 5*x^2 + 4*x + 4 3*x^3 + 3*x^2 + 2*x + 4]
[3 1 2*x + 1]

reduce(B, shifts=None, row_wise=True, return_quotient=False)

Reduce self, i.e. compute its normal form, modulo the row space of B with respect to shifts.

If self is a $k \times n$ polynomial matrix (written $A$ below), and the input $B$ is an $m \times n$ polynomial matrix, this computes the normal form $R$ of $A$ with respect to the row space of $B$ and the monomial order defined by shifts (written $s$ below). This means that the $i$th row of $R$ is equal to the $i$th row of $A$ up to addition of an element in the row space of $B$, and if $J = (j_1, \ldots, j_r)$ are the $s$-leading positions of the $s$-Popov form $P$ of $A$, then the submatrix $R_{s,J}$ (submatrix of $R$ formed by its columns in $J$) has column degrees smaller entrywise than the column degrees of $P_{s,J}$.

If the option row_wise is set to False, the same operation is performed, but with everything considered column-wise: column space of $B$, $i$th column of $R$ and $A$, column-wise $s$-leading positions and $s$-Popov form, and submatrices $R_{J,s}$ and $P_{J,s}$.

The operation above can be seen as a matrix generalization of division with remainder for univariate polynomials. If the option return_quotient is set to True, this method returns both the normal form $R$ and a quotient matrix $Q$ such that $A = QB + R$ (or $A = BQ + R$ if row_wise is False). Whereas the remainder is unique, this quotient is not unique unless $B$ has a trivial left kernel i.e. has full row rank (or right kernel, full column rank if row_wise is False).

This method checks whether $B$ is in $s$-Popov form, and if not, computes the $s$-Popov form $P$ of $B$, which can take some time. Therefore, if $P$ is already known or is to be re-used, this method should be called directly with $P$, yielding the same normal form $R$ since $P$ and $B$ have the same row space (or column space, if row_wise is False).

A ValueError is raised if the dimensions of the shifts and/or of the matrices are not conformal.

INPUT:

- $B$ – polynomial matrix.
- shifts – (default: None) list of integers; None is interpreted as shifts=[0, ..., 0].
- row_wise – (default: True) boolean, True if working row-wise (see the class description).
- return_quotient – (default: False). If this is True, the quotient will be returned as well.

OUTPUT: a polynomial matrix if return_quotient=False, two polynomial matrices otherwise.

EXAMPLES:

sage: pR.<x> = GF(7)[]
sage: B = Matrix(pR, [6*x+4, 5*x^3+5*x, 6*x^2+2*2*x+2], [6*2^4, 5*x^3+5*x, 6*x^2+2*2*x+2], [6*2^4, 5*x^3+5*x, 6*x^2+2*2*x+2]) (continues on next page)
....:

\[

\end{bmatrix}
\]

```
sage: A = Matrix(pR, 1, 3, [
4*x^4+3*x^3+4*x^2+2*x+5*x+1, x^4+x^3+5*x^2+4*x+4, 4*x^4+2*x^3+3*x+2*x+6
])
```

```
sage: Q, R = A.reduce(B, return_quotient=True); R
[3*x^4 + 3*x^3 + 4*x + 3 2*x + 2 2*x + 6]
sage: A == Q*B + R
True
```

```
sage: P = B.popov_form(); P.leading_positions(return_degree=True)
([1, 2], [2, 2])
sage: R.degree_matrix()
[4 1 1]
sage: A.reduce(P) == R
True
```

```
sage: A.reduce(P[:,:2])
Traceback (most recent call last):
...
ValueError: column dimension of self should be the column dimension of the input matrix
```

```python
>>> from sage.all import *
>>> pR = GF(Integer(7))['x']; (x,) = pR._first_ngens(1)
>>> B = Matrix(pR, [
... [Integer(6)*x+Integer(4), Integer(5)*x**Integer(3)+Integer(5)*x, ...
... Integer(6)*x**Integer(2)+Integer(2)*x+Integer(2)], ...
... [Integer(4)*x**Integer(2)+Integer(5)*x+Integer(2), ...
... x**Integer(4)+Integer(5)*x**Integer(2)+Integer(2)*x+Integer(4), ...
... Integer(4)*x**Integer(3)+Integer(6)*x**Integer(2)+Integer(6)*x+Integer(5)]])
>>> A = Matrix(pR, Integer(1), Integer(3), [
... [Integer(3)*x**Integer(4)+Integer(3)*x**Integer(3)+Integer(4)*x**Integer(2)+Integer(5)*x+Integer(1), ...
... x**Integer(4)+Integer(3)*x**Integer(3)+Integer(5)*x**Integer(2)+Integer(4)*x+Integer(4), ...
... Integer(4)*x**Integer(4)+Integer(2)*x**Integer(3)+x])
>>> Q, R = A.reduce(B, return_quotient=True); R
[3*x^4 + 3*x^3 + 4*x + 3 2*x + 2 2*x + 6]
>>> A == Q*B + R
True
>>> P = B.popov_form(); P.leading_positions(return_degree=True)
([1, 2], [2, 2])
>>> R.degree_matrix()
[4 1 1]
>>> A.reduce(P) == R
True
>>> A.reduce(P[:,:2])
Traceback (most recent call last):
...
ValueError: column dimension of self should be the column dimension of the input matrix
```

Demonstrating shifts:

```
sage: Qs, Rs = A.reduce(B, shifts=[0,2,4], return_quotient=True); Rs
[3*x^4 + 3*x^3 + 6*x + 2 4*x^3 + 5*x 0]
sage: A == Qs*B + Rs
```

(continues on next page)
If return_quotient is False, only the normal form is returned:

```python
sage: R == A.reduce(B) and Rs == A.reduce(B, shifts=[0,2,4])
True
```

Demonstrating column-wise normal forms, with a matrix $A$ which has several columns, and a matrix $B$ which does not have full column rank (its column-wise Popov form has a zero column):

```python
sage: A = Matrix(pR, 2, 2,
....: [[5*x^3 + 2*x^2 + 4*x + 1, x^3 + 4*x + 4],
....: [2*x^3 + 5*x^2 + 2*x + 4, 2*x^3 + 3*x + 2]])
```

```python
>>> from sage.all import *
>>> Q, R = A.reduce(B, row_wise=False, return_quotient=True); R
[[0, 3]
[0, 0]]
sage: A == B*Q + R
True
```

```python
sage: A == B*Q + R
True
```

```python
sage: P = B.popov_form(row_wise=False); P
[[x + 2, 6, 0],
[0, 1, 0]]
sage: P.leading_positions(row_wise=False, return_degree=True)
([0, 1, -1], [1, 0, -1])
sage: P.degree_matrix()
[-1, 0]
[-1, -1]
```

```python
>>> from sage.all import *
```
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

```python
>>> A = Matrix(pR, Integer(2), Integer(2),
...   [[Integer(5)*x**Integer(3) + Integer(2)*x**2 + Integer(4)*x +
   Integer(1), x**3 + Integer(4)*x + Integer(4)],
...    [Integer(2)*x**2 + Integer(5)*x**2 + Integer(2)*x +
   Integer(4), Integer(2)*x**2 + Integer(3)*x +
   Integer(2)]])
>>> (Q,R) = A.reduce(B,row_wise=False, return_quotient=True); R
[0 3]
[0 0]
>>> A == B*Q + R
True

[x + 2 -6 0]
[ 0 1 0]
>>> P.leading_positions(row_wise=False, return_degree=True)
([[0, 1, -1], [1, 0, -1])
>>> R.degree_matrix()
[-1 0]
[-1 -1]
```

See also:

`left_quo_rem()`, `right_quo_rem()`.

`reduced_form` (transformation=None, shifts=None, row_wise=True, include_zero_vectors=True)

Return a row reduced form of this matrix (resp. a column reduced form if the optional parameter row_wise is set to False).

An $m \times n$ univariate polynomial matrix $M$ is said to be in (shifted) row reduced form if it has $k$ nonzero rows with $k \leq n$ and its (shifted) leading matrix has rank $k$. See `is_reduced()` for more information.

Currently, the implementation of this method is a direct call to `weak_popov_form()`.

INPUT:

- `transformation` – (default: False). If this is True, the transformation matrix $U$ will be returned as well: this is a unimodular matrix over $K[x]$ such that self equals $UR$, where $R$ is the output matrix.
- `shifts` – (default: None) list of integers; None is interpreted as shifts=[0,...,0].
- `row_wise` – (default: True) boolean, True if working row-wise (see the class description).
- `include_zero_vectors` – (default: True) boolean, False if one does not allow zero rows in row reduced forms (resp. zero columns in column reduced forms).

OUTPUT:

- A polynomial matrix $R$ which is a reduced form of self if `transformation=False`; otherwise two polynomial matrices $R, U$ such that $UA = R$ and $R$ is reduced and $U$ is unimodular where $A$ is self.

EXAMPLES:

```python
sage: pR.<x> = GF(3)[]
sage: A = matrix(pR, 3, [x, x^2, x^3, x^2, x^1, 0, x^3, x^3, x^3])
sage: R = A.reduced_form(); R
[ x x^2 x^3]
[ x^2 x 0]
```

(continues on next page)
If the matrix is an \( n \times 1 \) matrix with at least one non-zero entry, \( R \) has a single non-zero entry and that entry is a scalar multiple of the greatest-common-divisor of the entries of the matrix:

\[
A = \begin{bmatrix} x \cdot (x-1) \cdot (x+1) \\ x \cdot (x-2) \cdot (x+2) \\ x \end{bmatrix}
\]

\[
R = \begin{bmatrix} x \\ \text{0} \\ \text{0} \end{bmatrix}
\]

A zero matrix is already reduced:
In the following example, the original matrix is already reduced, but the output is a different matrix: currently this method is an alias for \texttt{weak\_popov\_form()}, which is a stronger reduced form:

```
sage: \texttt{R.<x> = QQ['x']}
sage: A = \texttt{matrix}([[x,x,x],[0,0,x]]); A
[x x x]
[0 0 x]
sage: A.is\_reduced()
True
sage: W = A.reduced_form(); W
[x x x]
[-x -x 0]
sage: W.is\_weak\_popov()
True
```

The last example shows the usage of the transformation parameter:

```
sage: \# needs \texttt{sage.rings.finite\_rings}
sage: Fq.<a> = GF(2^3)
sage: pR.<x> = Fq[]
sage: A = \texttt{matrix}(pR, [[x^2+a, x^4+a],
...: [x^3, a*x^4]])
sage: W, U = A.reduced_form(transformation=\texttt{True})
sage: W, U
([ x^2 + a x^4 + a]  [1 0]
[x^3 + a*x^2 + a^2 a^2], [a 1])
sage: W.is\_reduced()
True
sage: U*W == A
True
sage: U.is\_invertible()
True
```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> Fq = GF(Integer(2)**Integer(3), names=('a',)); (a,) = Fq._first_ngens(1)
>>> pR = Fq['x']; (x,) = pR._first_ngens(1)
>>> A = matrix(pR, [[x**Integer(2)+a, x **Integer(4)+a],
... [ x **Integer(3), a *x**Integer(4)]])
>>> W, U = A.reduced_form(transformation=True)
>>> W, U
(([ x^2 + a x^4 + a] [1 0]
[ x^3 + a x^2 + a^2 a^2]), [a 1])
>>> W.is_reduced()
True
>>> U*W == A
True
>>> U.is_invertible()
True

See also:

`is_reduced()`, `weak_popov_form()`, `popov_form()`, `hermite_form()`.

reverse (degree=None, row_wise=True, entry_wise=False)

Return the matrix which is obtained from this matrix after reversing all its entries with respect to the degree as specified by degree.

Reversing a polynomial with respect to an integer 𝑑 follows the convention for univariate polynomials, in particular it uses truncation or zero-padding as necessary if 𝑑 differs from the degree of this polynomial.

If `entry_wise` is True: the input `degree` and `row_wise` are ignored, and all entries of the matrix are reversed with respect to their respective degrees.

If `entry_wise` is False (the default):

• if `degree` is an integer, all entries are reversed with respect to it;

• if `degree` is not provided, then all entries are reversed with respect to the degree of the whole matrix;

• if `degree` is a list (𝑑₁,...,𝑑ₘ) and `row_wise` is True, all entries of the 𝑖ᵗʰ row are reversed with respect to 𝑑ᵢ for each 𝑖;

• if `degree` is a list (𝑑₁,...,𝑑ₙ) and `row_wise` is False, all entries of the 𝑗ᵗℎ column are reversed with respect to 𝑑ᵢ for each 𝑗.

INPUT:

• `degree` – (default: None) a list of nonnegative integers, or a nonnegative integer.

• `row_wise` – (default: True) boolean, if True (resp. False) then `degree` should be a list of length equal to the row (resp. column) dimension of this matrix.

• `entry_wise` – (default: False) boolean, if True then the input `degree` and `row_wise` are ignored.

OUTPUT: a polynomial matrix.

EXAMPLES:

`sage`: pR.<x> = GF(7)[]
`sage`: M = Matrix([...])
(continues on next page)
Entry-wise reversing with respect to each entry’s degree:

```python
sage: M.reverse(entry_wise=True)
[ x^3 + 5*x^2 + 5*x + 1 5 6*x + 4 0]
[ x^3 + 3*x^2 + 6*x + 4 5*x + 1 2*x^2 + 5*x + 5 x^2 + 5*x + 6]
```

(continues on next page)
>>> from sage.all import *
>>> M.reverse(entry_wise=True)
[[x^3 + 5*x^2 + 5*x + 1
  4*x + 6
  x^2 + 3*x + 6  2
  [4*x^3 + 6*x^2 + 4*x + 2  x + 5  5*x^2 + 5*x + 2  6*x^2 + 5*x + 1
  5*x + 2  6*x^2 + 5*x + 1]

Row-wise and column-wise degree reversing are available:

sage: M.reverse([2,3,1])
[[x^2 + 5*x + 5  5*x^2  4*x^2 + 6*x  0]
  [x^3 + 3*x^2 + 6*x  x^3  2*x^3  0]
  [4*x + 6  x + 5  5*x + 5  6*x + 5]

sage: M.reverse(M.column_degrees(), row_wise=False)
[[x^3 + 5*x^2 + 5*x + 1  5*x  4*x^2
  5*x
  [x^3 + 3*x^2 + 6*x  x
  2*x^2  0]
  [4*x^3 + 6*x^2 + 4*x + 2  x + 5  5*x^2 + 5*x + 2  6*x^2 + 5*x + 1
  5*x + 2  6*x^2 + 5*x + 1]

Wrong length or negativity of input degree raise errors:

sage: M.reverse([1,3,1,4]) Traceback (most recent call last): … ValueError: length of input degree list should be the row dimension of the input matrix

sage: M.reverse([5,2,1], row_wise=False) Traceback (most recent call last): … ValueError: length of input degree list should be the column dimension of the input matrix

sage: M.reverse([2,3,-1]) Traceback (most recent call last): … ValueError: degree argument must be a non-negative integer, got -1
right_quo_rem(B)

Return, if it exists, the quotient and remainder \((Q, R)\) such that \(\text{self} = QB + R\), where \(R\) has column degrees less than those of \(B\) entrywise.

If \(\text{self}\) is a \(k \times m\) polynomial matrix (written \(A\) below), and the input \(B\) is an \(m \times m\) polynomial matrix in column reduced form, then \((Q, R)\) is unique. Both \(Q\) and \(R\) have dimensions \(k \times m\). In this case, this method implements Newton iteration of a reversed polynomial matrix \(B\), generalizing to matrices the fast division of univariate polynomials.

If \(A\) is a \(k \times n\) polynomial matrix, and the input \(B\) is an \(m \times n\) polynomial matrix such that \(B\) has full column rank, or more generally such that the matrix equation \(A = XB\) has a rational solution, then there exists such a \((Q, R)\) but it may not be unique; the algorithm returns one such quotient and remainder. Here \(Q\) is \(k \times m\) and \(R\) is \(k \times n\). In this case, this method follows the folklore approach based on solving the matrix equation \(A = XB\) and splitting \(X\) into its polynomial part and proper fraction part.

Finally, if the matrix equation \(A = XB\) has no rational solution, this method computes the normal form \(R\) and quotient \(Q\) of the rows of \(A\) with respect to the row space of \(B\) (see \(\text{reduce()}\)). Doing this for a well-chosen shift ensures that either \(R\) does not have column degrees less than those of \(B\), and then there is no valid quotient and remainder, or it does satisfy this degree constraint, and then this \(R\) can be returned as a remainder along with the quotient \(Q\).

A \text{ValueError} is raised if the dimensions of \(\text{self}\) and \(B\) are not conformal, or if there exists no quotient and remainder.

**EXAMPLES:**

Case where \(B\) is a square, column reduced matrix:

```python
sage: pR.<x> = GF(7)[]
sage: A = Matrix(pR, 2, 3,
           ....: [[3*x^3 + 3*x, 3*x^3 + 6*x + 5, 2*x^3 + 2*x + 6],
           ....: [2*x^3 + 4, 6*x^3 + 5*x^2 + 1, 3*x^2 + 2*x + 2]])
sage: B = Matrix(pR, 3, 3,
           ....: [[4*x^2 + 3*x + 3, 3*x^2 + 3*x + 1, 4*x^2 + x + 4],
           ....: [6*x^2 + 2*x + 3, 4*x^2 + 3*x, 3*x^2 + 4*x],
           ....: [5*x^2 + 3*x + 6, 6*x^2 + x + 4, 3*x^2 + 3*x + 2]])
sage: B.is_reduced(row_wise=False)
True
sage: Q, R = A.right_quo_rem(B); Q, R
([ 4*x  x + 2 6*x + 1]  [  x + 2 6*x + 1 5*x + 4]
 [4*x + 3  x + 6 3*x + 4], [4*x + 2 2*x + 3 4*x + 3])
sage: A == Q*B+R and R.degree() < 2
True
sage: A[:,1:2].right_quo_rem(B)
Traceback (most recent call last):
...
ValueError: column dimension of self should be the column dimension of the input matrix
```

(continues on next page)
sage: B.is_reduced(row_wise=False)
True
sage: Q, R = A.right_quo_rem(B); Q, R

      Integer(4)*x**Integer(2) + x + Integer(4)],
...     [x + Integer(3), Integer(4)*x**Integer(2) + x + Integer(4),
      Integer(6)*x**Integer(2) + x + Integer(4)],
...     [Integer(6), Integer(6)*x**Integer(2) + x + Integer(4),
      Integer(3)*x**Integer(2) + x + Integer(4)]])
>>> B.is_reduced(row_wise=False)
True

```python
>>> Q, R = A.right_quo_rem(B); Q, R
([2*x^2 + 4*x + 6 3*x^2 + 5*x 6*x^2 + 3*x]
[6*x^2 + 4*x + 1 2*x^2 + x + 5 4*x^2 + 6*x + 1],
[BLANKLINE]
[3 6 2*x + 3]
[1 5*x^2 + 2*x + 3 6*x + 3])
```

```python
>>> cdegR = R.column_degrees(); cdegB = B.column_degrees()
>>> A == Q*B+R and all([cdegR[i] < cdegB[i] for i in range(Integer(3))])
True
```

With a nonsingular but also non-reduced matrix, there exists a solution, but it might not be unique:

```python
sage: B = Matrix(pR, 3, 3,
....:      [[ 5, 0, 2*x + 6],
....:       [4*x, 3*x^2 + 4*x + 5, x + 1],
....:       [3*x^2 + 5*x + 2, 6*x^3 + 4*x + 6, 3])
```

```python
sage: B.det() != 0 and (not B.is_reduced(row_wise=False))
True
```

```python
sage: Q, R = A.right_quo_rem(B); Q, R
([ 6*x^2 + 3*x 4*x^2 + 3*x + 1 5*x + 1]
[ x^2 + 5*x + 5 5*x^2 + 3*x + 5 x + 2],
[ 4*x + 5 x^2 + 2*x + 1 2]
[ 6*x + 3 5*x^2 + 6 3])
```

```python
sage: cdegR = R.column_degrees(); cdegB = B.column_degrees()
sage: A == Q*B+R and all(cdegR[i] < cdegB[i] for i in range(3))
True
```

```python
sage: Q2 = Matrix(pR, 2, 3,
....:       [[6*x^2 + 3*x + 1, 4*x^2 + 3*x + 6, 5*x + 1],
....:        [ x^2 + 5*x + 3, 5*x^2 + 3*x + 2, x + 2]])
sage: R2 = Matrix(pR, 2, 3,
....:       [[ 5*x, 3*x + 4, 5],
....:        [4*x + 6, 5*x, 4]])
sage: A == Q2*B + R2
True
```

```python
>>> from sage.all import *
```

```python
>>> B = Matrix(pR, Integer(3), Integer(3),
...      [[ 0, 2*x + 6],
...       [4*x, 3*x^2 + 4*x + 5, x + 1],
...       [3*x^2 + 5*x + 2, 6*x^3 + 4*x + 6, 3]])
```

```python
>>> B.det() != 0 and (not B.is_reduced(row_wise=False))
True
```

```python
>>> Q, R = A.right_quo_rem(B); Q, R
([ 6*x^2 + 3*x 4*x^2 + 3*x + 1 5*x + 1]
[ x^2 + 5*x + 5 5*x^2 + 3*x + 5 x + 2],
[6*x^2 + 4*x + 1 2*x^2 + x + 5 4*x^2 + 6*x + 1])
```

(continues on next page)
The same remark holds more generally for full column rank matrices: there exists a solution, but it might not be unique. However, for all other cases (rank-deficient matrix $B$ or matrix $B$ having strictly fewer rows than columns) there may be no solution:

```
sage: C = B.stack(B[1,:]+B[2,:])  # 4 x 3, full column rank
sage: Q, R = A.right_quo_rem(C); Q, R
(0

sage: A.right_quo_rem(B[:,1:])  # matrix 2 x 3, full row rank                      
Traceback (most recent call last):
...
ValueError: division of these matrices does not admit a remainder
with the required degree property
```

```
sage: D = copy(B); D[2,:] = B[0,:]+B[1,:]  # square, singular
sage: A.right_quo_rem(D)
Traceback (most recent call last):
...
ValueError: division of these matrices does not admit a remainder
with the required degree property
```
>>> A.right_quo_rem(B[:Integer(2),:])  # matrix 2 x 3, full row rank
   # needs sage.rings.finite_rings
Traceback (most recent call last):
...
ValueError: division of these matrices does not admit a remainder
with the required degree property

>>> D = copy(B); D[Integer(2),:] = B[Integer(0),:]+B[Integer(1),:]  # square,
   --> singular
>>> A.right_quo_rem(D)
Traceback (most recent call last):
...
ValueError: division of these matrices does not admit a remainder
with the required degree property

In the latter case (rank-deficient or strictly fewer rows than columns, with no solution to \( A = X B \)), there
might still be a quotient and remainder, in which case this method will find it via normal form computation:

sage: B = Matrix(pR, 1, 2, [[x, x]])
sage: A = Matrix(pR, 1, 2, [[x, x+2]])
sage: A.right_quo_rem(B)
   (1, [0 2])
sage: A == 1*B + Matrix([[0,2]])
True

>>> from sage.all import *

>>> B = Matrix(pR, Integer(1), Integer(2), [[x, x]])
>>> A = Matrix(pR, Integer(1), Integer(2), [[x, x+Integer(2)]])
>>> A.right_quo_rem(B)
   (1, [0 2])
>>> A == Integer(1)*B + Matrix([[Integer(0),Integer(2)]])
True

See also:

\texttt{left\_quo\_rem()}, \texttt{reduce()}.

\texttt{row\_degrees} (shifts=None)

Return the (shifted) row degrees of this matrix.

For a given polynomial matrix \( M = (M_{i,j})_{i,j} \) with \( m \) rows and \( n \) columns, its row degrees is the tuple
\( (d_1, \ldots, d_m) \) where \( d_i = \max_j (\deg(M_{i,j})) \) for \( 1 \leq i \leq m \). Thus, \( d_i = -1 \) if the \( i \)-th row of \( M \) is zero,
and \( d_i \geq 0 \) otherwise.

For given shifts \( s_1, \ldots, s_n \in \mathbb{Z} \), the shifted row degrees of \( M \) is \( (d_1, \ldots, d_m) \) where \( d_i = \max_j (\deg(M_{i,j}) +
   s_j) \). Here, if the \( i \)-th row of \( M \) is zero then \( d_i = \min(s_1, \ldots, s_n) - 1 \); otherwise, \( d_i \) is larger than this value.

INPUT:

- \texttt{shifts} – (default: None) list of integers; None is interpreted as \texttt{shifts=[0, \ldots, 0]}.

OUTPUT: a list of integers.

REFERENCES:

- [Wol1974] (Section 2.5, without shifts), and [VBB1992] (Section 3).
- Up to changes of signs, shifted row degrees coincide with the notion of \textit{defect} commonly used in the
  rational approximation literature (see for example [Bec1992]).
EXAMPLES:

```python
sage: pR.<x> = GF(7)[]
sage: M = Matrix(pR, [[3*x+1, 0, 1], [x^3+3, 0, 0]])
sage: M.row_degrees()
[1, 3]
sage: M.row_degrees(shifts=[0,1,2])
[2, 3]
```

```
>>> from sage.all import *
>>> pR = GF(Integer(7))[x]; (x,) = pR._first_ngens(1)
>>> M = Matrix(pR, [[Integer(3)*x+Integer(1), Integer(0), Integer(1)],
                   [x**Integer(3)+Integer(3), Integer(0), Integer(0)]])
>>> M.row_degrees()
[1, 3]
>>> M.row_degrees(shifts=[Integer(0),Integer(1),Integer(2)])
[2, 1, -3]
```

A zero row in a polynomial matrix can be identified in the (shifted) row degrees as the entries equal to \(\min(shifts) - 1\):

```python
sage: M = Matrix(pR, [[3*x+1, 0, 1], [x^3+3, 0, 0], [0, 0, 0]])
sage: M.row_degrees()
[1, 3, -1]
sage: M.row_degrees(shifts=[-2,1,2])
[2, 1, -3]
```

```
>>> from sage.all import *
>>> M = Matrix(pR, [3*x+1, 0, 1], [x^3+3, 0, 0], [0, 0, 0])
>>> M.row_degrees()
[1, 3, -1]
>>> M.row_degrees(shifts=[-2,1,2])
[2, 1, -3]
```

The row degrees of an empty matrix (\(0 \times n \) or \(m \times 0\)) is not defined:

```python
sage: M = Matrix(pR, 0, 3)
sage: M.row_degrees()
Traceback (most recent call last):
  ...
ValueError: empty matrix does not have row degrees
```

```python
sage: M = Matrix(pR, 3, 0)
sage: M.row_degrees()
Traceback (most recent call last):
  ...
ValueError: empty matrix does not have row degrees
```

```
>>> from sage.all import *
>>> M = Matrix(pR, Integer(0), Integer(3))
>>> M.row_degrees()
```

(continues on next page)
shift \((d, \text{row\_wise}=\text{True})\)

Return the matrix which is obtained from this matrix after shifting all its entries as specified by \(d\).

- if \(d\) is an integer, the shift is by \(d\) for all entries;
- if \(d\) is a list \((d_1, \ldots, d_m)\) and \(\text{row\_wise}\) is \text{True}, all entries of the \(i\)th row are shifted by \(d_i\) for each \(i\);
- if \(d\) is a list \((d_1, \ldots, d_n)\) and \(\text{row\_wise}\) is \text{False}, all entries of the \(j\)th column are shifted by \(d_j\) for each \(j\).

Shifting by \(d\) means multiplying by the variable to the power \(d\); if \(d\) is negative then terms of negative degree after shifting are discarded.

**INPUT:**

- \(d\) – a list of integers, or an integer,
- \(\text{row\_wise}\) – (default: \text{True}) boolean, if \text{True} (resp. \text{False}) then \(d\) should be a list of length equal to the row (resp. column) dimension of this matrix.

**OUTPUT:** a polynomial matrix.

**EXAMPLES:**

\[
\begin{align*}
\text{sage: } & \ pR.<x> = GF(7)[] \\
\text{sage: } & \ M = \text{Matrix}([ \ldots]) \\
\text{sage: } & \ M.\text{shift}(-2) \\
\end{align*}
\]

\[
\begin{bmatrix}
  x + 5 & 0 & 0 & 0 \\
  6 & 0 & 0 & 0 \\
  2*x + 4 & 0 & 2 & 1 \\
\end{bmatrix}
\]

\[
\begin{align*}
\text{>>> from } \text{sage}\text{.all import } * \\
\text{>>> pR } & \text{ = GF(Integer(7))['x']; } (x,) & \text{ = pR._first_ngens(1)} \\
\text{>>> M } & \text{ = Matrix([ \ldots])} \\
\text{>>> } & \text{[x**Integer(3)+Integer(5)*x**Integer(2)+Integer(5)*x+Integer(1),} \\
& \text{ x**Integer(3)+Integer(5)*x**Integer(2)+Integer(5)*x+Integer(1),} \\
& \text{ ...]} \\
\end{align*}
\]

(continues on next page)
Row-wise and column-wise shifting are available:

```
sage: M.shift([-1,2,-2])
[ x^2 + 5*x + 5 0 6 → 0]
[6*x^4 + 3*x^3 + x^2 x^2 2*x^2 → 0]
[2*x + 4 0 2 → 1]
```

```
sage: M.shift([-1,1,0,0], row_wise=False)
[ x^2 + 5*x + 5 5*x 6*x + 4 0]
[6*x + 3 x 2 0]
[2*x^2 + 4*x + 6 5*x^2 + x 2*x^2 + 5*x + 5 x^2 + 5*x + 6]
```

```
sage: M.shift([-d for d in M.row_degrees()]) == M.leading_matrix()
True
```

Length of input shift degree list is checked:

```
sage: M.shift([1,3,1,4])
Traceback (most recent call last):
...
ValueError: length of input shift list should be the row
dimension of the input matrix
```

```
sage: M.shift([5,2,1], row_wise=False)
Traceback (most recent call last):
...
ValueError: length of input shift list should be the column
dimension of the input matrix
```
\begin{verbatim}
>>> from sage.all import *

>>> M = Matrix([Integer(1), Integer(3), Integer(1), Integer(4)])

Traceback (most recent call last):
...
ValueError: length of input shift list should be the row
dimension of the input matrix

>>> M.shift([Integer(5), Integer(2), -Integer(1)], row_wise=False)

Traceback (most recent call last):
...
ValueError: length of input shift list should be the column
dimension of the input matrix

See also:

sage.rings.polynomial.polynomial_element.Polynomial.shift()

solve_left_series_trunc(B, d)

Try to find a solution \( X \) to the equation \( XA = B \), at precision \( d \).

If \( \text{self} \) is a matrix \( A \), then this function returns a vector or matrix \( X \) such that \( XA = B \mod x^d \). If \( B \) is a vector then \( X \) is a vector, and if \( B \) is a matrix then \( X \) is a matrix.

Raises ValueError if \( d \) is not strictly positive, or if there is a dimension mismatch between \( A \) and \( B \), or if there is no solution to the given matrix equation at the specified precision.

INPUT:

- \( B \) – a polynomial matrix or polynomial vector.
- \( d \) – a positive integer.

OUTPUT:

A solution to the matrix equation, returned as polynomial matrix of degree less than \( d \) if \( B \) is a polynomial matrix; a polynomial vector of degree less than \( d \) if \( B \) is a polynomial vector.

ALGORITHM:

If \( A \) is square with invertible constant term, then the unique solution is found by calling \texttt{inverse_series_trunc()} and using the Dixon & Moenck-Carter iteration. Otherwise, a left minimal approximant basis of a matrix formed by \( A \) and \( B \) is computed, for an appropriate shift which ensures that this basis reveals either a solution \( X \) or the fact that no such solution exists.

EXAMPLES:

\begin{verbatim}
sage: pR.<x> = GF(7)[]
sage: A = Matrix(pR, 3, 3,
            ....: [[4*x+5, 5*x^2 + x + 1, 4*x^2 + 4],
            ....: [6*x^2 + 6*x + 6, 4*x^2 + 5*x, 4*x^2 + x + 3],
            ....: [3*x^2 + 2, 4*x + 1, x^2 + 3*x]])
sage: A.is_square() and A.constant_matrix().is_invertible()
True

sage: B = vector([2*x^2 + 6*x + 6, 0, x + 6])
sage: X = A.solve_left_series_trunc(B, 4); X
(3*x^3 + 3*x^2 + 2*x + 4, 4*x^2 + x^2 + 2*x + 6, 6*x^3 + x^2 + 3*x)
sage: B == X*A % x**4
True

sage: B = Matrix(pR, 2, 3,
            ....: [[3*x, x^2 + x + 2, x^2 + 2*x + 3],
            ....: ...

(continues on next page)
\end{verbatim}
\end{verbatim}
sage: A.solve_left_series_trunc(B, 3)
\[
\begin{bmatrix}
6*x^2 + 2*x + 2 & 4*x + 3 & 2*x^2 + 3*x \\
3*x^2 + 4*x + 5 & 4*x^2 + 3 & x^2 + 6*x + 3
\end{bmatrix}
\]
sage: X = A.solve_left_series_trunc(B, 37); B == X*A % x**37
True

>>> from sage.all import *

>>> pR = GF(Integer(7))[x]; (x,) = pR._first_ngens(1)
>>> A = Matrix(pR, Integer(3), Integer(3),
... [
... [Integer(4)*x+Integer(5), x+Integer(1), Integer(4)*x**Integer(2) + Integer(4)],
... [Integer(6)*x**Integer(2) + Integer(6)*x + Integer(6), x**Integer(2) + Integer(3)],
... [Integer(3)*x**Integer(2) + Integer(2), x + Integer(1), x**Integer(2) + x + Integer(3)]
... ]
True
>>> A.is_square() and A.constant_matrix().is_invertible()
True
>>> B = vector([Integer(2)*x**Integer(2) + Integer(6)*x + Integer(6), 0, x + Integer(6)])
>>> X = A.solve_left_series_trunc(B, Integer(4)); X
(3*x^3 + 3*x^2 + 2*x + 4, 4*x^3 + x^2 + 2*x + 6, 6*x^3 + x + 3)
>>> B == X*A % x**Integer(4)
True

>>> B = Matrix(pR, Integer(2), Integer(3),
... [Integer(3)*x, x**Integer(2) + x + Integer(2), x**Integer(2) + 2*x + Integer(3)],
... [Integer(0), Integer(6)*x**Integer(2) + Integer(1), Integer(1)])
>>> A.solve_left_series_trunc(B, Integer(3))
\[
\begin{bmatrix}
6*x^2 + 2*x + 2 & 4*x + 3 & 2*x^2 + 3*x \\
3*x^2 + 4*x + 5 & 4*x^2 + 3 & x^2 + 6*x + 3
\end{bmatrix}
\]
sage: A.solve_left_series_trunc(B[:,2:], 3)
Traceback (most recent call last):
... ValueError: number of columns of self must equal number of columns of right-hand side

>>> from sage.all import *

>>> A.solve_left_series_trunc(B[:,Integer(2)], Integer(3))
Traceback (most recent call last):
... ValueError: number of columns of self must equal number of columns of right-hand side

 Raises an exception when no solution:
... ValueError: matrix equation has no solutions

sage: Ax = x*A; C = vector(pR, [1,1,1])
sage: Ax.solve_left_series_trunc(C, 5)
Traceback (most recent call last):
... ValueError: matrix equation has no solutions

>>> from sage.all import *
>>> A[:,:2].solve_left_series_trunc(B[:,:2], 4)
Traceback (most recent call last):
... ValueError: matrix equation has no solutions

solve_left_series_trunc().

truncate \( (d, \text{row\_wise}=\text{True}) \)

Return the matrix which is obtained from this matrix after truncating all its entries according to precisions specified by \( d \):

- if \( d \) is an integer, the truncation is at precision \( d \) for all entries;
- if \( d \) is a list \( (d_1, \ldots, d_m) \) and \( \text{row\_wise} \) is \text{True}, all entries of the \( i \)’throw are truncated at precision \( d_i \) for each \( i \);
• if \( d \) is a list \((d_1, \ldots, d_n)\) and \(\text{row\_wise} \) is \(\text{False} \), all entries of the \(j\)th column are truncated at precision \(d_j\) for each \(j\).

Here the convention for univariate polynomials is to take zero for the truncation for a negative \(d\).

**INPUT:**

• \(d\) – a list of integers, or an integer,

• \(\text{row\_wise} \) – (default: \(\text{True}\)) boolean, if \(\text{True} \) (resp. \(\text{False}\)) then \(d\) should be a list of length equal to the row (resp. column) dimension of this matrix.

**OUTPUT:** a polynomial matrix.

**EXAMPLES:**

```python
sage: pR.<x> = GF(7)[]
sage: M = Matrix([...
        [ x^3+5*x^2+5*x+1, 5, 6*x+4, 0],
        [ 6*x^2+3*x+1, 1, 2, 0],
        [2*x^3+4*x^2+6*x+4, 5*x + 1, 2*x^2+5*x+5, x^2+5*x+6]...
    ])
sage: M.truncate(2)
[5*x + 1 5 6*x + 4 0]
[3*x + 1 1 2 0]
[6*x + 4 5*x + 1 5*x + 5 5*x + 6]
sage: M.truncate(1) == M.constant_matrix()
True
```

```python
>>> from sage.all import *
>>> pR = GF(Integer(7))['x']; (x,) = pR._first_ngens(1)

>>> M = Matrix([...
        [ x**Integer(3)+Integer(5)*x**Integer(2)+Integer(5)*x+Integer(1),...
          Integer(5), Integer(6)*x+Integer(4), Integer(0)],
        [ Integer(6)*x**Integer(2)+Integer(3)*x+Integer(1),...
          Integer(1), Integer(2), Integer(0)],
        ...])

>>> M.truncate(Integer(2))
[5*x + 1 5 6*x + 4 0]
[3*x + 1 1 2 0]
[6*x + 4 5*x + 1 5*x + 5 5*x + 6]
>>> M.truncate(Integer(1)) == M.constant_matrix()
True
```

Row-wise and column-wise truncation are available:

```python
sage: M.truncate([3,2,1])
[5*x^2 + 5*x + 1 5 6*x + 4 0]
[ 3*x + 1 1 2 0]
[ 4 1 5 6]
sage: M.truncate([2,1,1,2], row_wise=False)
[5*x + 1 5 4 0]
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

\[
\begin{bmatrix}
3x + 1 & 1 & 2 & 0 \\
6x + 4 & 1 & 5x + 6
\end{bmatrix}
\]

```python
>>> from sage.all import *
```

```python
>>> M.truncate([Integer(3), Integer(2), Integer(1)])
\[
\begin{bmatrix}
5x^2 + 5x + 1 & 5 & 6x + 4 & 0 \\
3x + 1 & 1 & 2 & 0 \\
4 & 1 & 5 & 6
\end{bmatrix}
```

```python
>>> M.truncate([Integer(2), Integer(1), Integer(1), Integer(2)], row_wise=False)
\[
\begin{bmatrix}
5x + 1 & 5 & 4 & 0 \\
3x + 1 & 1 & 2 & 0 \\
6x + 4 & 1 & 5 & 5x + 6
\end{bmatrix}
```

Length of list of truncation orders is checked:

```python
sage: M.truncate([2, 1, 1, 2])
Traceback (most recent call last):
... ValueError: length of input precision list should be the row
dimension of the input matrix
```

```python
sage: M.truncate([3, 2, 1], row_wise=False)
Traceback (most recent call last):
... ValueError: length of input precision list should be the column
dimension of the input matrix
```

```python
>>> from sage.all import *
```

```python
>>> M.truncate([Integer(2), Integer(1), Integer(1), Integer(2)], row_wise=False)
Traceback (most recent call last):
... ValueError: length of input precision list should be the row
dimension of the input matrix
```

```python
>>> M.truncate([Integer(3), Integer(2), Integer(1)], row_wise=False)
Traceback (most recent call last):
... ValueError: length of input precision list should be the column
dimension of the input matrix
```

See also:

```python
sage.rings.polynomial.polynomial_element.Polynomial.truncate()
```

`weak_popov_form` (transformation=False, shifts=None, row_wise=True, ordered=False, include_zero_vectors=True)

Return a (shifted) (ordered) weak Popov form of this matrix.

See `is_weak_popov()` for a definition of weak Popov forms. If the input matrix is \( A \), a weak Popov form of \( A \) is any matrix \( P \) in weak Popov form and such that \( UA = P \) for some unimodular matrix \( U \). The latter matrix is called the transformation, and the first optional argument allows one to specify whether to return this transformation.

Sometimes, one forbids weak Popov forms to have zero rows (resp. columns) in the above definitions; an optional parameter allows one to adopt this more restrictive setting. If zero rows (resp. columns) are allowed,
the convention here is to place them as the bottommost rows (resp. the rightmost columns) of the output weak Popov form.

Note that, if asking for the transformation and discarding zero vectors (i.e. \texttt{transformation=True} and \texttt{include_zero_vectors=False}), then the returned transformation is still the complete unimodular matrix, including its bottommost rows (resp. rightmost columns) which correspond to zero rows (resp. columns) of the complete weak Popov form. In fact, this bottom part of the transformation yields a basis of the left (resp. right) kernel of the input matrix.

**INPUT:**

- \texttt{transformation} – (default: False). If this is True, the transformation matrix \( U \) will be returned as well.
- \texttt{shifts} – (default: None) list of integers; None is interpreted as \texttt{shifts=[0, \ldots, 0]}.
- \texttt{row_wise} – (default: True) boolean, True if working row-wise (see the class description).
- \texttt{ordered} – (default: False) boolean, True if seeking an ordered weak Popov form.
- \texttt{include_zero_vectors} – (default: True) boolean, False if zero rows (resp. zero columns) should be discarded from the (ordered) weak Popov forms.

**OUTPUT:**

- A polynomial matrix which is a weak Popov form of \texttt{self} if \texttt{transformation} is False; otherwise two polynomial matrices which are a weak Popov form of \texttt{self} and the corresponding unimodular transformation.

**ALGORITHM:**

This method implements the Mulders-Storjohann algorithm of [MS2003], straightforwardly extended to the case of shifted forms.

**EXAMPLES:**

```python
sage: pR.<x> = GF(7)[x]
sage: M = Matrix(pR, [6*x^2+4, 5*x^3+3*x, 6*x^2+2*x+2], [4*x^2+5*x+2, x^4+5*x^2+2*x+4, 4*x^3+6*x^2+6*x+5])
sage: P, U = M.weak_popov_form(transformation=True)
sage: P
[ 4  x^2 6*x^2 + x + 2]
[ 2 4*x^2 + 2*x + 4 5]
sage: U
[2*x^2 + 1 4*x]
[ 4*x 1]
sage: P.is_weak_popov() and U.is_invertible() and U*M == P
True
```

```python
from sage.all import *

>>> pR = GF(Integer(7))[x]; (x,) = pR._first_ngens(1)
>>> M = Matrix(pR, [Integer(6)*x+Integer(4),...
Integer(5)*x^2+Integer(3)+Integer(5)*x+...
Integer(6)*x^2+Integer(2)+Integer(2)*x+Integer(2)],...
Integer(4)*x^2+Integer(2)+Integer(5)*x+Integer(2),...
Integer(4)*x^2+Integer(3)+Integer(6)*x^2+Integer(2)+Integer(6)*x+Integer(5)])
>>> P, U = M.weak_popov_form(transformation=True)
>>> P
```
Matrices and Spaces of Matrices, Release 10.4

[ 4 x^2 6*x^2 + x + 2]
[ 2 4*x^2 + 2*x + 4 5]

>>> U
[2*x^2 + 1 4*x]
[ 4*x 1]

>>> P.is_weak_popov() and U.is_invertible() and U*M == P
True

Demonstrating the ordered option:

sage: P.leading_positions()
[2, 1]
sage: PP = M.weak_popov_form(ordered=True); PP
[ 4 4*x 6*x^2 + x + 2]
[ 2 4*x^2 + 2*x + 4 5]
sage: PP.leading_positions()
[1, 2]

>>> from sage.all import *

>>> P.leading_positions()
[2, 1]

>>> PP = M.weak_popov_form(ordered=True); PP
[ 4 4*x 6*x^2 + x + 2]
[ 2 4*x^2 + 2*x + 4 5]

Demonstrating shifts:

sage: P = M.weak_popov_form(shifts=[0,2,4]); P
[ 6*x^2 + 6*x + 4 5*x^4 + 4*x^3 + 5*x^2 + 5*x ⦇
→ 2*x + 2]
[ 4 2 4*x^2 + 2*x + 4 ⦇
→ 5]
sage: P == M.weak_popov_form(shifts=[-10,-8,-6])
True

>>> from sage.all import *

>>> P = M.weak_popov_form(shifts=[Integer(0),Integer(2),Integer(4)]); P
[ 6*x^2 + 6*x + 4 5*x^4 + 4*x^3 + 5*x^2 + 5*x ⦇
→ 2*x + 2]
[ 4 2 4*x^2 + 2*x + 4 ⦇
→ 5]

Column-wise form is the row-wise form of the transpose:

sage: M.weak_popov_form() == M.T.weak_popov_form(row_wise=False).T
True

>>> from sage.all import *

>>> M.weak_popov_form() == M.T.weak_popov_form(row_wise=False).T
True

Zero vectors can be discarded:
sage: M.weak_popov_form(row_wise=False)
[[x + 4  6  0]
 [ 5  1  0]]

sage: # needs sage.combinat
sage: P, U = M.weak_popov_form(transformation=True,  
.....:   row_wise=False,  
.....:   include_zero_vectors=False)

sage: P
[[x + 4  6]
 [ 5  1]]

sage: U
[[ 5*x + 2  5*x^2 + 4*x + 4  3*x^3 + 3*x^2 + 2*x + 4]
 [ 1  1  2*x + 1]
 [ 5*x + 5  2  6]]

sage: M*U[:,Integer(2)]= P and (M*U[:,Integer(2)]).is_zero()
True

See also:

is_weak_popov(), reduced_form(), popov_form(), hermite_form().
DENSE MATRICES OVER MULTIVARIATE POLYNOMIALS OVER FIELDS

This implementation inherits from Matrix_generic_dense, i.e. it is not optimized for speed only some methods were added.

AUTHOR:

• Martin Albrecht <malb@informatik.uni-bremen.de>

class sage.matrix.matrix_mpolynomial_dense.Matrix_mpolynomial_dense
Bases: Matrix_generic_dense
Dense matrix over a multivariate polynomial ring over a field.

determinant (algorithm=None)
Return the determinant of this matrix.

INPUT:
• algorithm—ignored

EXAMPLES:

We compute the determinant of the arbitrary 3x3 matrix:

```
sage: R = PolynomialRing(QQ, 9, 'x')
sage: A = matrix(R, 3, R.gens())
sage: A
[x0 x1 x2]
[x3 x4 x5]
[x6 x7 x8]
sage: A.determinant()
-x2*x4*x6 + x1*x5*x6 + x2*x3*x7 - x0*x5*x7 - x1*x3*x8 + x0*x4*x8
```

```
>>> from sage.all import *
>>> R = PolynomialRing(QQ, Integer(9), 'x')
>>> A = matrix(R, Integer(3), R.gens())
>>> A
[x0 x1 x2]
[x3 x4 x5]
[x6 x7 x8]
>>> A.determinant()
-x2*x4*x6 + x1*x5*x6 + x2*x3*x7 - x0*x5*x7 - x1*x3*x8 + x0*x4*x8
```

We check if two implementations agree on the result:
sage: R.<x,y> = QQ[]
sage: C = matrix(R, [[-6/5*x*y - y^2, -6*y^2 - 1/4*y],
....: [-1/3*x*y - 3, x*y - x]])
sage: C.determinant()
-6/5*x^2*y^2 - 3*x*y^3 + 6/5*x^2*y + 11/12*x*y^2 - 18*y^2 - 3/4*y
sage: C.change_ring(R.change_ring(QQbar)).det()
(-6/5)*x^2*y^2 + (-3)*x*y^3 + 6/5*x^2*y + 11/12*x*y^2 + (-18)*y^2 + (-3/4)*y

Finally, we check whether the Singular interface is working:

sage: R.<x,y> = RR[]
sage: C = matrix(R, [[0.368965517352886*y^2 + 0.425700773972636*x, -0.800362171389760*y^2 - 0.807635024852870],
....: [0.706173594231220*y^2 - 0.915986060298440, 0.897165181570476*y + 0.107903532401500]])
sage: C.determinant()
0.565194587390682*y^4 + 0.33102301536914...*y^3 + 0.381923912175852*x*y - 0.122977163520282*y^2 + 0.0459345303240150*x - 0.739782862078649

ALGORITHM: Calls Singular, libSingular or native implementation.

echelon_form(algorithm='row_reduction', **kwds)

Return an echelon form of self using chosen algorithm.

By default only a usual row reduction with no divisions or column swaps is returned.

If Gauss-Bareiss algorithm is chosen, column swaps are recorded and can be retrieved via swapped_columns().

INPUT:

- algorithm=string, which algorithm to use (default: 'row_reduction'). Valid options are:
  - 'row_reduction' (default) – reduce as far as possible, only divide by constant entries
Matrices and Spaces of Matrices, Release 10.4

- 'frac' – reduced echelon form over fraction field
- 'bareiss' – fraction free Gauss-Bareiss algorithm with column swaps

OUTPUT:

The row echelon form of \( A \) depending on the chosen algorithm, as an immutable matrix. Note that \( \text{self} \) is not changed by this command. Use \( A.echelonize() \) to change \( A \) in place.

EXAMPLES:

```python
sage: P.<x,y> = PolynomialRing(GF(127), 2)
sage: A = matrix(P, 2, 2, [1, x, 1, y])
sage: A
[1 x]
[1 y]
sage: A.echelon_form()
[ 1 x]
[ 0 -x + y]
```

The reduced row echelon form over the fraction field is as follows:

```python
sage: A.echelon_form(frac)  # over fraction field
[1 0]
[0 1]
```

Alternatively, the Gauss-Bareiss algorithm may be chosen:

```python
sage: E = A.echelon_form(bareiss); E
[ 1 y]
[ 0 x - y]
```

After the application of the Gauss-Bareiss algorithm the swapped columns may inspected:

```python
sage: E.swapped_columns(), E.pivots()
((0, 1), (0, 1))
sage: A.swapped_columns(), A.pivots()
(None, (0, 1))
```
Another approach is to row reduce as far as possible:

```python
>>> from sage.all import *
>>> E.swapped_columns(), E.pivots()
((0, 1), (0, 1))
>>> A.swapped_columns(), A.pivots()
(None, (0, 1))
```

```
echelonize(algorithm='row_reduction', **kwds)
```

Transform self into a matrix in echelon form over the same base ring as self.

If Gauss-Bareiss algorithm is chosen, column swaps are recorded and can be retrieved via `swapped_columns()`.

INPUT:

- **algorithm** – string, which algorithm to use. Valid options are:
  - 'row_reduction' – reduce as far as possible, only divide by constant entries
  - 'bareiss' – fraction free Gauss-Bareiss algorithm with column swaps

EXAMPLES:

```python
sage: P.<x,y> = PolynomialRing(QQ, 2)
sage: A = matrix(P, 2, 2, [1/2, x, 1, 3/4*y+1])
sage: A
[ 1/2  x]
[   1 3/4*y + 1]
sage: B = copy(A)
sage: B.echelonize('bareiss'); B
[  1 3/4*y + 1]
[0 -3/8*y - 1/2]
sage: B = copy(A)
sage: B.echelonize('row_reduction'); B
[1 2*x]
[0 -2*x + 3/4*y + 1]
sage: P.<x,y> = PolynomialRing(QQ, 2)
sage: A = matrix(P,2,3,[2,x,0,3,y,1]); A
[2  x  0]
[3  y  1]
sage: E = A.echelon_form('bareiss'); E
[1 3  y]
[0 2  x]
sage: E.swapped_columns()
(2, 0, 1)
```
```
sage: A.pivots()
(0, 1, 2)
```

```python
>>> from sage.all import *

>>> P = PolynomialRing(QQ, Integer(2), names=('x', 'y')); (x, y,) = P._first_ngens(2)

>>> A = matrix(P, Integer(2), Integer(2), [Integer(1)/Integer(2), x,
                                        Integer(1), Integer(3)/Integer(4)*y+Integer(1)])

>>> A
[ 1/2 x]
[ 1  3/4*y + 1]

>>> B = copy(A)

>>> B.echelonize('bareiss'); B
[ 1  3/4*y + 1]
[ 0 x - 3/8*y - 1/2]

>>> B = copy(A)

>>> B.echelonize('row_reduction'); B
[ 1  2*x]
[ 0 -2*x + 3/4*y + 1]

```

```
Enter
sage: A = matrix(P,Integer(2),Integer(3),[Integer(2),x,Integer(0),Integer(3),y,
                                        Integer(1)]); A

[2 x 0]
[3 y 1]

>>> E = A.echelon_form('bareiss'); E
[1 3 y]
[0 2 x]

>>> E.swapped_columns()
(2, 0, 1)
```

```
pivots()

Return the pivot column positions of this matrix as a list of integers.

This returns a list, of the position of the first nonzero entry in each row of the echelon form.

OUTPUT:
A list of Python ints.

EXAMPLES:
```
sage: matrix([PolynomialRing(GF(2), 2, 'x').gen()]).pivots()
(0,)
sage: K = QQ['x,y']
sage: x, y = K.gens()
sage: m = matrix(K, [(-x, 1, y, x - y), (-x*y, y, y^2 - 1, x*y - y^2 + x), (-x*y + x, y - 1, y^2 - y - 2, x*y - y^2 + x + y)])
sage: m.pivots()
(0, 2)
sage: m.rank()
2
```
swapped_columns()

Return which columns were swapped during the Gauss-Bareiss reduction

OUTPUT:

Return a tuple representing the column swaps during the last application of the Gauss-Bareiss algorithm (see echelon_form() for details).

The tuple as length equal to the rank of self and the value at the $i$-th position indicates the source column which was put as the $i$-th column.

If no Gauss-Bareiss reduction was performed yet, None is returned.

EXAMPLES:

```python
sage: R.<x,y> = QQ[]
sage: C = random_matrix(R, 2, 2, terms=2)
sage: while C.rank() != 2:
    ....: C = random_matrix(R, 2, 2, terms=2)
sage: C.swapped_columns()
sage: E = C.echelon_form('bareiss')
sage: sorted(E.swapped_columns())
[0, 1]
```

```python
from sage.all import *
R = QQ['x', 'y']; (x, y,) = R._first_ngens(2)
C = random_matrix(R, Integer(2), Integer(2), terms=Integer(2))
while C.rank() != Integer(2):
    ... C = random_matrix(R, Integer(2), Integer(2), terms=Integer(2))
C.swapped_columns()
E = C.echelon_form('bareiss')
sorted(E.swapped_columns())
[0, 1]
```
MATRICES OVER CYCLOTOMIC FIELDS

The underlying matrix for a Matrix_cyclo_dense object is stored as follows: given an \( n \times m \) matrix over a cyclotomic field of degree \( d \), we store a \( d \times (nm) \) matrix over \( \mathbb{Q} \), each column of which corresponds to an element of the original matrix. This can be retrieved via the _rational_matrix method. Here is an example illustrating this:

**EXAMPLES:**

```sage
sage: F.<zeta> = CyclotomicField(5)
sage: M = Matrix(F, 2, 3, [zeta, 3, zeta**4+5, (zeta+1)**4, 0, 1])
sage: M
\[
\begin{bmatrix}
zeta & 3 & -zeta^3 - zeta^2 - zeta + 4 \\
3*zeta^3 + 5*zeta^2 + 3*zeta & 0 & _
\end{bmatrix}
\]
sage: M._rational_matrix()
\[
\begin{bmatrix}
0 & 3 & 4 & 0 & 0 & 1 \\
1 & 0 & -1 & 3 & 0 & 0 \\
0 & 0 & -1 & 5 & 0 & 0 \\
0 & 0 & -1 & 3 & 0 & 0 \\
\end{bmatrix}
\]
```

```python
>>> from sage.all import *

>>> F = CyclotomicField(Integer(5), names=(zeta,)); (zeta,) = F._first_ngens(1)

>>> M = Matrix(F, Integer(2), Integer(3), [zeta, Integer(3), zeta**Integer(4)+Integer(5), \( (zeta+Integer(1))**Integer(4), Integer(0), Integer(1)\])

>>> M
\[
\begin{bmatrix}
zeta & 3 & -zeta^3 - zeta^2 - zeta + 4 \\
3*zeta^3 + 5*zeta^2 + 3*zeta & 0 & _
\end{bmatrix}
\]

>>> M._rational_matrix()
\[
\begin{bmatrix}
0 & 3 & 4 & 0 & 0 & 1 \\
1 & 0 & -1 & 3 & 0 & 0 \\
0 & 0 & -1 & 5 & 0 & 0 \\
0 & 0 & -1 & 3 & 0 & 0 \\
\end{bmatrix}
\]
```

**AUTHORS:**

- William Stein
- Craig Citro

```python
class sage.matrix.matrix_cyclo_dense.Matrix_cyclo_dense
Bases: Matrix_dense

Initialize a newly created cyclotomic matrix.
```
INPUT:

- **parent** – a matrix space over a cyclotomic number field
- **entries** – see `matrix()`
- **copy** – ignored (for backwards compatibility)
- **coerce** – if False, assume without checking that the entries lie in the base ring

EXAMPLES:

This function is called implicitly when you create new cyclotomic dense matrices:

```python
sage: W.<a> = CyclotomicField(100)
sage: A = matrix(2, 3, [1, 1/a, 1-a,a, -2/3*a, a^19])
sage: A
[ 1 -a^39 + a^29 - a^19 + a^9 -a + 1]
[ a -2/3*a a^19]
sage: TestSuite(A).run()
```

```
>>> from sage.all import *
>>> W = CyclotomicField(Integer(100), names=(a,)); (a,) = W._first_ngens(1)
>>> A = matrix(Integer(2), Integer(3), [Integer(1), Integer(1)/a, Integer(1)-a,...
˓→-Integer(2)/Integer(3)*a, a**Integer(19)])
>>> A
[ 1 -a^39 + a^29 - a^19 + a^9]
[ a -2/3*a a^19]
>>> TestSuite(A).run()
```

**charpoly**( `var='x'`, `algorithm='multimodular'`, `proof=None` )

Return the characteristic polynomial of self, as a polynomial over the base ring.

INPUT:

- **algorithm**
  - `'multimodular'` (default): reduce modulo primes, compute charpoly mod p, and lift (very fast)
  - `'pari'`: use pari (quite slow; comparable to Magma v2.14 though)
  - `'hessenberg'`: put matrix in Hessenberg form (double dog slow)
- **proof** – bool (default: None) proof flag determined by global linalg proof.

OUTPUT:

polynomial

EXAMPLES:

```python
sage: K.<z> = CyclotomicField(5)
sage: a = matrix(K, 3, [1,z,1+z^2, z/3,1,2,3,z^2,1-z])
sage: f = a.charpoly(); f
x^3 + (z - 3)*x^2 + (-16/3*z^2 - 2*z)*x - 2/3*z^3 + 16/3*z^2 - 5*z + 5/3
sage: f(a)
[0 0 0]
[0 0 0]
[0 0 0]
sage: a.charpoly(algorithm='pari')
x^3 + (z - 3)*x^2 + (-16/3*z^2 - 2*z)*x - 2/3*z^3 + 16/3*z^2 - 5*z + 5/3
sage: a.charpoly(algorithm='hessenberg')
x^3 + (z - 3)*x^2 + (-16/3*z^2 - 2*z)*x - 2/3*z^3 + 16/3*z^2 - 5*z + 5/3
```
coefficient_bound()

Return an upper bound for the (complex) absolute values of all entries of self with respect to all embeddings. Use self.height() for a sharper bound.

This is computed using just the Cauchy-Schwarz inequality, i.e., we use the fact that

\[ |\sum_i a_i \zeta^i| \leq \sum_i |a_i|, \]

as \(|\zeta| = 1\).

EXAMPLES:

\[
\begin{align*}
\text{sage: } & W.<z> = \text{CyclotomicField}(5) \\
\text{sage: } & A = \text{matrix}(W, 2, 2, [1+z, 0, 9*z+7, -3 + 4*z]); A \\
& \quad [z + 1, 0] \\
& \quad [9*z + 7 4*z - 3] \\
\text{sage: } & A.\text{coefficient_bound()} \\
& \quad 16
\end{align*}
\]
>>> from sage.all import *
>>> W = CyclotomicField(Integer(5), names=('z',)); (z,) = W._first_ngens(1)
>>> A = matrix(W, Integer(2), Integer(2), [Integer(1)+z, Integer(0),
˓→Integer(9)*z+Integer(7), -Integer(3) + Integer(4)*z]); A
\[
\begin{bmatrix}
  z + 1 & 0 \\
  9z + 7 & 4z - 3
\end{bmatrix}
\]
>>> A.coefficient_bound()
16

The above bound is just $9 + 7$, coming from the lower left entry. A better bound would be the following:

\[
\text{sage: } (A[1,0]).abs()
12.997543663...
\]

\[
\text{sage: from sage.all import *}
\]
\[
\text{sage: } (A[Integer(1),Integer(0)]).abs()
12.997543663...
\]

denominator()

Return the denominator of the entries of this matrix.

**OUTPUT:**

integer – the smallest integer $d$ so that $d \times self$ has
entries in the ring of integers

**EXAMPLES:**

\[
\text{sage: W.<z> = CyclotomicField(5)}
\]
\[
\text{sage: A = matrix(W, 2, 2, [-2/7, 2/3*z+z^2, -z, 1+z/19]); A}
\]
\[
\begin{bmatrix}
  -2/7 & z^2 + 2/3*z \\
  -z & 1/19*z + 1
\end{bmatrix}
\]
\[
\text{sage: d = A.denominator(); d}
399
\]

\[
\text{sage: from sage.all import *}
\]
\[
\text{sage: W = CyclotomicField(Integer(5), names=('z',)); (z,) = W._first_ngens(1)}
\]
\[
\text{sage: A = matrix(W, Integer(2), Integer(2), [-Integer(2)/Integer(7), Integer(2)/
˓→Integer(3)*z+z**Integer(2), -z, Integer(1)+z/Integer(19)]); A}
\]
\[
\begin{bmatrix}
  -2/7 & z^2 + 2/3*z \\
  -z & 1/19*z + 1
\end{bmatrix}
\]
\[
\text{sage: d = A.denominator(); d}
399
\]

echelon_form (algorithm='multimodular', height_guess=None)

Find the echelon form of self, using the specified algorithm.

The result is cached for each algorithm separately.

**EXAMPLES:**

\[
\text{sage: W.<z> = CyclotomicField(3)}
\]
\[
\text{sage: A = matrix(W, 2, 3, [1+z, 2/3, 9*z+7, -3 + 4*z, z, -7*z]); A}
\]
\[
\begin{bmatrix}
  z + 1 & 2/3 & 9z + 7 \\
  4*z - 3 & z & -7z
\end{bmatrix}
\]
\[
\text{sage: A.echelon_form()}
\]
\[
\begin{bmatrix}
  1 & 0 & -192/97*z - 361/97
\end{bmatrix}
\]

(continues on next page)
We verify that the result is cached and that the caches are separate:

```
sage: A.echelon_form() is A.echelon_form()
True
sage: A.echelon_form() is A.echelon_form(algorithm='classical')
False
```

height()  
Return the height of self.

If we let \( a_{ij} \) be the \( i, j \) entry of self, then we define the height of self to be

\[
\max_v \max_{i,j} |a_{ij}| \nu,
\]

where \( \nu \) runs over all complex embeddings of \( \text{self.base_ring()} \).

EXAMPLES:

```
sage: W.<z> = CyclotomicField(5)
sage: A = matrix(W, 2, 2, [1+z, 0, 9*z+7, -3 + 4*z]); A
[ 1 0]
[9*z + 7 4*z - 3]
sage: A.height()
12.997543663...
sage: (A[1,0]).abs()
12.997543663...
```

(continues on next page)
randomize \( (\text{density}=1, \text{num\_bound}=2, \text{den\_bound}=2, \text{distribution}=\text{None}, \text{nonzero}=\text{False}, *\text{args}, **\text{kwds}) \)

Randomize the entries of \texttt{self}.

Choose rational numbers according to \texttt{distribution}, whose numerators are bounded by \texttt{num\_bound} and whose denominators are bounded by \texttt{den\_bound}.

EXAMPLES:

```
sage: A = Matrix(CyclotomicField(5),2,2,range(4)) ; A
[0 1]
[2 3]
sage: A.randomize()
sage: A # random output
[1/2*zeta5^2 + zeta5 1/2]
[-zeta5^2 + 2*zeta5 -2*zeta5^3 + 2*zeta5^2 + 2]
```

set_immutable()

Change this matrix so that it is immutable.

EXAMPLES:

```
sage: W.<z> = CyclotomicField(5)
sage: A = matrix(W, 2, 2, [1,2/3*z+z^2,-z,1+z/2])
sage: A[0,0] = 10
sage: A.set_immutable()
sage: A[0,0] = 20
Traceback (most recent call last):
... ValueError: matrix is immutable; please change a copy instead (i.e., use...
```
... 
ValueError: matrix is immutable; please change a copy instead (i.e., use →
copy(M) to change a copy of M).

Note that there is no function to set a matrix to be mutable again, since such a function would violate the whole point. Instead make a copy, which is always mutable by default:

```
sage: A.set_mutable()
Traceback (most recent call last):
...
AttributeError: 'sage.matrix.matrix_cyclo_dense.Matrix_cyclo_dense' object...
sage: B = A.__copy__()
sage: B[0,0] = 20
sage: B[0,0]
20
```

```
>>> from sage.all import *

>>> C = CyclotomicField(Integer(12))

>>> M = matrix.random(C, Integer(3), Integer(3))
```

```
tensor_product (A, subdivide=True)

Return the tensor product of two matrices.

INPUT:

- A – a matrix
- subdivide – (default: True) whether or not to return natural subdivisions with the matrix

OUTPUT:

Replace each element of self by a copy of A, but first create a scalar multiple of A by the element it replaces. So if self is an $m \times n$ matrix and $A$ is a $p \times q$ matrix, then the tensor product is an $mp \times nq$ matrix. By default, the matrix will be subdivided into submatrices of size $p \times q$.

EXAMPLES:

```
sage: C = CyclotomicField(12)
sage: M = matrix.random(C, 3, 3)
sage: N = matrix.random(C, 50, 50)
sage: M.tensor_product(M) == super(type(M), M).tensor_product(M)
True
sage: N = matrix.random(C, 15, 20)
sage: M.tensor_product(N) == super(type(M), M).tensor_product(N)
True
```

```
>>> from sage.all import *

>>> C = CyclotomicField(Integer(12))

>>> M = matrix.random(C, Integer(3), Integer(3))
```
```python
>>> N = matrix.random(C, Integer(50), Integer(50))
>>> M.tensor_product(M) == super(type(M), M).tensor_product(M)
True
>>> N = matrix.random(C, Integer(15), Integer(20))
>>> M.tensor_product(N) == super(type(M), M).tensor_product(N)
True
```
This module implements general operation tables, which are very matrix-like.

\texttt{class sage.matrix.operation_table.OperationTable( S, operation, names='letters', elements=None) }

\textbf{Bases:} SageObject

An object that represents a binary operation as a table.

Primarily this object is used to provide a \texttt{multiplication_table()} for objects in the category of magmas (monoids, groups, ...) and \texttt{addition_table()} for objects in the category of commutative additive magmas (additive monoids, groups, ...).

\textbf{INPUT:}

- \texttt{S} – a finite algebraic structure (or finite iterable)
- \texttt{operation} – a function of two variables that accepts pairs of elements from \texttt{S}. A natural source of such functions is the Python \texttt{operator} module, and in particular \texttt{operator.add()} and \texttt{operator.mul()}. This may also be a function defined with \texttt{lambda} or \texttt{def}.
- \texttt{names} – (default: 'letters') The type of names used, values are:
  - 'letters' – lowercase ASCII letters are used for a base 26 representation of the elements' positions in the list given by \texttt{column_keys()}, padded to a common width with leading 'a's.
  - 'digits' – base 10 representation of the elements' positions in the list given by \texttt{column_keys()}, padded to a common width with leading zeros.
  - 'elements' – the string representations of the elements themselves.
  - a list - a list of strings, where the length of the list equals the number of elements.
- \texttt{elements} – (default: None) A list of elements of \texttt{S}, in forms that can be coerced into the structure, e.g. their string representations. This may be used to impose an alternate ordering on the elements of \texttt{S}, perhaps when this is used in the context of a particular structure. The default is to use whatever ordering the \texttt{S.list()} method returns. \texttt{elements} can also be a subset which is closed under the operation, useful perhaps when the set is infinite.

\textbf{OUTPUT:} An object with methods that abstracts multiplication tables, addition tables, Cayley tables, etc. It should be general enough to be useful for any finite algebraic structure whose elements can be combined with a binary operation. This is not necessarily meant be constructed directly, but instead should be useful for constructing operation tables of various algebraic structures that have binary operations.

\textbf{EXAMPLES:}

In its most basic use, the table needs a structure and an operation:
sage: from sage.matrix.operation_table import OperationTable
sage: G = SymmetricGroup(3)
# needs sage.groups
sage: OperationTable(G, operation=operator.mul)
# needs sage.groups
* a b c d e f
+------------
a| a b c d e f b| b a d c f e c| c e a f b d d| d f b e a c e| e c f a d b f| f d e b c a

With two operations present, we can specify which operation we want:

sage: from sage.all import *
>>> from sage.matrix.operation_table import OperationTable
>>> G = SymmetricGroup(Integer(3))
# needs sage.groups
>>> OperationTable(G, operation=operator.mul)
# needs sage.groups
* a b c d e f
+------------
a| a b c d e f b| b c d e f a c| c d e f a b d| d e f a b c e| e f a b c d f| f a b c d e

>>> from sage.all import *
>>> from sage.matrix.operation_table import OperationTable
>>> R = Integers(Integer(6))
>>> OperationTable(R, operation=operator.add)
+ a b c d e f
+------------
a| a b c d e f b| b c d e f a c| c d e f a b d| d e f a b c e| e f a b c d f| f a b c d e

The default symbol set for elements is lowercase ASCII letters, which take on a base 26 flavor for structures with
Matrices and Spaces of Matrices, Release 10.4

more than 26 elements.

```python
sage: from sage.matrix.operation_table import OperationTable
sage: G = DihedralGroup(14)
  # needs sage.groups

sage: OperationTable(G, operator.mul, names='letters')  # needs sage.groups
```

```

(continues on next page)
If the group’s elements are not too cumbersome, or the group is small, then the string representation of the elements can be used.

```python
sage: from sage.matrix.operation_table import OperationTable
sage: G = AlternatingGroup(3)
# needs sage.groups
sage: OperationTable(G, operator.mul, names='elements')  # needs sage.groups
* () (1,2,3) (1,3,2)
+------------------------
() | () (1,2,3) (1,3,2)
(1,2,3) | (1,2,3) (1,3,2) ()
(1,3,2) | (1,3,2) () (1,2,3)
```

You can give the elements any names you like, but they need to be ordered in the same order as returned by the `column_keys()` method.

```python
sage: # needs sage.groups
sage: from sage.matrix.operation_table import OperationTable
sage: G = QuaternionGroup()
```

```python
sage: T = OperationTable(G, operator.mul)
sage: T.column_keys()
(((), (1,2,3,4)(5,6,7,8), ..., (1,8,3,6)(2,7,4,5))
sage: names=['I', 'I', '-1', '-I', 'J', '-K', '-J', 'K']
sage: T.change_names(names=names)
sage: sorted(T.translation().items())
[(-1, (1,3)(2,4)(5,7)(6,8)), ..., (K, (1,8,3,6)(2,7,4,5))]
sage: T
* 1 I -1 -I J -K -J K
+------------------------
1| 1 I -1 -I J -K -J K
I| I -1 -I 1 K J -K -J
-1| -1 -I 1 I -J K J -K
-I| -I 1 I -1 -K -J K J
J| J -K -J K -1 -I 1 I
-K| -K -J K J I -1 -I 1
```

(continues on next page)
```
>>> from sage.all import *
>>> # needs sage.groups
>>> from sage.matrix.operation_table import OperationTable

G = QuaternionGroup()
T = OperationTable(G, operator.mul)
T.column_keys()

>>> names=[1, I, -1, -I, J, -K, -J, K]
T.change_names(names=names)

T.translation().items()

>>> sorted(T.translation().items())

>>> T

* 1 I -1 -I J -K -J K
+------------------------
1| 1 I -1 -I J -K -J K
I| I -1 -I 1 K J -K -J
-1| -1 -I 1 I -J K J -K
-I| -I 1 I -1 -K -J K J
J| J -K -J K -1 -I 1 I
-K| -K -J K J -1 -I 1
-J| -J K J -K 1 I -1 -I
K| K J -K -J -I 1 I -1

With the right functions and a list comprehension, custom names can be easier. A multiplication table for hex digits (without carries):

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```

```
This should be flexible enough to create a variety of such tables.

```python
sage: from sage.matrix.operation_table import OperationTable
sage: from operator import xor
sage: T=OperationTable(ZZ, xor, elements=range(8))
sage: T
  a b c d e f g h
+-------
a| a b c d e f g h  
b| b a d c f e h g 
c| c d a b g h e f 
d| d c b a h g f e 
e| e f g h a b c d  
f| f e h g b a d c  
g| g h e f c d a b  
h| h g f e d c b a  
sage: names=['000', '001', '010', '011', '100', '101', '110', '111']
sage: T.change_names(names)
sage: T.set_print_symbols('^', '\land')
sage: T
  ^ 000 001 010 011 100 101 110 111
 +-----------------------------
000| 000 001 010 011 100 101 110 111
001| 001 000 011 010 101 100 111 110
010| 010 011 000 001 110 111 100 101
011| 011 010 001 000 111 110 101 100
100| 100 101 110 111 000 001 010 011
101| 101 100 111 110 001 000 011 010
110| 110 111 100 101 010 011 000 001
111| 111 110 101 100 011 010 001 000

sage: T = OperationTable([False, True], operator.or_, names = 'elements')
sage: T
  False True
 +-------
False| False True
True| True True
```
from sage.all import *
from sage.matrix.operation_table import OperationTable
from operator import xor

T = OperationTable(ZZ, xor, elements=range(Integer(8)))
T

>>> names=['000', '001', '010', '011', '100', '101', '110', '111']

• Bruno Edwards (2022-10-31)

change_names(names)

For an existing operation table, change the names used for the elements.

INPUT:

• names – the type of names used, values are:
  – 'letters' – lowercase ASCII letters are used for a base 26 representation of the elements' positions in the list given by list(), padded to a common width with leading 'a's.
  – 'digits' – base 10 representation of the elements' positions in the list given by list(), padded to a common width with leading zeros.
  – 'elements' – the string representations of the elements themselves.
  – a list - a list of strings, where the length of the list equals the number of elements.
OUTPUT: None. This method changes the table “in-place”, so any printed version will change and the output of the `dict()` will also change. So any items of interest about a particular table need to be copied/saved prior to calling this method.

EXAMPLES:

More examples can be found in the documentation for `OperationTable` since creating a new operation table uses the same routine.

```python
sage: # needs sage.groups
sage: from sage.matrix.operation_table import OperationTable
sage: D = DihedralGroup(2)
sage: T = OperationTable(D, operator.mul)
sage: T
* a b c d
  +---------
 a| a b c d
 b| b a d c
 c| c d a b
 d| d c b a
sage: T.translation()['c']
(1,2)
sage: T.change_names(digits)
sage: T
* 0 1 2 3
  +---------
 0| 0 1 2 3
 1| 1 0 3 2
 2| 2 3 0 1
 3| 3 2 1 0
sage: T.translation()['2']
(1,2)
sage: T.change_names(elements)
sage: T
* () (3,4) (1,2) (1,2)(3,4)
  +--------------------------------------------
  ()| () (3,4) (1,2) (1,2)(3,4)
 (3,4)| (3,4) () (1,2)(3,4) (1,2)
 (1,2)| (1,2) (1,2)(3,4) () (3,4)
(1,2)(3,4)| (1,2)(3,4) (1,2) (3,4) ()
```

```python
>>> from sage.all import *
>>> # needs sage.groups
>>> from sage.matrix.operation_table import OperationTable
>>> D = DihedralGroup(Integer(2))
>>> T = OperationTable(D, operator.mul)
```

(continues on next page)
color_table (element_names=True, cmap=None, **options)

Return a graphic image as a square grid where entries are color coded.

INPUT:

- element_names – (default: True) Whether to display text with element names on the image
- cmap – (default: matplotlib.cm.gist_rainbow) color map for plot, see matplotlib.cm
- **options – passed on to matrix_plot()

EXAMPLES:

sage: from sage.matrix.operation_table import OperationTable
sage: OTa = OperationTable(SymmetricGroup(3), operation=operator.mul)  #...
→ needs sage.groups
sage: OTa.color_table()  #...
→ needs sage.groups sage.plot

(continues on next page)
column_keys()

Returns a tuple of the elements used to build the table.

**Note:** column_keys and row_keys are identical. Both list the elements in the order used to label the table.

**OUTPUT:**

The elements of the algebraic structure used to build the table, as a list. But most importantly, elements are present in the list in the order which they appear in the table’s column headings.

**EXAMPLES:**

```
sage: from sage.matrix.operation_table import OperationTable
sage: G = AlternatingGroup(3)  # needs sage.groups
sage: T = OperationTable(G, operator.mul)  # needs sage.groups
sage: T.column_keys()  # needs sage.groups
{((), (1,2,3), (1,3,2))}
```
gray_table(**options)

Return a graphic image as a square grid where entries are displayed in grayscale.

**INPUT:**

- element_names – (default: True) whether to display text with element names on the image
- **options** – passed on to matrix_plot()

**EXAMPLES:**

```
sage: from sage.matrix.operation_table import OperationTable
sage: OTa = OperationTable(SymmetricGroup(3), operation=operator.mul)  # needs sage.groups
sage: OTa.gray_table()  # needs sage.groups sage.plot
Graphics object consisting of 37 graphics primitives
```

```
>> from sage.all import *
>> from sage.matrix.operation_table import OperationTable
>> OTa = OperationTable(SymmetricGroup(Integer(3)), operation=operator.mul)  # needs sage.groups
>> OTa.gray_table()  # needs sage.groups sage.plot
Graphics object consisting of 37 graphics primitives
```

```
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>
<td>a</td>
<td>d</td>
<td>c</td>
<td>e</td>
</tr>
<tr>

<td>d</td>
<td>e</td>
<td>b</td>
<td>c</td>
<td>a</td>
</tr>
</tbody>
</table>
```

matrix_of_variables()
This method provides some backward compatibility for Cayley tables of groups, whose output was restricted to this single format.

EXAMPLES:

The output here is from the doctests for the old `cayley_table()` method for permutation groups.

```
sage: # needs sage.groups
sage: from sage.matrix.operation_table import OperationTable
sage: G = PermutationGroup(['(1,2,3)', '(2,3)'])
sage: T = OperationTable(G, operator.mul)
sage: T.matrix_of_variables()
[x0 x1 x2 x3 x4 x5]
[x1 x0 x3 x2 x5 x4]
[x2 x4 x0 x5 x1 x3]
[x3 x5 x1 x4 x0 x2]
[x4 x2 x5 x0 x3 x1]
[x5 x3 x4 x1 x2 x0]
sage: T.column_keys()[2]*T.column_keys()[2] == T.column_keys()[0]
True
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> from sage.matrix.operation_table import OperationTable

>>> G = PermutationGroup(['(1,2,3)', '(2,3)'])
>>> T = OperationTable(G, operator.mul)

>>> T.matrix_of_variables()
[x0 x1 x2 x3 x4 x5]
[x1 x0 x3 x2 x5 x4]
[x2 x4 x0 x5 x1 x3]
[x3 x5 x1 x4 x0 x2]
[x4 x2 x5 x0 x3 x1]
[x5 x3 x4 x1 x2 x0]

>>> T.column_keys()[Integer(2)]*T.column_keys()[Integer(2)] == T.column_keys()[Integer(0)]
True
```

`row_keys()`

Returns a tuple of the elements used to build the table.

Note: `column_keys` and `row_keys` are identical. Both list the elements in the order used to label the table.

OUTPUT:

The elements of the algebraic structure used to build the table, as a list. But most importantly, elements are present in the list in the order which they appear in the table's column headings.

EXAMPLES:
set_print_symbols (ascii, latex)

Set the symbols used for text and LaTeX printing of operation tables.

INPUT:

• ascii – a single character for text table
• latex – a string to represent an operation in LaTeX math mode. Note the need for double-backslashes to escape properly.

EXAMPLES:

```python
sage: from sage.all import *
sage: from sage.matrix.operation_table import OperationTable
sage: G = AlternatingGroup(3)
sage: T = OperationTable(G, operator.mul)
sage: T.set_print_symbols('@', '\times')
```

```
a | a b c  
+-----
| a b c  
\ b c a  
c | c a b  
```

```
{sage: T._latex_()}
'\begin{array}{r|*{3}{r}}
\multicolumn{1}{c|}{\times} & a & b & c \\
\hline
a & a & b & c \\
| b & c & a \\
| c & a & b \\
\end{array}
'```

```python
>>> from sage.all import *  
>>> G = AlternatingGroup(3)  
>>> T = OperationTable(G, operator.mul)  
>>> T.set_print_symbols('@', '\times')  
>>> T
```

```
    @  a b c  
   +-----
   | a b c  
    b c a  
   c | c a b  
```

```
>>> T._latex_()  
'{\setlength{\arraycolsep}{2ex}\begin{array}{r|*{3}{r}}  
\multicolumn{1}{c|}{\times} & a & b & c \\
\hline
a & a & b & c \\
| b & c & a \\
| c & a & b \\
\end{array}}'  
```
table()
Returns the table as a list of lists, using integers to reference the elements.

OUTPUT: The rows of the table, as a list of rows, each row being a list of integer entries. The integers correspond to the order of the elements in the headings of the table and the order of the output of the list() method.

EXAMPLES:

generate code

translation()
Returns a dictionary associating names with elements.

OUTPUT: A dictionary whose keys are strings used as names for entries of the table and values that are the actual elements of the algebraic structure.

EXAMPLES:

generate code
Warning: The class `MatrixMulAction` and its descendants extends the class `Action`. As a consequence objects from these classes only keep weak references to the underlying sets which are acted upon. This decision was made in Issue #715 in order to allow garbage collection within the coercion framework, where actions are mainly used, and avoid memory leaks.

To ensure that the underlying set of such an object does not get garbage collected, it is sufficient to explicitly create a strong reference to it before creating the action.

```sage
sage: MSQ = MatrixSpace(QQ, 2)
sage: MSZ = MatrixSpace(ZZ['x'], 2)
sage: A = MSQ.get_action(MSZ)
sage: A
Left action by Full MatrixSpace of 2 by 2 dense matrices over Rational Field
on Full MatrixSpace of 2 by 2 dense matrices
    over Univariate Polynomial Ring in x over Integer Ring
sage: import gc
sage: _ = gc.collect()
sage: A
Left action by Full MatrixSpace of 2 by 2 dense matrices over Rational Field
on Full MatrixSpace of 2 by 2 dense matrices
    over Univariate Polynomial Ring in x over Integer Ring
```

Note: The `MatrixSpace()` function caches the objects it creates. Therefore, the underlying set `MSZ` in the above example will not be garbage collected, even if it is not strongly ref'ed. Nonetheless, there is no guarantee that the set that
is acted upon will always be cached in such a way, so that following the above example is good practice.

**EXAMPLES:**

An action requires a common parent for the base rings, so the following doesn’t work (see Issue #17859):

```python
sage: vector(QQ, [1]) * matrix(Zmod(2), [[1]])
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: 'Vector space of dimension 1 over Rational Field' and 'Full MatrixSpace of 1 by 1 dense matrices over Ring of integers modulo 2'
```

```python
>>> from sage.all import *

>>> vector(QQ, [Integer(1)]) * matrix(Zmod(Integer(2)), [[Integer(1)]])
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: 'Vector space of dimension 1 over Rational Field' and 'Full MatrixSpace of 1 by 1 dense matrices over Ring of integers modulo 2'
```

**AUTHOR:**

**class** `sage.matrix.action.MatrixMatrixAction`

 `Bases:` `MatrixMulAction`

Action of a matrix on another matrix.

This is always implemented as a left action.

**EXAMPLES:**

By Issue #715, there only is a weak reference on the underlying set, so that it can be garbage collected if only the action itself is explicitly referred to. Hence, we first assign the involved matrix spaces to a variable:

```python
sage: R.<x> = ZZ[]
sage: MSR = MatrixSpace(R, 3, 3)
sage: MSQ = MatrixSpace(QQ, 3, 2)
sage: from sage.matrix.action import MatrixMatrixAction
sage: A = MatrixMatrixAction(MSR, MSQ); A
Left action
by Full MatrixSpace of 3 by 3 dense matrices
over Univariate Polynomial Ring in x over Integer Ring
on Full MatrixSpace of 3 by 2 dense matrices over Rational Field
sage: A.codomain()
Full MatrixSpace of 3 by 2 dense matrices
over Univariate Polynomial Ring in x over Rational Field
sage: A(matrix(R, 3, 3, x), matrix(QQ, 3, 2, range(6)))
[ 0  x]
[2*x 3*x]
[4*x 5*x]
```

```python
>>> from sage.all import *

>>> R = ZZ['x']; (x,) = R._first_ngens(1)

>>> MSR = MatrixSpace(R, Integer(3), Integer(3))

>>> MSQ = MatrixSpace(QQ, Integer(3), Integer(2))

>>> from sage.matrix.action import MatrixMatrixAction

(continues on next page)
A = MatrixMatrixAction(MSR, MSQ); A
Left action
by Full MatrixSpace of 3 by 3 dense matrices
over Univariate Polynomial Ring in x over Integer Ring
on Full MatrixSpace of 3 by 2 dense matrices over Rational Field
A.codomain()
Full MatrixSpace of 3 by 2 dense matrices
over Univariate Polynomial Ring in x over Rational Field
A(matrix(R, Integer(3), Integer(3), x), matrix(QQ, Integer(3), Integer(2),
→range(Integer(6))))
[ 0 x]
[2*x 3*x]
[4*x 5*x]

Note: The MatrixSpace() function caches the object it creates. Therefore, the underlying set MSZ in the
above example will not be garbage collected, even if it is not strongly ref’ed. Nonetheless, there is no guarantee
that the set that is acted upon will always be cached in such a way, so that following the above example is good
practice.

class sage.matrix.action.MatrixMulAction
Bases: Action
Abstract base class for a matrix space acting on something.

EXAMPLES:

sage: MSQ = MatrixSpace(QQ, 2)
sage: MSZ = MatrixSpace(ZZ['x'], 2)
sage: A = MSQ.get_action(MSZ); A
Left action by Full MatrixSpace of 2 by 2 dense matrices over Rational Field
on Full MatrixSpace of 2 by 2 dense matrices
over Univariate Polynomial Ring in x over Integer Ring
sage: A.actor()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
sage: A.domain()
Full MatrixSpace of 2 by 2 dense matrices
over Univariate Polynomial Ring in x over Integer Ring
sage: A.codomain()
Full MatrixSpace of 2 by 2 dense matrices
over Univariate Polynomial Ring in x over Rational Field

>>> from sage.all import *

>>> MSQ = MatrixSpace(QQ, Integer(2))
>>> MSZ = MatrixSpace(ZZ['x'], Integer(2))
>>> A = MSQ.get_action(MSZ); A
Left action by Full MatrixSpace of 2 by 2 dense matrices over Rational Field
on Full MatrixSpace of 2 by 2 dense matrices
over Univariate Polynomial Ring in x over Integer Ring
>>> A.actor()
Full MatrixSpace of 2 by 2 dense matrices over Rational Field
>>> A.domain()
Full MatrixSpace of 2 by 2 dense matrices
over Univariate Polynomial Ring in x over Integer Ring
>>> A.codomain()
class sage.matrix.action.MatrixPolymapAction
    Bases: MatrixMulAction
    
    Left action of a matrix on a scheme polynomial morphism

class sage.matrix.action.MatrixSchemePointAction
    Bases: MatrixMulAction
    
    Action class for left multiplication of schemes points by matrices.

class sage.matrix.action.MatrixVectorAction
    Bases: MatrixMulAction
    
    Left action of a matrix on a vector

class sage.matrix.action.PolymapMatrixAction
    Bases: MatrixMulAction
    
    Right action of a matrix on a scheme polynomial morphism

class sage.matrix.action.VectorMatrixAction
    Bases: MatrixMulAction
    
    Right action of a matrix on a vector
sage.matrix.change_ring.integer_to_real_double_dense(A)

Fast conversion of a matrix over the integers to a matrix with real double entries.

**INPUT:**

- A – a dense matrix over the integers

**OUTPUT:**

- a dense real double matrix

**EXAMPLES:**

```python
sage: a = matrix(ZZ,2,3,[-2,-5,3,4,8,1030339830489349908])
sage: a.change_ring(RDF)
[ -2.0  -5.0   3.0]
[   4.0  8.0 1.0303398304893499e+18]
sage: import sage.matrix.change_ring
sage: sage.matrix.change_ring.integer_to_real_double_dense(a)
[ -2.0  -5.0   3.0]
[   4.0  8.0 1.0303398304893499e+18]
```

```python
>>> from sage.all import *
>>> a = matrix(ZZ,Integer(2),Integer(3),[-Integer(2),-Integer(5),Integer(3),Integer(4),Integer(8),Integer(1030339830489349908)])
>>> a.change_ring(RDF)
[ -2.0  -5.0   3.0]
[   4.0  8.0 1.0303398304893499e+18]
>>> import sage.matrix.change_ring
>>> sage.matrix.change_ring.integer_to_real_double_dense(a)
[ -2.0  -5.0   3.0]
[   4.0  8.0 1.0303398304893499e+18]
```
CHAPTER

THIRTYEIGHT

ECHELON MATRICES OVER FINITE FIELDS.

sage.matrix.echelon_matrix.reduced_echelon_matrix_iterator (K, k, n, sparse=False, copy=True, set Immutable=False)

An iterator over \((k, n)\) reduced echelon matrices over the finite field \(K\).

INPUT:

• \(K\) – a finite field
• \(k\) – number of rows (or the size of the subspace)
• \(n\) – number of columns (or the dimension of the ambient space)
• \(\text{sparse} = \text{boolean (default is False)}\)
• \(\text{copy} = \text{boolean. If set to False then iterator yields the same matrix over and over (but with different entries). Default is True which is safer but might be slower.}\)
• \(\text{set Immutable} = \text{boolean. If set to True then the output matrices are immutable. This option automatically turns copy into True.}\)

Note: We ensure that the iteration order is so that all matrices with given pivot columns are generated consecutively. Furthermore, the order in which the pivot columns appear is lexicographic.

It would be faster to generate the pivots columns following a Gray code. There would be only one pivot changing at a time, avoiding the possibly expensive \(m0.__copy__()\). However that would modify the generation order some functions depend upon.

EXAMPLES:

```python
sage: from sage.matrix.echelon_matrix import reduced_echelon_matrix_iterator
sage: it = reduced_echelon_matrix_iterator(GF(2), 2, 3)
sage: for m in it:
    ....:     print(m)
    ....:     print(m.pivots())
    ....:     print("*******")
[1 0 0]
[0 1 0]

```

1024 Chapter 38. Echelon matrices over finite fields.
Return the polynomial of the sums of permanental minors of $A$.

INPUT:

- $A$ – a matrix
- `permanent_only` – if True, return only the permanent of $A$
- `var` – name of the polynomial variable
- `prec` – if prec is not None, truncate the polynomial at precision `prec`

The polynomial of the sums of permanental minors is

$$\sum_{i=0}^{\min(nrows, ncols)} p_i(A)x^i$$

where $p_i(A)$ is the $i$-th permanental minor of $A$ (that can also be obtained through the method `permanental_minor()` via $A$.permanental_minor(i)).

The algorithm implemented by that function has been developed by P. Butera and M. Pernici, see [BP2015]. Its complexity is $O(2^m n^2)$ where $m$ and $n$ are the number of rows and columns of $A$. Moreover, if $A$ is a banded matrix with width $w$, that is $A_{ij} = 0$ for $|i - j| > w$ and $w < n/2$, then the complexity of the algorithm is $O(4^w(w + 1)n^2)$.

INPUT:

- $A$ – matrix
- `permanent_only` – optional boolean. If True, only the permanent is computed (might be faster).
- `var` – a variable name

EXAMPLES:

```python
sage: from sage.matrix.matrix_misc import permanental_minor_polynomial
sage: m = matrix([[1, 1], [1, 2]])
sage: permanental_minor_polynomial(m)
3*t^2 + 5*t + 1
sage: permanental_minor_polynomial(m, permanent_only=True)
3
sage: permanental_minor_polynomial(m, prec=2)
5*t + 1
```
An example over $\mathbb{Q}$:

```
sage: M = MatrixSpace(QQ,2,2)
sage: A = M([1/5,2/7,3/2,4/5])
sage: permanent_minor_polynomial(A, True)
103/175
```

An example with polynomial coefficients:

```
sage: R.<a> = PolynomialRing(ZZ)
sage: A = MatrixSpace(R,2)([[a,1], [a,a+1]])
sage: permanent_minor_polynomial(A, True)
a^2 + 2*a
```

A usage of the `var` argument:

```
sage: R = PolynomialRing(ZZ, names=('a',)); (a,) = R._first_ngens(1)
sage: A = MatrixSpace(R,Integer(2))([[a,Integer(1)], [a,a+Integer(1)]])
sage: permanent_minor_polynomial(A, True)
a^2 + 2*a
```
ALGORITHM:

The permanent \( \text{perm}(A) \) of a \( n \times n \) matrix \( A \) is the coefficient of the \( x_1 x_2 \ldots x_n \) monomial in

\[
\prod_{i=1}^{n} \left( \sum_{j=1}^{n} A_{ij} x_j \right)
\]

Evaluating this product one can neglect \( x_i^2 \), that is \( x_i \) can be considered to be nilpotent of order 2.

To formalize this procedure, consider the algebra \( R = K[\eta_1, \eta_2, \ldots, \eta_n] \) where the \( \eta_i \) are commuting, nilpotent of order 2 (i.e. \( \eta_i^2 = 0 \)). Formally it is the quotient ring of the polynomial ring in \( \eta_1, \eta_2, \ldots, \eta_n \) quotiented by the ideal generated by the \( \eta_i^2 \).

We will mostly consider the ring \( R[t] \) of polynomials over \( R \). We denote a generic element of \( R[t] \) by \( p(\eta_1, \ldots, \eta_n) \) if we want to emphasize that some monomials in the \( \eta_i \) are missing.

Introduce an “integration” operation \( \langle p \rangle \) over \( R \) and \( R[t] \) consisting in the sum of the coefficients of the non-vanishing monomials in \( \eta_i \) (i.e. the result of setting all variables \( \eta_i \) to 1). Let us emphasize that this is not a morphism of algebras as \( \langle \eta_1^2 \rangle = 1 \) while \( \langle \eta_1^2 \rangle = 0! \)

Let us consider an example of computation. Let \( p_1 = 1 + t \eta_1 + t \eta_2 \) and \( p_2 = 1 + t \eta_1 + t \eta_3 \). Then

\[
p_1p_2 = 1 + 2t \eta_1 + t(\eta_2 + \eta_3) + t^2(\eta_1 \eta_2 + \eta_1 \eta_3 + \eta_2 \eta_3)
\]

and

\[
\langle p_1p_2 \rangle = 1 + 4t + 3t^2
\]

In this formalism, the permanent is just

\[
\text{perm}(A) = \langle \prod_{i=1}^{n} \sum_{j=1}^{n} A_{ij} \eta_j \rangle
\]

A useful property of \( \langle \cdot \rangle \) which makes this algorithm efficient for band matrices is the following: let \( p_1(\eta_1, \ldots, \eta_n) \) and \( p_2(\eta_j, \ldots, \eta_n) \) be polynomials in \( R[t] \) where \( j \geq 1 \). Then one has

\[
\langle p_1(\eta_1, \ldots, \eta_n) p_2 \rangle = \langle p_1(1, \ldots, 1, \eta_j, \ldots, \eta_n) p_2 \rangle
\]

where \( \eta_1, \ldots, \eta_{j-1} \) are replaced by 1 in \( p_1 \). Informally, we can “integrate” these variables before performing the product. More generally, if a monomial \( \eta_i \) is missing in one of the terms of a product of two terms, then it can be integrated in the other term.

Now let us consider an \( m \times n \) matrix with \( m \leq n \). The sum of permanental \( 'k' \)-minors of \( 'A' \) is

\[
\text{perm}(A, k) = \sum_{r,c} \text{perm}(A_{r,c})
\]
where the sum is over the \( k \)-subsets \( r \) of rows and \( k \)-subsets \( c \) of columns and \( A_{r,c} \) is the submatrix obtained from \( A \) by keeping only the rows \( r \) and columns \( c \). Of course \( \text{perm}(A, \min(m, n)) = \text{perm}(A) \) and note that \( \text{perm}(A, 1) \) is just the sum of all entries of the matrix.

The generating function of these sums of permanental minors is

\[
g(t) = \prod_{i=1}^{m} \left( 1 + t \sum_{j=1}^{n} A_{ij} \eta_j \right)
\]

In fact the \( t^k \) coefficient of \( g(t) \) corresponds to choosing \( k \) rows of \( A \); \( \eta_i \) is associated to the \( i \)-th column; nilpotency avoids having twice the same column in a product of \( A \)'s.

For more details, see the article [BP2015].

From a technical point of view, the product in \( K[\eta_1, \ldots, \eta_n][t] \) is implemented as a subroutine in \texttt{prm_mul()}. The indices of the rows and columns actually start at 0, so the variables are \( \eta_0, \ldots, \eta_{n-1} \). Polynomials are represented in dictionary form: to a variable \( \eta_i \) is associated the key \( 2^i \) (or in Python \( 1 << i \)). The keys associated to products are obtained by considering the development in base 2: to the monomial \( \eta_{i_1} \cdots \eta_{i_k} \) is associated the key \( 2^{i_1} + \cdots + 2^{i_k} \). So the product \( \eta_1 \eta_2 \) corresponds to the key 6 = (110)\_2 while \( \eta_0 \eta_3 \) has key 9 = (1001)\_2. In particular all operations on monomials are implemented via bitwise operations on the keys.

\[
\text{sage.matrix.matrix_misc.pm mul}(p1, p2, mask_free, prec)
\]

Return the product of \( p1 \) and \( p2 \), putting free variables in \( mask_free \) to 1.

This function is mainly use as a subroutine of \texttt{permanental_minor_polynomial()}. 

INPUT:

- \( p1,p2 \) – polynomials as dictionaries
- \( mask\_free \) – an integer mask that give the list of free variables (the \( i \)-th variable is free if the \( i \)-th bit of \( mask\_free \) is 1)
- \( prec \) – if \( prec \) is not \( None \), truncate the product at precision \( prec \)

EXAMPLES:

\[
\begin{align*}
\text{sage: from sage.matrix.matrix_misc import pm mul} \\
\text{sage: t = polygen(ZZ, 't')} \\
\text{sage: p1 = {0: 1, 1: t, 4: t}} \\
\text{sage: p2 = {0: 1, 1: t, 2: t}} \\
\text{sage: pm mul(p1, p2, 1, None)} \\
\{0: 2*t + 1, 2: t^2 + t, 4: t^2 + t, 6: t^2}\end{align*}
\]

\[
\begin{align*}
>>> \text{from sage.all import *} \\
>>> \text{from sage.matrix.matrix_misc import pm mul} \\
>>> t = polygen(ZZ, 't') \\
>>> p1 = {Integer(0): Integer(1), Integer(1): t, Integer(4): t} \\
>>> p2 = {Integer(0): Integer(1), Integer(1): t, Integer(2): t} \\
>>> pm mul(p1, p2, Integer(1), None) \\
\{0: 2*t + 1, 2: t^2 + t, 4: t^2 + t, 6: t^2}\end{align*}
\]

\[
\begin{align*}
\text{sage.matrix.matrix_misc.row iterator}(A)\end{align*}
\]
class sage.matrix.matrix_window.MatrixWindow
    Bases: object
    
    add(A)
    add_prod(A, B)
    
    echelon_in_place()
    Calculate the echelon form of this matrix, returning the list of pivot columns
    
    element_is_zero(i, j)
    get_unsafe(i, j)
    
    matrix()
    Returns the underlying matrix that this window is a view of.
    
    matrix_window(row, col, n_rows, n_cols)
    Returns a matrix window relative to this window of the underlying matrix.
    
    ncols()
    
    new_empty_window(nrows, ncols)
    
    new_matrix_window(matrix, row, col, n_rows, n_cols)
    This method is here only to provide a fast cdef way of constructing new matrix windows. The only implicit
    assumption is that self._matrix and matrix are over the same base ring (so share the zero).
    
    nrows()
    
    set(src)
    
    set_to(A)
    Change self, making it equal A.
    
    set_to_diff(A, B)
    set_to_prod(A, B)
    set_to_sum(A, B)
    set_to_zero()
    
    set_unsafe(i, j, x)
\texttt{subtract}(A)

\texttt{subtract\_prod}(A, B)

\texttt{swap\_rows}(a, b)

\texttt{to\_matrix}()

Returns an actual matrix object representing this view.
sage.matrix.misc.cmp_pivots(x, y)

Compare two sequences of pivot columns.

If \( x \) is shorter than \( y \), return \(-1\), i.e., \( x < y \), “not as good”. If \( x \) is longer than \( y \), then \( x > y \), so “better” and return +1. If the length is the same, then \( x \) is better, i.e., \( x > y \) if the entries of \( x \) are correspondingly \( \leq \) those of \( y \) with one being strictly less.

INPUT:

• \( x, y \) – lists or tuples of integers

EXAMPLES:

We illustrate each of the above comparisons.

```python
sage: from sage.matrix.misc import cmp_pivots
cmp_pivots([1,2,3], [4,5,6,7])
-1
sage: cmp_pivots([1,2,3,5], [4,5,6])
1
sage: cmp_pivots([1,2,4], [1,2,3])
-1
sage: cmp_pivots([1,2,3], [1,2,3])
0
sage: cmp_pivots([1,2,3], [1,2,4])
1
```

```python
>>> from sage.all import *
>>> from sage.matrix.misc import cmp_pivots
>>> cmp_pivots([Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5),
Integer(6),Integer(7)])
-1
>>> cmp_pivots([Integer(1),Integer(2),Integer(3),Integer(5)], [Integer(4),
Integer(5),Integer(6)])
1
>>> cmp_pivots([Integer(1),Integer(2),Integer(3),Integer(5)], [Integer(4),
Integer(5),Integer(6)])
1
>>> cmp_pivots([Integer(1),Integer(2),Integer(4)], [Integer(1),Integer(2),
Integer(3)])
-1
>>> cmp_pivots([Integer(1),Integer(2),Integer(3)], [Integer(1),Integer(2),
Integer(3)])
0
>>> cmp_pivots([Integer(1),Integer(2),Integer(3)], [Integer(1),Integer(2),
Integer(4)])
1
```
Given a sparse matrix over the integers and an integer modulus, do rational reconstruction on all entries of the matrix, viewed as numbers mod $N$.

**EXAMPLES:**

```python
sage: A = matrix(ZZ, 3, 4, [(1/3)%500, 2, 3, (-4)%500, 7, 2, 3, 4, 3, 4, (5/7)%500], sparse=True)
sage: from sage.matrix.misc import matrix_integer_sparse_rational_reconstruction
sage: matrix_integer_sparse_rational_reconstruction(A, 500)
[1/3 2 3 -4]
[ 7 2 2 3]
[ 4 3 4 5/7]
```

```python
>>> from sage.all import *
>>>
A = matrix(ZZ, Integer(3), Integer(4), [(Integer(1)/Integer(3))%Integer(500),
                                           Integer(2), Integer(3), (-Integer(4))%Integer(500), Integer(7), Integer(2),
                                           Integer(2), Integer(3), Integer(4), Integer(3), Integer(4), (Integer(5)/
                                           Integer(7))%Integer(500)], sparse=True)
>>> from sage.matrix.misc import matrix_integer_sparse_rational_reconstruction
>>> matrix_integer_sparse_rational_reconstruction(A, Integer(500))
[1/3 2 3 -4]
[ 7 2 2 3]
[ 4 3 4 5/7]
```

**sage.matrix.misc.matrix_rational_echelon_form_multimodular**

**REFERENCE:** Chapter 7 of Stein’s “Explicitly Computing Modular Forms”.

**INPUT:**

- `height_guess` – integer or None
- `proof` – boolean or None (default: None, see proof.linear_algebra or sage.structure.proof). Note that the global Sage default is proof=True

**OUTPUT:** a pair consisting of a matrix in echelon form and a tuple of pivot positions.

**ALGORITHM:**

The following is a modular algorithm for computing the echelon form. Define the height of a matrix to be the max of the absolute values of the entries.

Given Matrix $A$ with $n$ columns (self).

0. Rescale input matrix $A$ to have integer entries. This does not change echelon form and makes reduction modulo lots of primes significantly easier if there were denominators. Henceforth we assume $A$ has integer entries.

1. Let $c$ be a guess for the height of the echelon form. E.g., $c=1000$, e.g., if matrix is very sparse and application is to computing modular symbols.

2. Let $M = n \cdot c \cdot H(A) + 1$, where $n$ is the number of columns of $A$.

3. List primes $p_1, p_2, \ldots$, such that the product of the $p_i$ is at least $M$.

4. Try to compute the rational reconstruction CRT echelon form of $A$ mod the product of the $p_i$. If rational reconstruction fails, compute 1 more echelon forms mod the next prime, and attempt again. Make sure to keep the result of CRT on the primes from before, so we don’t have to do that computation again. Let $E$ be this matrix.
5. Compute the denominator $d$ of $E$. Attempt to prove that result is correct by checking that
\[ H(d*E)*\text{nrows}(A)*H(A) < (\text{prod of reduction primes}) \]
where $H$ denotes the height. If this fails, do step 4 with a few more primes.

EXAMPLES:

```sage
sage: A = matrix(QQ, 3, 7, [1..21])
sage: from sage.matrix.misc import matrix_rational_echelon_form_multimodular
sage: E, pivots = matrix_rational_echelon_form_multimodular(A)
sage: E
\[
\begin{bmatrix}
1 & 0 & -1 & -2 & -3 & -4 & -5 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 \\
0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
\]
sage: pivots
(0, 1)

sage: A = matrix(QQ, 3, 4, [0,0] + [1..9] + [-1/2^20])
sage: E, pivots = matrix_rational_echelon_form_multimodular(A)
sage: E
\[
\begin{bmatrix}
1 & 0 & 0 & -10485761/1048576 \\
0 & 1 & 0 & 27262979/4194304 \\
0 & 0 & 1 & 2
\end{bmatrix}
\]
sage: pivots
(0, 1, 2)
```

```bash
>>> from sage.all import *
>>> A = matrix(QQ, Integer(3), Integer(7), (ellipsis_range(Integer(1),Ellipsis, Integer(21))))
>>> from sage.matrix.misc import matrix_rational_echelon_form_multimodular
>>> E, pivots = matrix_rational_echelon_form_multimodular(A)
>>> E
\[
\begin{bmatrix}
1 & 0 & -1 & -2 & -3 & -4 & -5 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 \\
0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
\]
>>> pivots
(0, 1)

>>> A = matrix(QQ, Integer(3), Integer(4), [Integer(0),Integer(0)] + (ellipsis_range(Integer(1),Ellipsis,Integer(9))) + [-Integer(1)/Integer(2)**Integer(20)])
>>> E, pivots = matrix_rational_echelon_form_multimodular(A)
>>> E
\[
\begin{bmatrix}
1 & 0 & 0 & -10485761/1048576 \\
0 & 1 & 0 & 27262979/4194304 \\
0 & 0 & 1 & 2
\end{bmatrix}
\]
>>> pivots
(0, 1, 2)
```

```bash
>>> A.echelon_form()
\[
\begin{bmatrix}
1 & 0 & 0 & -10485761/1048576 \\
0 & 1 & 0 & 27262979/4194304 \\
0 & 0 & 1 & 2
\end{bmatrix}
\]
>>> A.pivots()
(0, 1, 2)
```
\[
\begin{bmatrix}
0 & 0 & 1 & 2
\end{bmatrix}
\]

```python
>>> A.pivots()
(0, 1, 2)
```
MISC MATRIX ALGORITHMS USING MPFR

\texttt{sage.matrix.misc_mpfr.hadamard_row_bound_mpfr(A)}

Given a matrix \( A \) with entries that coerce to \( \mathbb{R} \), compute the row Hadamard bound on the determinant.

**INPUT:**

\begin{itemize}
  \item \( A \) – a matrix over \( \mathbb{R} \)
\end{itemize}

**OUTPUT:**

integer – an integer \( n \) such that the absolute value of the determinant of this matrix is at most \( 10^n \).

**EXAMPLES:**

We create a very large matrix, compute the row Hadamard bound, and also compute the row Hadamard bound of the transpose, which happens to be sharp.

\begin{verbatim}
sage: a = matrix(ZZ, 2, [2^10000, 3^10000, 2^50, 3^19292])
sage: from sage.matrix.misc_mpfr import hadamard_row_bound_mpfr
sage: hadamard_row_bound_mpfr(a.change_ring(RR))
13976
sage: len(str(a.det()))
12215
sage: hadamard_row_bound_mpfr(a.transpose().change_ring(RR))
12215
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> a = matrix(ZZ, 2, [Integer(2)**Integer(10000),
Integer(3)**Integer(10000),
Integer(2)**Integer(50),
Integer(3)**Integer(19292)])
>>> from sage.matrix.misc_mpfr import hadamard_row_bound_mpfr
>>> hadamard_row_bound_mpfr(a.change_ring(RR))
13976
>>> len(str(a.det()))
12215
>>> hadamard_row_bound_mpfr(a.transpose().change_ring(RR))
12215
\end{verbatim}

Note that in the above example using RDF would overflow:

\begin{verbatim}
sage: b = a.change_ring(RDF)
sage: b._hadamard_row_bound()
Traceback (most recent call last):
... 
OverflowError: cannot convert float infinity to integer
\end{verbatim}
```python
>>> from sage.all import *
>>> b = a.change_ring(RDF)
>>> b._hadamard_row_bound()
Traceback (most recent call last):
...
OverflowError: cannot convert float infinity to integer
```
sage.matrix.misc_flint.matrix_integer_dense_rational_reconstruction(A, N)

Given a matrix over the integers and an integer modulus, do rational reconstruction on all entries of the matrix, viewed as numbers mod \( N \). This is done efficiently by assuming there is a large common factor dividing the denominators.

**INPUT:**

- \( A \) – matrix
- \( N \) – an integer

**EXAMPLES:**

```python
sage: B = ((matrix(ZZ, 3, 4, [1, 2, 3, -4, 7, 2, 18, 3, 4, 3, 4, 5])/3)%500).change_ring(ZZ)
sage: from sage.matrix.misc_flint import matrix_integer_dense_rational_reconstruction
sage: matrix_integer_dense_rational_reconstruction(B, 500)
[ 1/3  2/3  1  -4/3]
[ 7/3  2/3  6   1]
[ 4/3  1  4/3  5/3]
```

```python
>>> from sage.all import *
>>> B = ((matrix(ZZ, Integer(3), Integer(4), [Integer(1), Integer(2), Integer(3), -Integer(4), Integer(7), Integer(2), Integer(18), Integer(3), Integer(4), Integer(3), Integer(4), Integer(5)])/Integer(3))%Integer(500)).change_ring(ZZ)
>>> from sage.matrix.misc_flint import matrix_integer_dense_rational_reconstruction
>>> matrix_integer_dense_rational_reconstruction(B, Integer(500))
[ 1/3  2/3  1  -4/3]
[ 7/3  2/3  6   1]
[ 4/3  1  4/3  5/3]
```
CALCULATE SYMPLECTIC BASES FOR MATRICES OVER FIELDS AND THE INTEGERS.

This module finds a symplectic basis for an anti-symmetric, alternating matrix M defined over a field or the integers. Anti-symmetric means that $M = -M^t$, where $M^t$ denotes the transpose of $M$. Alternating means that the diagonal of $M$ is identically zero.

A symplectic basis is a basis of the form $e_1, \ldots, e_j, f_1, \ldots, f_j, z_1, \ldots, z_k$ such that

- $z_i M v^t = 0$ for all vectors $v$;
- $e_i M e_j^t = 0$ for all $i, j$;
- $f_i M f_j^t = 0$ for all $i, j$;
- $e_i M f_j^t = 0$ for all $i$ not equal $j$;

and such that the non-zero terms

- $e_i M f_i^t$ are “as nice as possible”: 1 over fields, or integers satisfying divisibility properties otherwise.

REFERENCES:

Bourbaki gives a nice proof that can be made constructive but is not efficient (see Section 5, Number 1, Theorem 1, page 79):

Kuperberg gives a more efficient and constructive exposition (see Theorem 18).

Todo: The routine over the integers applies over general principal ideal domains.

Warning: This code is not a good candidate for conversion to Cython. The majority of the execution time is spent adding multiples of columns and rows, which is already fast. It would be better to devise a better algorithm, perhaps modular or based on a fast smith_form implementation.

AUTHOR:

- Nick Alexander: initial implementation
- David Loeffler (2008-12-08): changed conventions for consistency with smith_form
sage.matrix.symplectic_basis.symplectic_basis_over_ZZ(M)

Find a symplectic basis for an anti-symmetric, alternating matrix M defined over the integers.

Returns a pair (F, C) such that the rows of C form a symplectic basis for M and F = C * M * C.transpose().

Anti-symmetric means that $M = -M^t$. Alternating means that the diagonal of $M$ is identically zero.

A symplectic basis is a basis of the form $e_1, \ldots, e_j, f_1, \ldots, f_j, z_1, \ldots, z_k$ such that

- $z_i M v^t = 0$ for all vectors $v$;
- $e_i M e_j^t = 0$ for all $i, j$;
- $f_i M f_j^t = 0$ for all $i, j$;
- $e_i M f_i^t = d_i$ for all $i$, where $d_i$ are positive integers such that $d_i | d_{i+1}$ for all $i$;
- $e_i M f_j^t = 0$ for all $i$ not equal $j$.

The ordering for the factors $d_i | d_{i+1}$ and for the placement of zeroes was chosen to agree with the output of smith_form.

See the examples for a pictorial description of such a basis.

EXAMPLES:

```python
sage: from sage.matrix.symplectic_basis import symplectic_basis_over_ZZ

>>> from sage.all import *
>>> from sage.matrix.symplectic_basis import symplectic_basis_over_ZZ

An example which does not have full rank:

```python
sage: E = matrix(ZZ, 4, 4, [0, 16, 0, 2, -16, 0, 0, -4, 0, 0, 0, 0, -2, 4, 0, 0]); E
[ 0 16 0 2]
[-16 0 0 -4]
[ 0 0 0 0]
[ -2 4 0 0]

sage: F, C = symplectic_basis_over_ZZ(E)

sage: F
[ 0 2 0 0]
[-2 0 0 0]
[ 0 0 0 0]
[ 0 0 0 0]

sage: C * E * C.transpose() == F
True
```
A larger example:

```

sage.matrix.symplectic_basis.symplectic_basis_over_field(M)

Find a symplectic basis for an anti-symmetric, alternating matrix M defined over a field.

Returns a pair (F, C) such that the rows of C form a symplectic basis for M and F = C * M * C.transpose().

Anti-symmetric means that $M = -M^t$. Alternating means that the diagonal of $M$ is identically zero.

A symplectic basis is a basis of the form $e_1, \ldots, e_j, f_1, \ldots f_j, z_1, \ldots, z_k$ such that

- $z_i M v^t = 0$ for all vectors $v$;
- $e_i M e_j^t = 0$ for all $i, j$;
- $f_i M f_j^t = 0$ for all $i, j$;
- $e_i M f_i^t = 1$ for all $i$;
- $e_i M f_j^t = 0$ for all $i$ not equal $j$.

See the examples for a pictorial description of such a basis.

EXAMPLES:

$J$-IDEALS OF MATRICES

Let $B$ be an $n \times n$-matrix over a principal ideal domain $D$.

For an ideal $J$, the $J$-ideal of $B$ is defined to be $N_J(B) = \{ f \in D[X] \mid f(B) \in M_n(J) \}$.

For a prime element $p$ of $D$ and $t \geq 0$, a $(p^t)$-minimal polynomial of $B$ is a monic polynomial $f \in N_{(p^t)}(B)$ of minimal degree.

This module computes these minimal polynomials.

Let $p$ be a prime element of $D$. Then there is a finite set $S_p$ of positive integers and monic polynomials $\nu_{ps}$ for $s \in S_p$ such that for $t \geq 1$,

$$N_{(p^t)}(B) = \mu_B D[X] + p^t D[X] + \sum_{s \in S_p, s \leq b(t)} p^{\max(0,t-s)} \nu_{ps} D[X]$$

holds where $b(t) = \min\{r \in S_p \mid r \geq s\}$. The degree of $\nu_{ps}$ is strictly increasing in $s \in S_p$ and $\nu_{ps}$ is a $(p^s)$-minimal polynomial. If $t \leq \max S_p$, then the summand $\mu_B D[X]$ can be omitted.

All computations are done by the class `ComputeMinimalPolynomials` where various intermediate results are cached. It provides the following methods:

- `p_minimal_polynomials()` computes $S_p$ and the monic polynomials $\nu_{ps}$.
- `null_ideal()` determines $N_{(p^t)}(B)$.
- `prime_candidates()` determines all primes $p$ where $S_p$ might be non-empty.
- `integer_valued_polynomials_generators()` determines the generators of the ring $\{ f \in K[X] \mid f(B) \in M_n(D) \}$ of integer valued polynomials on $B$.

**EXAMPLES:**

```python
sage: from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: C = ComputeMinimalPolynomials(B)
sage: C.prime_candidates()
[2, 3, 5]
sage: for t in range(4):
....:    print(C.null_ideal(2^t))
Principal ideal (1) of
  Univariate Polynomial Ring in x over Integer Ring
Ideal (2, x^2 + x) of
  Univariate Polynomial Ring in x over Integer Ring
Ideal (4, x^2 + 3*x + 2) of
  Univariate Polynomial Ring in x over Integer Ring
Ideal (8, x^3 + x^2 - 12*x - 20, 2*x^2 + 6*x + 4) of
```

(continues on next page)
Matrices and Spaces of Matrices, Release 10.4

(continued from previous page)

Univariate Polynomial Ring in x over Integer Ring

\[\text{sage: } C\text{.p\_minimal\_polynomials}(2)\]
\[\{2: x^2 + 3x + 2\}\]

\[\text{sage: } C\text{.integer\_valued\_polynomials\_generators()}\]
\[(x^3 + x^2 - 12x - 20, [1, 1/4*x^2 + 3/4*x + 1/2])\]

\[\text{>>> from sage.all import } *\]
\[\text{>>> from sage.matrix.compute_J_ideal import } \text{ComputeMinimalPolynomials}\]
\[\text{>>> B = matrix(ZZ, }[[\text{Integer}(1), \text{Integer}(0), \text{Integer}(1)], [\text{Integer}(1), -\text{Integer}(2), -\text{Integer}(1)], [\text{Integer}(10), \text{Integer}(0), \text{Integer}(0)]])\]
\[\text{>>> C = ComputeMinimalPolynomials(B)}\]
\[\text{>>> C.prime\_candidates()}\]
\[\{2, 3, 5\}\]
\[\text{>>> for } t \text{ in range(Integer(4)):\ }
... \quad \text{print}(C\text{.null\_ideal(Integer(2)**t)))\]
Principal ideal (1) of
Univariate Polynomial Ring in x over Integer Ring
Ideal (2, x^2 + x) of
Univariate Polynomial Ring in x over Integer Ring
Ideal (4, x^2 + 3x + 2) of
Univariate Polynomial Ring in x over Integer Ring
Ideal (8, x^3 + x^2 - 12x - 20, 2*x^2 + 6*x + 4) of
Univariate Polynomial Ring in x over Integer Ring

\[\text{>>> C\text{.p\_minimal\_polynomials(Integer(2))}}\]
\[\{2: x^2 + 3x + 2\}\]

\[\text{>>> C\text{.integer\_valued\_polynomials\_generators()}}\]
\[(x^3 + x^2 - 12x - 20, [1, 1/4*x^2 + 3/4*x + 1/2])\]

The last output means that

\[\{f \in \mathbb{Q}[X] \mid f(B) \in M_3(\mathbb{Z})\} = (x^3 + x^2 - 12x - 20)\mathbb{Q}[X] + \mathbb{Z}[X] + \frac{1}{4}(x^2 + 3x + 2)\mathbb{Z}[X].\]

**Todo:** Test code over PIDs other than ZZ.

This requires implementation of `frobenius()` over more general domains than ZZ.

Additionally, `lifting()` requires modification or a bug needs fixing, see AskSage Question 35555.

45.1 Classes and Methods

```python
class sage.matrix.compute_J_ideal.ComputeMinimalPolynomials(B):
    Bases: SageObject

    Create an object for computing \((p^t)\)-minimal polynomials and \(J\)-ideals.

    For an ideal \(J\) and a square matrix \(B\) over a principal ideal domain \(D\), the \(J\)-ideal of \(B\) is defined to be \(N_J(B) = \{f \in D[X] \mid f(B) \in M_n(J)\}\).

    For a prime element \(p\) of \(D\) and \(t \geq 0\), a \((p^t)\)-minimal polynomial of \(B\) is a monic polynomial \(f \in N_{(p^t)}(B)\) of minimal degree.

    The characteristic polynomial of \(B\) is denoted by \(\chi_B\); \(n\) is the size of \(B\).

    INPUT:

    • \(B\) – a square matrix over a principal ideal domain \(D\)

    OUTPUT:

    An object which allows to call \(p\text{-minimal\_polynomials()}\), \(null\_ideal()\) and \(integer\text{-valued\_polynomials\_generators()}\).

    EXAMPLES:
```

```python
sage: from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
```

```python
sage: C = ComputeMinimalPolynomials(B)
```

```python
sage: C.prime_candidates()

[2, 3, 5]
```

```python
sage: for t in range(4):
    ....:     print(C.null_ideal(2^t))
```

```
Principal ideal (1) of
    Univariate Polynomial Ring in x over Integer Ring
Ideal (2, x^2 + x) of
    Univariate Polynomial Ring in x over Integer Ring
Ideal (4, x^2 + 3*x + 2) of
    Univariate Polynomial Ring in x over Integer Ring
Ideal (8, x^3 + x^2 - 12*x - 20, 2*x^2 + 6*x + 4) of
    Univariate Polynomial Ring in x over Integer Ring
```

```python
sage: C.p_minimal_polynomials(2)

{2: x^2 + 3*x + 2}
```

```python
sage: C.integer_valued_polynomials_generators()

([x^3 + x^2 - 12*x - 20, 1, 1/4*x^2 + 3/4*x + 1/2])
```

```python
>>> from sage.all import *
```

```python
>>> from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
```

```python
>>> B = matrix(ZZ, [[Integer(1), Integer(0), Integer(1)], [Integer(1), -Integer(2), -Integer(1)], [Integer(10), Integer(0), Integer(0)]]
```

```python
>>> C = ComputeMinimalPolynomials(B)
```

```python
>>> C.prime_candidates()

Ideal (2, x^2 + x) of
    Univariate Polynomial Ring in x over Integer Ring
```

(continues on next page)
current\_nu\( (p, t, pt\_generators, prev\_nu) \)

Compute \((p^t)\)-minimal polynomial of \(B\).

\textbf{INPUT:}

\begin{itemize}
  \item \(p\) – a prime element of \(D\)
  \item \(t\) – a positive integer
  \item \(pt\_generators\) – a list \((g_1, \ldots, g_s)\) of polynomials in \(D[X]\) such that \(N(p^t)B = (g_1, \ldots, g_s) + pN(p^{t-1})B\)
  \item \(prev\_nu\) – a \((p^{t-1})\)-minimal polynomial of \(B\)
\end{itemize}

\textbf{OUTPUT:}

A \((p^t)\)-minimal polynomial of \(B\).

\textbf{EXAMPLES:}

```python
sage: from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: C = ComputeMinimalPolynomials(B)
sage: x = polygen(ZZ, 'x')
sage: nu_1 = x**Integer(2) + x
sage: generators_4 = [Integer(2)*x**Integer(2) + Integer(2)*x, x**Integer(2) + Integer(2)]
>>> C.current_nu(Integer(2), Integer(2), generators_4, nu_1)
```

\textbf{ALGORITHM:}

[HR2016], Algorithm 4.

\textbf{find\_monic\_replacements\( (p, t, pt\_generators, prev\_nu) \)}

Replace possibly non-monic generators of \(N(p^t)B\) by monic generators.

\textbf{INPUT:}

\begin{itemize}
  \item \(p\) – a prime element of \(D\)
• \( t \) - a non-negative integer

• \( pt\_generators \) - a list \((g_1, \ldots, g_s)\) of polynomials in \( D[X] \) such that \( N_{(p^t)}(B) = (g_1, \ldots, g_s) + pN_{(p^{t-1})}(B) \)

• \( prev\_nu \) - a \((p^{t-1})\)-minimal polynomial of \( B \)

**OUTPUT:**
A list \((h_1, \ldots, h_r)\) of monic polynomials such that \( N_{(p^t)}(B) = (h_1, \ldots, h_r) + pN_{(p^{t-1})}(B) \).

**EXAMPLES:**

```python
sage: from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: C = ComputeMinimalPolynomials(B)
sage: x = polygen(ZZ, 'x')
sage: nu_1 = x^2 + x
sage: generators_4 = [2*x^2 + 2*x, x^2 + 3*x + 2]
sage: C.find_monic_replacements(2, 2, generators_4, nu_1)
[x^2 + 3*x + 2]
```

**ALGORITHM:**
[HR2016], Algorithms 2 and 3.

**integer_valued_polynomials_generators()**

Determine the generators of the ring of integer valued polynomials on \( B \).

**OUTPUT:**
A pair \((\mu_B, P)\) where \( P \) is a list of polynomials in \( K[X] \) such that
\[
\{ f \in K[X] \mid f(B) \in M_n(D) \} = \mu_B K[X] + \sum_{g \in P} gD[X]
\]
where \( K \) denotes the fraction field of \( D \).

**EXAMPLES:**

```python
sage: from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: C = ComputeMinimalPolynomials(B)
sage: C.integer_valued_polynomials_generators()
(x^3 + x^2 - 12*x - 20, [1, 1/4*x^2 + 3/4*x + 1/2])
```

```python
>>> from sage.all import *
>>> from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
>>> B = matrix(ZZ, [[Integer(1), Integer(0), Integer(1)], [Integer(1), -Integer(2), -Integer(1)], [Integer(10), Integer(0), Integer(0)]])
>>> C = ComputeMinimalPolynomials(B)
>>> x = polygen(ZZ, 'x')
>>> nu_1 = x**Integer(2) + x
>>> generators_4 = [Integer(2)*x**Integer(2) + Integer(2)*x, x**Integer(2) + Integer(10)*x + Integer(0)]
>>> C.find_monic_replacements(Integer(2), Integer(2), generators_4, nu_1)
[x^2 + 3*x + 2]
```
mccoy_column \((p, t, nu)\)

Compute matrix for McCoy's criterion.

**INPUT:**
- \(p\) – a prime element in \(D\)
- \(t\) – a positive integer
- \(nu\) – a \((p^t)\)-minimal polynomial of \(B\)

**OUTPUT:**
An \((n^2 + 1) \times 1\) matrix \(g\) with first entry \(nu\) such that \((b - \chi B I) g \equiv 0 \pmod{p^t}\) where \(b\) consists of the entries of \(\text{adj}(X - B)\).

**EXAMPLES:**

```python
sage: from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: C = ComputeMinimalPolynomials(B)
sage: x = polygen(ZZ, x)
sage: nu_4 = x^2 + 3*x + 2
sage: g = C.mccoy_column(2, 2, nu_4)
sage: b = matrix(ZZ, (x - B).adjugate().list())
sage: M = matrix.block([[b, -B.charpoly(x)*matrix.identity(9)]])
sage: (M*g % 4).is_zero()
```

```
True
```

**ALGORITHM:**

[HR2016], Algorithm 5.

null_ideal \((b=0)\)

Return the \((b)\)-ideal \(N_{(b)}(B) = \{ f \in D[X] \mid f(B) \in M_n(bD) \}\).

**INPUT:**
- \(b\) – an element of \(D\) (default: 0)

**OUTPUT:**
An ideal in $D[X]$.

**EXAMPLES:**

```python
sage: from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: C = ComputeMinimalPolynomials(B)
sage: C.null_ideal()
Principal ideal (x^3 + x^2 - 12*x - 20) of
  Univariate Polynomial Ring in x over Integer Ring
sage: C.null_ideal(2)

```

**p_minimal_polynomials**: ($p$, $s_{max}=None$)

Compute ($p^s$)-minimal polynomials $\nu_s$ of $B$.

Compute a finite subset $S$ of the positive integers and ($p^s$)-minimal polynomials $\nu_s$ for $s \in S$.

For $0 < t \leq \max S$, a ($p^t$)-minimal polynomial is given by $\nu_s$ where $s = \min\{r \in S \mid r \geq t\}$. For $t > \max S$, the minimal polynomial of $B$ is also a ($p^t$)-minimal polynomial.

**INPUT:**
• $p$ – a prime in $D$

• $s_{\text{max}}$ – a positive integer (default: None); if set, only $(p^s)$-minimal polynomials for $s \leq s_{\text{max}}$ are computed (see below for details)

OUTPUT:

A dictionary. Keys are the finite set $\mathcal{S}$, the values are the associated $(p^s)$-minimal polynomials $\nu_s, s \in \mathcal{S}$.

Setting $s_{\text{max}}$ only affects the output if $s_{\text{max}}$ is at most $\max \mathcal{S}$ where $\mathcal{S}$ denotes the full set. In that case, only those $\nu_s$ with $s \leq s_{\text{max}}$ are returned where $s_{\text{max}}$ is always included even if it is not included in the full set $\mathcal{S}$.

>>> set_verbose(Integer(0))
>>> C.p_minimal_polynomials(Integer(2), s_max=Integer(1))
(1: x^2 + x)
>>> C.p_minimal_polynomials(Integer(2), s_max=Integer(2))
(2: x^2 + 3*x + 2)
>>> C.p_minimal_polynomials(Integer(2), s_max=Integer(3))
(2: x^2 + 3*x + 2)
```

**ALGORITHM:**

[HR2016], Algorithm 5.

`prime_candidates()`

Determine those primes $p$ where $\mu_B$ might not be a $(p)$-minimal polynomial.
OUTPUT:
A list of primes.

EXAMPLES:

```python
sage: from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
sage: B = matrix(ZZ, [[1, 0, 1], [1, -2, -1], [10, 0, 0]])
sage: C = ComputeMinimalPolynomials(B)
sage: C.prime_candidates()
[2, 3, 5]
sage: C.p_minimal_polynomials(2)
{2: x^2 + 3*x + 2}
sage: C.p_minimal_polynomials(3)
{}
sage: C.p_minimal_polynomials(5)
{}
```

This means that 3 and 5 were candidates, but actually, \( \mu_B \) turns out to be a \((3)\)-minimal polynomial and a \((5)\)-minimal polynomial.

```python
>>> from sage.all import *
>>> from sage.matrix.compute_J_ideal import ComputeMinimalPolynomials
>>> B = matrix(ZZ, [[Integer(1), Integer(0), Integer(1)], [Integer(1), -Integer(2), -Integer(1)], [Integer(10), Integer(0), Integer(0)]])
>>> C = ComputeMinimalPolynomials(B)
>>> C.prime_candidates()
[2, 3, 5]
>>> C.p_minimal_polynomials(Integer(2))
{2: x^2 + 3*x + 2}
>>> C.p_minimal_polynomials(Integer(3))
{}
>>> C.p_minimal_polynomials(Integer(5))
{}
```

sage.matrix.compute_J_ideal.lifting \( (p, t, A, G) \)
Compute generators of \( \{ f \in D[X]^d \mid Af \equiv 0 \pmod{p^t} \} \) given generators of \( \{ f \in D[X]^d \mid Af \equiv 0 \pmod{p^{t-1}} \} \).

INPUT:
- \( p \) – a prime element of some principal ideal domain \( D \)
- \( t \) – a non-negative integer
- \( A \) – a \( c \times d \) matrix over \( D[X] \)
- \( G \) – a matrix over \( D[X] \). The columns of \( (p^{t-1}I \ G) \) are generators of \( \{ f \in D[X]^d \mid Af \equiv 0 \pmod{p^{t-1}} \} \); can be set to None if \( t \) is zero

OUTPUT:
A matrix \( F \) over \( D[X] \) such that the columns of \( (p^tI \ F \ pG) \) are generators of \( \{ f \in D[X]^d \mid Af \equiv 0 \pmod{p^t} \} \).

EXAMPLES:

```python
sage: from sage.matrix.compute_J_ideal import lifting
sage: X = polygen(ZZ, 'X')
sage: A = matrix([[1, X], [2*X, X^2]])
sage: G0 = lifting(5, 0, A, None)
```

(continues on next page)
sage: G1 = lifting(5, 1, A, G0); G1
[]
sage: (A^G1 % 5).is_zero()
True
sage: A = matrix([[1, X, X^2], [2*X, X^2, 3*X^3]])
sage: G0 = lifting(5, 0, A, None)
sage: G1 = lifting(5, 1, A, G0); G1
[3*X^2]
[ X]
[ 1]
sage: (A^G1 % 5).is_zero()
True
sage: G2 = lifting(5, 2, A, G1); G2
[15*X^2 23*X^2]
[ 5*X X]
[ 5 1]
sage: (A^G2 % 25).is_zero()
True
sage: lifting(5, 10, A, G1)
Traceback (most recent call last):

>> from sage.all import *
>> from sage.matrix.compute_J_ideal import lifting
>> X = polygen(ZZ, 'X')
>> A = matrix([[Integer(1), X], [Integer(2)*X, X**Integer(2)]]))
>> G0 = lifting(Integer(5), Integer(0), A, None)
>> G1 = lifting(Integer(5), Integer(1), A, G0); G1
[]
>> (A^G1 % Integer(5)).is_zero()
True
>> A = matrix([[Integer(1), X, X**Integer(2)], [Integer(2)*X, X**Integer(2),…
...-Integer(3)*X**Integer(3)]]))
>> G0 = lifting(Integer(5), Integer(0), A, None)
>> G1 = lifting(Integer(5), Integer(1), A, G0); G1
[3*X^2]
[ X]
[ 1]
>> (A^G1 % Integer(5)).is_zero()
True
>> G2 = lifting(Integer(5), Integer(2), A, G1); G2
[15*X^2 23*X^2]
[ 5*X X]
[ 5 1]
>> (A^G2 % Integer(25)).is_zero()
True
>> lifting(Integer(5), Integer(10), A, G1)
Traceback (most recent call last):
... ValueError: A*G not zero mod 5^9

ALGORITHM:

[HR2016], Algorithm 1.
sage.matrix.compute_J_ideal.p_part(f, p)
Compute the $p$-part of a polynomial.

INPUT:

- $f$ – a polynomial over $D$
- $p$ – a prime in $D$

OUTPUT:

A polynomial $g$ such that $\deg g \leq \deg f$ and all non-zero coefficients of $f - pg$ are not divisible by $p$.

EXAMPLES:

```sage
sage: from sage.matrix.compute_J_ideal import p_part
sage: X = polygen(ZZ, 'X')
sage: f = X^3 + 5*X + 25
sage: g = p_part(f, 5); g
X + 5
sage: f - 5*g
X^3
```

```python
>>> from sage.all import *
>>> from sage.matrix.compute_J_ideal import p_part
>>> X = polygen(ZZ, 'X')
>>> f = X**Integer(3) + Integer(5)*X + Integer(25)
>>> g = p_part(f, Integer(5)); g
X + 5
>>> f - Integer(5)*g
X^3
```

CHAPTER
FORTYSIX

BENCHMARKS FOR MATRICES

This file has many functions for computing timing benchmarks of various methods for random matrices with given bounds for the entries. The systems supported are Sage and Magma.

The basic command syntax is as follows:

```python
sage: import sage.matrix.benchmark as b
sage: print("starting"); import sys; sys.stdout.flush(); b.report([b.det_ZZ], 'Test', systems=['sage'])
starting...
```

```
>>> from sage.all import *
>>> import sage.matrix.benchmark as b
>>> print("starting"); import sys; sys.stdout.flush(); b.report([b.det_ZZ], 'Test', systems=['sage'])
starting...
```

```python
sage.matrix.benchmark.MatrixVector_QQ(n=1000, h=100, system='sage', times=1)
```

Compute product of square $n$ matrix by random vector with num and denom bounded by $h$ the given number of times.

INPUT:

- $n$ – matrix dimension (default: 300)
- $h$ – numerator and denominator bound (default: bnd)
- system – either ‘sage’ or ‘magma’ (default: ‘sage’)
- times – number of experiments (default: 1)

EXAMPLES:

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.MatrixVector_QQ(500)
sage: tm = b.MatrixVector_QQ(500, system='magma')  # optional - magma
```
sage.matrix.benchmark.charpoly_GF\( (n=100, \ p=16411, \ \text{system}='\text{sage}') \)

Given a \( n \times n \) matrix over GF with random entries, compute the charpoly.

**INPUT:**

- \( n \) – matrix dimension (default: 100)
- \( p \) – prime number (default: 16411)
- \( \text{system} \) – either ‘magma’ or ‘sage’ (default: ‘sage’)

**EXAMPLES:**

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.charpoly_GF(100)
sage: tm = b.charpoly_GF(100, system='magma')  # optional - magma
```

sage.matrix.benchmark.charpoly_ZZ\( (n=100, \ \text{min}=0, \ \text{max}=9, \ \text{system}='\text{sage}') \)

Characteristic polynomial over ZZ: Given a \( n \times n \) matrix over ZZ with random entries between \( \text{min} \) and \( \text{max} \), compute the charpoly.

**INPUT:**

- \( n \) – matrix dimension (default: 100)
- \( \text{min} \) – minimal value for entries of matrix (default: 0)
- \( \text{max} \) – maximal value for entries of matrix (default: 9)
- \( \text{system} \) – either ‘sage’ or ‘magma’ (default: ‘sage’)

**EXAMPLES:**

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.charpoly_ZZ(100)
sage: tm = b.charpoly_ZZ(100, system='magma')  # optional - magma
```

sage.matrix.benchmark.det_GF\( (n=400, \ p=16411, \ \text{system}='\text{sage}') \)

Dense determinant over GF\( (p) \). Given an \( n \times n \) matrix \( A \) over GF with random entries compute \( \det(A) \).

**INPUT:**

- \( n \) – matrix dimension (default: 300)
- \( p \) – prime number (default: 16411)
- \( \text{system} \) – either ‘magma’ or ‘sage’ (default: ‘sage’)

---

1068 Chapter 46. Benchmarks for matrices
EXAMPLES:

sage: import sage.matrix.benchmark as b
sage: ts = b.det_GF(1000)
sage: tm = b.det_GF(1000, system='magma')  # optional - magma

>>> from sage.all import *
>>> import sage.matrix.benchmark as b

sage.matrix.benchmark.det_QQ(n=300, num_bound=10, den_bound=10, system='sage')
Dense rational determinant over QQ. Given an n x n matrix A over QQ with random entries with numerator bound and denominator bound, compute det(A).

INPUT:

• n – matrix dimension (default: 200)
• num_bound – numerator bound, inclusive (default: 10)
• den_bound – denominator bound, inclusive (default: 10)
• system – either 'sage' or 'magma' (default: 'sage')

EXAMPLES:

sage: import sage.matrix.benchmark as b
sage: ts = b.det_QQ(200)
sage: tm = b.det_QQ(10, num_bound=100000, den_bound=10000)

sage.matrix.benchmark.det_ZZ(n=200, min=1, max=100, system='sage')
Dense integer determinant over ZZ. Given an n x n matrix A over ZZ with random entries between min and max, inclusive, compute det(A).

INPUT:

• n – matrix dimension (default: 200)
• min – minimal value for entries of matrix (default: 1)
• max – maximal value for entries of matrix (default: 100)
• system – either 'sage' or 'magma' (default: 'sage')

EXAMPLES:

sage: import sage.matrix.benchmark as b
sage: ts = b.det_ZZ(200)
sage: tm = b.det_ZZ(200, system='magma')  # optional - magma
sage.matrix.benchmark.det_hilbert_QQ(n=80, system='sage')
Runs the benchmark for calculating the determinant of the hilbert matrix over rationals of dimension n.

INPUT:

• n – matrix dimension (default: 300)
• system – either 'sage' or 'magma' (default: 'sage')

EXAMPLES:

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.det_hilbert_QQ(50)
sage: tm = b.det_hilbert_QQ(50, system='magma') # optional - magma
```

sage.matrix.benchmark.echelon_QQ(n=100, min=0, max=9, system='sage')
Given a n x (2*n) matrix over QQ with random integer entries between min and max, compute the reduced row echelon form.

INPUT:

• n – matrix dimension (default: 300)
• min – minimal value for entries of matrix (default: -9)
• max – maximal value for entries of matrix (default: 9)
• system – either 'sage' or 'magma' (default: 'sage')

EXAMPLES:

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.echelon_QQ(100)
sage: tm = b.echelon_QQ(100, system='magma') # optional - magma
```

sage.matrix.benchmark.hilbert_matrix(n)
Returns the Hilbert matrix of size n over rationals.

EXAMPLES:

```python
sage: import sage.matrix.benchmark as b
sage: b.hilbert_matrix(3)

[[1 1/2 1/3]
 [1/2 1/3 1/4]
 [1/3 1/4 1/5]]
```
sage.matrix.benchmark.inverse_QQ \( (n=100, \ min=0, \ max=9, \ system='sage') \)

Given a \( n \times n \) matrix over \( \mathbb{Q} \) with random integer entries between \( \min \) and \( \max \), compute the reduced row echelon form.

**INPUT:**
- \( n \) – matrix dimension (default: 300)
- \( \min \) – minimal value for entries of matrix (default: -9)
- \( \max \) – maximal value for entries of matrix (default: 9)
- \( \text{system} \) – either ‘sage’ or ‘magma’ (default: ‘sage’)

**EXAMPLES:**

```
sage: import sage.matrix.benchmark as b
sage: ts = b.inverse_QQ(100)  
sage: tm = b.inverse_QQ(100, system=magma)  # optional - magma
```

sage.matrix.benchmark.invert_hilbert_QQ \( (n=40, \ system='sage') \)

Runs the benchmark for calculating the inverse of the hilbert matrix over rationals of dimension \( n \).

**INPUT:**
- \( n \) – matrix dimension (default: 300)
- \( \text{system} \) – either ‘sage’ or ‘magma’ (default: ‘sage’)

**EXAMPLES:**

```
sage: import sage.matrix.benchmark as b
sage: ts = b.invert_hilbert_QQ(30)  
sage: tm = b.invert_hilbert_QQ(30, system=magma)  # optional - magma
```

sage.matrix.benchmark.matrix_add_GF \( (n=1000, \ p=16411, \ system='sage', \ times=100) \)

Given two \( n \times n \) matrix over GF(\( p \)) with random entries, add them.

**INPUT:**
- \( n \) – matrix dimension (default: 300)
- \( p \) – prime number (default: 16411)
• system – either ‘magma’ or ‘sage’ (default: ‘sage’)
• times – number of experiments (default: 100)

EXAMPLES:

```
sage: import sage.matrix.benchmark as b
sage: ts = b.matrix_add_GF(500, p=19)
sage: tm = b.matrix_add_GF(500, p=19, system='magma')  # optional - magma
```

>>> from sage.all import *
>>> import sage.matrix.benchmark as b
>>>
sage.matrix.benchmark.matrix_add_ZZ(n=200, min=-9, max=9, system='sage', times=50)
Matrix addition over ZZ. Given an n x n matrix A and B over ZZ with random entries between min and max, inclusive, compute A + B times times.

INPUT:
• n – matrix dimension (default: 200)
• min – minimal value for entries of matrix (default: -9)
• max – maximal value for entries of matrix (default: 9)
• system – either ‘sage’ or ‘magma’ (default: ‘sage’)
• times – number of experiments (default: 50)

EXAMPLES:

```
sage: import sage.matrix.benchmark as b
sage: ts = b.matrix_add_ZZ(200)
sage: tm = b.matrix_add_ZZ(200, system=magma)  # optional - magma
```

```
>>> from sage.all import *
>>> import sage.matrix.benchmark as b
>>>
sage.matrix.benchmark.matrix_add_ZZ_2(n=200, bits=16, system='sage', times=50)
Matrix addition over ZZ. Given an n x n matrix A and B over ZZ with random bits-bit entries, compute A + B.

INPUT:
• n – matrix dimension (default: 200)
• bits – bitsize of entries
• system – either ‘sage’ or ‘magma’ (default: ‘sage’)
• times – number of experiments (default: 50)

EXAMPLES:

```
sage: import sage.matrix.benchmark as b
sage: ts = b.matrix_add_ZZ_2(200)
sage: tm = b.matrix_add_ZZ_2(200, system='magma')  # optional - magma
```
sage.matrix.benchmark.matrix_multiply_GF \( (n=100, p=16411, \text{system}='\text{sage}', \text{times}=3) \)

Given an \( n \times n \) matrix \( A \) over \( \text{GF}(p) \) with random entries, compute \( A \times (A+1) \).

**INPUT:**

- \( n \) – matrix dimension (default: 100)
- \( p \) – prime number (default: 16411)
- \( \text{system} \) – either ‘magma’ or ‘sage’ (default: ‘sage’)
- \( \text{times} \) – number of experiments (default: 3)

**EXAMPLES:**

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.matrix_multiply_GF(100, p=19)
sage: tm = b.matrix_multiply_GF(100, p=19, system='magma')  # optional - magma
```

sage.matrix.benchmark.matrix_multiply_QQ \( (n=100, bnd=2, \text{system}='\text{sage}', \text{times}=1) \)

Given an \( n \times n \) matrix \( A \) over \( \text{QQ} \) with random entries whose numerators and denominators are bounded by \( bnd \), compute \( A \times (A+1) \).

**INPUT:**

- \( n \) – matrix dimension (default: 300)
- \( bnd \) – numerator and denominator bound (default: \( bnd \))
- \( \text{system} \) – either ‘sage’ or ‘magma’ (default: ‘sage’)
- \( \text{times} \) – number of experiments (default: 1)

**EXAMPLES:**

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.matrix_multiply_QQ(100)
sage: tm = b.matrix_multiply_QQ(100, system='magma')  # optional - magma
```

sage.matrix.benchmark.matrix_multiply_ZZ \( (n=300, \text{min}=-9, \text{max}=9, \text{system}='\text{sage}', \text{times}=1) \)

Matrix multiplication over \( \text{ZZ} \). Given an \( n \times n \) matrix \( A \) over \( \text{ZZ} \) with random entries between \( \text{min} \) and \( \text{max} \), inclusive, compute \( A \times (A+1) \).

**INPUT:**
Matrices and Spaces of Matrices, Release 10.4

- \( n \) – matrix dimension (default: 300)
- \( \min \) – minimal value for entries of matrix (default: -9)
- \( \max \) – maximal value for entries of matrix (default: 9)
- \( \text{system} \) – either ‘sage’ or ‘magma’ (default: ‘sage’)
- \( \text{times} \) – number of experiments (default: 1)

**EXAMPLES:**

```
sage: import sage.matrix.benchmark as b
sage: ts = b.matrix_multiply_ZZ(200)
```
```
sage: tm = b.matrix_multiply_ZZ(200, system=magma)
# optional - magma
```

```
>>> from sage.all import *
>>> import sage.matrix.benchmark as b
```
```

```
```
sage.matrix.benchmark.nullspace_GF \((n=300, p=16411, \text{system}=\text{\textquoteleft}sage\textquoteright)\)

Given a \( n+1 \times n \) matrix over \( GF(p) \) with random entries, compute the nullspace.

**INPUT:**

- \( n \) – matrix dimension (default: 300)
- \( p \) – prime number (default: 16411)
- \( \text{system} \) – either ‘magma’ or ‘sage’ (default: ‘sage’)

**EXAMPLES:**

```
sage: import sage.matrix.benchmark as b
sage: ts = b.nullspace_GF(300)
```
```
sage: tm = b.nullspace_GF(300, system=magma)
# optional - magma
```

```
>>> from sage.all import *
>>> import sage.matrix.benchmark as b
```
```
>>>
```
```
sage.matrix.benchmark.nullspace_RDF \((n=300, \min=0, \max=10, \text{system}=\text{\textquoteleft}sage\textquoteright)\)

Nullspace over RDF: Given a \( n+1 \times n \) matrix over RDF with random entries between \( \min \) and \( \max \), compute the nullspace.

**INPUT:**

- \( n \) – matrix dimension (default: 300)
- \( \min \) – minimal value for entries of matrix (default: 0)
- \( \max \) – maximal value for entries of matrix (default: 10)
- \( \text{system} \) – either ‘sage’ or ‘magma’ (default: ‘sage’)

**EXAMPLES:**

```
sage: import sage.matrix.benchmark as b
sage: ts = b.nullspace_RDF(100)  # long time
```
```
sage: tm = b.nullspace_RDF(100, system='magma')  # optional - magma
```

---

1074 Chapter 46. Benchmarks for matrices
sage.matrix.benchmark.nullspace_RR \( (n=300, \ min=0, \ max=10, \ system='sage') \)
Nullspace over RR: Given a \( n+1 \times n \) matrix over RR with random entries between min and max, compute the nullspace.

INPUT:
- \( n \) – matrix dimension (default: 300)
- \( \min \) – minimal value for entries of matrix (default: 0)
- \( \max \) – maximal value for entries of matrix (default: 10)
- \( \text{system} \) – either 'sage' or 'magma' (default: 'sage')

EXAMPLES:
```python
sage: import sage.matrix.benchmark as b
sage: ts = b.nullspace_RR(100)
sage: tm = b.nullspace_RR(100, system='magma') # optional - magma
```

sage.matrix.benchmark.nullspace_ZZ \( (n=200, \ min=0, \ max=2^{32}, \ system='sage') \)
Nullspace over ZZ: Given a \( n+1 \times n \) matrix over ZZ with random entries between min and max, compute the nullspace.

INPUT:
- \( n \) – matrix dimension (default: 200)
- \( \min \) – minimal value for entries of matrix (default: 0)
- \( \max \) – maximal value for entries of matrix (default: \( 2^{32} \))
- \( \text{system} \) – either 'sage' or 'magma' (default: 'sage')

EXAMPLES:
```python
sage: import sage.matrix.benchmark as b
sage: ts = b.nullspace_ZZ(200)
sage: tm = b.nullspace_ZZ(200, system='magma') # optional - magma
```

sage.matrix.benchmark.rank2_GF \( (n=500, \ p=16411, \ system='sage') \)
Rank over GF\( (p) \): Given a \( (n + 10) \times n \) matrix over GF\( (p) \) with random entries, compute the rank.

INPUT:
- \( n \) – matrix dimension (default: 300)
• $p$ – prime number (default: 16411)
• system – either ‘magma’ or ‘sage’ (default: ‘sage’)

EXAMPLES:

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.rank2_GF(500)
```

```python
>>> from sage.all import *
>>> import sage.matrix.benchmark as b
>>> ts = b.rank2_GF(Integer(500))
```

```python
sage.matrix.benchmark.rank2_ZZ(n=400, min=0, max=18446744073709551616, system='sage')
```

Rank 2 over ZZ: Given a $(n + 10) \times n$ matrix over ZZ with random entries between min and max, compute the rank.

INPUT:

• $n$ – matrix dimension (default: 400)
• min – minimal value for entries of matrix (default: 0)
• max – maximal value for entries of matrix (default: $2 \times 64$)
• system – either `sage' or `magma' (default: ‘sage')

EXAMPLES:

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.rank2_ZZ(300)
```

```python
>>> from sage.all import *
>>> import sage.matrix.benchmark as b
>>> ts = b.rank2_ZZ(Integer(300))
```

```python
sage.matrix.benchmark.rank_GF(n=500, p=16411, system='sage')
```

Rank over GF($p$): Given a $n \times (n+10)$ matrix over GF($p$) with random entries, compute the rank.

INPUT:

• $n$ – matrix dimension (default: 300)
• $p$ – prime number (default: 16411)
• system – either ‘magma’ or ‘sage’ (default: ‘sage')

EXAMPLES:

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.rank_GF(1000)
```

```python
>>> from sage.all import *
>>> import sage.matrix.benchmark as b
>>> ts = b.rank_GF(Integer(1000))
```
sage.matrix.benchmark.rank_ZZ \((n=700, \ min=0, \ max=9, \ \text{system}='sage')\)

Rank over ZZ: Given a \(n \times (n+10)\) matrix over ZZ with random entries between \(\min\) and \(\max\), compute the rank.

**INPUT:**
- \(n\) – matrix dimension (default: 700)
- \(\min\) – minimal value for entries of matrix (default: 0)
- \(\max\) – maximal value for entries of matrix (default: 9)
- \(\text{system}\) – either ‘sage’ or ‘magma’ (default: ‘sage’)

**EXAMPLES:**

```
sage: import sage.matrix.benchmark as b
dsage: ts = b.rank_ZZ(300)
dsage: tm = b.rank_ZZ(300, \text{system}='magma') \quad \# \text{optional - magma}
```

```
>>> \text{from sage.all import *}
>>> \text{import sage.matrix.benchmark as b}
>>> ts = b.rank_ZZ(Integer(300))
>>> tm = b.rank_ZZ(Integer(300), \text{system}='magma') \quad \# \text{optional - magma}
```

sage.matrix.benchmark.report \((F, \ \text{title}, \ \text{systems}=['sage', \ 'magma'], **kwds)\)

Run benchmarks with default arguments for each function in the list \(F\).

**INPUT:**
- \(F\) – a list of callables used for benchmarking
- \(\text{title}\) – a string describing this report
- \(\text{systems}\) – a list of systems (supported entries are ‘sage’ and ‘magma’)
- \(**kwds\) – keyword arguments passed to all functions in \(F\)

**EXAMPLES:**

```
sage: \text{import sage.matrix.benchmark as b}
sage: \text{print("starting"); import sys; sys.stdout.flush(); b.report([b.det_ZZ, \ 'Test', \ \text{systems}=['sage'])
starting...
======================================================================
Test
======================================================================
... 1077
```

```
>>> \text{from sage.all import *}
>>> \text{import sage.matrix.benchmark as b}
>>> \text{print("starting"); import sys; sys.stdout.flush(); b.report([b.det_ZZ, \ 'Test
\text{\rightarrow', \ \text{systems}=['sage'])
starting...
======================================================================
Test
======================================================================
... 1077
```
sage.matrix.benchmark.report_GF(p=16411, **kwds)

Runs all the reports for finite field matrix operations, for prime p=16411.

INPUT:

- p – ignored
- **kwds – passed through to report()

**Note:** right now, even though p is an input, it is being ignored! If you need to check the performance for other primes, you can call individual benchmark functions.

EXAMPLES:

```python
sage: import sage.matrix.benchmark as b
sage: print("starting"); import sys; sys.stdout.flush(); b.report_GF(systems=['sage'])
starting...
======================================================================
Dense benchmarks over GF with prime 16411
======================================================================
...`
sage.matrix.benchmark.smithform_ZZ ($n=128$, $min=0$, $max=9$, $system='sage'$)

Smith Form over ZZ. Given an $n \times n$ matrix over ZZ with random entries between $min$ and $max$, compute the Smith normal form.

**INPUT:**

- $n$ – matrix dimension (default: 128)
- $min$ – minimal value for entries of matrix (default: 0)
- $max$ – maximal value for entries of matrix (default: 9)
- $system$ – either ‘sage’ or ‘magma’ (default: ‘sage’)

**EXAMPLES:**

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.smithform_ZZ(100)
sage: tm = b.smithform_ZZ(100, system=magma)  # optional - magma
```

sage.matrix.benchmark.vecmat_ZZ ($n=300$, $min=-9$, $max=9$, $system='sage'$, $times=200$)

Vector matrix multiplication over ZZ.

Given an $n \times n$ matrix $A$ over ZZ with random entries between $min$ and $max$, inclusive, and $v$ the first row of $A$, compute the product $v \times A$.

**INPUT:**

- $n$ – matrix dimension (default: 300)
- $min$ – minimal value for entries of matrix (default: -9)
- $max$ – maximal value for entries of matrix (default: 9)
- $system$ – either ‘sage’ or ‘magma’ (default: ‘sage’)
- $times$ – number of runs (default: 200)

**EXAMPLES:**

```python
sage: import sage.matrix.benchmark as b
sage: ts = b.vecmat_ZZ(300)  # long time
sage: tm = b.vecmat_ZZ(300, system=magma)  # optional - magma
```

Matrices and Spaces of Matrices, Release 10.4

867  eigenvectors_left()  (sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse method), 889
889  eigenvectors_left_approx()  (sage.matrix.matrix_complex_ball_dense.Matrix_complex_ball_dense method), 911
911  eigenvectors_right()  (sage.matrix.matrix2.Matrix method), 350
911  eigenvectors_right()  (sage.matrix.matrix_complex_ball_dense.Matrix_complex_ball_dense method), 911
911  eigenvectors_right()  (sage.matrix.matrix_double_dense.Matrix_double_dense method), 744
911  eigenvectors_right()  (sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense method), 870
911  eigenvectors_right()  (sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse method), 892
911  eigenvectors_right_approx()  (sage.matrix.matrix_complex_ball_dense.Matrix_complex_ball_dense method), 912
912  element()  (sage.matrix.args.MatrixArgs method), 115
912  element_is_zero()  (sage.matrix.matrix_window.MatrixWindow method), 1029
912  elementary_divisors()  (sage.matrix.matrix2.Matrix method), 351
912  elementary_divisors()  (sage.matrix.matrix_integer_dense.Matrix_integer_dense method), 626
912  elementary_divisors()  (sage.matrix.matrix_integer_sparse.Matrix_integer_sparse method), 654
912  elementary_matrix()  (in module sage.matrix.special), 65
912  elementwise_product()  (sage.matrix.matrix2.Matrix method), 352
913  entries()  (sage.matrix.args.MatrixArgs attribute), 117
917  entry()  (sage.matrix.args.SparseEntry attribute), 127
917  exp()  (sage.matrix.matrix2.Matrix method), 356
917  exp()  (sage.matrix.matrix_complex_ball_dense.Matrix_complex_ball_dense method), 913
917  exp()  (sage.matrix.matrix_double_dense.Matrix_double_dense method), 746
917  exp()  (sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense method), 871
917  exp()  (sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse method), 893
917  expand()  (sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense method), 873
917  expand()  (sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse method), 895
917  extended_echelon_form()  (sage.matrix.matrix2.Matrix method), 357
917  extract_ones_data()  (in module sage.matrix.matrix_integer_dense_hnf), 668

F
factor()  (sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense method), 874
factor()  (sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse method), 896
fcp()  (sage.matrix.matrix2.Matrix method), 362
fcp()  (sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense method), 874
fcp()  (sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse method), 896
finalized()  (sage.matrix.args.MatrixArgs method), 117
find()  (sage.matrix.matrix2.Matrix method), 363
find_monic_replacements()  (sage.matrix.compute_I_ideal.ComputeMinimalPolynomials method), 1054
fitting_ideal()  (sage.matrix.matrix2.Matrix method), 364
frobenius()  (sage.matrix.matrix_integer_dense.Matrix_integer_dense method), 628
frobenius_form()  (sage.matrix.matrix_integer_dense.Matrix_integer_dense method), 628
from_png()  (in module sage.matrix.matrix_mod2_dense), 796
from_vector()  (sage.matrix.matrix_space.MatrixSpace method), 14
function()  (sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense method), 875
function()  (sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse method), 897

G
gcd()  (sage.matrix.matrix_integer_dense.Matrix_integer_dense method), 630
gen()  (sage.matrix.matrix_space.MatrixSpace method), 15
get_matrix_class()  (in module sage.matrix.matrix_space), 25
get_subdivisions()  (sage.matrix.matrix2.Matrix method), 367
get_unsafe()  (sage.matrix.matrix_window.MatrixWindow method), 1029
gram_schmidt()  (sage.matrix.matrix2.Matrix method), 368
gray_table()  (sage.matrix.operation_table.OperationTable method), 1013

H
H  (sage.matrix.matrix2.Matrix attribute), 252
hadamard_bound()  (sage.matrix.matrix2.Matrix method), 379

Index 1089
hadamard_row_bound_mpfr() (in module sage.matrix.mpc). 1035
hankel() (in module sage.matrix.special), 71
height() (sage.matrix.matrix_cyclo_dense.Matrix_cyclo_dense). 997
height() (sage.matrix.matrix_integer_dense.Matrix_integer_dense). 630
height() (sage.matrix.matrix_rational_dense.Matrix_rational_dense). 698
height() (sage.matrix.matrix_rational_sparse.Matrix_rational_sparse). 714
hermite_form() (sage.matrix.matrix_integer_dense.Matrix_integer_dense). 630
hermite_form() (sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense). 928
hessenberg_form() (sage.matrix.matrix2.Matrix). 381
hessenbergize() (sage.matrix.matrix2.Matrix). 382
hessenbergize() (sage.matrix.matrix_modn_dense_double.Matrix_modn_dense_double, matrix_modn_dense_template). 819
hessenbergize() (sage.matrix.matrix_modn_dense_float.Matrix_modn_dense_float). 839
hilbert() (in module sage.matrix.special). 73
hilbert() (in module sage.matrix.benchmark). 1070
hnf() (in module sage.matrix.matrix_integer_dense_hnf). 669
hnf() (in module sage.matrix.matrix_integer_dense_hnf). 670
hnf_square() (in module sage.matrix.matrix_integer_dense_hnf). 670
hnf_with_transformation() (in module sage.matrix.matrix_integer_dense_hnf). 670
hnf_with_transformation_tests() (in module sage.matrix.matrix_integer_dense_hnf). 671
i (sage.matrix.arg.SparseEntry attribute). 127
ideal_or_fractional() (in module sage.matrix.matrix2). 581
identical() (sage.matrix.matrix_complex_ball_dense.Matrix_complex_ball_dense). 914
identity_matrix() (in module sage.matrix.special). 73
identity_matrix() (sage.matrix.matrix_space.MatrixSpace). 15
indefinite_factorization() (sage.matrix.matrix2.Matrix). 384
index_in_saturation() (in module sage.matrix.matrix_integer_dense_saturation). 683
index_in_saturation() (sage.matrix.matrix_integer_dense.Matrix_integer_dense). 634
insert_row() (sage.matrix.matrix_integer_dense.Matrix_integer_dense). 634
int_range (class in sage.matrix.strassen). 583
integer_kernel() (sage.matrix.matrix2.Matrix). 388
integer_to_real_double_dense() (in module sage.matrix.change_ring). 1021
integer_valued_polynomials_generators() (sage.matrix.compute_I_ideal.ComputeMinimalPolynomials). 1055
integer_valued_polynomials_generators() (sage.matrix.matrix_integer_dense.Matrix_integer_dense). 635
interleave_matrices() (in module sage.matrix.matrix_integer_dense_hnf). 671
intervals() (sage.matrix.strassen.int_range). 584
inverse_of_unit() (sage.matrix.matrix0.Matrix). 149
inverse_positive_definite() (sage.matrix.matrix2.Matrix). 390
inverse QQ() (in module sage.matrix.benchmark). 1071
inverse_series_trunc() (sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense). 929
invert_hilbert QQ() (in module sage.matrix.benchmark). 1071
is_alternating() (sage.matrix.matrix0.Matrix). 151
is_bistochastic() (sage.matrix.matrix2.Matrix). 394
is_constant() (sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense). 931
is_cross_positive_on() (sage.matrix.matrix2.Matrix). 395
is_dense() (sage.matrix.matrix0.Matrix). 151
is_dense() (sage.matrix.matrix_space.MatrixSpace). 16
jordan_block() (in module sage.matrix.special), 77
jordan_decomposition() (sage.matrix.matrix2.Matrix method), 428
jordan_form() (sage.matrix.matrix2.Matrix method), 430
jordan_form() (sage.matrix.matrix_symbolic_dense.Matrix_symbolic_dense method), 875
jordan_form() (sage.matrix.matrix_symbolic_sparse.Matrix_symbolic_sparse method), 897
K
kernel() (sage.matrix.matrix2.Matrix method), 433
kernel_on() (sage.matrix.matrix2.Matrix method), 437
kwds (sage.matrix.args.MatrixArgs attribute), 120
L
leading_matrix() (sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense method), 945
leading_positions() (sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense method), 946
left_eigenmatrix() (sage.matrix.matrix2.Matrix method), 439
left_eigenspaces() (sage.matrix.matrix2.Matrix method), 442
left_eigenvectors() (sage.matrix.matrix2.Matrix method), 451
left_eigenvectors() (sage.matrix.matrix_double_dense.Matrix_double_dense method), 761
left_kernel() (sage.matrix.matrix2.Matrix method), 452
left_kernel_matrix() (sage.matrix.matrix2.Matrix method), 456
left_nullity() (sage.matrix.matrix2.Matrix method), 456
left_quo_rem() (sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense method), 948
lehmer() (in module sage.matrix.special), 77
lift() (sage.matrix.matrix1.Matrix method), 223
lift() (sage.matrix.matrix_modn_dense_double.Matrix_modn_dense_double_template method), 819
lift() (sage.matrix.matrix_modn_dense_float.Matrix_modn_dense_template method), 839
lift_centered() (sage.matrix.matrix1.Matrix method), 224
lifting() (in module sage.matrix.compute_J_ideal), 1063
linear_combination_of_columns() (sage.matrix.matrix0.Matrix method), 166
linear_combination_of_rows() (sage.matrix.matrix0.Matrix method), 168
list() (sage.matrix.add.MatrixArgs method), 120
list() (sage.matrix.matrix0.Matrix method), 170
LLL() (sage.matrix.matrix_integer_dense.Matrix_integer_dense method), 612
LLL() (sage.matrix.matrix_rational_dense.Matrix_rational_dense method), 689
LLL() (sage.matrix.matrix2.Matrix method), 253
log_determinant() (sage.matrix.matrix_double_dense.Matrix_double_dense method), 763
LU() (sage.matrix.matrix2.Matrix method), 255
LU() (sage.matrix.matrix_double_dense.Matrix_double_dense method), 718
LU_valid() (sage.matrix.matrix_double_dense.Matrix_double_dense method), 721
M
M4RIE_finite_field (class in sage.matrix.matrix_gf2e_dense), 802
Matrix (class in sage.matrix.matrix0), 141
Matrix (class in sage.matrix.matrix1), 211
Matrix (class in sage.matrix.matrix2), 252
Matrix() (in module sage.matrix.constructor), 31
matrix() (in module sage.matrix.constructor), 38
matrix() (sage.matrix.add.MatrixArgs method), 121
Matrix() (sage.matrix.matrix_space.MatrixSpace method), 17
matrix() (sage.matrix.matrix_window.MatrixWindow method), 1029
matrix_add_GF() (in module sage.matrix.benchmark), 1071
matrix_add_2Z() (in module sage.matrix.benchmark), 1072
matrix_add_2Z_2() (in module sage.matrix.benchmark), 1072
Matrix_complex_ball_dense (class in sage.matrix.matrix_complex_ball_dense), 907
Matrix_complex_double_dense (class in sage.matrix.matrix_complex_double_dense), 905
Matrix_cyclo_dense (class in sage.matrix.matrix_cyclo_dense), 993
Matrix_dense (class in sage.matrix.matrix_dense), 591
Matrix_double_dense (class in sage.matrix.matrix_double_dense), 717
matrix_from_columns() (sage.matrix.matrix1.Matrix method), 225
matrix_from_columns() (sage.matrix.matrix_modn_dense_double.Matrix_modn_dense_template method), 820
matrix_from_columns() (sage.matrix.matrix_modn_dense_float.Matrix_modn_dense_template method), 840
MatrixVectorAction (class in sage.matrix.action), 1020
MatrixWindow (class in sage.matrix.matrix_rational_dense), 688
MatrixWindow (class in sage.matrix.matrix_window), 1029
max_det_prime() (in module sage.matrix.matrix_integer_dense_hnf), 673
maxspin() (sage.matrix.matrix2.Matrix method), 458
mccoy_column() (sage.matrix.compute_J_ideal.ComputeMinimalPolynomials method), 1056
minimal_approximant_basis() (sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense method), 950
minimal_kernel_basis() (sage.matrix.matrix_polynomial_dense.Matrix_polynomial_dense method), 950
minimal_polynomial() (sage.matrix.matrix2.Matrix method), 459
minpoly() (sage.matrix.matrix2.Matrix method), 460
minpoly() (sage.matrix.matrix_integer_dense.Matrix_integer_dense method), 639
minpoly() (sage.matrix.matrix_integer_sparse.Matrix_integer_sparse method), 656
minpoly() (sage.matrix.matrix_modn_dense_double.Matrix_modn_dense_template method), 822
minpoly() (sage.matrix.matrix_modn_dense_float.Matrix_modn_dense_template method), 833
minpoly() (sage.matrix.matrix_modn_sparse.Matrix_modn_sparse method), 853
minpoly() (sage.matrix.matrix_modn_sparse.Matrix_modn_sparse method), 853
minpoly() (sage.matrix.matrix_modn_sparse.Matrix_modn_sparse method), 853
mod() (sage.matrix.matrix0.Matrix method), 171
