This tutorial outlines what you need to know in order to use \( p \)-adics in Sage effectively.

Our goal is to create a rich structure of different options that will reflect the mathematical structures of the \( p \)-adics. This is very much a work in progress: some of the classes that we eventually intend to include have not yet been written, and some of the functionality for classes in existence has not yet been implemented. In addition, while we strive for perfect code, bugs (both subtle and not-so-subtle) continue to evade our clutches. As a user, you serve an important role. By writing non-trivial code that uses the \( p \)-adics, you both give us insight into what features are actually used and also expose problems in the code for us to fix.

Our design philosophy has been to create a robust, usable interface working first, with simple-minded implementations underneath. We want this interface to stabilize rapidly, so that users’ code does not have to change. Once we get the framework in place, we can go back and work on the algorithms and implementations underneath. All of the current \( p \)-adic code is currently written in pure Python, which means that it does not have the speed advantage of compiled code. Thus our \( p \)-adics can be painfully slow at times when you’re doing real computations. However, finding and fixing bugs in Python code is far easier than finding and fixing errors in the compiled alternative within Sage (Cython), and Python code is also faster and easier to write. We thus have significantly more functionality implemented and working than we would have if we had chosen to focus initially on speed. And at some point in the future, we will go back and improve the speed. Any code you have written on top of our \( p \)-adics will then get an immediate performance enhancement.

If you do find bugs, have feature requests or general comments, please email sage-support@groups.google.com or roed@math.harvard.edu.

1.1 Terminology and types of \( p \)-adics

To write down a general \( p \)-adic element completely would require an infinite amount of data. Since computers do not have infinite storage space, we must instead store finite approximations to elements. Thus, just as in the case of floating point numbers for representing reals, we have to store an element to a finite precision level. The different ways of doing this account for the different types of \( p \)-adics.

We can think of \( p \)-adics in two ways. First, as a projective limit of finite groups:

\[
\mathbb{Z}_p = \lim_{\leftarrow n} \mathbb{Z}/p^n\mathbb{Z}.
\]

Secondly, as Cauchy sequences of rationals (or integers, in the case of \( \mathbb{Z}_p \)) under the \( p \)-adic metric. Since we only need to consider these sequences up to equivalence, this second way of thinking of the \( p \)-adics is the same as considering power series in \( p \) with integral coefficients in the range 0 to \( p - 1 \). If we only allow nonnegative powers of \( p \) then these power series converge to elements of \( \mathbb{Z}_p \), and if we allow bounded negative powers of \( p \) then we get \( \mathbb{Q}_p \).
Both of these representations give a natural way of thinking about finite approximations to a $p$-adic element. In the first representation, we can just stop at some point in the projective limit, giving an element of $\mathbb{Z}/p^n\mathbb{Z}$. As $\mathbb{Z}_{p}/p^n\mathbb{Z}_{p} \cong \mathbb{Z}/p^n\mathbb{Z}$, this is equivalent to specifying our element modulo $p^n\mathbb{Z}_{p}$.

The absolute precision of a finite approximation $\bar{x} \in \mathbb{Z}/p^n\mathbb{Z}$ to $x \in \mathbb{Z}_{p}$ is the non-negative integer $n$.

In the second representation, we can achieve the same thing by truncating a series

$$a_0 + a_1p + a_2p^2 + \cdots$$

at $p^n$, yielding

$$a_0 + a_1p + \cdots + a_{n-1}p^{n-1} + O(p^n).$$

As above, we call this $n$ the absolute precision of our element.

Given any $x \in \mathbb{Q}_{p}$ with $x \neq 0$, we can write $x = p^n u$ where $v \in \mathbb{Z}$ and $u \in \mathbb{Z}_{p}^\times$. We could thus also store an element of $\mathbb{Q}_{p}$ (or $\mathbb{Z}_{p}$) by storing $v$ and a finite approximation of $u$. This motivates the following definition: the relative precision of an approximation to $x$ is defined as the absolute precision of the approximation minus the valuation of $x$. For example, if $x = a_kp^k + a_{k+1}p^{k+1} + \cdots + a_{n-1}p^{n-1} + O(p^n)$ then the absolute precision of $x$ is $n$, the valuation of $x$ is $k$ and the relative precision of $x$ is $n - k$.

There are three different representations of $\mathbb{Z}_{p}$ in Sage and one representation of $\mathbb{Q}_{p}$:

- the fixed modulus ring
- the capped absolute precision ring
- the capped relative precision ring, and
- the capped relative precision field.

### 1.1.1 Fixed Modulus Rings

The first, and simplest, type of $\mathbb{Z}_{p}$ is basically a wrapper around $\mathbb{Z}/p^n\mathbb{Z}$, providing a unified interface with the rest of the $p$-adics. You specify a precision, and all elements are stored to that absolute precision. If you perform an operation that would normally lose precision, the element does not track that it no longer has full precision.

The fixed modulus ring provides the lowest level of convenience, but it is also the one that has the lowest computational overhead. Once we have ironed out some bugs, the fixed modulus elements will be those most optimized for speed.

As with all of the implementations of $\mathbb{Z}_{p}$, one creates a new ring using the constructor $\text{Zp}$, and passing in ‘fixed-mod’ for the type parameter. For example,

```sage
sage: R = Zp(5, prec = 10, type = 'fixed-mod', print_mode = 'series')
sage: R
5-adic Ring of fixed modulus 5^{10}
```

One can create elements as follows:

```sage
sage: a = R(375)
sage: a
3*5^3
sage: b = R(105)
sage: b
5 + 4*5^2
```

Now that we have some elements, we can do arithmetic in the ring.
Floor division (\texttt{//}) divides even though the result isn’t really known to the claimed precision; note that division isn’t defined:

\begin{verbatim}
\texttt{sage: a // 5}
3*5^2
\end{verbatim}

Since elements don’t actually store their actual precision, one can only divide by units:

\begin{verbatim}
\texttt{sage: a / 2}
4*5^3 + 2*5^4 + 2*5^5 + 2*5^6 + 2*5^7 + 2*5^8 + 2*5^9
\texttt{sage: a / b}
Traceback (most recent call last):
...  
ValueError: cannot invert non-unit
\end{verbatim}

If you want to divide by a non-unit, do it using the \texttt{//} operator:

\begin{verbatim}
\texttt{sage: a // b}
3*5^2 + 3*5^3 + 2*5^5 + 5^6 + 4*5^7 + 2*5^8 + 3*5^9
\end{verbatim}

### 1.1.2 Capped Absolute Rings

The second type of implementation of $\mathbb{Z}_p$ is similar to the fixed modulus implementation, except that individual elements track their known precision. The absolute precision of each element is limited to be less than the precision cap of the ring, even if mathematically the precision of the element would be known to greater precision (see Appendix A for the reasons for the existence of a precision cap).

Once again, use $\mathbb{Z}_p$ to create a capped absolute $p$-adic ring.

\begin{verbatim}
\texttt{sage: R = Zp(5, prec = 10, type = 'capped-abs', print_mode = 'series')}
\texttt{sage: R}
5-adic Ring with capped absolute precision 10
\end{verbatim}

We can do similar things as in the fixed modulus case:

\begin{verbatim}
\texttt{sage: a = R(375)}
\texttt{sage: a}
3*5^3 + O(5^10)
\texttt{sage: b = R(105)}
\texttt{sage: b}
5 + 4*5^2 + O(5^10)
\texttt{sage: a + b}
\end{verbatim}
Note that when we divided by 5, the precision of \( c \) dropped. This lower precision is now reflected in arithmetic.

\[
\begin{align*}
\text{sage: } c + b \\
5 + 2 \cdot 5^2 + 5^3 + O(5^9)
\end{align*}
\]

Division is allowed: the element that results is a capped relative field element, which is discussed in the next section:

\[
\begin{align*}
\text{sage: } 1 / (c + b) \\
5^{^{-1}} + 3 + 2 \cdot 5 + 5^2 + 4 \cdot 5^3 + 4 \cdot 5^4 + 3 \cdot 5^6 + O(5^7)
\end{align*}
\]

### 1.1.3 Capped Relative Rings and Fields

Instead of restricting the absolute precision of elements (which doesn’t make much sense when elements have negative valuations), one can cap the relative precision of elements. This is analogous to floating point representations of real numbers. As in the reals, multiplication works very well: the valuations add and the relative precision of the product is the minimum of the relative precisions of the inputs. Addition, however, faces similar issues as floating point addition: relative precision is lost when lower order terms cancel.

To create a capped relative precision ring, use \( \mathbb{Z}_p \) as before. To create capped relative precision fields, use \( \mathbb{Q}_p \).

\[
\begin{align*}
\text{sage: } R = \mathbb{Z}_p(5, \text{prec} = 10, \text{type} = \text{'capped-rel'}, \text{print_mode} = \text{'series'}) \\
\text{sage: } R \\
5-adic Ring with capped relative precision 10 \\
\text{sage: } K = \mathbb{Q}_p(5, \text{prec} = 10, \text{type} = \text{'capped-rel'}, \text{print_mode} = \text{'series'}) \\
\text{sage: } K \\
5-adic Field with capped relative precision 10
\end{align*}
\]

We can do all of the same operations as in the other two cases, but precision works a bit differently: the maximum precision of an element is limited by the precision cap of the ring.

\[
\begin{align*}
\text{sage: } a = R(375) \\
\text{sage: } a \\
3 \cdot 5^3 + O(5^{13}) \\
\text{sage: } b = K(105) \\
\text{sage: } b \\
5 + 4 \cdot 5^2 + O(5^{11}) \\
\text{sage: } a + b \\
5 + 4 \cdot 5^2 + 3 \cdot 5^3 + O(5^{11}) \\
\text{sage: } a \cdot b \\
3 \cdot 5^4 + 2 \cdot 5^5 + 2 \cdot 5^6 + O(5^{14}) \\
\text{sage: } c = a / 5 \\
\text{sage: } c \\
3 \cdot 5^2 + O(5^{12}) \\
\text{sage: } c + 1 \\
1 + 3 \cdot 5^2 + O(5^{10})
\end{align*}
\]
As with the capped absolute precision rings, we can divide, yielding a capped relative precision field element.

\[
\text{sage: } \frac{1}{c + b} \\
5^{\text{-}1} + 3 + 2 \cdot 5 + 5^2 + 4 \cdot 5^3 + 4 \cdot 5^4 + 3 \cdot 5^6 + 2 \cdot 5^7 + 5^8 + O(5^9)
\]

### 1.1.4 Unramified Extensions

One can create unramified extensions of \( \mathbb{Z}_p \) and \( \mathbb{Q}_p \) using the functions \( \text{Zq} \) and \( \text{Qq} \).

In addition to requiring a prime power as the first argument, \( \text{Zq} \) also requires a name for the generator of the residue field. One can specify this name as follows:

\[
\text{sage: } R.<c> = \text{Zq}(125, \text{prec = 20}); R \\
5\text{-adic Unramified Extension Ring in c defined by } x^3 + 3\cdot x + 3
\]

### 1.1.5 Eisenstein Extensions

It is also possible to create Eisenstein extensions of \( \mathbb{Z}_p \) and \( \mathbb{Q}_p \). In order to do so, create the ground field first:

\[
\text{sage: } R = \text{Zp}(5, 2)
\]

Then define the polynomial yielding the desired extension:

\[
\begin{align*}
\text{sage: } & S.<x> = \text{ZZ}[x] \\
\text{sage: } & f = x^5 - 25\cdot x^3 + 15\cdot x - 5
\end{align*}
\]

Finally, use the \texttt{ext} function on the ground field to create the desired extension:

\[
\text{sage: } W.<w> = R\text{.ext}(f)
\]

You can do arithmetic in this Eisenstein extension:

\[
\text{sage: } (1 + w)^7 \\
1 + 2\cdot w + w^2 + w^5 + 3\cdot w^6 + 3\cdot w^7 + 3\cdot w^8 + w^9 + O(w^{10})
\]

Note that the precision cap increased by a factor of 5, since the ramification index of this extension over \( \mathbb{Z}_p \) is 5.
This file contains the constructor classes and functions for \( p \)-adic rings and fields.

**AUTHORS:**

- David Roe

```python
sage.rings.padics.factory.QpCR(p, prec=None, *args, **kwds)
```

A shortcut function to create capped relative \( p \)-adic fields.

Same functionality as \( \text{Qp} \). See documentation for \( \text{Qp} \) for a description of the input parameters.

**EXAMPLES:**

```python
sage: QpCR(5, 40)
5-adic Field with capped relative precision 40
```

```python
sage.rings.padics.factory.QpER(p, prec=None, halt=None, secure=False, *args, **kwds)
```

A shortcut function to create relaxed \( p \)-adic fields.

See \( \text{ZpER}() \) for more information about this model of precision.

**EXAMPLES:**

```python
sage: R = QpER(2)
sage: R
2-adic Field handled with relaxed arithmetics
```

```python
sage.rings.padics.factory.QpFP(p, prec=None, *args, **kwds)
```

A shortcut function to create floating point \( p \)-adic fields.

Same functionality as \( \text{Qp} \). See documentation for \( \text{Qp} \) for a description of the input parameters.

**EXAMPLES:**

```python
sage: QpFP(5, 40)
5-adic Field with floating precision 40
```

```python
sage.rings.padics.factory.QpLC(p, prec=None, *args, **kwds)
```

A shortcut function to create \( p \)-adic fields with lattice precision.

See \( \text{ZpLC}() \) for more information about this model of precision.

**EXAMPLES:**

```python
sage: R = QpLC(2)
sage: R
2-adic Field with lattice-cap precision
```
sage.rings.padics.factory.QpLF(p, prec=None, *args, **kwds)
A shortcut function to create \( p \)-adic fields with lattice precision.
See \( \mathrm{ZpLC}() \) for more information about this model of precision.

EXAMPLES:

```python
sage: R = QpLF(2)
sage: R
2-adic Field with lattice-float precision
```

class sage.rings.padics.factory.Qp_class
Bases: sage.structure.factory.UniqueFactory

A creation function for \( p \)-adic fields.

INPUT:

- \( p \) – integer: the \( p \) in \( \mathbb{Q}_p \)
- \( \text{prec} \) – integer (default: 20) the precision cap of the field. In the lattice capped case, \( \text{prec} \) can either be a pair (relative\_cap, absolute\_cap) or an integer (understood at relative cap). In the relaxed case, \( \text{prec} \) can be either a pair (default\_prec, halting\_prec) or an integer (understood at default precision). Except in the floating point case, individual elements keep track of their own precision. See TYPES and PRECISION below.
- \( \text{type} \) – string (default: 'capped-rel') Valid types are 'capped-rel', 'floating-point', 'lattice-cap', 'lattice-float'. See TYPES and PRECISION below
- \( \text{print\_mode} \) – string (default: None). Valid modes are 'series', 'val-unit', 'terse', 'digits', and 'bars'. See PRINTING below
- \( \text{names} \) – string or tuple (default to a string representation of \( p \)). What to use whenever \( p \) is printed.
- \( \text{ram\_name} \) – string. Another way to specify the name; for consistency with the \( \mathbb{Q}_q \) and \( \mathbb{Z}_q \) and extension functions.
- \( \text{print\_pos} \) – bool (default None) Whether to only use positive integers in the representations of elements. See PRINTING below.
- \( \text{print\_sep} \) – string (default None) The separator character used in the 'bars' mode. See PRINTING below.
- \( \text{print\_alphabet} \) – tuple (default None) The encoding into digits for use in the 'digits' mode. See PRINTING below.
- \( \text{print\_max\_terms} \) – integer (default None) The maximum number of terms shown. See PRINTING below.
- \( \text{show\_prec} \) – a boolean or a string (default None) Specify how the precision is printed. See PRINTING below.
- \( \text{check} \) – bool (default True) whether to check if \( p \) is prime. Non-prime input may cause seg-faults (but can also be useful for base \( n \) expansions for example)
- \( \text{label} \) – string (default None) used for lattice precision to create parents with different lattices.

OUTPUT:

- The corresponding \( p \)-adic field.

TYPES AND PRECISION:

There are two main types of precision for a \( p \)-adic element. The first is relative precision, which gives the number of known \( p \)-adic digits:
\begin{verbatim}
sage: R = Qp(5, 20, 'capped-rel', 'series'); a = R(675); a
2*5^2 + 5^4 + O(5^22)
sage: a.precision_relative()
20
\end{verbatim}

The second type of precision is absolute precision, which gives the power of \( p \) that this element is defined modulo:

\begin{verbatim}
\texttt{sage: a.precision_absolute()}
22
\end{verbatim}

There are several types of \( p \)-adic fields, depending on the methods used for tracking precision. Namely, we have:

- capped relative fields (type='capped-rel')
- capped absolute fields (type='capped-abs')
- fixed modulus fields (type='fixed-mod')
- floating point fields (type='floating-point')
- lattice precision fields (type='lattice-cap' or type='lattice-float')
- exact fields with relaxed arithmetics (type='relaxed')

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.

\begin{verbatim}
\texttt{sage: R = Qp(5, 5, 'capped-rel', 'series'); a = R(4006); a}
1 + 5 + 2*5^3 + 5^4 + O(5^5)
\texttt{sage: b = R(4025); b}
5^2 + 2*5^3 + 5^4 + 5^5 + O(5^7)
\texttt{sage: a + b}
1 + 5 + 5^2 + 4*5^3 + 2*5^4 + O(5^5)
\end{verbatim}

In the floating point case, elements do not track their precision, but the relative precision of elements is truncated during arithmetic to the precision cap of the field.

In the lattice case, precision on elements is tracked by a global lattice that is updated after every operation, yielding better precision behavior at the cost of higher memory and runtime usage. We refer to the documentation of the function \texttt{ZpLC()} for a small demonstration of the capabilities of this precision model.

Finally, the model for relaxed \( p \)-adics is quite different from any of the other types. In addition to storing a finite approximation, one also stores a method for increasing the precision. A quite interesting feature with relaxed \( p \)-adics is the possibility to create (in some cases) self-referent numbers, that are numbers whose \( n \)-th digit is defined by the previous ones. We refer to the documentation of the function \texttt{ZpL()} for a small demonstration of the capabilities of this precision model.

PRINTING:

There are many different ways to print \( p \)-adic elements. The way elements of a given field print is controlled by options passed in at the creation of the field. There are five basic printing modes (series, val-unit, terse, digits and bars), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different \( p \)-adic fields are considered equal.

1. \texttt{series}: elements are displayed as series in \( p \).
print_pos controls whether negatives can be used in the coefficients of powers of $p$.

```
sage: S = Qp(5, print_mode='series', print_pos=False); a = S(70700); a
-2*5^2 + 5^3 - 2*5^4 - 2*5^5 + 5^7 + O(5^22)
sage: b = S(-70700); b
2*5^2 - 5^3 + 2*5^4 + 2*5^5 - 5^7 + O(5^22)
```

print_max_terms limits the number of terms that appear.

```
sage: T = Qp(5, print_mode='series', print_max_terms=4); b = R(-70700);
repr(b)
'2*5^2 + 4*5^3 + 5^4 + 2*5^5 + ... + O(5^22)'
```

names affects how the prime is printed.

```
sage: U.<p> = Qp(5); p
p + O(p^21)
```

show_prec determines how the precision is printed. It can be either ‘none’ (or equivalently False), ‘bigoh’ (or equivalently True) or ‘bigoh’. The default is False for the 'floating-point' type and True for all other types.

```
sage: Qp(5)(6)
1 + 5 + O(5^20)
sage: Qp(5, show_prec='none')(6)
1 + 5
sage: QpFP(5)(6)
1 + 5
```

print_sep and print_alphabet have no effect in series mode.

Note that print options affect equality:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

2. val-unit: elements are displayed as $p^k*u$:

```
sage: R = Qp(5, print_mode='val-unit'); a = R(70700); a
5^2 * 2828 + O(5^22)
sage: b = R(-707/5); b
5^-1 * 95367431639918 + O(5^19)
```

print_pos controls whether to use a balanced representation or not.
\begin{verbatim}
sage: S = Qp(5, print_mode='val-unit', print_pos=False); b = S(-70700); b
5^2 * (-2828) + O(5^22)

names affects how the prime is printed.

sage: T = Qp(5, print_mode='val-unit', names='pi'); a = T(70700); a
pi^2 * 2828 + O(pi^22)

show_prec determines how the precision is printed. It can be either 'none' (or equivalently False) or 'bigoh' (or equivalently True). The default is False for the 'floating-point' type and True for all other types.

sage: Qp(5, print_mode='val-unit', show_prec=False)(30)
5 * 6

print_max_terms, print_sep and print_alphabet have no effect.

Equality again depends on the printing options:

sage: R == S, R == T, S == T
(False, False, False)

3. terse: elements are displayed as an integer in base 10 or the quotient of an integer by a power of \( p \) (still in base 10):

\begin{verbatim}
sage: R = Qp(5, print_mode='terse'); a = R(70700); a
70700 + O(5^22)
sage: b = R(-70700); b
2384185790944925 + O(5^22)
sage: c = R(-707/5); c
95367431639918/5 + O(5^19)
\end{verbatim}

The denominator, as of version 3.3, is always printed explicitly as a power of \( p \), for predictability.

\begin{verbatim}
sage: d = R(707/5^2); d
707/5^2 + O(5^18)
\end{verbatim}

print_pos controls whether to use a balanced representation or not.

\begin{verbatim}
sage: S = Qp(5, print_mode='terse', print_pos=False); b = S(-70700); b
-70700 + O(5^22)
sage: c = S(-707/5); c
-707/5 + O(5^19)
\end{verbatim}

name affects how the name is printed.

\begin{verbatim}
sage: T.<unif> = Qp(5, print_mode='terse'); c = T(-707/5); c
95367431639918/unif + O(unif^19)
sage: d = T(-707/5^10); d
95367431639918/unif^10 + O(unif^10)
\end{verbatim}

show_prec determines how the precision is printed. It can be either 'none' (or equivalently False) or 'bigoh' (or equivalently True). The default is False for the 'floating-point' type and True for all other types.
\end{verbatim}
4. **digits**: elements are displayed as a string of base \( p \) digits

Restriction: you can only use the digits printing mode for small primes. Namely, \( p \) must be less than the length of the alphabet tuple (default alphabet has length 62).

```python
sage: R = Qp(5, print_mode='digits'); a = R(70700); repr(a) 
'...0000000000000004230300'
sage: b = R(-70700); repr(b) 
'...4444444444440214200'
sage: c = R(-707/5); repr(c) 
'...44444444444443413.3'
sage: d = R(-707/5^2); repr(d) 
'...4444444444444341.33'
```

Observe that the significant 0's are printed even if they are located in front of the number. On the contrary, unknown digits located after the comma appears as question marks. The precision can therefore be read in this mode as well. Here are more examples:

```python
sage: p = 7
sage: K = Qp(p, prec=10, print_mode='digits')
sage: repr(K(1)) 
'...0000000001'
sage: repr(K(p^2)) 
'...00000000100'
sage: repr(K(p^-5)) 
'...0000.00001'
sage: repr(K(p^-20)) 
'...?.????????????0000000001'
```

**print_max_terms** limits the number of digits that are printed. Note that if the valuation of the element is very negative, more digits will be printed.

```python
sage: S = Qp(5, print_max_terms=4); S(-70700) 
2*5^2 + 4*5^3 + 5^4 + 2*5^5 + ... + 0(5^22)
sage: S(-707/5^2) 
3*5^-2 + 3*5^-1 + 1 + 4*5 + ... + 0(5^18)
sage: S(-707/5^6) 
3*5^-6 + 3*5^-5 + 5^-4 + 4*5^-3 + ... + 0(5^-14)
sage: S(-707/5^6, absprec=-2) 
3*5^-6 + 3*5^-5 + 5^-4 + 4*5^-3 + 0(5^-2)
sage: S(-707/5^4) 
3*5^-4 + 3*5^-3 + 5^-2 + 4*5^-1 + ... + 0(5^-16)
```

**print_alphabet** controls the symbols used to substitute for digits greater than 9.

```
sage: T = Qp(5, print_mode='digits', print_alphabet=('1', '2', '3', '4', '5'))
  repr(T(-70700))
'...5555555555555551325311'
```

*show_prec* determines how the precision is printed. It can be either ‘none’ (or equivalently False), ‘dots’ (or equivalently True) or ‘bigoh’. The default is False for the 'floating-point' type and True for all other types.

```
sage: repr(Zp(5, print_mode='digits', show_prec=True)(6))
'...00000000000000000011'
sage: repr(Zp(5, print_mode='digits', show_prec='bigoh')(6))
'11 + O(5^20)'
```

*print_pos*, *name* and *print_sep* have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, S == T
(False, False, False)
```

5. **bars**: elements are displayed as a string of base \( p \) digits with separators:

```
sage: R = Qp(5, print_mode='bars'); a = R(70700); repr(a)
'...4|2|3|0|3|0|0'
sage: b = R(-70700); repr(b)
'...4|4|4|4|4|4|4|4|4|4|4|4|4|4|4|4|0|2|1|4|2|0|0'
sage: d = R(-707/5^2); repr(d)
'...4|4|4|4|4|4|4|4|4|4|4|4|4|4|4|4|3|4|1|.|3|3'
```

Again, note that it’s not possible to read off the precision from the representation in this mode.

*print_pos* controls whether the digits can be negative.

```
sage: S = Qp(5, print_mode='bars',print_pos=False); b = S(-70700); repr(b)
'...-1|0|2|2|-1|2|0|0'
```

*print_max_terms* limits the number of digits that are printed. Note that if the valuation of the element is very negative, more digits will be printed.

```
sage: T = Qp(5, print_max_terms=4); T(-70700)
2*5^2 + 4*5^3 + 5^4 + 2*5^5 + ... + O(5^22)
sage: T(-707/5^2)
3*5^-2 + 3*5^-1 + 1 + 4*5 + ... + O(5^-18)
sage: T(-707/5^6)
3*5^-6 + 3*5^-5 + 5^-4 + 4*5^-3 + ... + O(5^-14)
sage: T(-707/5^6, absprec=-2)
3*5^-6 + 3*5^-5 + 5^-4 + 4*5^-3 + O(5^-2)
sage: T(-707/5^4)
3*5^-4 + 3*5^-3 + 5^-2 + 4*5^-1 + ... + O(5^-16)
```

13
print_sep controls the separation character.

```python
sage: U = Qp(5, print_mode='bars', print_sep=']; a = U(70700); repr(a)
'...4][2][3][0][3][0][0'
```

show_prec determines how the precision is printed. It can be either 'none' (or equivalently False), 'dots' (or equivalently True) or 'bigoh' The default is False for the 'floating-point' type and True for all other types.

```python
sage: repr(Qp(5, print_mode='bars', show_prec='bigoh')(6))
'...1|1 + O(5^20)'
```

name and print_alphabet have no effect.

Equality depends on printing options:

```python
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

EXAMPLES:

```python
sage: K = Qp(15, check=False); a = K(999); a
9 + 6*15 + 4*15^2 + O(15^20)
```

create_key(
  p, prec=None, type='capped-rel', print_mode=None, names=None, ram_name=None,
  print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None,
  show_prec=None, check=True, label=None)

Creates a key from input parameters for Qp.

See the documentation for Qp for more information.

create_object(version, key)

Creates an object using a given key.

See the documentation for Qp for more information.

sage.rings.padics.factory.QQ(q, prec=None, type='capped-rel', modulus=None, names=None,
  print_mode=None, ram_name=None, res_name=None, print_pos=None,
  print_sep=None, print_max_ram_terms=None,
  print_max_unram_terms=None, print_max_terse_terms=None,
  show_prec=None, check=True, implementation='FLINT')

Given a prime power \( q = p^n \), return the unique unramified extension of \( \mathbb{Q}_p \) of degree \( n \).

INPUT:

- \( q \) – integer, list, tuple or Factorization object. If \( q \) is an integer, it is the prime power \( q \) in \( \mathbb{Q}_q \). If \( q \) is a Factorization object, it is the factorization of the prime power \( q \). As a tuple it is the pair \((p, n)\), and as a list it is a single element list \([p, n]\).

- prec – integer (default: 20) the precision cap of the field. Individual elements keep track of their own precision. See TYPES and PRECISION below.

- type – string (default: 'capped-rel') Valid types are 'capped-rel', 'floating-point', 'lattice-cap' and 'lattice-float'. See TYPES and PRECISION below

- modulus – polynomial (default None) A polynomial defining an unramified extension of \( \mathbb{Q}_p \). See MODULUS below.

- names – string or tuple (None is only allowed when \( q = p \)). The name of the generator, reducing to a generator of the residue field.
• **print_mode** – string (default: `None`). Valid modes are 'series', 'val-unit', 'terse', and 'bars'. See PRINTING below.

• **ram_name** – string (defaults to string representation of $p$ if `None`). `ram_name` controls how the prime is printed. See PRINTING below.

• **res_name** – string (defaults to `None`, which corresponds to adding a '0' to the end of the name). Controls how elements of the reside field print.

• **print_pos** – bool (default `None`) Whether to only use positive integers in the representations of elements. See PRINTING below.

• **print_sep** – string (default `None`) The separator character used in the 'bars' mode. See PRINTING below.

• **print_max_ram_terms** – integer (default `None`) The maximum number of powers of $p$ shown. See PRINTING below.

• **print_max_unram_terms** – integer (default `None`) The maximum number of entries shown in a coefficient of $p$. See PRINTING below.

• **print_max_terse_terms** – integer (default `None`) The maximum number of terms in the polynomial representation of an element (using 'terse'). See PRINTING below.

• **show_prec** – bool (default `None`) whether to show the precision for elements. See PRINTING below.

• **check** – bool (default `True`) whether to check inputs.

**OUTPUT:**

• The corresponding unramified $p$-adic field.

**TYPES AND PRECISION:**

There are two types of precision for a $p$-adic element. The first is relative precision, which gives the number of known $p$-adic digits:

```sage
R.<a> = Qq(25, 20, 'capped-rel', print_mode='series'); b = 25*a; b
a*5^2 + O(5^22)
sage: b.precision_relative()
20
```

The second type of precision is absolute precision, which gives the power of $p$ that this element is defined modulo:

```sage
b.precision_absolute()
22
```

There are two types of unramified $p$-adic fields: capped relative fields, floating point fields.

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.

```sage
R.<a> = Qq(9, 5, 'capped-rel', print_mode='series'); b = (1+2*a)^4; b
2 + (2*a + 2)*3 + (2*a + 1)*3^2 + 0(3^5)
sage: c = R(3249); c
3^2 + 3^4 + 3^5 + 3^6 + 0(3^7)
sage: b + c
2 + (2*a + 2)*3 + (2*a + 2)*3^2 + 3^4 + 0(3^5)
```
In the floating point case, elements do not track their precision, but the relative precision of elements is truncated during arithmetic to the precision cap of the field.

**MODULUS:**
The modulus needs to define an unramified extension of \( \mathbb{Q}_p \): when it is reduced to a polynomial over \( \mathbb{F}_p \) it should be irreducible.

The modulus can be given in a number of forms.

1. **A polynomial.**

The base ring can be \( \mathbb{Z}, \mathbb{Q}, \mathbb{Z}_p, \mathbb{Q}_p, \mathbb{F}_p \).

```
sage: P.<x> = ZZ[]
sage: R.<a> = Qq(27, modulus = x^3 + 2*x + 1); R.modulus()
(1 + O(3^20))*x^3 + O(3^20)*x^2 + (2 + O(3^20))*x + 1 + O(3^20)
sage: P.<x> = QQ[]
sage: S.<a> = Qq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = Zp(3)[]
sage: T.<a> = Qq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = Qp(3)[]
sage: U.<a> = Qq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = GF(3)[]
sage: V.<a> = Qq(27, modulus = x^3 + 2*x + 1)
```

Which form the modulus is given in has no effect on the unramified extension produced:

```
sage: R == S, S == T, T == U, U == V
(True, True, True, False)
```

unless the precision of the modulus differs. In the case of \( V \), the modulus is only given to precision 1, so the resulting field has a precision cap of 1.

```
sage: V.precision_cap()
1
sage: U.precision_cap()
20
sage: P.<x> = Qp(3)[]
sage: modulus = x^3 + (2 + O(3^7))*x + (1 + O(3^10))
sage: modulus
(1 + O(3^20))*x^3 + (2 + O(3^7))*x + 1 + O(3^10)
sage: W.<a> = Qq(27, modulus = modulus); W.precision_cap()
7
```

2. **The modulus can also be given as a symbolic expression.**

```
sage: x = var('x')
sage: X.<a> = Qq(27, modulus = x^3 + 2*x + 1); X.modulus()
(1 + O(3^20))*x^3 + 0(3^20)*x^2 + (2 + O(3^20))*x + 1 + O(3^20)
sage: X == R
True
```

By default, the polynomial chosen is the standard lift of the generator chosen for \( \mathbb{F}_q \).
sage: GF(125, 'a').modulus()
x^3 + 3*x + 3
sage: Y.<a> = Qq(125); Y.modulus()
(1 + 0(5^20))*x^3 + 0(5^20)*x^2 + (3 + 0(5^20))*x + 3 + 0(5^20)

However, you can choose another polynomial if desired (as long as the reduction to \( \mathbb{F}_p[x] \) is irreducible).

sage: P.<x> = ZZ[]
sage: Z.<a> = Qq(125, modulus = x^3 + 3*x^2 + x + 1); Z.modulus()
(1 + O(5^20))*x^3 + O(5^20)*x^2 + (3 + O(5^20))*x + 1 + O(5^20)
sage: Y == Z
False

PRINTING:

There are many different ways to print \( p \)-adic elements. The way elements of a given field print is controlled by options passed in at the creation of the field. There are four basic printing modes ('series', 'val-unit', 'terse' and 'bars'; 'digits' is not available), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different \( p \)-adic fields are considered equal.

1. series: elements are displayed as series in \( p \).

```
sage: R.<a> = Qq(9, 20, 'capped-rel', print_mode='series'); (1+2*a)^4
2 + (2*a + 2)*3 + (2*a + 1)*3^2 + 0(3^20)
sage: -3*(1+2*a)^4
3 + a*3^2 + 3^3 + (-a - 1)*3^4 + O(3^21)
```

`print_pos` controls whether negatives can be used in the coefficients of powers of \( p \).

```
sage: S.<b> = Qq(9, print_mode='series', print_pos=False); (1+2*b)^4
-1 - b*3 - 3^2 + (b + 1)*3^3 + 0(3^20)
sage: -3*(1+2*b)^4
3 + b*3^2 + 3^3 + (-b - 1)*3^4 + O(3^21)
```

`ram_name` controls how the prime is printed.

```
sage: T.<d> = Qq(9, print_mode='series', ram_name='p'); 3*(1+2*d)^4
2*p + (2*d + 2)*p^2 + (2*d + 1)*p^3 + 0(p^21)
```

`print_max_ram_terms` limits the number of powers of \( p \) that appear.

```
sage: U.<e> = Qq(9, print_mode='series', print_max_ram_terms=4); repr(-3*(1+2*e)^4)
'3 + e*3^2 + 3^3 + (2*e + 2)*3^4 + ... + O(3^21)'
```
print_max_unram_terms limits the number of terms that appear in a coefficient of a power of \( p \).

\[
\text{sage: } V.<f> = Qq(128, \text{prec} = 8, \text{print_mode}='\text{series}'); \text{repr}((1+f)^9)
\]

\[\begin{align*}
(f^3 + 1) + (f^5 + f^4 + f^3 + f^2)*2 + (f^6 + f^5 + f^4 + f^3 + f^2 + f + 1)*2^2 + (f^\rightarrow 5 + f^4 + f^3 + f^2 + f + 1)*2^3 + (f^6 + f^5 + f^4 + f^3 + f^2 + f + 1)*2^4 + \\
(f^5 + f^4)*2^5 + (f^6 + f^5 + f^4 + f^3 + f + 1)*2^6 + (f + 1)*2^7 + O(2^8)
\end{align*}
\]

\[
\text{sage: } V.<f> = Qq(128, \text{prec} = 8, \text{print_mode}='\text{series}', \text{print_max_unram_terms}_x = 3); \text{repr}((1+f)^9)
\]

\[\begin{align*}
(f^3 + 1) + (f^5 + f^4 + \ldots + f^2)*2 + (f^6 + f^5 + \ldots + 1)*2^2 + (f^5 + \ldots + 1)*2^3 + (f^6 + \ldots + 1)*2^4 + (f^5 + f^4)*2^5 + (f^6 + \ldots + 1)*2^6 + (f + \ldots + 1)*2^7 + O(2^8)
\end{align*}
\]

\[
\text{sage: } V.<f> = Qq(128, \text{prec} = 8, \text{print_mode}='\text{series}', \text{print_max_unram_terms}_x = 2); \text{repr}((1+f)^9)
\]

\[\begin{align*}
(f^3 + 1) + (f^5 + \ldots + f^2)*2 + (f^6 + \ldots + 1)*2^2 + (f^5 + \ldots + 1)*2^3 + (f^6 + \ldots + 1)*2^4 + (f^5 + f^4)*2^5 + (f^6 + \ldots + 1)*2^6 + (f + \ldots + 1)*2^7 + O(2^8)
\end{align*}
\]

\[
\text{sage: } V.<f> = Qq(128, \text{prec} = 8, \text{print_mode}='\text{series}', \text{print_max_unram_terms}_x = 1); \text{repr}((1+f)^9)
\]

\[\begin{align*}
(f^3 + \ldots + f^2)*2 + (f^6 + \ldots + 1)*2^2 + (f^5 + \ldots + 1)*2^3 + (f^6 + \ldots + 1)*2^4 + (f^5 + f^4)*2^5 + (f^6 + \ldots + 1)*2^6 + (f + \ldots + 1)*2^7 + O(2^8)
\end{align*}
\]

\[
\text{sage: } V.<f> = Qq(128, \text{prec} = 8, \text{print_mode}='\text{series}', \text{print_max_unram_terms}_x = 0); \text{repr}((1+f)^9 - 1 - f^3)
\]

\[\begin{align*}
(\ldots)*2 + (\ldots)*2^2 + (\ldots)*2^3 + (\ldots)*2^4 + (\ldots)*2^5 + (\ldots)*2^6 + (\ldots)*2^7 + O(2^8)
\end{align*}
\]

\[\text{(continues on next page)}\]
ram_name affects how the prime is printed.

\[
\begin{align*}
\text{sage: } & A.<x> = \text{Qp(next_prime(10^6), print_mode='val-unit')}[] \\
& \text{sage: } T.<a> = \text{Qq(next_prime(10^6)^3, 4, print_mode='val-unit', ram_name='p', modulus=x^3+385831*x^2+106556*x+321036)}; b = -(\text{next_prime(10^6)}^2(a^2 + a - 4)); b \\
& \text{sage: } b * (a^2 + a - 4) \\
& p^{-2} * 1 + O(p^2)
\end{align*}
\]

print_max_terse_terms controls how many terms of the polynomial appear in the unit part.

\[
\begin{align*}
\text{sage: } & U.<a> = \text{Qq(17^4, 6, print_mode='val-unit', print_max_terse_terms=3);} \\
& \text{sage: } b = -(17^4(a^3-a+14)); b \\
& 17^{-1} * (22110411 + 11317400*a + 20656972*a^2 + \ldots) + O(17^5)
\end{align*}
\]

show_prec determines how the precision is printed. It can be either ‘none’ (or equivalently False), ‘bigoh’ (or equivalently True). The default is False for the ‘floating-point’ type and True for all other types.

\[
\begin{align*}
\text{sage: } & U.<e> = \text{Qq(9, 2, print_mode='val-unit', show_prec=False); repr(-3^3(1\text{+2*e})^4)} \\
& '3 * (1 + 3*e)'
\end{align*}
\]

print_sep, print_max_ram_terms and print_max_unram_terms have no effect.

Equality again depends on the printing options:

\[
\begin{align*}
\text{sage: } & R == S, R == T, R == U, S == T, S == U, T == U \\
& \text{(False, False, False, False, False, False)}
\end{align*}
\]

3. terse: elements are displayed as a polynomial of degree less than the degree of the extension.

\[
\begin{align*}
\text{sage: } & R.<a> = \text{Qq(125, print_mode='terse')} \\
& \text{sage: } (a+5)^{177} \\
& 68210977979428 + 9313850704069*a + 73948093055069*a^2 + O(5^{20}) \\
& \text{sage: } (a/5+1)^{177} \\
& 68210977979428/5^{177} + 9313850704069/5^{177}*a + 73948093055069/5^{177}*a^2 + O(5^{177})
\end{align*}
\]

As of version 3.3, if coefficients of the polynomial are non-integral, they are always printed with an explicit power of \( p \) in the denominator.

\[
\begin{align*}
\text{sage: } & 5*a + a^2/25 \\
& 5*a + 1/5^2*a^2 + O(5^{18})
\end{align*}
\]

print_pos controls whether to use a balanced representation or not.
\begin{verbatim}sage: (a-5)^6
22864 + 95367431627998*a + 8349*a^2 + O(5^20)
sage: S.<a> = Qq(125, print_mode='terse', print_pos=False); b = (a-5)^6; b
22864 - 12627*a + 8349*a^2 + O(5^20)
sage: (a - 1/5)^6
-20624/5^6 + 18369/5^5*a + 1353/5^3*a^2 + O(5^14)
\end{verbatim}

\textit{ram_name} affects how the prime is printed.

\begin{verbatim}sage: T.<a> = Qq(125, print_mode='terse', ram_name='p'); (a - 1/5)^6
95367431620001/p^6 + 18369/p^5*a + 1353/p^3*a^2 + O(p^14)
\end{verbatim}

\textit{print_max_terse_terms} controls how many terms of the polynomial are shown.

\begin{verbatim}sage: U.<a> = Qq(625, print_mode='terse', print_max_terse_terms=2); (a-1/5)^6
106251/5^6 + 49994/5^5*a + ... + O(5^14)
\end{verbatim}

\textit{show_prec} determines how the precision is printed. It can be either 'none' (or equivalently False), 'bigoh' (or equivalently True). The default is False for the 'floating-point' type and True for all other types.

\begin{verbatim}sage: U.<e> = Qq(9, 2, print_mode='terse', show_prec=False); repr((-3*(1+2*e)^4)
'3 + 9*e'
\end{verbatim}

\textit{print_sep}, \textit{print_max_ram_terms} and \textit{print_max_unram_terms} have no effect.

Equality again depends on the printing options:

\begin{verbatim}sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
\end{verbatim}

4. \textbf{digits}: This print mode is not available when the residue field is not prime.

It might make sense to have a dictionary for small fields, but this isn’t implemented.

5. \textbf{bars}: elements are displayed in a similar fashion to series, but more compactly.

\begin{verbatim}sage: R.<a> = Qq(125); (a+5)^6
(4*a^2 + 3*a + 4) + (3*a^2 + 2*a)*5 + (a^2 + a + 1)*5^2 + (3*a + 2)*5^3 + (3*a^2 + 2 + a + 3)*5^4 + (2*a^2 + 3*a + 2)*5^5 + 0(5^20)
sage: R.<a> = Qq(125, print_mode='bars', prec=8); repr((a+5)^6)
'...[2, 3, 2][3, 1, 3][2, 3][1, 1, 1][0, 2, 3][4, 3, 4]'
sage: repr((a-5)^6)
'...[0, 4][1, 4][2, 0, 2][1, 4, 3][2, 3, 1][4, 4, 3][2, 4, 4][4, 3, 4]'
\end{verbatim}

Note that elements with negative valuation are shown with a decimal point at valuation 0.

\begin{verbatim}sage: repr((a+1/5)^6)
'...[3][4, 1, 3].|[1, 2, 3][3, 3][0, 0, 3][0, 1][0, 1][1]'
sage: repr((a+1/5)^2)
'...[0, 0, 1].|[0, 2][1]'\end{verbatim}

If not enough precision is known, '?' is used instead.
Note that it's not possible to read off the precision from the representation in this mode.

```python
sage: b = a + 3; repr(b)
'...[3, 1]'
sage: c = a + R(3, 4); repr(c)
'...[3, 1]'
sage: b.precision_absolute()
8
sage: c.precision_absolute()
4
```

`print_pos` controls whether the digits can be negative.

```python
sage: S.<a> = Qq(125, print_mode='bars', print_pos=False); repr((a-5)^6)
'...[1, -1, 1][2, 1, -2][2, 0, -2][-2, -1, 2][0, 0, -1][-2][-1, -2, -1][1]'  
sage: repr((a-1/5)^6)
'...[0, 1, 2][-1, 1, 1].[-2, -1, -1][2, 2, 1][0, 0, -2][0, -1][0, -1][1]
```

`print_max_ram_terms` controls the maximum number of “digits” shown. Note that this puts a cap on the relative precision, not the absolute precision.

```python
sage: T.<a> = Qq(125, print_max_ram_terms=3, print_pos=False); (a-5)^6
(-a^2 - 2*a - 1) - 2*5 - a^2*5^2 + ... + O(5^20)
sage: 5*(a-5)^6 + 50
(-a^2 - 2*a - 1)*5 - a^2*5^3 + (2*a^2 - a - 2)*5^4 + ... + O(5^21)
```

`print_sep` controls the separating character (" | " by default).

```python
sage: U.<a> = Qq(625, print_mode='bars', print_sep=''); b = (a+5)^6; repr(b)
'...[0, 1][4, 0, 2][3, 2, 2, 3][4, 2, 2, 4][0, 3][1, 1, 3][3, 1, 4, 1]'
```

`print_max_unram_terms` controls how many terms are shown in each “digit”:

```python
sage: with local_print_mode(U, {'max_unram_terms': 3}): repr(b)
'...[0, 1][4, ..., 0, 2][3, ..., 2, 3][4, ..., 2, 4][0, 3][1, ..., 1, 3][3, ..., 4, 1]'  
sage: with local_print_mode(U, {'max_unram_terms': 2}): repr(b)
'...[0, 1][4, ..., 2][3, ..., 3][4, ..., 4][0, 3][1, ..., 3][3, ..., 1]'  
sage: with local_print_mode(U, {'max_unram_terms': 1}): repr(b)
'...[3, ..., 1][..., 2][..., 3][..., 4][..., 3][..., 3][..., 1]'  
sage: with local_print_mode(U, {'max_unram_terms':0}): repr(b-75*a)
'...[...]...[...]...[...]...[...]...[...]
```

`show_prec` determines how the precision is printed. It can be either ‘none’ (or equivalently False), ‘dots’ (or equivalently True) or ‘bigoh’ The default is False for the 'floating-point' type and True for all other types.
```python
sage: U.<e> = Qq(9, 2, print_mode='bars', show_prec=True); repr(-3*(1+2*e)^4)
'...[0, 1][1][[]'
```

`ram_name` and `print_max_terse_terms` have no effect.

Equality depends on printing options:

```python
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

EXAMPLES:

Unlike for `Qp`, you can’t create `Qq(N)` when `N` is not a prime power.

However, you can use `check=False` to pass in a pair in order to not have to factor. If you do so, you need to use names explicitly rather than the `R.<a>` syntax.

```python
sage: p = next_prime(2^123)
sage: k = Qp(p)
sage: R.<x> = k[]
sage: K = Qq([(p, 5)], modulus=x^5+x+4, names='a', ram_name='p', print_pos=False, check=False)
sage: K.0^5
(-a - 4) + O(p^20)
```

In tests on `sage.math.washington.edu`, the creation of `K` as above took an average of 1.58ms, while:

```python
sage: K = Qq(p^5, modulus=x^5+x+4, names='a', ram_name='p', print_pos=False, check=True)
```

took an average of 24.5ms. Of course, with smaller primes these savings disappear.

`sage.rings.padics.factory.QqCR(q, prec=None, *args, **kwds)`
A shortcut function to create capped relative unramified \( p \)-adic fields.

Same functionality as `Qq`. See documentation for `Qq` for a description of the input parameters.

EXAMPLES:

```python
sage: R.<a> = QqCR(25, 40); R
5-adic Unramified Extension Field in a defined by x^2 + 4*x + 2
```

`sage.rings.padics.factory.QqFP(q, prec=None, *args, **kwds)`
A shortcut function to create floating point unramified \( p \)-adic fields.

Same functionality as `Qq`. See documentation for `Qq` for a description of the input parameters.

EXAMPLES:

```python
sage: R.<a> = QqFP(25, 40); R
5-adic Unramified Extension Field in a defined by x^2 + 4*x + 2
```

`sage.rings.padics.factory.ZpCA(p, prec=None, *args, **kwds)`
A shortcut function to create capped absolute \( p \)-adic rings.

See documentation for `Zp()` for a description of the input parameters.

EXAMPLES:
sage: ZpCA(5, 40)
5-adic Ring with capped absolute precision 40

sage.rings.padics.factory.ZpCR(p, prec=None, *args, **kwds)
A shortcut function to create capped relative $p$-adic rings.

Same functionality as Zp. See documentation for Zp for a description of the input parameters.

EXAMPLES:

sage: ZpCR(5, 40)
5-adic Ring with capped relative precision 40

sage.rings.padics.factory.ZpER(p, prec=None, halt=None, secure=False, *args, **kwds)
A shortcut function to create relaxed $p$-adic rings.

INPUT:

- prec – an integer (default: 20), the default precision
- halt – an integer (default: twice prec), the halting precision
- secure – a boolean (default: False); if False, consider indistinguishable elements at the working precision as equal; otherwise, raise an error.

See documentation for Zp() for a description of the other input parameters.

A SHORT INTRODUCTION TO RELAXED $p$-ADICS:

The model for relaxed $p$-adics is quite different from any of the other types of $p$-adics. In addition to storing a finite approximation, one also stores a method for increasing the precision.

Relaxed $p$-adic rings are created by the constructor ZpER():

sage: R = ZpER(5, print_mode="digits")
sage: R
5-adic Ring handled with relaxed arithmetics

The precision is not capped in $R$:

sage: R.precision_cap()
+Infinity

However, a default precision is fixed. This is the precision at which the elements will be printed:

sage: R.default_prec()
20

A default halting precision is also set. It is the default absolute precision at which the elements will be compared. By default, it is twice the default precision:

sage: R.halting_prec()
40

However, both the default precision and the halting precision can be customized at the creation of the parent as follows:

sage: S = ZpER(5, prec=10, halt=100) sage: S.default_prec() 10 sage: S.halting_prec() 100

One creates elements as usual:
Here we notice that 20 digits (that is the default precision) are printed. However, the computation model is designed in order to guarantee that more digits of $a$ will be available on demand. This feature is reflected by the fact that, when we ask for the precision of $a$, the software answers $+\infty$:

```python
sage: a.precision_absolute()
+Infinity
```

Asking for more digits is achieved by the methods `at_precision_absolute()` and `at_precision_relative()`:

```python
sage: a.at_precision_absolute(30)
...?244200244200244200244200244201
```

As a shortcut, one can use the bracket operator:

```python
sage: a[:30]
...?244200244200244200244200244201
```

Of course, standard operations are supported:

```python
sage: b = R(42/17)
sage: a + b
...0323201121322140002
sage: a - b
...42311334324023403400
sage: a * b
...00000000000000000001
sage: a / b
...12442142113021233401
sage: sqrt(a)
...2004233114021142101
```

We observe again that only 20 digits are printed but, as before, more digits are available on demand:

```python
sage: sqrt(a)[:30]
...?14244334212004233114021142101
```
Equality tests

Checking equalities between relaxed \( p \)-adics is a bit subtle and can sometimes be puzzling at first glance.

When the parent is created with `secure=False` (which is the default), elements are compared at the current precision, or at the default halting precision if it is higher:

```
sage: a == b
False
sage: a == sqrt(a)^2
True
sage: a == sqrt(a)^2 + 5^50
True
```

In the above example, the halting precision is 40; it is the reason why a congruence modulo \( 5^{50} \) is considered as an equality. However, if both sides of the equalities have been previously computed with more digits, those digits are taken into account. Hence comparing two elements at different times can produce different results:

```
sage: aa = sqrt(a)^2 + 5^50
sage: a == aa
True
sage: a[:60]
...244200244200244200244200244200244200244200244200244200244201
sage: aa[:60]
...244200244300244200244200244200244200244200244200244200244201
sage: a == aa
False
```

This annoying situation, where the output of \( a == aa \) may change depending on previous computations, cannot occur when the parent is created with `secure=True`. Indeed, in this case, if the equality cannot be decided, an error is raised:

```
sage: S = ZpER(5, secure=True)
sage: u = S.random_element()
sage: uu = u + 5^50
sage: u == uu
Traceback (most recent call last):
  ... PrecisionError: unable to decide equality; try to bound precision
sage: u[:60] == uu
False
```

Self-referent numbers

A quite interesting feature with relaxed \( p \)-adics is the possibility to create (in some cases) self-referent numbers. Here is an example. We first declare a new variable as follows:

```
sage: x = R.unknown()
sage: x
```

We then use the method `set()` to define \( x \) by writing down an equation it satisfies:
The variable \(x\) now contains the unique solution of the equation \(x = 1 + 5x^2\):

\[
\text{sage: } x \text{.set}(1 + 5^*x^2) \\
\text{True}
\]

This works because the \(n\)-th digit of the right hand size of the defining equation only involves the \(i\)-th digits of \(x\) with \(i < n\) (this is due to the factor 5).

As a comparison, the following does not work:

\[
\text{sage: } y = R\text{.unknown()} \\
\text{sage: } y\text{.set}(1 + 3*y^2) \\
\text{True} \\
\text{sage: } y \\
...?.0 \\
\text{sage: } y[:20] \\
\text{Traceback (most recent call last):} \\
... \\
\text{RecursionError: definition looks circular}
\]

Self-referent definitions also work with systems of equations:

\[
\text{sage: } u = R\text{.unknown()} \\
\text{sage: } v = R\text{.unknown()} \\
\text{sage: } w = R\text{.unknown()} \\
\text{sage: } u\text{.set}(1 + 2*v + 3*w^2 + 5*u*v*w) \\
\text{True} \\
\text{sage: } v\text{.set}(2 + 4*w + \sqrt{1 + 5*u + 10*v + 15*w}) \\
\text{True} \\
\text{sage: } w\text{.set}(3 + 25*(u*v + v*w + u*w)) \\
\text{True}
\]

\[
\text{sage: } u \\
...31203130103131131433 \\
\text{sage: } v \\
...33441043031103114240 \\
\text{sage: } w \\
...3021242204110244403
\]

A shortcut function to create fixed modulus \(p\)-adic rings.

See documentation for \(\text{Zp}\) for a description of the input parameters.

\textbf{EXAMPLES:}

\[
\text{sage: } \text{ZpFM}(5, 40) \\
5\text{-adic Ring of fixed modulus } 5^{40}
\]

\text{A shortcut function to create floating point \(p\)-adic rings.}
Same functionality as \( \mathbb{Z}_p \). See documentation for \( \mathbb{Z}_p \) for a description of the input parameters.

**EXAMPLES:**

```python
sage: ZpFP(5, 40)
5-adic Ring with floating precision 40
```

```
sage.rings.padics.factory.ZpLC(p, prec=None, *args, **kwds)
A shortcut function to create \( p \)-adic rings with lattice precision (precision is encoded by a lattice in a large vector space and tracked using automatic differentiation).

See documentation for Zp() for a description of the input parameters.

**EXAMPLES:**

Below is a small demo of the features by this model of precision:

```python
sage: R = ZpLC(3, print_mode='terse')
sage: R
3-adic Ring with lattice-cap precision
sage: x = R(1,10)
```

Of course, when we multiply by 3, we gain one digit of absolute precision:

```python
sage: 3*x
3 + O(3^11)
```

The lattice precision machinery sees this even if we decompose the computation into several steps:

```python
sage: y = x+x
sage: y
2 + O(3^10)
```

The same works for the multiplication:

```python
sage: z = x^2
sage: z
1 + O(3^10)
```

This can be more surprising when we are working with elements given at different precisions:

```python
sage: R = ZpLC(2, print_mode='terse')
sage: x = R(1,10)
sage: y = R(1,5)
sage: z = x+y; z
2 + O(2^5)
```

```python
sage: t = x-y; t
O(2^5)
```

```
sage: z+t  # observe that z+t = 2*x
2 + O(2^11)
```

```
sage: z-t  # observe that z-t = 2*y
```

(continues on next page)
The SOMOS sequence is the sequence defined by the recurrence:

\[ u_n = \frac{u_{n-1}u_{n-3} + u_{n-2}^2}{u_{n-4}} \]

It is known for its numerical instability. On the one hand, one can show that if the initial values are invertible in \( \mathbb{Z}_p \) and known at precision \( O(p^n) \) then all the next terms of the SOMOS sequence will be known at the same precision as well. On the other hand, because of the division, when we unroll the recurrence, we lose a lot of precision. Observe:

```
sage: R = Zp(2, 30, print_mode='terse')
sage: a, b, c, d = R(1, 15), R(1, 15), R(1, 15), R(3, 15)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  4 + O(2^15)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  13 + O(2^15)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  55 + O(2^15)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  21975 + O(2^15)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  6639 + O(2^13)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  7186 + O(2^13)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  569 + O(2^13)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  253 + O(2^13)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  4149 + O(2^13)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  2899 + O(2^12)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  3072 + O(2^12)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  349 + O(2^12)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  619 + O(2^12)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  243 + O(2^12)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  3 + O(2^2)
sage: a, b, c, d = b, c, d, (b*d + c*c)/a; print(d)
  2 + O(2^2)
```
If instead, we use the lattice precision, everything goes well:

```
sage: R = ZpLC(2, 30, print_mode='terse')
sage: a,b,c,d = R(1,15), R(1,15), R(1,15), R(3,15)
sage: a,b,c,d = b,c,d,(b*d+c*c)/a; print(d)
  4 + O(2^15)
sage: a,b,c,d = b,c,d,(b*d+c*c)/a; print(d)
  13 + O(2^15)
sage: a,b,c,d = b,c,d,(b*d+c*c)/a; print(d)
  55 + O(2^15)
sage: a,b,c,d = b,c,d,(b*d+c*c)/a; print(d)
  21975 + O(2^15)
sage: a,b,c,d = b,c,d,(b*d+c*c)/a; print(d)
  23023 + O(2^15)
sage: a,b,c,d = b,c,d,(b*d+c*c)/a; print(d)
  31762 + O(2^15)
sage: a,b,c,d = b,c,d,(b*d+c*c)/a; print(d)
  16953 + O(2^15)
sage: a,b,c,d = b,c,d,(b*d+c*c)/a; print(d)
  16637 + O(2^15)
sage: for _ in range(100):
    ....:   a,b,c,d = b,c,d,(b*d+c*c)/a
sage: a
  15519 + O(2^15)
sage: b
  32042 + O(2^15)
sage: c
  17769 + O(2^15)
sage: d
  20949 + O(2^15)
```

ALGORITHM:

The precision is global. It is encoded by a lattice in a huge vector space whose dimension is the number of elements having this parent. Precision is tracked using automatic differentiation techniques (see [CRV2014] and [CRV2018]).

Concretely, this precision datum is an instance of the class `sage.rings.padic.lattice_precision`. `PrecisionLattice`. It is attached to the parent and is created at the same time as the parent. (It is actually a bit more subtle because two different parents may share the same instance; this happens for instance for a \(p\)-adic ring and its field of fractions.)

This precision datum is accessible through the method `precision()`:

```
sage: R = ZpLC(5, print_mode='terse')
sage: prec = R.precision()
sage: prec
  Precision lattice on 0 objects
```

This instance knows about all elements of the parent. It is automatically updated when a new element (of this parent) is created:

```
sage: x = R(3513,10)
sage: prec
```

(continues on next page)
The method `tracked_elements()` provides the list of all tracked elements:

```python
sage: prec.tracked_elements()
[3513 + O(5^10), 176 + O(5^5), ...]
```

Similarly, when a variable is collected by the garbage collector, the precision lattice is updated. Note however that the update might be delayed. We can force it with the method `del_elements()`:

```python
sage: z = 0
sage: prec
# random output, could be 2 objects if the garbage collector is fast
sage: prec.del_elements()
sage: prec
Precision lattice on 2 objects
```

The method `precision_lattice()` returns (a matrix defining) the lattice that models the precision. Here we have:

```python
sage: prec.precision_lattice()
[9765625 0]
[ 0 3125]
```

Observe that $5^4 = 9765625$ and $5^5 = 3125$. The above matrix then reflects the precision on $x$ and $y$.

Now, observe how the precision lattice changes while performing computations:

```python
sage: x, y = 3*x+2*y, 2*(x-y)
sage: prec.del_elements()
sage: prec.precision_lattice()
[ 3125 48825000]
[ 0 48828125]
```

The matrix we get is no longer diagonal, meaning that some digits of precision are diffused among the two new elements $x$ and $y$. They nevertheless show up when we compute for instance $x + y$:

```python
sage: x
1516 + O(5^5)
sage: y
424 + O(5^5)
sage: x+y
17565 + O(5^11)
```

These diffused digits of precision (which are tracked but do not appear on the printing) allow to be always sharp on precision.

NOTE:
Each elementary operation requires significant manipulations on the precision lattice and therefore is costly. Precisely:

- The creation of a new element has a cost $O(n)$ where $n$ is the number of tracked elements.
- The destruction of one element has a cost $O(m^2)$ where $m$ is the distance between the destroyed element and the last one. Fortunately, it seems that $m$ tends to be small in general (the dynamics of the list of tracked elements is rather close to that of a stack).

It is nevertheless still possible to manipulate several hundred variables (e.g. square matrices of size 5 or polynomials of degree 20).

The class `PrecisionLattice` provides several features for introspection, especially concerning timings. See `history()` and `timings()` for details.

**See also:**

`sage.rings.padics.factory.ZpLF(p, prec=None, *args, **kwds)`

A shortcut function to create $p$-adic rings where precision is encoded by a module in a large vector space.

See documentation for `Zp()` for a description of the input parameters.

**NOTE:**

The precision is tracked using automatic differentiation techniques (see [CRV2018] and [CRV2014]). Floating point $p$-adic numbers are used for the computation of the differential (which is then not exact).

**EXAMPLES:**

```
sage: R = ZpLF(5, 40)
sage: R
5-adic Ring with lattice-float precision
```

**See also:**

`sage.rings.padics.factory.ZpLC()`

**class** `sage.rings.padics.factory.Zp_class`

Bases: `sage.structure.factory.UniqueFactory`

A creation function for $p$-adic rings.

**INPUT:**

- **$p$** – integer: the $p$ in $\mathbb{Z}_p$
- **prec** – integer (default: 20) the precision cap of the ring. In the lattice capped case, `prec` can either be a pair (relative_cap, absolute_cap) or an integer (understood at relative cap). In the relaxed case, `prec` can be either a pair (default_prec, halting_prec) or an integer (understood at default precision). Except for the fixed modulus and floating point cases, individual elements keep track of their own precision. See TYPES and PRECISION below.
- **type** – string (default: 'capped-rel') Valid types are 'capped-rel', 'capped-abs', 'fixed-mod', 'floating-point', 'lattice-cap', 'lattice-float', 'relaxed' See TYPES and PRECISION below.
- **print_mode** – string (default: None). Valid modes are 'series', 'val-unit', 'terse', 'digits', and 'bars'. See PRINTING below.
- **names** – string or tuple (defaults to a string representation of $p$). What to use whenever $p$ is printed.
- **print_pos** – bool (default None) Whether to only use positive integers in the representations of elements. See PRINTING below.
• print_sep – string (default None) The separator character used in the 'bars' mode. See PRINTING below.
• print_alphabet – tuple (default None) The encoding into digits for use in the 'digits' mode. See PRINTING below.
• print_max_terms – integer (default None) The maximum number of terms shown. See PRINTING below.
• show_prec – bool (default None) whether to show the precision for elements. See PRINTING below.
• check – bool (default True) whether to check if $p$ is prime. Non-prime input may cause seg-faults (but can also be useful for base $n$ expansions for example)
• label – string (default None) used for lattice precision to create parents with different lattices.

OUTPUT:
• The corresponding $p$-adic ring.

TYPES AND PRECISION:
There are two main types of precision. The first is relative precision; it gives the number of known $p$-adic digits:

```
sage: R = Zp(5, 20, 'capped-rel', 'series'); a = R(675); a
2*5^2 + 5^4 + O(5^22)
sage: a.precision_relative()
20
```

The second type of precision is absolute precision, which gives the power of $p$ that this element is defined modulo:

```
sage: a.precision_absolute()
22
```

There are several types of $p$-adic rings, depending on the methods used for tracking precision. Namely, we have:
• capped relative rings (type='capped-rel')
• capped absolute rings (type='capped-abs')
• fixed modulus rings (type='fixed-mod')
• floating point rings (type='floating-point')
• lattice precision rings (type='lattice-cap' or type='lattice-float')
• exact fields with relaxed arithmetics (type='relaxed')

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.

```
sage: R = Zp(5, 5, 'capped-rel', 'series'); a = R(4006); a
1 + 5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(4025); b
5^2 + 2*5^3 + 5^4 + 5^5 + O(5^7)
sage: a + b
1 + 5 + 5^2 + 4*5^3 + 2*5^4 + O(5^5)
```

In the capped absolute type, instead of having a cap on the relative precision of an element there is instead a cap on the absolute precision. Elements still store their own precisions, and as with the capped relative case, exact elements are truncated when cast into the ring.
The fixed modulus type is the leanest of the \( p \)-adic rings: it is basically just a wrapper around \( \mathbb{Z}/p^n\mathbb{Z} \) providing a unified interface with the rest of the \( p \)-adics. This is the type you should use if your sole interest is speed. It does not track precision of elements.

The floating point case is similar to the fixed modulus type in that elements do not track their own precision. However, relative precision is truncated with each operation rather than absolute precision.

On the contrary, the lattice type tracks precision using lattices and automatic differentiation. It is rather slow but provides sharp (often optimal) results regarding precision. We refer to the documentation of the function \texttt{ZpLC()} for a small demonstration of the capabilities of this precision model.

Finally, the model for relaxed \( p \)-adics is quite different from any of the other types. In addition to storing a finite approximation, one also stores a method for increasing the precision. A quite interesting feature with relaxed \( p \)-adics is the possibility to create (in some cases) self-referent numbers, that are numbers whose \( n \)-th digit is defined by the previous ones. We refer to the documentation of the function \texttt{ZpL()} for a small demonstration of the capabilities of this precision model.

**PRINTING:**

There are many different ways to print \( p \)-adic elements. The way elements of a given ring print is controlled by options passed in at the creation of the ring. There are five basic printing modes (series, val-unit, terse, digits and bars), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different \( p \)-adic fields are considered equal.

1. **series:** elements are displayed as series in \( p \).

   ```sage```
   sage: R = Zp(5, 5, 'capped-abs', 'series'); a = R(4005); a
   5 + 2*5^3 + 5^4 + O(5^5)
   sage: b = R(4025); b
   5^2 + 2*5^3 + 5^4 + O(5^5)
   sage: a * b
   5^3 + 2*5^4 + O(5^5)
   sage: (a * b) // 5^3
   1 + 2*5 + O(5^2)
   ```

   The fixed modulus type is the leanest of the \( p \)-adic rings: it is basically just a wrapper around \( \mathbb{Z}/p^n\mathbb{Z} \) providing a unified interface with the rest of the \( p \)-adics. This is the type you should use if your sole interest is speed. It does not track precision of elements.

   ```sage```
   sage: R = Zp(5, 5, 'fixed-mod', 'series'); a = R(4005); a
   5 + 2*5^3 + 5^4
   sage: a // 5
   1 + 2*5^2 + 5^3
   ```

   The floating point case is similar to the fixed modulus type in that elements do not track their own precision. However, relative precision is truncated with each operation rather than absolute precision.

   ```sage```
   sage: R = Zp(5, 5, 'fixed-mod', 'series'); a = R(4005); a
   5 + 2*5^3 + 5^4
   sage: a // 5
   1 + 2*5^2 + 5^3
   ```

   On the contrary, the lattice type tracks precision using lattices and automatic differentiation. It is rather slow but provides sharp (often optimal) results regarding precision. We refer to the documentation of the function \texttt{ZpLC()} for a small demonstration of the capabilities of this precision model.

   ```sage```
   sage: R = Zp(5, 5, 'fixed-mod', 'series'); a = R(4005); a
   5 + 2*5^3 + 5^4
   sage: a // 5
   1 + 2*5^2 + 5^3
   ```

   Finally, the model for relaxed \( p \)-adics is quite different from any of the other types. In addition to storing a finite approximation, one also stores a method for increasing the precision. A quite interesting feature with relaxed \( p \)-adics is the possibility to create (in some cases) self-referent numbers, that are numbers whose \( n \)-th digit is defined by the previous ones. We refer to the documentation of the function \texttt{ZpL()} for a small demonstration of the capabilities of this precision model.

   ```sage```
   sage: R = Zp(5, 5, 'fixed-mod', 'series'); a = R(4005); a
   5 + 2*5^3 + 5^4
   sage: a // 5
   1 + 2*5^2 + 5^3
   ```

   **PRINTING:**

   There are many different ways to print \( p \)-adic elements. The way elements of a given ring print is controlled by options passed in at the creation of the ring. There are five basic printing modes (series, val-unit, terse, digits and bars), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different \( p \)-adic fields are considered equal.

   1. **series:** elements are displayed as series in \( p \).

   ```sage```
   sage: R = Zp(5, 5, 'series'); a = R(4005); a
   3*5^2 + 3*5^4 + 2*5^5 + 4*5^6 + O(5^22)
   sage: b = R(4005); b
   2*5^2 + 4*5^3 + 5^4 + 2*5^5 + 4*5^7 + 4*5^9 + 4*5^10 + 4*5^11 + 4*5^12 + 4*5^13 + 4*5^14 + 4*5^15 + 4*5^16 + 4*5^17 + 4*5^18 + 4*5^19 + 4*5^20 + 4*5^21 + O(5^22)
   ```

   ```sage```
   sage: s = Zp(5, 5, 'series', print_pos=False); a = S(70700); a
   -2*5^2 + 5*3 - 2*5^4 - 2*5^5 + 5^7 + O(5^22)
   sage: b = S(-70700); b
   2*5^2 - 5^3 + 2*5^4 + 2*5^5 - 5^7 + O(5^22)
   ```

   **print_pos** controls whether negatives can be used in the coefficients of powers of \( p \).

   ```sage```
   sage: s = Zp(5, 5, 'series', print_pos=False); a = S(70700); a
   -2*5^2 + 5*3 - 2*5^4 - 2*5^5 + 5^7 + O(5^22)
   sage: b = S(-70700); b
   2*5^2 - 5^3 + 2*5^4 + 2*5^5 - 5^7 + O(5^22)
   ```

   **print_max_terms** limits the number of terms that appear.
\begin{verbatim}
sage: T = Zp(5, print_mode='series', print_max_terms=4); b = R(-70700); b
2*5^2 + 4*5^3 + 5^4 + 2*5^5 + ... + 0(5^22)
\end{verbatim}

\emph{names} affects how the prime is printed.

\begin{verbatim}
sage: U.<p> = Zp(5); p
p + O(p^21)
\end{verbatim}

\emph{show_prec} determines how the precision is printed. It can be either 'none' (or equivalently False), 'bigoh' (or equivalently True). The default is False for the 'floating-point' and 'fixed-mod' types and True for all other types.

\begin{verbatim}
sage: Zp(5, show_prec=False)(6)
1 + 5
\end{verbatim}

\emph{print_sep} and \emph{print_alphabet} have no effect.

Note that print options affect equality:

\begin{verbatim}
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
\end{verbatim}

2. \texttt{val-unit}: elements are displayed as $p^ku$:

\begin{verbatim}
sage: R = Zp(5, print_mode='val-unit'); a = R(70700); a
5^2 * 2828 + O(5^22)
sage: b = R(-707*5); b
5 * 95367431639918 + O(5^21)
\end{verbatim}

\emph{print_pos} controls whether to use a balanced representation or not.

\begin{verbatim}
sage: S = Zp(5, print_mode='val-unit', print_pos=False); b = S(-70700); b
5^2 * (-2828) + O(5^22)
\end{verbatim}

\emph{names} affects how the prime is printed.

\begin{verbatim}
sage: T = Zp(5, print_mode='val-unit', names='pi'); a = T(70700); a
pi^2 * 2828 + O(pi^22)
\end{verbatim}

\emph{show_prec} determines how the precision is printed. It can be either 'none' (or equivalently False), 'bigoh' (or equivalently True). The default is False for the 'floating-point' and 'fixed-mod' types and True for all other types.

\begin{verbatim}
sage: Zp(5, print_mode='val-unit', show_prec=False)(30)
5 * 6
\end{verbatim}

\emph{print_max_terms}, \emph{print_sep} and \emph{print_alphabet} have no effect.

Equality again depends on the printing options:

\begin{verbatim}
sage: R == S, R == T, S == T
(False, False, False)
\end{verbatim}

3. \texttt{terse}: elements are displayed as an integer in base 10:
\texttt{sage: } R = \text{Zp}(5, \text{print\_mode}='\text{terse}'); \ a = R(70700); \ a \\
70700 + 0(5^{22}) \\
\texttt{sage: } b = R(-70700); \ b \\
2384185790944925 + 0(5^{22}) \\
\texttt{print\_pos controls whether to use a balanced representation or not.}

\texttt{sage: } S = \text{Zp}(5, \text{print\_mode}='\text{terse}', \text{print\_pos}=\text{False}); \ b = S(-70700); \ b \\
-70700 + 0(5^{22}) \\
\texttt{name affects how the name is printed. Note that this interacts with the choice of shorter string for denominators.}

\texttt{sage: } T.\text{<\text{unif}>} = \text{Zp}(5, \text{print\_mode}=\text{'terse'}); \ c = T(-707); \ c \\
95367431639918 + 0(\text{unif}^{20}) \\
\texttt{show\_prec determines how the precision is printed. It can be either 'none' (or equivalently False), 'bigoh' (or equivalently True). The default is False for the 'floating-point' and 'fixed-mod' types and True for all other types.}

\texttt{sage: } \text{Zp}(5, \text{print\_mode}=\text{'terse'}, \text{show\_prec}=\text{False})(30) \\
30 \\
\texttt{print\_max\_terms, print\_sep and print\_alphabet have no effect.}

Equality depends on printing options:

\texttt{sage: } R == S, \ R == T, \ S == T \\
(False, False, False) \\
\texttt{4. digits: elements are displayed as a string of base p digits}

Restriction: you can only use the digits printing mode for small primes. Namely, \( p \) must be less than the length of the alphabet tuple (default alphabet has length 62).

\texttt{sage: } R = \text{Zp}(5, \text{print\_mode}='\text{digits}'); \ a = R(70700); \ \text{repr}(a) \\
'...4230300' \\
\texttt{sage: } b = R(-70700); \ \text{repr}(b) \\
'...4444444444440214200' \\
\texttt{Note that it's not possible to read off the precision from the representation in this mode.}

\texttt{print\_max\_terms limits the number of digits that are printed.}

\texttt{sage: } S = \text{Zp}(5, \text{print\_max\_terms}=4); \ S(-70700) \\
2*5^2 + 4*5^3 + 5^4 + 2*5^5 + ... + 0(5^{22}) \\

\texttt{sage: } T = \text{Zp}(5, \text{print\_mode}=\text{'digits'}, \text{print\_alphabet}=('1', '2', '3', '4', '5')); \ _{\text{~repr}}(T(-70700)) \\
'...55555555555555551325311'
show_prec determines how the precision is printed. It can be either 'none' (or equivalently False), 'dots' (or equivalently True) or 'bigoh'. The default is False for the 'floating-point' and 'fixed-mod' types and True for all other types.

```
sage: repr(Zp(5, 2, print_mode='digits', show_prec=True)(6))
'...11'
sage: repr(Zp(5, 2, print_mode='digits', show_prec='bigoh')(6))
'11 + O(5^2)'
```

print_pos, name and print_sep have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, S == T
(False, False, False)
```

5. bars: elements are displayed as a string of base $p$ digits with separators:

```
sage: R = Zp(5, print_mode='bars'); a = R(70700); repr(a)
'...4|2|3|0|3|0|0'
sage: b = R(-70700); repr(b)
'...4|4|4|4|4|4|4|4|4|4|4|4|4|4|4|0|2|1|4|2|0|0'
```

Again, note that it's not possible to read off the precision from the representation in this mode.

print_pos controls whether the digits can be negative.

```
sage: S = Zp(5, print_mode='bars',print_pos=False); b = S(-70700); repr(b)
'...1|0|2|2|-1|2|0|0'
```

print_max_terms limits the number of digits that are printed.

```
sage: T = Zp(5, print_max_terms=4); T(-70700)
2*5^2 + 4*5^3 + 5^4 + 2*5^5 + ... + O(5^22)
```

print_sep controls the separation character.

```
sage: U = Zp(5, print_mode='bars', print_sep='[]'); a = U(70700); repr(a)
'...4[2][3][0][3][0][0]
```

show_prec determines how the precision is printed. It can be either 'none' (or equivalently False), 'dots' (or equivalently True) or 'bigoh'. The default is False for the 'floating-point' and 'fixed-mod' types and True for all other types.

```
sage: repr(Zp(5, 2, print_mode='bars', show_prec=True)(6))
'...1|1'
sage: repr(Zp(5, 2, print_mode='bars', show_prec=False)(6))
'1|1'
```

name and print_alphabet have no effect.

Equality depends on printing options:

```
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```
EXAMPLES:

We allow non-prime $p$, but only if `check = False`. Note that some features will not work.

```
sage: K = Zp(15, check=False); a = K(999); a
9 + 6*15 + 4*15^2 + 0(15^20)
```

We create rings with various parameters:

```
sage: Zp(7)
7-adic Ring with capped relative precision 20
sage: Zp(9)
Traceback (most recent call last):
  ... ValueError: p must be prime
sage: Zp(17, 5)(-1)
16 + 16*17 + 16*17^2 + 16*17^3 + 16*17^4 + 0(17^5)
```

It works even with a fairly huge cap:

```
sage: Zp(next_prime(10^50), 100000)
100000-adic Ring with capped relative precision 100000
```

We create each type of ring:

```
sage: Zp(7, 20, 'capped-rel')
7-adic Ring with capped relative precision 20
sage: Zp(7, 20, 'fixed-mod')
7-adic Ring of fixed modulus 7^20
sage: Zp(7, 20, 'capped-abs')
7-adic Ring with capped absolute precision 20
```

We create a capped relative ring with each print mode:

```
sage: k = Zp(7, 8, print_mode='series'); k
7-adic Ring with capped relative precision 8
sage: k(7*(19))
5*7 + 2*7^2 + 0(7^9)
sage: k(7*(-19))
2*7 + 4*7^2 + 6*7^3 + 6*7^4 + 6*7^5 + 6*7^6 + 6*7^7 + 6*7^8 + 0(7^9)
```

```
sage: k = Zp(7, print_mode='val-unit'); k
7-adic Ring with capped relative precision 20
sage: k(7*(19))
7 * 19 + 0(7^21)
sage: k(7*(-19))
7 * 79792266297611982 + 0(7^21)
```

```
sage: k = Zp(7, print_mode='terse'); k
7-adic Ring with capped relative precision 20
sage: k(7*(19))
```

(continues on next page)
Note that \( p \)-adic rings are cached (via weak references):

```python
sage: a = Zp(7); b = Zp(7)
sage: a is b
True
```

We create some elements in various rings:

```python
sage: R = Zp(5); a = R(4); a
4 + O(5^20)
sage: S = Zp(5, 10, type = 'capped-abs'); b = S(2); b
2 + O(5^10)
sage: a + b
1 + 5 + O(5^10)
```

```
create_key(p, prec=None, type='capped-rel', print_mode=None, names=None, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None, show_prec=None, check=True, label=None)
```

Creates a key from input parameters for \( \mathbb{Z}_p \).

See the documentation for \( \mathbb{Z}_p \) for more information.

```
create_object(version, key)
```

Creates an object using a given key.

See the documentation for \( \mathbb{Z}_p \) for more information.

```
sage.rings.padics.factory.Zq(q, prec=None, type='capped-rel', modulus=None, names=None, print_mode=None, names=None, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_terms=None, show_prec=None, check=True, implementation='FLINT')
```

Given a prime power \( q = p^n \), return the unique unramified extension of \( \mathbb{Z}_p \) of degree \( n \).

INPUT:

- \( q \) – integer, list or tuple: the prime power in \( \mathbb{Q}_q \). Or a factorization object, single element list \([(p, n)]\) where \( p \) is a prime and \( n \) a positive integer, or the pair \((p, n)\).
- \( \text{prec} \) – integer (default: 20) the precision cap of the field. Individual elements keep track of their own precision. See TYPES and PRECISION below.
- \( \text{type} \) – string (default: 'capped-rel') Valid types are 'capped-abs', 'capped-rel', 'fixed-mod', and 'floating-point'. See TYPES and PRECISION below.
- \( \text{modulus} \) – polynomial (default None) A polynomial defining an unramified extension of \( \mathbb{Z}_p \). See MODULUS below.
- \( \text{names} \) – string or tuple (None is only allowed when \( q = p \)). The name of the generator, reducing to a generator of the residue field.
- \( \text{print_mode} \) – string (default: None). Valid modes are 'series', 'val-unit', 'terse', and 'bars'. See PRINTING below.
• \texttt{ram} \_name – string (defaults to string representation of \(p\) if \texttt{None}). \texttt{ram} \_name controls how the prime is printed. See PRINTING below.

• \texttt{res} \_name – string (defaults to \texttt{None}, which corresponds to adding a ‘0’ to the end of the name). Controls how elements of the residue field print.

• \texttt{print} \_pos – bool (default \texttt{None}) Whether to only use positive integers in the representations of elements. See PRINTING below.

• \texttt{print} \_sep – string (default \texttt{None}) The separator character used in the ‘bars’ mode. See PRINTING below.

• \texttt{print} \_max \_ram \_terms – integer (default \texttt{None}) The maximum number of powers of \(p\) shown. See PRINTING below.

• \texttt{print} \_max \_unram \_terms – integer (default \texttt{None}) The maximum number of entries shown in a coefficient of \(p\). See PRINTING below.

• \texttt{print} \_max \_terse \_terms – integer (default \texttt{None}) The maximum number of terms in the polynomial representation of an element (using ‘terse’). See PRINTING below.

• \texttt{show} \_prec – bool (default \texttt{None}) Whether to show the precision for elements. See PRINTING below.

• \texttt{check} – bool (default \texttt{True}) whether to check inputs.

• \texttt{implementation} – string (default \texttt{FLINT}) which implementation to use. \texttt{NTL} is the other option.

OUTPUT:

• The corresponding unramified \(p\)-adic ring.

TYPES AND PRECISION:

There are two types of precision for a \(p\)-adic element. The first is relative precision (default), which gives the number of known \(p\)-adic digits:

\begin{verbatim}
sage: R.<a> = Zq(25, 20, 'capped-rel', print_mode='series'); b = 25^a; b
a*5^2 + O(5^22)
sage: b.precision_relative()
20
\end{verbatim}

The second type of precision is absolute precision, which gives the power of \(p\) that this element is defined modulo:

\begin{verbatim}
sage: b.precision_absolute()
22
\end{verbatim}

There are many types of \(p\)-adic rings: capped relative rings (type='\texttt{capped-rel}'), capped absolute rings (type='\texttt{capped-abs}'), fixed modulus rings (type='\texttt{fixed-mod}'), and floating point rings (type='\texttt{floating-point}').

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.

\begin{verbatim}
sage: R.<a> = Zq(9, 5, 'capped-rel', print_mode='series'); b = (1+2*a)^4; b
2 + (2*a + 2)*3 + (2*a + 1)*3^2 + 0(3^5)
sage: c = R(3249); c
3^2 + 3^4 + 3^5 + 3^6 + O(3^7)
sage: b + c
2 + (2*a + 2)*3 + (2*a + 2)*3^2 + 3^4 + O(3^5)
\end{verbatim}
One can invert non-units: the result is in the fraction field.

```
sage: d = ~(3*b+c); d
2*3^-1 + (a + 1) + (a + 1)*3 + a*3^3 + O(3^4)
sage: d.parent()
3-adic Unramified Extension Field in a defined by x^2 + 2*x + 2
```

The capped absolute case is the same as the capped relative case, except that the cap is on the absolute precision rather than the relative precision.

```
sage: R.<a> = Zq(9, 5, 'capped-abs', print_mode='series'); b = 3^(1+2*a)^4; b
2*3 + (2*a + 2)*3^2 + (2*a + 1)*3^3 + O(3^5)
sage: c = R(3^2); c
3^2 + 3^4 + O(3^5)
sage: b^c
2*3^3 + (2*a + 2)*3^4 + O(3^5)
sage: b^c >> 1
2*3^2 + (2*a + 2)*3^3 + O(3^4)
```

The fixed modulus case is like the capped absolute, except that individual elements don’t track their precision.

```
sage: R.<a> = Zq(9, 5, 'fixed-mod', print_mode='series'); b = 3^(1+2*a)^4; b
2*3 + (2*a + 2)*3^2 + (2*a + 1)*3^3
sage: c = R(3^2); c
3^2 + 3^4
sage: b^c
2*3^3 + (2*a + 2)*3^4
sage: b^c >> 1
2*3^2 + (2*a + 2)*3^3
```

The floating point case is similar to the fixed modulus type in that elements do not track their own precision. However, relative precision is truncated with each operation rather than absolute precision.

**MODULUS:**

The modulus needs to define an unramified extension of \( \mathbb{Z}_p \): when it is reduced to a polynomial over \( \mathbb{F}_p \) it should be irreducible.

The modulus can be given in a number of forms.

1. **A polynomial.**

   The base ring can be \( \mathbb{Z}, \mathbb{Q}, \mathbb{Z}_p, \mathbb{F}_p \), or anything that can be converted to \( \mathbb{Z}_p \).

```
sage: P.<x> = ZZ[]
sage: R.<a> = Zq(27, modulus = x^3 + 2*x + 1); R.modulus()
(1 + O(3^20))*x^3 + O(3^20)*x^2 + (2 + O(3^20))*x + 1 + O(3^20)
sage: P.<x> = QQ[]
sage: S.<a> = Zq(27, modulus = x^3 + 2/7*x + 1)
sage: P.<x> = Zp(3)[]
sage: T.<a> = Zq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = Qp(3)[]
sage: U.<a> = Zq(27, modulus = x^3 + 2*x + 1)
sage: P.<x> = GF(3)[]
sage: V.<a> = Zq(27, modulus = x^3 + 2*x + 1)
```

Which form the modulus is given in has no effect on the unramified extension produced:
unless the modulus is different, or the precision of the modulus differs. In the case of \( V \), the modulus is only given to precision 1, so the resulting field has a precision cap of 1.

```
sage: V.precision_cap()
1
sage: U.precision_cap()
20
sage: modulus = x^3 + (2 + O(3^7))*x + (1 + O(3^10))
sage: modulus
(1 + O(3^20))*x^3 + (2 + O(3^7))*x + 1 + O(3^10)
sage: W.<a> = Zq(27, modulus = modulus); W.precision_cap()
7
```

2. The modulus can also be given as a **symbolic expression**.

```
sage: x = var('x')
sage: X.<a> = Zq(27, modulus = x^3 + 2*x + 1); X.modulus()
(1 + O(3^20))*x^3 + O(3^20)*x^2 + (2 + O(3^20))*x + 1 + O(3^20)
```

By default, the polynomial chosen is the standard lift of the generator chosen for \( F_q \).

```
sage: GF(125, 'a').modulus()
x^3 + 3*x + 3
```

However, you can choose another polynomial if desired (as long as the reduction to \( F_p[\alpha] \) is irreducible).

```
sage: P.<x> = ZZ[]
sage: Z.<a> = Zq(125, modulus = x^3 + 3*x^2 + x + 1); Z.modulus()
(1 + 0(5^20))*x^3 + (3 + 0(5^20))*x^2 + (1 + 0(5^20))*x + 1 + 0(5^20)
```

**PRINTING:**

There are many different ways to print \( p \)-adic elements. The way elements of a given field print is controlled by options passed in at the creation of the field. There are four basic printing modes ("series", "val-unit", "terse" and "bars"; "digits" is not available), as well as various options that either hide some information in the print representation or sometimes make print representations more compact. Note that the printing options affect whether different \( p \)-adic fields are considered equal.

1. **series**: elements are displayed as series in \( p \).

```
sage: R.<a> = Zq(9, 20, 'capped-rel', print_mode='series'); (1+2*a)^4
2 + (2*a + 2)*3 + (2*a + 1)*3^2 + 0(3^20)
```
Continued from previous page:

```
sage: -3*(1+2*a)^4
3 + a*3^2 + 3^3 + (2*a + 2)*3^4 + (2*a + 2)*3^5 + (2*a + 2)*3^6 + (2*a + 2)*3^7 +
→ (2*a + 2)*3^8 + (2*a + 2)*3^9 + (2*a + 2)*3^10 + (2*a + 2)*3^11 + (2*a + 2)*3^12 +
→ (2*a + 2)*3^13 + (2*a + 2)*3^14 + (2*a + 2)*3^15 + (2*a + 2)*3^16 +
→ (2*a + 2)*3^17 + (2*a + 2)*3^18 + (2*a + 2)*3^19 + (2*a + 2)*3^20 + O(3^21)
sage: b = ~(3*a+18); b
(a + 2)*3^-1 + 1 + 2*3 + (a + 1)*3^2 + 3^3 + 2*3^4 + (a + 1)*3^5 + 3^6 + 2*3^7 +
→ (a + 1)*3^8 + 3^9 + 2*3^10 + (a + 1)*3^11 + 3^12 + 2*3^13 + (a + 1)*3^14 +
→ 3^15 + 2*3^16 + (a + 1)*3^17 + 3^18 + O(3^19)
sage: b.parent() is R.fraction_field()
True
```

`print_pos` controls whether negatives can be used in the coefficients of powers of `p`.

```
sage: S.<b> = Zq(9, print_mode='series', print_pos=False); (1+2*b)^4
-1 - b*3 - 3^2 + (b + 1)*3^3 + O(3^20)
sage: -3*(1+2*b)^4
3 + b*3^2 + 3^3 + (-b - 1)*3^4 + O(3^21)
```

`ram_name` controls how the prime is printed.

```
sage: T.<d> = Zq(9, print_mode='series', ram_name='p'); 3*(1+2*d)^4
2*p + (2*d + 2)*p^2 + (2*d + 1)*p^3 + O(p^21)
```

`print_max_ram_terms` limits the number of powers of `p` that appear.

```
sage: U.<e> = Zq(9, print_mode='series', print_max_ram_terms=4); repr(-3*(1+2*e)^4)
'3 + e*3^2 + 3^3 + (2*e + 2)*3^4 + ... + O(3^21)'
```

`print_max_unram_terms` limits the number of terms that appear in a coefficient of a power of `p`.

```
sage: V.<f> = Zq(128, prec=8, print_mode='series', print_max_unram_terms=3); repr((1+f)^9)
'(f^3 + 1) + (f^5 + f^4 + ... + f^2)*2 + (f^6 + f^5 + ... + 1)*2^2 + (f + 1)*2^3 + (f^3 + f^2 + f + 1)*2^4 +
→ (f^6 + f^5 + ... + 1)*2^5 + (f^6 + f^5 + ... + 1)*2^4 + (f + 1)*2^7 + O(2^8)'
sage: V.<f> = Zq(128, prec=8, print_max_unram_terms=2); repr((1+f)^9)
'(f^3 + 1) + (f^5 + f^4 + ... + f^2)*2 + (f^6 + f^5 + ... + 1)*2^2 + (f^5 +
→ f^4 + ... + 1)*2^3 + (f^6 + f^5 + ... + 1)*2^4 + (f^5 + f^4)*2^5 + (f^6 +
→ f^5 + ... + 1)*2^6 + (f + 1)*2^7 + O(2^8)'
sage: V.<f> = Zq(128, prec=8, print_max_unram_terms=1); repr((1+f)^9)
'(f^3 + 1) + (f^5 + ... + f^2)*2 + (f^6 + ... + 1)*2^2 + (f^5 + ... + 1)*2^3 +
→ (f^6 + ... + 1)*2^4 + (f^5 + f^4)*2^5 + (f^6 + ... + 1)*2^6 + (f +
→ 1)*2^7 + O(2^8)'
sage: V.<f> = Zq(128, prec=8, print_max_unram_terms=0); repr((1+f)^9)
'(f^3 + ...) + (f^5 + ...)*2 + (f^6 + ...)*2^2 + (f^5 + ...)*2^3 + (f^6 +
→ ...)2^4 + (f^5 + ...)2^5 + (f^6 + ...)2^6 + (f + ...)*2^7 + O(2^8)'
sage: V.<f> = Zq(128, prec=8, print_max_unram_terms=0); repr((1+f)^9 - 1 - f^3)
```

(continues on next page)
\(p\)-adics, Release 9.6

(continued from previous page)

\[
\cdot \ldots \cdot^2 + (\ldots)^{2^2} + (\ldots)^{2^3} + (\ldots)^{2^4} + (\ldots)^{2^5} + (\ldots)^{2^6} + (\ldots)^{2^7} + O(2^8)\]

\textit{show\_prec} determines how the precision is printed. It can be either ‘none’ (or equivalently False), ‘bigo\_h’ (or equivalently True). The default is False for the ‘floating-point’ and ‘fixed-mod’ types and True for all other types.

\begin{verbatim}
sage: U.<e> = Zq(9, 2, show\_prec=False); repr(-3*(1+2*e)^4) '3 + e*3^2'
\end{verbatim}

\textit{print\_sep} and \textit{print\_max\_terse\_terms} have no effect.

Note that print options affect equality:

\begin{verbatim}
\end{verbatim}

\section{val\_unit} elements are displayed as \(p^k u\):

\begin{verbatim}
sage: R.<a> = Zq(9, 7, print\_mode='val\_unit'); b = (1+3*a)^9 - 1; b 3^3 * (15 + 64*a) + O(3^7)
sage: ~b 3^-3 * (41 + a) + O(3)
\end{verbatim}

\textit{print\_pos} controls whether to use a balanced representation or not.

\begin{verbatim}
sage: S.<a> = Zq(9, 7, print\_mode='val\_unit', print\_pos=False); b = (1+3*a)^9 - 1; b 3^3 * (15 - 17*a) + O(3^7)
sage: ~b 3^-3 * (-40 + a) + O(3)
\end{verbatim}

\textit{ram\_name} affects how the prime is printed.

\begin{verbatim}
sage: A.<x> = Zp(next\_prime(10^6), print\_mode='val\_unit')[]
sage: T.<a> = Zq(next\_prime(10^6)^3, 4, print\_mode='val\_unit', ram\_name='p', modulus=x^3+385831*x^2+106556*x+321036); b = (next\_prime(10^6)^2*(a^2 + \ldots a - 4)^4); b p^2 * (8799618711883757387483 + 246348888344392418464080*a + \ldots -1353538653775332610349*a^2) + O(p^6)
sage: b * (a^2 + a - 4)^-4 p^2 * 1 + O(p^6)
\end{verbatim}

\textit{print\_max\_terse\_terms} controls how many terms of the polynomial appear in the unit part.

\begin{verbatim}
sage: U.<a> = Zq(17^4, 6, print\_mode='val\_unit', print\_max\_terse\_terms=3); \ldots b = (17*(a^3-a+14)^6); b 17 * (12131797 + 12076378*a + 10809706*a^2 + \ldots) + O(17^7)
\end{verbatim}

\textit{show\_prec} determines how the precision is printed. It can be either ‘none’ (or equivalently False), ‘bigo\_h’ (or equivalently True). The default is False for the ‘floating-point’ and ‘fixed-mod’ types and True for all other types.
\texttt{sage:} U.<e> = Zq(9, 2, print_mode='val-unit', show_prec=False); repr(-\rightarrow 3*(1+2*e)^4)
'3 * (1 + 3*e)'

\textit{print_sep, print_max_ram_terms and print_max_unram_terms} have no effect.

Equality again depends on the printing options:

\texttt{sage:} R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)

3. \textbf{terse}: elements are displayed as a polynomial of degree less than the degree of the extension.

\texttt{sage:} R.<a> = Zq(125, print_mode='terse')
\texttt{sage:} (a+5)^177
68210977979428 + 90313850704069*a + 73948093055069*a^2 + O(5^20)
\texttt{sage:} (a/5+1)^177
68210977979428/5^177 + 90313850704069/5^177*a + 73948093055069/5^177*a^2 + O(5^-157)

Note that in this last computation, you get one fewer \( p \)-adic digit than one might expect. This is because \( R \) is capped absolute, and thus 5 is cast in with relative precision 19.

As of version 3.3, if coefficients of the polynomial are non-integral, they are always printed with an explicit power of \( p \) in the denominator.

\texttt{sage:} 5*a + a^2/25
5*a + 1/5^2*a^2 + O(5^18)

\textit{print_pos} controls whether to use a balanced representation or not.

\texttt{sage:} (a-5)^6
22864 + 95367431627998*a + 8349*a^2 + 0(5^20)
\texttt{sage:} S.<a> = Zq(125, print_mode='terse', print_pos=False); b = (a-5)^6; b
22864 - 12627*a + 8349*a^2 + 0(5^20)
\texttt{sage:} (a - 1/5)^6
-20624/5^6 + 18369/5^5*a + 1353/5^3*a^2 + O(5^14)

\textit{ram_name} affects how the prime is printed.

\texttt{sage:} T.<a> = Zq(125, print_mode='terse', ram_name='p'); (a - 1/5)^6
95367431620001/p^6 + 18369/p^5*a + 1353/p^3*a^2 + O(p^14)

\textit{print_max_terse_terms} controls how many terms of the polynomial are shown.

\texttt{sage:} U.<a> = Zq(625, print_mode='terse', print_max_terse_terms=2); (a-1/5)^6
106251/5^6 + 49994/5^5*a + ... + O(5^14)

\textit{show_prec} determines how the precision is printed. It can be either 'none' (or equivalently False), 'bigoh' (or equivalently True). The default is False for the 'floating-point' and 'fixed-mod' types and True for all other types.
\textbf{print\_sep, print\_max\_ram\_terms and print\_max\_unram\_terms} have no effect.

Equality again depends on the printing options:

\begin{verbatim}
sage: R == S, R == U, S == T, S == U, T == U
(False, False, False, False, False)
\end{verbatim}

4. \textbf{digits}: This print mode is not available when the residue field is not prime. It might make sense to have a dictionary for small fields, but this isn’t implemented.

5. \textbf{bars}: elements are displayed in a similar fashion to series, but more compactly.

\begin{verbatim}
sage: R.<a> = Zq(125); (a+5)^6
(4*a^2 + 3*a + 4) + (3*a^2 + 2*a)*5 + (a^2 + a + 1)*5^2 + (3*a + 2)*5^3 + (3*a^2 + 3*a + 2)*5^4 + (2*a^2 + 3*a + 2)*5^5 + O(5^20)
\end{verbatim}

Note that it’s not possible to read off the precision from the representation in this mode.

\begin{verbatim}
sage: S.<a> = Zq(125, print\_mode='bars', print\_pos=False); repr((a-1/5)^6)
'...[0, 1, 2]|[-1, 1, 1]|[-2, 1, 1]|[-2, 1, -2]|[0, 0, -2]|[0, -1]|[0, 0, -1]|[-2]|[-1]'
\end{verbatim}

\textbf{print\_pos} controls whether the digits can be negative.

\begin{verbatim}
sage: S.<a> = Zq(125, print\_mode='bars', print\_pos=False); repr((a-5)^6)
'...[1, -1, 1]|[-1, 1, -2]|[-2, 1, -2]|[0, 0, 1]|[-2]|[-1, -2, -1]'
\end{verbatim}

\textbf{print\_max\_ram\_terms} controls the maximum number of “digits” shown. Note that this puts a cap on the relative precision, not the absolute precision.

\begin{verbatim}
sage: T.<a> = Zq(125, print\_max\_ram\_terms=3, print\_pos=False); (a-5)^6
(-a^2 - 2*a - 1) - 2*5 - a^2*5^2 + ... + 0(5^20)
\end{verbatim}

\begin{verbatim}
sage: 5*(a-5)^6 + 50
(-a^2 - 2*a - 1)*5 - a^2*5^3 + (2*a^2 - a - 2)*5^4 + ... + 0(5^21)
\end{verbatim}

\begin{verbatim}
sage: (a-1/5)^6
5^6 - a*5^5 - a*5^4 + ... + 0(5^14)
\end{verbatim}
print_mode controls the separating character ('|' by default).

```python
sage: U.<a> = Zq(625, print_mode='bars', print_sep=''); b = (a+5)^6; repr(b)
'...[0, 1][4, 0, 2][3, 2, 2, 3][4, 2, 2, 4][0, 3][1, 1, 3][3, 1, 4, 1]'
```

print_max_unram_terms controls how many terms are shown in each 'digit':

```python
sage: with local_print_mode(U, {'max_unram_terms': 3}): repr(b)
'...[0, 1][4,..., 0, 2][3,..., 2, 3][4,..., 2, 4][0, 3][1,..., 1, 3][3,...,..., 4, 1]'
```

show_prec determines how the precision is printed. It can be either 'none' (or equivalently False), 'dots' (or equivalently True) or 'bigoh'. The default is False for the 'floating-point' and 'fixed-mod' types and True for all other types.

```python
sage: with local_print_mode(U, {'max_unram_terms': 2}): repr(b)
'...[0, 1][4,..., 2][3,..., 3][4,..., 4][0, 3][1,..., 3][3,..., 1]'
```

ram_name and print_max_terse_terms have no effect.

Equality depends on printing options:

```python
sage: R == S, R == T, R == U, S == T, S == U, T == U
(False, False, False, False, False, False)
```

EXAMPLES:

Unlike for $\mathbb{Z}_p$, you can’t create $\mathbb{Z}_q(N)$ when $N$ is not a prime power.

However, you can use check=False to pass in a pair in order to not have to factor. If you do so, you need to use names explicitly rather than the $R.<a>$ syntax.

```python
sage: p = next_prime(2^123)
sage: k = Zp(p)
sage: R.<x> = k[]
sage: K = Zq([([p, 5]), modulus=x^5+x+4, names='a', ram_name='p', print_pos=False, ...
˓→check=False)
sage: K.0^5
(-a - 4) + O(p^20)
```

In tests on sage.math, the creation of $K$ as above took an average of 1.58ms, while:

```python
sage: K = Zq(p^5, modulus=x^5+x+4, names='a', ram_name='p', print_pos=False, ...
˓→check=True)
```

took an average of 24.5ms. Of course, with smaller primes these savings disappear.

sage.rings.padics.factory.ZqCA(q, prec=None, *args, **kwds)
A shortcut function to create capped absolute unramified $p$-adic rings.
See documentation for \texttt{Zq()} for a description of the input parameters.

**EXAMPLES:**

```python
sage: R.<a> = ZqCA(25, 40); R
5-adic Unramified Extension Ring in a defined by \(x^2 + 4\times + 2\)
```

\texttt{sage.rings.padics.factory.ZqCR}(\texttt{q}, \texttt{prec=None}, \texttt{*args}, \texttt{**kwds})

A shortcut function to create capped relative unramified \(p\)-adic rings.

Same functionality as \texttt{Zq}. See documentation for \texttt{Zq} for a description of the input parameters.

**EXAMPLES:**

```python
sage: R.<a> = ZqCR(25, 40); R
5-adic Unramified Extension Ring in a defined by \(x^2 + 4\times + 2\)
```

\texttt{sage.rings.padics.factory.ZqFM}(\texttt{q}, \texttt{prec=None}, \texttt{*args}, \texttt{**kwds})

A shortcut function to create fixed modulus unramified \(p\)-adic rings.

See documentation for \texttt{Zq()} for a description of the input parameters.

**EXAMPLES:**

```python
sage: R.<a> = ZqFM(25, 40); R
5-adic Unramified Extension Ring in a defined by \(x^2 + 4\times + 2\)
```

\texttt{sage.rings.padics.factory.ZqFP}(\texttt{q}, \texttt{prec=None}, \texttt{*args}, \texttt{**kwds})

A shortcut function to create floating point unramified \(p\)-adic rings.

Same functionality as \texttt{Zq}. See documentation for \texttt{Zq} for a description of the input parameters.

**EXAMPLES:**

```python
sage: R.<a> = ZqFP(25, 40); R
5-adic Unramified Extension Ring in a defined by \(x^2 + 4\times + 2\)
```

\texttt{sage.rings.padics.factory.get_key_base}(\texttt{p}, \texttt{prec}, \texttt{type}, \texttt{print_mode}, \texttt{names}, \texttt{ram_name}, \texttt{print_pos}, \texttt{print_sep}, \texttt{print_alphabet}, \texttt{print_max_terms}, \texttt{show_prec}, \texttt{check}, \texttt{valid_types}, \texttt{label=None})

This implements create_key for \texttt{Zp} and \texttt{Qp}: moving it here prevents code duplication.

It fills in unspecified values and checks for contradictions in the input. It also standardizes irrelevant options so that duplicate parents are not created.

**EXAMPLES:**

```python
sage: from sage.rings.padics.factory import get_key_base
generate: get_key_base(11, 5, 'capped-rel', None, None, None, None, ':', None, None,
˓→False, True, ['capped-rel'])
(11, 5, 'capped-rel', 'series', '11', True, ':', (), -1, 'None', None)
```
sage.rings.padics.factory.\texttt{is\_eisenstein}(\textit{poly})

Returns True iff this monic polynomial is Eisenstein.

A polynomial is Eisenstein if it is monic, the constant term has valuation 1 and all other terms have positive valuation.

EXAMPLES:

```python
sage: R = \text{Zp}(5)
sage: S.<x> = R[]
sage: from sage.rings.padics.factory import \texttt{is\_eisenstein}
sage: f = x^4 - 75*x + 15
sage: is\_eisenstein(f)
True
sage: g = x^4 + 75
sage: is\_eisenstein(g)
False
sage: h = x^7 + 27*x - 15
sage: is\_eisenstein(h)
False
```

sage.rings.padics.factory.\texttt{is\_unramified}(\textit{poly})

Returns true iff this monic polynomial is unramified.

A polynomial is unramified if its reduction modulo the maximal ideal is irreducible.

EXAMPLES:

```python
sage: R = \text{Zp}(5)
sage: S.<x> = R[]
sage: from sage.rings.padics.factory import \texttt{is\_unramified}
sage: f = x^4 + 14*x + 9
sage: is\_unramified(f)
True
sage: g = x^6 + 17*x + 6
sage: is\_unramified(g)
False
```

sage.rings.padics.factory.\texttt{krasner\_check}(\textit{poly}, \textit{prec})

Returns True iff \textit{poly} determines a unique isomorphism class of extensions at precision \textit{prec}.

Currently just returns True (thus allowing extensions that are not defined to high enough precision in order to specify them up to isomorphism). This will change in the future.

EXAMPLES:

```python
sage: from sage.rings.padics.factory import krasner\_check
sage: krasner\_check(1, 2) \#this is a stupid example.
True
```
class sage.rings.padics.factory.pAdicExtension_class
Bases: sage.structure.factory.UniqueFactory

A class for creating extensions of $p$-adic rings and fields.

EXAMPLES:

```python
sage: R = Zp(5, 3)
sage: S.<x> = ZZ[]
sage: W.<w> = pAdicExtension(R, x^4-15)
sage: W
5-adic Eisenstein Extension Ring in w defined by x^4 - 15
sage: W.precision_cap()
12
```

create_key_and_extra_args(base, modulus, prec=None, print_mode=None, names=None, var_name=None, res_name=None, unram_name=None, ram_name=None, print_pos=None, print_sep=None, print_alphabet=None, print_max_ram_terms=None, print_max_unram_terms=None, print_max_terse_terms=None, show_prec=None, check=True, unram=False, implementation='FLINT')

Creates a key from input parameters for pAdicExtension.

See the documentation for Qq for more information.

create_object(version, key, approx_modulus=None, shift_seed=None)

Creates an object using a given key.

See the documentation for pAdicExtension for more information.

sage.rings.padics.factory.split(poly, prec)

Given a polynomial poly and a desired precision prec, computes upoly and epoly so that the extension defined by poly is isomorphic to the extension defined by first taking an extension by the unramified polynomial upoly, and then an extension by the Eisenstein polynomial epoly.

We need better $p$-adic factoring in Sage before this function can be implemented.

EXAMPLES:

```python
sage: k = Qp(13)
sage: x = polygen(k)
sage: f = x^2+1
sage: from sage.rings.padics.factory import split

Traceback (most recent call last):
  ... Not Implemented Error: Extensions by general polynomials not yet supported. Please use an unramified or Eisenstein polynomial.
```

sage.rings.padics.factory.truncate_to_prec(poly, R, absprec)

Truncates the unused precision off of a polynomial.

EXAMPLES:

```python
sage: R = Zp(5)
sage: S.<x> = R[]
sage: from sage.rings.padics.factory import truncate_to_prec
sage: f = x^4 + (3+O(5^6))*x^3 + O(5^4)
```

```python
sage: truncate_to_prec(f, R, 5)
(1 + O(5^5))*x^4 + (3 + O(5^5))*x^3 + O(5^5)*x^2 + O(5^5)*x + O(5^4)
```
LOCAL GENERIC

Superclass for \(p\)-adic and power series rings.

AUTHORS:

- David Roe

```python
class sage.rings.padics.local_generic.LocalGeneric(base, prec, names, element_class, category=None):
    Bases: sage.rings.ring.CommutativeRing
    Initialize self.
    EXAMPLES:

    sage: R = Zp(5)  # indirect doctest
    sage: R.precision_cap()  
    20
```

In trac ticket #14084, the category framework has been implemented for \(p\)-adic rings:

```python
sage: TestSuite(R).run()
sage: K = Qp(7)
sage: TestSuite(K).run()
```

**absolute_degree()**

Return the degree of this extension over the prime \(p\)-adic field/ring.

EXAMPLES:

```python
sage: K.<a> = Qq(3^5)
sage: K.absolute_degree()  
5
```

```python
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.absolute_degree()  
2
```

**absolute_e()**

Return the absolute ramification index of this ring/field.

EXAMPLES:

```python
sage: K.<a> = Qq(3^5)
sage: K.absolute_e()  
```

(continues on next page)
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.absolute_e()

absolute_f()
Return the degree of the residue field of this ring/field over its prime subfield.

EXAMPLES:

sage: K.<a> = Qq(3^5)
sage: K.absolute_f()
5

sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.absolute_f()
1

absolute_inertia_degree()
Return the degree of the residue field of this ring/field over its prime subfield.

EXAMPLES:

sage: K.<a> = Qq(3^5)
sage: K.absolute_inertia_degree()
5

sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.absolute_inertia_degree()
1

absolute_ramification_index()
Return the absolute ramification index of this ring/field.

EXAMPLES:

sage: K.<a> = Qq(3^5)
sage: K.absolute_ramification_index()
1

sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.absolute_ramification_index()
2

change(**kwds)
Return a new ring with changed attributes.

INPUT:

The following arguments are applied to every ring in the tower:

- type – string, the precision type
- p – the prime of the ground ring. Defining polynomials will be converted to the new base rings.
- print_mode – string
• print_pos – bool
• print_sep – string
• print_alphabet – dict
• show_prec – bool
• check – bool
• label – string (only for lattice precision)

The following arguments are only applied to the top ring in the tower:
• var_name – string
• res_name – string
• unram_name – string
• ram_name – string
• names – string
• modulus – polynomial

The following arguments have special behavior:
• prec – integer. If the precision is increased on an extension ring, the precision on the base is increased as necessary (respecting ramification). If the precision is decreased, the precision of the base is unchanged.
• field – bool. If True, switch to a tower of fields via the fraction field. If False, switch to a tower of rings of integers.
• q – prime power. Replace the initial unramified extension of \( \mathbb{Q}_p \) or \( \mathbb{Z}_p \) with an unramified extension of residue cardinality \( q \). If the initial extension is ramified, add in an unramified extension.
• base – ring or field. Use a specific base ring instead of recursively calling change() down the tower.

See the constructors for more details on the meaning of these arguments.

EXAMPLES:

We can use this method to change the precision:

```
sage: Zp(5).change(prec=40)
5-adic Ring with capped relative precision 40
```

or the precision type:

```
sage: Zp(5).change(type="capped-abs")
5-adic Ring with capped absolute precision 20
```

or even the prime:

```
sage: ZpCA(3).change(p=17)
17-adic Ring with capped absolute precision 20
```

You can switch between the ring of integers and its fraction field:

```
sage: ZpCA(3).change(field=True)
3-adic Field with capped relative precision 20
```
You can also change print modes:

```
sage: R = Zp(5).change(prec=5, print_mode='digits')
sage: repr(~R(17))
'...13403'
```

Changing print mode to ‘digits’ works for Eisenstein extensions:

```
sage: S.<x> = ZZ[]
sage: W.<w> = Zp(3).extension(x^4 + 9*x^2 + 3*x - 3)
sage: W.print_mode()
'series'
sage: W.change(print_mode='digits').print_mode()
'digits'
```

You can change extensions:

```
sage: K.<a> = QqFP(125, prec=4)
sage: K.change(q=64)
2-adic Unramified Extension Field in a defined by x^6 + x^4 + x^3 + x + 1
sage: R.<x> = QQ[]
sage: K.change(modulus = x^2 - x + 2, print_pos=False)
5-adic Unramified Extension Field in a defined by x^2 - x + 2
```

and variable names:

```
sage: K.change(names='b')
5-adic Unramified Extension Field in b defined by x^3 + 3*x + 3
```

and precision:

```
sage: Kup = K.change(prec=8); Kup
5-adic Unramified Extension Field in a defined by x^3 + 3*x + 3
sage: Kup.precision_cap()
8
sage: Kup.base_ring()
5-adic Field with floating precision 8
```

If you decrease the precision, the precision of the base stays the same:

```
sage: Kdown = K.change(prec=2); Kdown
5-adic Unramified Extension Field in a defined by x^3 + 3*x + 3
sage: Kdown.precision_cap()
2
sage: Kdown.base_ring()
5-adic Field with floating precision 4
```

Changing the prime works for extensions:

```
sage: x = polygen(ZZ)
sage: R.<a> = Zp(5).extension(x^2 + 2)
sage: S = R.change(p=7)
sage: S.defining_polynomial(exact=True)
x^2 + 2
sage: A.<y> = Zp(5)[]
```

(continues on next page)
sage: R.<a> = Zp(5).extension(y^2 + 2)
sage: S = R.change(p=7)
sage: S.defining_polynomial(exact=True)
y^2 + 2

sage: R.<a> = Zq(5^3)
sage: S = R.change(prec=50)
sage: S.defining_polynomial(exact=True)
x^3 + 3*x + 3

Changing label for lattice precision (the precision lattice is not copied):

sage: R = ZpLC(37, (8,11))
sage: S = R.change(label = "change"); S
37-adic Ring with lattice-cap precision (label: change)
sage: S.change(label = "new")
37-adic Ring with lattice-cap precision (label: new)

defining_polynomial(var='x', exact=False)
Return the defining polynomial of this local ring

INPUT:
- var – string (default: 'x'), the name of the variable
- exact – a boolean (default: False), whether to return the underlying exact defining polynomial rather than the one with coefficients in the base ring.

OUTPUT:
The defining polynomial of this ring as an extension over its ground ring

EXAMPLES:

sage: R = Zp(3, 3, 'fixed-mod')
sage: R.defining_polynomial().parent()
Univariate Polynomial Ring in x over 3-adic Ring of fixed modulus 3^3
sage: R.defining_polynomial('foo')
foo
sage: R.defining_polynomial(exact=True).parent()
Univariate Polynomial Ring in x over Integer Ring

degree()
Return the degree of this extension.
Raise an error if the base ring/field is itself an extension.

EXAMPLES:

sage: K.<a> = Qq(3^5)
sage: K.degree()
5
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.degree()
2

\texttt{e()}  
Return the ramification index of this extension.  
Raise an error if the base ring/field is itself an extension.  
EXAMPLES:

\begin{verbatim}
sage: K.<a> = Qq(3^5)
sage: K.e()
1
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.e()
2
\end{verbatim}

\texttt{ext(*args, **kwds)}  
Construct an extension of self. See \texttt{extension()} for more details.  
EXAMPLES:

\begin{verbatim}
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.uniformiser()
t + O(t^21)
\end{verbatim}

\texttt{f()}  
Return the degree of the residual extension.  
Raise an error if the base ring/field is itself an extension.  
EXAMPLES:

\begin{verbatim}
sage: K.<a> = Qq(3^5)
sage: K.f()
5
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.f()
1
\end{verbatim}

\texttt{ground_ring()}  
Return \texttt{self}.  
Will be overridden by extensions.  
INPUT:  
• \texttt{self} – a local ring  
OUTPUT:  
The ground ring of \texttt{self}, i.e., itself.  
EXAMPLES:
sage: R = Zp(3, 5, 'fixed-mod')
sage: S = Zp(3, 4, 'fixed-mod')
sage: R.ground_ring() is R
True
sage: S.ground_ring() is R
False

ground_ring_of_tower()
Return self.
Will be overridden by extensions.

INPUT:

• self – a $p$-adic ring

OUTPUT:
The ground ring of the tower for self, i.e., itself.

EXAMPLES:

sage: R = Zp(5)
sage: R.ground_ring_of_tower()
5-adic Ring with capped relative precision 20

inertia_degree()
Return the degree of the residual extension.
Raise an error if the base ring/field is itself an extension.

EXAMPLES:

sage: K.<a> = Qq(3^5)
sage: K.inertia_degree()
5
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.inertia_degree()
1

inertia_subring()
Return the inertia subring, i.e. self.

INPUT:

• self – a local ring

OUTPUT:

• the inertia subring of self, i.e., itself

EXAMPLES:

sage: R = Zp(5)
sage: R.inertia_subring()
5-adic Ring with capped relative precision 20

is_capped_absolute()
Return whether this $p$-adic ring bounds precision in a capped absolute fashion.
The absolute precision of an element is the power of \( p \) modulo which that element is defined. In a capped absolute ring, the absolute precision of elements are bounded by a constant depending on the ring.

EXAMPLES:

```python
sage: R = ZpCA(5, 15)
sage: R.is_capped_absolute()
True
sage: R(5^7)
5^7 + O(5^15)
sage: S = Zp(5, 15)
sage: S.is_capped_absolute()
False
sage: S(5^7)
5^7 + O(5^22)
```

**is_capped_relative()**

Return whether this \( p \)-adic ring bounds precision in a capped relative fashion.

The relative precision of an element is the power of \( p \) modulo which the unit part of that element is defined. In a capped relative ring, the relative precision of elements are bounded by a constant depending on the ring.

EXAMPLES:

```python
sage: R = ZpCA(5, 15)
sage: R.is_capped_relative()
False
sage: R(5^7)
5^7 + O(5^15)
sage: S = Zp(5, 15)
sage: S.is_capped_relative()
True
sage: S(5^7)
5^7 + O(5^22)
```

**is_exact()**

Return whether this \( p \)-adic ring is exact, i.e. \( False \).

EXAMPLES:

```python
sage: R = Zp(5, 3, 'fixed-mod'); R.is_exact()
False
```

**is_fixed_mod()**

Return whether this \( p \)-adic ring bounds precision in a fixed modulus fashion.

The absolute precision of an element is the power of \( p \) modulo which that element is defined. In a fixed modulus ring, the absolute precision of every element is defined to be the precision cap of the parent. This means that some operations, such as division by \( p \), don’t return a well defined answer.

EXAMPLES:

```python
sage: R = ZpFM(5,15)
sage: R.is_fixed_mod()
True
sage: R(5^7,absprec=9)
```

(continues on next page)
5^7
sage: S = ZpCA(5, 15)
sage: S.is_fixed_mod()
False
sage: S(5^7, absprec=9)
5^7 + O(5^9)

is_floating_point()
Return whether this $p$-adic ring bounds precision in a floating point fashion.

The relative precision of an element is the power of $p$ modulo which the unit part of that element is defined. In a floating point ring, elements do not store precision, but arithmetic operations truncate to a relative precision depending on the ring.

EXAMPLES:

```
sage: R = ZpCR(5, 15)
sage: R.is_floating_point()
False
sage: R(5^7)
5^7 + O(5^22)
sage: S = ZpFP(5, 15)
sage: S.is_floating_point()
True
sage: S(5^7)
5^7
```

is_lattice_prec()
Return whether this $p$-adic ring bounds precision using a lattice model.

In lattice precision, relationships between elements are stored in a precision object of the parent, which allows for optimal precision tracking at the cost of increased memory usage and runtime.

EXAMPLES:

```
sage: R = ZpCR(5, 15)
sage: R.is_lattice_prec()
False
sage: x = R(25, 8)
sage: x - x
O(5^8)
sage: S = ZpLC(5, 15)
doctest:...: FutureWarning: This class/method/function is marked as experimental. It, its functionality or its interface might change without a formal deprecation.
See http://trac.sagemath.org/23505 for details.
sage: S.is_lattice_prec()
True
sage: x = S(25, 8)
sage: x - x
O(5^30)
```

is_relaxed()
Return whether this $p$-adic ring bounds precision in a relaxed fashion.

In a relaxed ring, elements have mechanisms for computing themselves to greater precision.
EXAMPLES:

```python
sage: R = Zp(5)
sage: R.is_relaxed()
False
```

**maximal_unramified_subextension()**

Return the maximal unramified subextension.

INPUT:

- `self` – a local ring

OUTPUT:

- the maximal unramified subextension of `self`

EXAMPLES:

```python
sage: R = Zp(5)
sage: R.maximal_unramified_subextension()
5-adic Ring with capped relative precision 20
```

**precision_cap()**

Return the precision cap for this ring.

EXAMPLES:

```python
sage: R = Zp(3, 10, 'fixed-mod'); R.precision_cap()
10
sage: R = Zp(3, 10, 'capped-rel'); R.precision_cap()
10
sage: R = Zp(3, 10, 'capped-abs'); R.precision_cap()
10
```

**Note:** This will have different meanings depending on the type of local ring. For fixed modulus rings, all elements are considered modulo `self.prime()` * `self.precision_cap()`. For rings with an absolute cap (i.e. the class `pAdicRingCappedAbsolute`), each element has a precision that is tracked and is bounded above by `self.precision_cap()`. Rings with relative caps (e.g. the class `pAdicRingCappedRelative`) are the same except that the precision is the precision of the unit part of each element.

**ramification_index()**

Return the ramification index of this extension.

Raise an error if the base ring/field is itself an extension.

EXAMPLES:

```python
sage: K.<a> = Qq(3^5)
sage: K.ramification_index()
1

sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.ramification_index()
2
```
relative_degree()
Return the degree of this extension over its base field/ring.

EXAMPLES:

```
sage: K.<a> = Qq(3^5)
sage: K.relative_degree()
5
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.relative_degree()
2
```

relative_e()
Return the ramification index of this extension over its base ring/field.

EXAMPLES:

```
sage: K.<a> = Qq(3^5)
sage: K.relative_e()
1
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.relative_e()
2
```

relative_f()
Return the degree of the residual extension over its base ring/field.

EXAMPLES:

```
sage: K.<a> = Qq(3^5)
sage: K.relative_f()
5
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.relative_f()
1
```

relative_inertia_degree()
Return the degree of the residual extension over its base ring/field.

EXAMPLES:

```
sage: K.<a> = Qq(3^5)
sage: K.relative_inertia_degree()
5
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.relative_inertia_degree()
1
```

relative_ramification_index()
Return the ramification index of this extension over its base ring/field.

EXAMPLES:
```python
sage: K.<a> = Qq(3^5)
sage: K.relative_ramification_index()
1

sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.relative_ramification_index()
2
```

**residue_characteristic()**

Return the characteristic of self’s residue field.

**INPUT:**

- `self` – a p-adic ring.

**OUTPUT:**

The characteristic of the residue field.

**EXAMPLES:**

```python
sage: R = Zp(3, 5, 'capped-rel'); R.residue_characteristic()
3
```

**uniformiser()**

Return a uniformiser for self, i.e., a generator for the unique maximal ideal.

**EXAMPLES:**

```python
sage: R = Zp(5)
sage: R.uniformiser()
5 + O(5^21)
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.uniformiser()
t + O(t^21)
```

**uniformiser_pow(n)**

Return the \( n \) (as an element of self).

**EXAMPLES:**

```python
sage: R = Zp(5)
sage: R.uniformiser_pow(5)
5^5 + O(5^25)
```
A generic superclass for all p-adic parents.

AUTHORS:

- David Roe
- Genya Zaytman: documentation

- Julian Rueth (2013-03-16): test methods for basic arithmetic

```python
class sage.rings.padics.padic_generic.ResidueLiftingMap
    Bases: sage.categories.morphism.Morphism

Lifting map to a p-adic ring or field from its residue field or ring.
These maps must be created using the `_create_()` method in order to support categories correctly.

EXAMPLES:

```python
sage: from sage.rings.padics.padic_generic import ResidueLiftingMap
sage: R.<a> = Zq(125); k = R.residue_field()
sage: f = ResidueLiftingMap._create_(k, R); f
Lifting morphism:
  From: Finite Field in a0 of size 5^3
  To: 5-adic Unramified Extension Ring in a defined by x^3 + 3*x + 3
```

```python
class sage.rings.padics.padic_generic.ResidueReductionMap
    Bases: sage.categories.morphism.Morphism

Reduction map from a p-adic ring or field to its residue field or ring.
These maps must be created using the `_create_()` method in order to support categories correctly.

EXAMPLES:

```python
sage: from sage.rings.padics.padic_generic import ResidueReductionMap
sage: R.<a> = Zq(125); k = R.residue_field()
sage: f = ResidueReductionMap._create_(R, k); f
Reduction morphism:
  From: 5-adic Unramified Extension Ring in a defined by x^3 + 3*x + 3
  To: Finite Field in a0 of size 5^3
```

```python
is_injective()
    The reduction map is far from injective.

EXAMPLES:
```
is_injective()

The reduction map is surjective.

EXAMPLES:

```python
sage: GF(5).convert_map_from(ZpCA(5)).is_injective()
False
```

is_surjective()

The reduction map is surjective.

```python
sage: GF(7).convert_map_from(Qp(7)).is_surjective()
True
```

section()

Return the section from the residue ring or field back to the p-adic ring or field.

EXAMPLES:

```python
sage: GF(3).convert_map_from(Zp(3)).section()
Lifting morphism:
  From: Finite Field of size 3
  To:  3-adic Ring with capped relative precision 20
```

sage.rings.padics.padic_generic.local_print_mode(obj, print_options, pos=None, ram_name=None)

Context manager for safely temporarily changing the print_mode of a p-adic ring/field.

EXAMPLES:

```python
sage: R = Zp(5)
sage: R(45)
4*5 + 5^2 + O(5^21)
sage: with local_print_mode(R, 'val-unit'):
    print(R(45))
5 * 9 + O(5^21)
```

Note: For more documentation see sage.structure.parent_gens.localvars.

class sage.rings.padics.padic_generic.pAdicGeneric(base, p, prec, print_mode, names, element_class, category=None)

Bases: sage.rings.ring.PrincipalIdealDomain, sage.rings.padics.local_generic.LocalGeneric

Initialize self.

INPUT:

- base – base ring
- p – prime
- print_mode – dictionary of print options
- names – how to print the uniformizer
- element_class – the class for elements of this ring

EXAMPLES:

```python
sage: R = Zp(17)  # indirect doctest
```
characteristic()

Return the characteristic of self, which is always 0.

EXAMPLES:

```
sage: R = Zp(3, 10, 'fixed-mod'); R.characteristic()
0
```
**frobenius_endomorphism**\((n=1)\)
Return the \(n\)-th power of the absolute arithmetic Frobenius endomorphism on this field.

**INPUT:**
- \(n\) – an integer (default: 1)

**EXAMPLES:**
```
sage: K.<a> = Qq(3^5)
sage: Frob = K.frobenius_endomorphism(); Frob
Frobenius endomorphism on 3-adic Unramified Extension
... lifting a |--> a^3 on the residue field
sage: Frob(a) == a.frobenius()
True
```
We can specify a power:
```
sage: K.frobenius_endomorphism(2)
Frobenius endomorphism on 3-adic Unramified Extension
... lifting a |--> a^(3^2) on the residue field
```
The result is simplified if possible:
```
sage: K.frobenius_endomorphism(6)
Frobenius endomorphism on 3-adic Unramified Extension
... lifting a |--> a^3 on the residue field
```
Comparisons work:
```
sage: K.frobenius_endomorphism(6) == Frob
True
```
**gens()**
Return a list of generators.

**EXAMPLES:**
```
sage: R = Zp(5); R.gens()
[5 + O(5^21)]
sage: Zq(25,names='a').gens()
[a + O(5^20)]
sage: S.<x> = ZZ[]; f = x^5 + 25*x -5; W.<w> = R.ext(f); W.gens()
[w + O(w^101)]
```
**integer_ring\((print_mode=None)\)**
Return the ring of integers of this ring or field.

For \(\mathbb{Q}_p\), this is the \(p\)-adic ring with the same options, and for extensions, it is just the extension of the ring of integers of the base determined by the same polynomial.

**INPUT:**
- \(print_mode\) – (optional) a dictionary containing print options; defaults to the same options as this ring

**OUTPUT:**
• the ring of elements of this field with nonnegative valuation

EXAMPLES:

```python
sage: K = Qp(5, print_mode='digits', show_prec=False)
sage: R = K.integer_ring(); R(1/3)
31313131313131313132
doctest:warning
...
DeprecationWarning: Use the change method if you want to change print options...
˓→in integer_ring()
See http://trac.sagemath.org/23227 for details.
3132
sage: U.<a> = Qq(17^4, 6, print_mode='val-unit', print_max_terse_terms=3)
sage: U.integer_ring()
17-adic Unramified Extension Ring in a defined by x^4 + 7*x^2 + 10*x + 3
doctest:warning
...
DeprecationWarning: Use the change method if you want to change print options...
˓→in fraction_field()
See http://trac.sagemath.org/23227 for details.
False
```

`ngens()`

Return the number of generators of `self`.

We conventionally define this as 1: for base rings, we take a uniformizer as the generator; for extension rings, we take a root of the minimal polynomial defining the extension.

EXAMPLES:

```python
sage: Zp(5).ngens()
1
sage: Zq(25,names='a').ngens()
1
```

`prime()`

Return the prime, i.e. the characteristic of the residue field.

OUTPUT:

The characteristic of the residue field.

EXAMPLES:

```python
sage: R = Zp(3,5,'fixed-mod')
sage: R.prime()
3
```

`primitive_root_of_unity(n=None, order=False)`

Return a generator of the group of n-th roots of unity in this ring.

INPUT:

• n – an integer or `None` (default: `None`)
• order – a boolean (default: `False`)

```python`
OUTPUT:

A generator of the group of \(n\)-th roots of unity. If \(n\) is None, a generator of the full group of roots of unity is returned.

If order is True, the order of the above group is returned as well.

EXAMPLES:

```
sage: R = Zp(5, 10)
sage: zeta = R.primitive_root_of_unity(); zeta
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10)
sage: zeta == R.teichmuller(2)
True
```

Now we consider an example with non trivial \(p\)-th roots of unity:

```
sage: W = Zp(3, 2)
sage: S.<x> = W[]
sage: R.<pi> = W.extension((x+1)^6 + (x+1)^3 + 1)

sage: zeta, order = R.primitive_root_of_unity(order=True)
sage: zeta
2 + 2*pi + 2*pi^3 + 2*pi^7 + 2*pi^8 + 2*pi^10 + pi^11 + O(pi^12)
sage: order
18
sage: zeta.multiplicative_order()
18

sage: zeta, order = R.primitive_root_of_unity(24, order=True)
sage: zeta
2 + pi^3 + 2*pi^7 + 2*pi^8 + 2*pi^10 + 2*pi^11 + O(pi^12)
sage: order  # equal to gcd(18,24)
6
sage: zeta.multiplicative_order()
6
```

print_mode()

Return the current print mode as a string.

EXAMPLES:

```
sage: R = Qp(7,5, 'capped-rel')
sage: R.print_mode()
'capped-rel'
```

residue_characteristic()

Return the prime, i.e., the characteristic of the residue field.

OUTPUT:

The characteristic of the residue field.

EXAMPLES:

```
sage: R = Zp(3,5, 'fixed-mod')
sage: R.residue_characteristic()
3
```
\texttt{residue_class_field()}

Return the residue class field.

EXAMPLES:

\begin{verbatim}
sage: R = Zp(3,5,'fixed-mod')
sage: k = R.residue_class_field()
sage: k
Finite Field of size 3
\end{verbatim}

\texttt{residue_field()}

Return the residue class field.

EXAMPLES:

\begin{verbatim}
sage: R = Zp(3,5,'fixed-mod')
sage: k = R.residue_field()
sage: k
Finite Field of size 3
\end{verbatim}

\texttt{residue_ring}(n)

Return the quotient of the ring of integers by the n-th power of the maximal ideal.

EXAMPLES:

\begin{verbatim}
sage: R = Zp(11)
sage: R.residue_ring(3)
Ring of integers modulo 1331
\end{verbatim}

\texttt{residue_system()}

Return a list of elements representing all the residue classes.

EXAMPLES:

\begin{verbatim}
sage: R = Zp(3, 5,'fixed-mod')
sage: R.residue_system()
[0, 1, 2]
\end{verbatim}

\texttt{roots_of_unity}(n=None)

Return all the n-th roots of unity in this ring.

INPUT:

\begin{itemize}
  \item n – an integer or \texttt{None} (default: None); if \texttt{None}, the full group of roots of unity is returned
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: R = Zp(5, 10)
sage: roots = R.roots_of_unity(); roots
[1 + O(5^10),
 2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10),
 4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + 4*5^6 + 4*5^7 + 4*5^8 + 4*5^9 + 0(5^→10),
 3 + 3*5 + 2*5^2 + 3*5^3 + 5^4 + 2*5^6 + 5^7 + 4*5^8 + 5^9 + 0(5^10)]
sage: R.roots_of_unity(10)
[1 + O(5^10),
 4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + 4*5^6 + 4*5^7 + 4*5^8 + 4*5^9 + 0(5^→10)]
\end{verbatim}
In this case, the roots of unity are the Teichmüller representatives:

```
sage: R.teichmuller_system()
[1 + O(5^10),
  2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10),
  3 + 3*5 + 2*5^2 + 3*5^3 + 5^4 + 2*5^6 + 5^7 + 4*5^8 + 5^9 + O(5^10),
  4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + 4*5^6 + 4*5^7 + 4*5^8 + 4*5^9 + O(5^10)]
```

In general, there might be more roots of unity (it happens when the ring has non trivial p-th roots of unity):

```
sage: W.<a> = Zq(3^2, 2)
sage: S.<x> = W[]
sage: R.<pi> = W.extension((x+1)^2 + (x+1) + 1)

sage: roots = R.roots_of_unity(); roots
[1 + O(pi^4),
 a + 2*a*pi + 2*a*pi^2 + a*pi^3 + O(pi^4),
 ... 1 + pi + O(pi^4),
 a + a*pi^2 + 2*a*pi^3 + O(pi^4),
 ... 1 + 2*pi + pi^2 + O(pi^4),
 a + a*pi + a*pi^2 + O(pi^4),
 ...]
sage: len(roots)
24
```

We check that the logarithm of each root of unity vanishes:

```
sage: for root in roots:
....:     if root.log() != 0:
....:         raise ValueError
```

`some_elements()`

Return a list of elements in this ring.

This is typically used for running generic tests (see `TestSuite`).

EXAMPLES:

```
sage: Zp(2,4).some_elements()
[0, 1 + O(2^4), 2 + O(2^5), 1 + 2^2 + 2^3 + O(2^4), 2 + 2^2 + 2^3 + 2^4 + O(2^5)]
```

`teichmuller(x, prec=None)`

Return the Teichmüller representative of `x`.

- `x` – something that can be cast into `self`

OUTPUT:

- the Teichmüller lift of `x`

EXAMPLES:
We check that trac ticket #23736 is resolved:

```
sage: R = Zp(5,10,'capped-rel','series')
sage: R.teichmuller(2)
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10)
sage: R = Qp(5,10,'capped-rel','series')
sage: R.teichmuller(2)
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10)
sage: R = Zp(5,10,'capped-abs','series')
sage: R.teichmuller(2)
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9 + O(5^10)
sage: R = Zp(5,10,'fixed-mod','series')
sage: R.teichmuller(2)
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 4*5^5 + 2*5^6 + 3*5^7 + 3*5^9
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: y = W.teichmuller(3); y
3 + 3*w^5 + w^7 + 2*w^9 + 2*w^10 + 4*w^11 + w^12 + 2*w^13 + 3*w^15
+ 2*w^16 + 3*w^17 + w^18 + 3*w^19 + 3*w^20 + 2*w^21 + 2*w^22
+ 3*w^23 + 4*w^24 + O(w^25)
sage: y^5 == y
True
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: b = A.teichmuller(1 + 2*a - a^2); b
(4*a^2 + 2*a + 1) + 2*a*5 + (3*a^2 + 1)*5^2 + (a + 4)*5^3
+ (a^2 + a + 1)*5^4 + O(5^5)
sage: b^125 == b
True
```

We check that trac ticket #20457 is fixed:

```
sage: R.teichmuller System(GF(5)(2))
2 + 5 + 2*5^2 + 5^3 + 3*5^4 + 0(5^5)
```

AUTHORS:

- Initial version: David Roe
- Quadratic time version: Kiran Kedlaya <kedlaya@math.mit.edu> (2007-03-27)

**teichmuller_system()**

Return a set of Teichmüller representatives for the invertible elements of \( \mathbb{Z}/p\mathbb{Z} \).

**OUTPUT:**

A list of Teichmüller representatives for the invertible elements of \( \mathbb{Z}/p\mathbb{Z} \).

**EXAMPLES:**

```
sage: R = Zp(3,5,'fixed-mod','terse')
sage: R.teichmuller System()([1, 242]
```

Check that trac ticket #20457 is fixed:
sage: F.<a> = Qq(5^2,6)
sage: F.teichmuller_system()[3]
(2*a + 2) + (4*a + 1)*5 + 4*5^2 + (2*a + 1)*5^3 + (4*a + 1)*5^4 + (2*a + 3)*5^5 → + O(5^6)

Note: Should this return 0 as well?

uniformizer_pow(n)
Return $p^n$, as an element of self.
If n is infinity, returns 0.
EXAMPLES:

sage: R = Zp(3, 5, 'fixed-mod')
sage: R.uniformizer_pow(3)
3^3
sage: R.uniformizer_pow(infinity)
0

valuation()
Return the $p$-adic valuation on this ring.
OUTPUT:
A valuation that is normalized such that the rational prime $p$ has valuation 1.
EXAMPLES:

sage: K = Qp(3)
sage: R.<a> = K[]
sage: L.<a> = K.extension(a^3 - 3)
sage: v = L.valuation(); v
3-adic valuation
sage: v(3)
1
sage: L(3).valuation()
3

The normalization is chosen such that the valuation restricts to the valuation on the base ring:

sage: v(3) == K.valuation()(3)
True
sage: v.restriction(K) == K.valuation()
True

See also:
NumberField_generic.valuation(), Order.valuation()
This file contains a bunch of intermediate classes for the $p$-adic parents, allowing a function to be implemented at the right level of generality.

```python
class sage.rings.padics.generic_nodes.CappedAbsoluteGeneric(base, prec, names, element_class, category=None):
    Bases: sage.rings.padics.local_generic.LocalGeneric

    @cached_method
    def is_capped_absolute(self):
        """Return whether this $p$-adic ring bounds precision in a capped absolute fashion."

        The absolute precision of an element is the power of $p$ modulo which that element is defined. In a capped absolute ring, the absolute precision of elements are bounded by a constant depending on the ring.

        EXAMPLES:

        sage: R = ZpCA(5, 15)
        sage: R.is_capped_absolute()
        True
        sage: R(5^7)
        5^7 + O(5^15)

        sage: S = Zp(5, 15)
        sage: S.is_capped_absolute()
        False
        sage: S(5^7)
        5^7 + O(5^22)
```

```python
class sage.rings.padics.generic_nodes.CappedRelativeFieldGeneric(base, prec, names, element_class, category=None):
    Bases: sage.rings.padics.generic_nodes.CappedRelativeGeneric

    @cached_method
    def is_capped_relative(self):
        """Return whether this $p$-adic ring bounds precision in a capped relative fashion."

        The relative precision of an element is the power of $p$ modulo which the unit part of that element is defined. In a capped relative ring, the relative precision of elements are bounded by a constant depending on the ring.

        EXAMPLES:

        sage: R = ZpCA(5, 15)
        sage: R.is_capped_relative()
        False
        sage: R(5^7)
        5^7 + O(5^15)

        sage: S = Zp(5, 15)
        sage: S.is_capped_relative()
        True
        sage: S(5^7)
        5^7 + O(5^22)
```
```
EXAMPLES:

```python
sage: R = ZpCA(5, 15)
sage: R.is_capped_relative()
False
sage: R(5^7)
5^7 + O(5^15)
sage: S = Zp(5, 15)
sage: S.is_capped_relative()
True
sage: S(5^7)
5^7 + O(5^22)
```

class `sage.rings.padics.generic_nodes.CappedRelativeRingGeneric`(
    `base`, `prec`, `names`,
    `element_class`, `category=None`
)

Bases: `sage.rings.padics.generic_nodes.CappedRelativeGeneric`

class `sage.rings.padics.generic_nodes.FixedModGeneric`(
    `base`, `prec`, `names`, `element_class`,
    `category=None`
)

Bases: `sage.rings.padics.local_generic.LocalGeneric`

`is_fixed_mod()`

Return whether this $p$-adic ring bounds precision in a fixed modulus fashion.

The absolute precision of an element is the power of $p$ modulo which that element is defined. In a fixed modulus ring, the absolute precision of every element is defined to be the precision cap of the parent. This means that some operations, such as division by $p$, don’t return a well defined answer.

EXAMPLES:

```python
sage: R = ZpFM(5,15)
sage: R.is_fixed_mod()
True
sage: R(5^7,absprec=9)
5^7
sage: S = ZpCA(5, 15)
sage: S.is_fixed_mod()
False
sage: S(5^7,absprec=9)
5^7 + O(5^9)
```

class `sage.rings.padics.generic_nodes.FloatingPointFieldGeneric`(
    `base`, `prec`, `names`,
    `element_class`, `category=None`
)

Bases: `sage.rings.padics.generic_nodes.FloatingPointGeneric`

class `sage.rings.padics.generic_nodes.FloatingPointGeneric`(
    `base`, `prec`, `names`, `element_class`,
    `category=None`
)

Bases: `sage.rings.padics.local_generic.LocalGeneric`

`is_floating_point()`

Return whether this $p$-adic ring uses a floating point precision model.

Elements in the floating point model are stored by giving a valuation and a unit part. Arithmetic is done where the unit part is truncated modulo a fixed power of the uniformizer, stored in the precision cap of the parent.

EXAMPLES:
```python
sage: R = ZpFP(5,15)
sage: R.is_floating_point()
True
sage: R(5^7,absprec=9)
5^7
sage: S = ZpCR(5,15)
sage: S.is_floating_point()
False
sage: S(5^7,absprec=9)
5^7 + O(5^9)
```

class sage.rings.padics.generic_nodes.FloatingPointRingGeneric(base, prec, names, element_class, category=None)

Bases: sage.rings.padics.generic_nodes.FloatingPointGeneric

sage.rings.padics.generic_nodes.is_pAdicField(R)
Return True if and only if R is a $p$-adic field.

EXAMPLES:
```python
sage: is_pAdicField(Zp(17))
doctest:warning...
DeprecationWarning: is_pAdicField is deprecated; use isinstance(..., sage.rings.abc.pAdicField) instead
See https://trac.sagemath.org/32750 for details.
False
sage: is_pAdicField(Qp(17))
True
```

sage.rings.padics.generic_nodes.is_pAdicRing(R)
Return True if and only if R is a $p$-adic ring (not a field).

EXAMPLES:
```python
sage: is_pAdicRing(Zp(5))
doctest:warning...
DeprecationWarning: is_pAdicRing is deprecated; use isinstance(..., sage.rings.abc.pAdicRing) instead
See https://trac.sagemath.org/32750 for details.
True
sage: is_pAdicRing(RR)
False
```

class sage.rings.padics.generic_nodes.pAdicCappedAbsoluteRingGeneric(base, p, prec, print_mode, names, element_class, category=None)

Bases: sage.rings.padics.generic_nodes.pAdicRingGeneric, sage.rings.padics.generic_nodes.CappedAbsoluteGeneric

class sage.rings.padics.generic_nodes.pAdicCappedRelativeFieldGeneric(base, p, prec, print_mode, names, element_class, category=None)

Bases: sage.rings.padics.generic_nodes.pAdicFieldGeneric, sage.rings.padics.generic_nodes.CappedRelativeFieldGeneric
class sage.rings.padics.generic_nodes.pAdicCappedRelativeRingGeneric(base, p, prec, print_mode, names, element_class, category=None):
    Bases: sage.rings.padics.generic_nodes.pAdicRingGeneric, sage.rings.padics.generic_nodes.CappedRelativeRingGeneric

class sage.rings.padics.generic_nodes.pAdicFieldBaseGeneric(p, prec, print_mode, names, element_class):
    Bases: sage.rings.padics.padic_base_generic.pAdicBaseGeneric, sage.rings.padics.generic_nodes.pAdicFieldGeneric

composite(subfield1, subfield2)
    Return the composite of two subfields of self, i.e., the largest subfield containing both

    INPUT:
    • self – a p-adic field
    • subfield1 – a subfield
    • subfield2 – a subfield

    OUTPUT:
    • the composite of subfield1 and subfield2

    EXAMPLES:

    sage: K = Qp(17); K.composite(K, K) is K
    True

construction(forbid_frac_field=False)
    Return the functorial construction of self, namely, completion of the rational numbers with respect to a given
    prime.

    Also preserves other information that makes this field unique (e.g. precision, rounding, print mode).

    INPUT:
    • forbid_frac_field – require a completion functor rather than a fraction field functor. This is used
      in the sage.rings.padics.local_generic.LocalGeneric.change() method.

    EXAMPLES:

    sage: K = Qp(17, 8, print_mode='val-unit', print_sep='&')
    sage: c, L = K.construction(); L
    17-adic Ring with capped relative precision 8
    sage: c
    FractionField
    sage: c(L)
    17-adic Field with capped relative precision 8
    sage: K == c(L)
    True

    We can get a completion functor by forbidding the fraction field:

    sage: c, L = K.construction(forbid_frac_field=True); L
    Rational Field
    sage: c
    Completion[17, prec=8]

(continues on next page)
sage: c(L)
17-adic Field with capped relative precision 8
sage: K == c(L)
True

subfield(list)
Return the subfield generated by the elements in list

INPUT:
• self – a $p$-adic field
• list – a list of elements of self

OUTPUT:
• the subfield of self generated by the elements of list

EXAMPLES:

sage: K = Qp(17); K.subfield([K(17), K(1827)]) is K
True

subfields_of_degree(n)
Return the number of subfields of self of degree $n$

INPUT:
• self – a $p$-adic field
• n – an integer

OUTPUT:
• integer – the number of subfields of degree $n$ over self.base_ring()

EXAMPLES:

sage: K = Qp(17)
sage: K.subfields_of_degree(1)
1

class sage.rings.padics.generic_nodes.pAdicFieldGeneric(base, p, prec, print_mode, names, element_class, category=None)
    Bases: sage.rings.padics.padic_generic.pAdicGeneric, sage.rings.abc.pAdicField
class sage.rings.padics.generic_nodes.pAdicFixedModRingGeneric(base, p, prec, print_mode, names, element_class, category=None)
    Bases: sage.rings.padics.generic_nodes.pAdicRingGeneric, sage.rings.padics.generic_nodes.FixedModGeneric
class sage.rings.padics.generic_nodes.pAdicFloatingPointFieldGeneric(base, p, prec, print_mode, names, element_class, category=None)
    Bases: sage.rings.padics.generic_nodes.pAdicFieldGeneric, sage.rings.padics.generic_nodes.FloatingPointFieldGeneric
class sage.rings.padics.generic_nodes.pAdicFloatingPointRingGeneric(base, p, prec, print_mode, names, element_class, category=None)

Bases: sage.rings.padics.generic_nodes.pAdicRingGeneric, sage.rings.padics.generic_nodes.FloatingPointRingGeneric

class sage.rings.padics.generic_nodes.pAdicLatticeGeneric(p, prec, print_mode, names, label=None)

Bases: sage.rings.padics.padic_generic.pAdicGeneric

An implementation of the $p$-adic rationals with lattice precision.

INPUT:

- $p$ – the underlying prime number
- prec – the precision
- subtype – either "cap" or "float", specifying the precision model used for tracking precision
- label – a string or None (default: None)

convert_multiple(*elts)
Convert a list of elements to this parent.

NOTE:

This function tries to be sharp on precision as much as possible. In particular, if the precision of the input elements are handled by a lattice, diffused digits of precision are preserved during the conversion.

EXAMPLES:

```sage
R = ZpLC(2)
sage: x = R(1, 10); y = R(1, 5)
sage: x, y = x+y, x-y
```

Remark that the pair $(x, y)$ has diffused digits of precision:

```sage
x
2 + O(2^5)
sage: y
0(2^5)
sage: x + y
2 + O(2^11)
```

```sage
R.precision().diffused_digits([x,y])
6
```

As a consequence, if we convert $x$ and $y$ separately, we loose some precision:

```sage
R2 = ZpLC(2, label='copy')
sage: x2 = R2(x); y2 = R2(y)
sage: x2
2 + O(2^5)
sage: y2
0(2^5)
sage: x2 + y2
2 + O(2^5)
```

(continues on next page)
sage: R2.precision().diffused_digits([x2,y2])

0

On the other hand, this issue disappears when we use multiple conversion:

sage: x2,y2 = R2.convert_multiple(x,y)
sage: x2 + y2
2 + O(2^11)
sage: R2.precision().diffused_digits([x2,y2])
6

**is_lattice_prec()**

Return whether this \( p \)-adic ring bounds precision using a lattice model.

In lattice precision, relationships between elements are stored in a precision object of the parent, which allows for optimal precision tracking at the cost of increased memory usage and runtime.

**EXAMPLES:**

```
sage: R = ZpCR(5, 15)
sage: R.is_lattice_prec()  # False
sage: x = R(25, 8)
sage: x - x
O(5^8)
sage: S = ZpLC(5, 15)
sage: S.is_lattice_prec()  # True
sage: x = S(25, 8)
sage: x - x
O(5^30)
```

**label()**

Return the label of this parent.

**NOTE:**

Labels can be used to distinguish between parents with the same defining data.

They are useful in the lattice precision framework in order to limit the size of the lattice modeling the precision (which is roughly the number of elements having this parent).

Elements of a parent with some label do not coerce to a parent with a different label. However conversions are allowed.

**EXAMPLES:**

```
sage: R = ZpLC(5)
sage: R.label()  # no label by default

sage: R = ZpLC(5, label='mylabel')

sage: R.label()  # 'mylabel'
```

Labels are typically useful to isolate computations. For example, assume that we first want to do some calculations with matrices:
sage: R = ZpLC(5, label='matrices')
sage: M = random_matrix(R, 4, 4)
sage: d = M.determinant()

Now, if we want to do another unrelated computation, we can use a different label:

sage: R = ZpLC(5, label='polynomials')
sage: S.<x> = PolynomialRing(R)
sage: P = (x-1)*(x-2)*(x-3)*(x-4)*(x-5)

Without labels, the software would have modeled the precision on the matrices and on the polynomials using the same lattice (manipulating a lattice of higher dimension can have a significant impact on performance).

precision()
Return the lattice precision object attached to this parent.

EXAMPLES:

sage: R = ZpLC(5, label='precision')
sage: R.precision()
Precision lattice on 0 objects (label: precision)

sage: x = R(1, 10); y = R(1, 5)
sage: R.precision()
Precision lattice on 2 objects (label: precision)

See also:
sage.rings.padics.lattice_precision.PrecisionLattice

precision_cap()
Return the relative precision cap for this ring if it is finite. Otherwise return the absolute precision cap.

EXAMPLES:

sage: R = ZpLC(3)
sage: R.precision_cap()
20

sage: R = ZpLC(3, prec=(infinity,20))
sage: R.precision_cap()
20

sage: R.precision_cap_relative()
+Infinity

See also:
precision_cap_relative(), precision_cap_absolute()

precision_cap_absolute()
Return the absolute precision cap for this ring.

EXAMPLES:
<table>
<thead>
<tr>
<th>sage: R = ZpLC(3)</th>
<th>sage: R.precision_cap_absolute()</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>sage: R = ZpLC(3, prec=(infinity,20))</th>
<th>sage: R.precision_cap_absolute()</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td></td>
</tr>
</tbody>
</table>

See also:

`precision_cap()`, `precision_cap_relative()`

**precision_cap_relative()**

Return the relative precision cap for this ring.

EXAMPLES:

<table>
<thead>
<tr>
<th>sage: R = ZpLC(3)</th>
<th>sage: R.precision_cap_relative()</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>sage: R = ZpLC(3, prec=(infinity,20))</th>
<th>sage: R.precision_cap_relative()</th>
</tr>
</thead>
<tbody>
<tr>
<td>+Infinity</td>
<td></td>
</tr>
</tbody>
</table>

See also:

`precision_cap()`, `precision_cap_absolute()`

**class** `sage.rings.padics.generic_nodes.pAdicRelaxedGeneric(base, p, prec, print_mode, names, element_class, category=None)`

Bases: `sage.rings.padics.padic_generic.pAdicGeneric`

Generic class for relaxed $p$-adics.

**INPUT:**

- $p$ – the underlying prime number
- `prec` – the default precision

**an_element**(unbounded=False)

Return an element in this ring.

**EXAMPLES:**

<table>
<thead>
<tr>
<th>sage: R = ZpER(7, prec=5)</th>
<th>sage: R.an_element()</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 + O(7^5)</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>sage: R.an_element(unbounded=True)</th>
</tr>
</thead>
</table>
| 7 + ...

**default_prec()**

Return the default precision of this relaxed $p$-adic ring.

The default precision is mostly used for printing: it is the number of digits which are printed for unbounded elements (that is elements having infinite absolute precision).

**EXAMPLES:**
halting_prec()
Return the default halting precision of this relaxed $p$-adic ring.

The halting precision is the precision at which elements of this parent are compared (unless more digits have been previously computed). By default, it is twice the default precision.

EXAMPLES:

```
sage: R = ZpER(5, print_mode="digits")
sage: R.halting_prec()
40
```

is_relaxed()
Return whether this $p$-adic ring is relaxed.

EXAMPLES:

```
sage: R = Zp(5)
sage: R.is_relaxed()
False
sage: S = ZpER(5)
sage: S.is_relaxed()
True
```

is_secure()
Return False if this $p$-adic relaxed ring is not secure (i.e. if indistinguishable elements at the working precision are considered as equal); True otherwise (in which case, an error is raised when equality cannot be decided).

EXAMPLES:

```
sage: R = ZpER(5)
sage: R.is_secure()
False
sage: x = R(20/21)
sage: y = x + 5^50
sage: x == y
True
sage: S = ZpER(5, secure=True)
sage: S.is_secure()
True
sage: x = S(20/21)
(continues on next page)
```
sage: y = x + 5^50
sage: x == y
Traceback (most recent call last):
...  PrecisionError: unable to decide equality; try to bound precision

precision_cap()
Return the precision cap of this $p$-adic ring, which is infinite in the case of relaxed rings.

EXAMPLES:

sage: R = ZpER(5)
sage: R.precision_cap()
+Infinity

random_element(integral=False, prec=None)
Return a random element in this ring.

INPUT:

• integral – a boolean (default: False); if True, return a random element in the ring of integers of this ring
• prec – an integer or None (default: None); if given, bound the precision of the output to prec

EXAMPLES:

sage: R = ZpER(5, prec=10)
By default, this method returns a unbounded element:

sage: a = R.random_element()
sage: a  # random
4 + 3*5 + 3*5^2 + 5^3 + 3*5^4 + 2*5^5 + 2*5^6 + 5^7 + 5^9 + ...
sage: a.precision_absolute()
+Infinity

The precision can be bounded by passing in a precision:

sage: b = R.random_element(prec=15)
sage: b  # random
2 + 3*5^2 + 5^3 + 3*5^4 + 5^5 + 3*5^6 + 3*5^8 + 3*5^9 + 4*5^10 + 5^11 + 4*5^12...
→ 5^13 + 2*5^14 + O(5^15)
sage: b.precision_absolute()
15

some_elements(unbounded=False)
Return a list of elements in this ring.

This is typically used for running generic tests (see TestSuite).

EXAMPLES:

sage: R = ZpER(7, prec=5)
sage: R.some_elements()
[O(7^5),
(continues on next page)
1 + O(7^5),
7 + O(7^5),
7 + O(7^5),
1 + 5*7 + 3*7^2 + 6*7^3 + O(7^5),
7 + 6*7^2 + 6*7^3 + 6*7^4 + O(7^5)]

sage: R.some_elements(unbounded=True)
[0,
1 + ....,
7 + ....,
7 + ....,
1 + 5*7 + 3*7^2 + 6*7^3 + ....,
7 + 6*7^2 + 6*7^3 + 6*7^4 + ...]

teichmuller(x)
Return the Teichmuller representative of x.

EXAMPLES:

sage: R = ZpER(5, print_mode="digits")
sage: R.teichmuller(2)
...40423140223032431212

teichmuller_system()
Return a set of teichmuller representatives for the invertible elements of \( \mathbb{Z}/p\mathbb{Z} \).

EXAMPLES:

sage: R = ZpER(7, print_mode="digits")
sage: R.teichmuller_system()
[...000000000000000001,
...1641212544326203642,
...1641212544326203643,
...50254541223240463024,
...50254541223240463025,
...66666666666666666]

unknown(start_val=0, digits=None)
Return a self-referent number in this ring.

INPUT:

- start_val – an integer (default: 0); a lower bound on the valuation of the returned element
- digits – an element, a list or None (default: None); the first digit or the list of the digits of the returned element

NOTE:

Self-referent numbers are numbers whose digits are defined in terms of the previous ones. This method is used to declare a self-referent number (and optionally, to set its first digits). The definition of the number itself will be given afterwards using to method meth:sage.rings.padic.relaxedemplate.RelaxedElement\_unknown.set of the element.

EXAMPLES:

sage: R = ZpER(5, prec=10)
We declare a self-referent number:

```
sage: a = R.unknown()
```

So far, we do not know anything on \(a\) (except that it has nonnegative valuation):

```
sage: a
0(5^0)
```

We can now use the method \texttt{method}\texttt{RelaxedElement\_unknown\_set} to define \(a\). Below, for example, we say that the digits of \(a\) have to agree with the digits of \(1 + 5a\). Note that the factor 5 shifts the digits; the \(n\)-th digit of \(a\) is then defined by the previous ones:

```
sage: a.set(1 + 5*a)
True
```

After this, \(a\) contains the solution of the equation \(a = 1 + 5a\), that is \(a = -1/4\):

```
sage: a
1 + 5 + 5^2 + 5^3 + 5^4 + 5^5 + 5^6 + 5^7 + 5^8 + 5^9 + ...
```

Here is another example with an equation of degree 2:

```
sage: b = R.unknown()
sage: b.set(1 - 5*b^2)
True
sage: b
1 + 4*5 + 5^2 + 3*5^4 + 4*5^6 + 4*5^8 + 2*5^9 + ...
sage: (sqrt(R(21)) - 1) / 10
1 + 4*5 + 5^2 + 3*5^4 + 4*5^6 + 4*5^8 + 2*5^9 + ...
```

Cross self-referent definitions are also allowed:

```
sage: u = R.unknown()
sage: v = R.unknown()
sage: w = R.unknown()

sage: u.set(1 + 2*v + 3*w^2 + 5*u*v*w)
True
sage: v.set(2 + 4*w + sqrt(1 + 5*u + 10*v + 15*w))
True
sage: w.set(3 + 25*(u*v + v*w + u*w))
True

sage: u
3 + 3*5 + 4*5^2 + 5^3 + 3*5^4 + 5^5 + 5^6 + 3*5^7 + 5^8 + 3*5^9 + ...
sage: v
4*5 + 2*5^2 + 4*5^3 + 5^4 + 5^5 + 3*5^6 + 5^8 + 5^9 + ...
sage: w
3 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + 2*5^6 + 5^8 + 5^9 + ...
```

```
construction(forbid_frac_field=False)
Return the functorial construction of self, namely, completion of the rational numbers with respect to a given prime.

Also preserves other information that makes this field unique (e.g. precision, rounding, print mode).

INPUT:
• forbid_frac_field – ignored, for compatibility with other p-adic types.

EXAMPLES:

```
sage: K = Zp(17, 8, print_mode='val-unit', print_sep='&')
sage: c, L = K.construction(); L
Integer Ring
sage: c(L)
17-adic Ring with capped relative precision 8
sage: K == c(L)
True
```

random_element(algorithm='default')
Return a random element of self, optionally using the algorithm argument to decide how it generates the element. Algorithms currently implemented:

• default: Choose $a_i$, $i > 0$, randomly between 0 and $p - 1$ until a nonzero choice is made. Then continue choosing $a_i$ randomly between 0 and $p - 1$ until we reach precision_cap, and return $\sum a_ip^i$.

EXAMPLES:

```
sage: Zp(5,6).random_element().parent() is Zp(5,6)
True
sage: ZpCA(5,6).random_element().parent() is ZpCA(5,6)
True
sage: ZpFM(5,6).random_element().parent() is ZpFM(5,6)
True
```

class sage.rings.padics.generic_nodes.pAdicRingGeneric(base, p, prec, print_mode, names, element_class, category=None)
Bases: sage.rings.padics.padic_generic.pAdicGeneric, sage.rings.abc.pAdicRing

is_field(proof=True)
Return whether this ring is actually a field, i.e. False.

EXAMPLES:

```
sage: Zp(5).is_field()
False
```

krull_dimension()
Return the Krull dimension of self, i.e. 1

INPUT:
• self – a p-adic ring

OUTPUT:
• the Krull dimension of self. Since self is a p-adic ring, this is 1.

EXAMPLES:
```
sage: Zp(5).krull_dimension()
1
```
A subclass for implementations of \( \mathbb{Z}_p \) and \( \mathbb{Q}_p \).

AUTHORS:

• David Roe

```python
class sage.rings.padics.padic_base_generic.pAdicBaseGeneric(p, prec, print_mode, names, element_class):
    Bases: sage.rings.padics.padic_generic.pAdicGeneric

Initialization

absolute_discriminant()
    Returns the absolute discriminant of this \( p \)-adic ring

EXAMPLES:

sage: Zp(5).absolute_discriminant()
1

discriminant(K=None)
    Returns the discriminant of this \( p \)-adic ring over \( K \)

INPUT:
    • self – a \( p \)-adic ring
    • K – a sub-ring of self or None (default: None)

OUTPUT:
    • integer – the discriminant of this ring over \( K \) (or the absolute discriminant if \( K \) is None)

EXAMPLES:

sage: Zp(5).discriminant()
1

exact_field()
    Returns the rational field.
    For compatibility with extensions of \( p \)-adics.

EXAMPLES:

sage: Zp(5).exact_field()
Rational Field
```
\textbf{exact\_ring()}

Returns the integer ring.

EXAMPLES:

\begin{verbatim}
  sage: Zp(5).exact_ring()
  Integer Ring
\end{verbatim}

\textbf{gen\((n=0)\)}

Returns the \(n\)th generator of this extension. For base rings-fields, we consider the generator to be the prime.

EXAMPLES:

\begin{verbatim}
  sage: R = Zp(5); R.gen()
  5 + O(5^21)
\end{verbatim}

\textbf{has\_pth\_root()}

Returns whether or not \(\mathbb{Z}_p\) has a primitive \(p^{th}\) root of unity.

EXAMPLES:

\begin{verbatim}
  sage: Zp(2).has_pth_root()
  True
  sage: Zp(17).has_pth_root()
  False
\end{verbatim}

\textbf{has\_root\_of\_unity\((n)\)}

Returns whether or not \(\mathbb{Z}_p\) has a primitive \(n^{th}\) root of unity.

INPUT:

\begin{itemize}
  \item \texttt{self} -- a \(p\)-adic ring
  \item \texttt{n} -- an integer
\end{itemize}

OUTPUT:

\begin{itemize}
  \item \texttt{boolean} -- whether \texttt{self} has primitive \(n^{th}\) root of unity
\end{itemize}

EXAMPLES:

\begin{verbatim}
  sage: R=Zp(37)
  sage: R.has_root_of_unity(12)
  True
  sage: R.has_root_of_unity(11)
  False
\end{verbatim}

\textbf{is\_abelian()}

Returns whether the Galois group is abelian, i.e. \texttt{True}. #should this be automorphism group?

EXAMPLES:

\begin{verbatim}
  sage: R = Zp(3, 10, 'fixed-mod'); R.is_abelian()
  True
\end{verbatim}

\textbf{is\_isomorphic\((\text{ring})\)}

Returns whether \texttt{self} and \texttt{ring} are isomorphic, i.e. whether \texttt{ring} is an implementation of \(\mathbb{Z}_p\) for the same prime as \texttt{self}.

INPUT:
- **self** – a $p$-adic ring
- **ring** – a ring

**OUTPUT:**

- **boolean** – whether **ring** is an implementation of $\mathbb{Z}_p$ for the same prime as **self**.

**EXAMPLES:**

```python
sage: R = Zp(5, 15, print_mode='digits'); S = Zp(5, 44, print_max_terms=4); R.is_isomorphic(S)
True
```

**is_normal()**

Returns whether or not this is a normal extension, i.e. True.

**EXAMPLES:**

```python
sage: R = Zp(3, 10, 'fixed-mod'); R.is_normal()
True
```

**modulus**(exact=False)

Returns the polynomial defining this extension.

For compatibility with extension fields; we define the modulus to be $x-1$.

**INPUT:**

- **exact** – boolean (default False), whether to return a polynomial with integer entries.

**EXAMPLES:**

```python
sage: Zp(5).modulus(exact=True)
x
```

**plot**(max_points=2500, **args)

Create a visualization of this $p$-adic ring as a fractal similar to a generalization of the Sierpiński triangle.

The resulting image attempts to capture the algebraic and topological characteristics of $\mathbb{Z}_p$.

**INPUT:**

- **max_points** – the maximum number or points to plot, which controls the depth of recursion (default 2500)
- ****args – color, size, etc. that are passed to the underlying point graphics objects

**REFERENCES:**

**EXAMPLES:**

```python
sage: Zp(3).plot()
Graphics object consisting of 1 graphics primitive
sage: Zp(5).plot(max_points=625)
Graphics object consisting of 1 graphics primitive
sage: Zp(23).plot(rgbcolor=(1,0,0))
Graphics object consisting of 1 graphics primitive
```
uniformizer()  
Returns a uniformizer for this ring.

EXAMPLES:

```
sage: R = Zp(3,5,'fixed-mod', 'series')
sage: R.uniformizer()
3
```

uniformizer_pow(n)  
Returns the $n$th power of the uniformizer of self (as an element of self).

EXAMPLES:

```
sage: R = Zp(5)
sage: R.uniformizer_pow(5)
5^5 + O(5^25)
sage: R.uniformizer_pow(infinity)
0
```

zeta(n=None)  
Returns a generator of the group of roots of unity.

INPUT:

- self – a $p$-adic ring
- n – an integer or None (default: None)

OUTPUT:

- element – a generator of the $n$th roots of unity, or a generator of the full group of roots of unity if $n$ is None

EXAMPLES:

```
sage: R = Zp(37,5)
sage: R.zeta(12)
8 + 24*37 + 37^2 + 29*37^3 + 23*37^4 + O(37^5)
```

zeta_order()  
Returns the order of the group of roots of unity.

EXAMPLES:

```
sage: R = Zp(37); R.zeta_order()
36
sage: Zp(2).zeta_order()
2
```
A common superclass for all extensions of $\mathbb{Q}_p$ and $\mathbb{Z}_p$.

AUTHORS:

- David Roe

**class** `sage.rings.padics.padic_extension_generic.DefPolyConversion`

**Bases:** `sage.categories.morphism.Morphism`

Conversion map between $p$-adic rings/fields with the same defining polynomial.

**INPUT:**

- $R$ – a $p$-adic extension ring or field.
- $S$ – a $p$-adic extension ring or field with the same defining polynomial.

**EXAMPLES:**

```
sage: K.<a> = Qq(125, print_mode='terse')
sage: V, fr, to = K.free_module()
sage: TestSuite(fr).run(skip=['_test_nonzero_equal'])  # skipped since Qq(125) doesn't have dimension()
```
**class** sage.rings.padics.padic_extension_generic.MapOneStepToFreeModule

**Bases:** sage.rings.padics.padic_extension_generic.pAdicModuleIsomorphism

The isomorphism from a one-step p-adic extension to its underlying free module

**EXAMPLES:**
```
sage: K.<a> = Qq(125)
sage: V, fr, to = K.free_module()
sage: TestSuite(to).run()
```

**class** sage.rings.padics.padic_extension_generic.MapTwoStepToFreeModule

**Bases:** sage.rings.padics.padic_extension_generic.pAdicModuleIsomorphism

The isomorphism from a two-step p-adic extension to its underlying free module

**EXAMPLES:**
```
sage: K.<a> = Qq(125)
sage: R.<x> = ZZ[]
sage: L.<b> = K.extension(x^2 - 5*x + 5)
sage: V, fr, to = L.free_module(base=Qp(5))
sage: TestSuite(to).run()
```

**class** sage.rings.padics.padic_extension_generic.pAdicExtensionGeneric(poly, prec, print_mode, names, element_class)

**Bases:** sage.rings.padics.padic_generic.pAdicGeneric

Initialization

**EXAMPLES:**
```
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f) #indirect doctest
```

**construction**(forbid_frac_field=False)

Returns the functorial construction of this ring, namely, the algebraic extension of the base ring defined by the given polynomial.

Also preserves other information that makes this ring unique (e.g. precision, rounding, print mode).

**INPUT:**

- **forbid_frac_field** – require a completion functor rather than a fraction field functor. This is used in the sage.rings.padics.local_generic.LocalGeneric.change() method.

**EXAMPLES:**

---
sage: R.<a> = Zq(25, 8, print_mode='val-unit')
sage: c, R0 = R.construction(); R0
5-adic Ring with capped relative precision 8
sage: c(R0)
5-adic Unramified Extension Ring in a defined by x^2 + 4*x + 2
sage: c(R0) == R
True

For a field, by default we return a fraction field functor.

sage: K.<a> = Qq(25, 8) sage: c, R = K.construction(); R
5-adic Unramified Extension Ring in a defined by x^2 + 4*x + 2 sage: c
FractionField
If you prefer an extension functor, you can use the forbid_frac_field keyword:

sage: c, R = K.construction(forbid_frac_field=True); R
5-adic Field with capped relative precision 8
sage: c
AlgebraicExtensionFunctor
sage: c(R)
is K
True

defining_polynomial(var=None, exact=False)
Returns the polynomial defining this extension.

INPUT:

• var – string (default: 'x'), the name of the variable

• exact – boolean (default False), whether to return the underlying exact defining polynomial rather than the one with coefficients in the base ring.

EXAMPLES:

sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: W.defining_polynomial()
(1 + O(5^5))*x^5 + O(5^6)*x^4 + (3*5^2 + O(5^6))*x^3 + (2*5 + 4*5^2 + 4*5^3 + ... + 4*5^4 + 4*5^5 + O(5^6))*x^2 + (5^3 + O(5^6))*x + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 +...
+ 4*5^5 + O(5^6)
sage: W.defining_polynomial(exact=True)
x^5 + 75*x^3 - 15*x^2 + 125*x - 5

sage: W.defining_polynomial(var='y', exact=True)
y^5 + 75*y^3 - 15*y^2 + 125*y - 5

See also:

t modulus() exact_field()
```python
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: W.exact_field()
Number Field in w with defining polynomial x^5 + 75*x^3 - 15*x^2 + 125*x - 5
```

See also:

- `defining_polynomial()`
- `modulus()`
- `exact_ring()`

Return the order with the same defining polynomial.

Will raise a `ValueError` if the coefficients of the defining polynomial are not integral.

**EXAMPLES:**

```python
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: W.exact_ring()
Order in Number Field in w with defining polynomial x^5 + 75*x^3 - 15*x^2 + 125*x - 5
```

```python
sage: T = Zp(5,5)
sage: U.<z> = T[]
sage: g = 2*z^4 + 1
sage: V.<v> = T.ext(g)
sage: V.exact_ring()
Traceback (most recent call last):
  ...
ValueError: each generator must be integral
```

```python
free_module(base=None, basis=None, map=True)
```

Return a free module $V$ over a specified base ring together with maps to and from $V$.

**INPUT:**

- `base` – a subring $R$ so that this ring/field is isomorphic to a finite-rank free $R$-module $V$
- `basis` – a basis for this ring/field over the base
- `map` – boolean (default True), whether to return $R$-linear maps to and from $V$

**OUTPUT:**

- A finite-rank free $R$-module $V$
- An $R$-module isomorphism from $V$ to this ring/field (only included if `map` is True)
- An $R$-module isomorphism from this ring/field to $V$ (only included if `map` is True)

**EXAMPLES:**

```python
sage: R.<x> = ZZ[]
sage: K.<a> = Qq(125)
sage: L.<pi> = K.extension(x^2-5)
```
sage: V, from_V, to_V = K.free_module()
sage: W, from_W, to_W = L.free_module()
sage: W0, from_W0, to_W0 = L.free_module(base=Qp(5))
sage: to_V(a + O(5^7))
(0(5^7), 1 + 0(5^7), 0(5^7))
sage: to_W(a)
(a + 0(5^20), 0(5^20))
sage: to_W0(a + O(5^7))
(0(5^7), 1 + 0(5^7), 0(5^7), 0(5^7), 0(5^7))
sage: to_W(pi)
(0(5^21), 1 + 0(5^20))
sage: to_W0(pi + O(pi^11))
(0(5^6), 0(5^6), 0(5^6), 1 + 0(5^5), 0(5^5), 0(5^5))
sage: X, from_X, to_X = K.free_module(K)
sage: to_X(a)
(a + 0(5^20))

ground_ring()

Returns the ring of which this ring is an extension.

EXAMPLES:

sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: W.ground_ring()
5-adic Ring with capped relative precision 5

ground_ring_of_tower()

Returns the p-adic base ring of which this is ultimately an extension.

Currently this function is identical to ground_ring(), since relative extensions have not yet been implemented.

EXAMPLES:

sage: Qq(27,30,names='a').ground_ring_of_tower()
3-adic Field with capped relative precision 30

modulus(exact=False)

Returns the polynomial defining this extension.

INPUT:

- exact -- boolean (default False), whether to return the underlying exact defining polynomial rather than the one with coefficients in the base ring.

EXAMPLES:

sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: W.modulus()
(1 + O(5^5))*x^5 + O(5^6)*x^4 + (3*5^2 + O(5^6))*x^3 + (2*5 + 4*5^2 + 4*5^3 + O(5^5) + 4*5^4 + 4*5^5 + O(5^6))*x^2 + (5^3 + O(5^6))*x + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + O(5^6)

sage: W.modulus(exact=True)
x^5 + 75*x^3 - 15*x^2 + 125*x - 5

See also:

defining_polynomial() exact_field()

polynomial_ring()

Returns the polynomial ring of which this is a quotient.

EXAMPLES:

sage: Qq(27,30,names='a').polynomial_ring()
Univariate Polynomial Ring in x over 3-adic Field with capped relative precision 30

random_element()

Return a random element of self.

This is done by picking a random element of the ground ring self.degree() times, then treating those elements as coefficients of a polynomial in self.gen().

EXAMPLES:

sage: R.<a> = Zq(125, 5)
sage: R.random_element().parent() is R
True
sage: R = Zp(5,3); S.<x> = ZZ []; f = x^5 + 25*x^2 - 5; W.<w> = R.ext(f)
sage: W.random_element().parent() is W
True

class sage.rings.padics.padic_extension_generic.pAdicModuleIsomorphism

Bases: sage.categories.map.Map

A base class for various isomorphisms between p-adic rings/fields and free modules

EXAMPLES:

sage: K.<a> = Qq(125)
sage: V, fr, to = K.free_module()
sage: from sage.rings.padics.padic_extension_generic import pAdicModuleIsomorphism
sage: isinstance(fr, pAdicModuleIsomorphism)
True

is_injective()

EXAMPLES:

sage: K.<a> = Qq(125)
sage: V, fr, to = K.free_module()
sage: fr.is_injective()
True
is_surjective()

EXAMPLES:

```python
sage: K.<a> = Qq(125)
sage: V, fr, to = K.free_module()
sage: fr.is_surjective()
True
```
This file implements the shared functionality for Eisenstein extensions.

AUTHORS:

• David Roe

class sage.rings.padics.eisenstein_extension_generic.EisensteinExtensionGeneric(poly, prec, print_mode, names, element_class)

Bases: sage.rings.padics.padic_extension_generic.pAdicExtensionGeneric

Initializes self.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7) #indirect doctest
```

**absolute_e()**

Return the absolute ramification index of this ring or field

EXAMPLES:

```
sage: K.<a> = Qq(3^5)
sage: K.absolute_e()
1

sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.absolute_e()
2
```

**gen(n=0)**

Returns a generator for self as an extension of its ground ring.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.gen()
t + O(t^21)
```
inertia_subring()
Returns the inertia subring.
Since an Eisenstein extension is totally ramified, this is just the ground field.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.inertia_subring()
7-adic Ring with capped relative precision 10
```

residue_class_field()
Returns the residue class field.

INPUT:
- self – a p-adic ring

OUTPUT:
- the residue field

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.residue_class_field()
Finite Field of size 7
```

residue_ring(n)
Return the quotient of the ring of integers by the nth power of its maximal ideal.

EXAMPLES:

```
sage: S.<x> = ZZ[]
sage: W.<w> = Zp(5).extension(x^2 - 5)
sage: W.residue_ring(1)
Ring of integers modulo 5
```

The following requires implementing more general Artinian rings:

```
sage: W.residue_ring(2)
Traceback (most recent call last):
  ...
NotImplementedError
```

uniformizer()
Returns the uniformizer of self, ie a generator for the unique maximal ideal.

EXAMPLES:

```
sage: A = Zp(7,10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2+7)
sage: B.uniformizer()
t + O(t^21)
```
**uniformizer_pow(n)**

Returns the nth power of the uniformizer of self (as an element of self).

**EXAMPLES:**

```sage
code
sage: A = Zp(7, 10)
sage: S.<x> = A[]
sage: B.<t> = A.ext(x^2 + 7)
sage: B.uniformizer_pow(5)
t^5 + O(t^25)
```
Chapter 8. Eisenstein Extension Generic
UNRAMIFIED EXTENSION GENERIC

This file implements the shared functionality for unramified extensions.

AUTHORS:
• David Roe

class sage.rings.padics.unramified_extension_generic.UnramifiedExtensionGeneric(poly, prec, print_mode, names, element_class)

Bases: sage.rings.padics.padic_extension_generic.pAdicExtensionGeneric

An unramified extension of Qp or Zp.

absolute_f()
Return the degree of the residue field of this ring/field over its prime subfield

EXAMPLES:

```
sage: K.<a> = Qq(3^5)
sage: K.absolute_f()
5
sage: L.<pi> = Qp(3).extension(x^2 - 3)
sage: L.absolute_f()
1
```

discriminant(K=None)
Returns the discriminant of self over the subring K.

INPUT:
• K – a subring/subfield (defaults to the base ring).

EXAMPLES:

```
sage: R.<a> = Zq(125)
sage: R.discriminant()
Traceback (most recent call last):
...
NotImplementedError
```

gen(n=0)
Returns a generator for this unramified extension.
This is an element that satisfies the polynomial defining this extension. Such an element will reduce to a generator of the corresponding residue field extension.

EXAMPLES:

```
sage: R.<a> = Zq(125); R.gen()
a + O(5^20)
```

**has_pth_root()**

Returns whether or not \( \mathbb{Z}_p \) has a primitive \( p \)th root of unity.

Since adjoining a \( p \)th root of unity yields a totally ramified extension, self will contain one if and only if the ground ring does.

**INPUT:**

- `self` – a \( p \)-adic ring

**OUTPUT:**

- boolean – whether self has primitive \( p \)th root of unity.

**EXAMPLES:**

```
sage: R.<a> = Zq(1024); R.has_pth_root()
True
sage: R.<a> = Zq(17^5); R.has_pth_root()
False
```

**has_root_of_unity(n)**

Return whether or not \( \mathbb{Z}_p \) has a primitive \( n \)th root of unity.

**INPUT:**

- `self` – a \( p \)-adic ring
- `n` – an integer

**OUTPUT:**

- boolean

**EXAMPLES:**

```
sage: R.<a> = Zq(37^8)
sage: R.has_root_of_unity(144)
True
sage: R.has_root_of_unity(89)
True
sage: R.has_root_of_unity(11)
False
```

**is_galois(K=None)**

Returns True if this extension is Galois.

Every unramified extension is Galois.

**INPUT:**

- `K` – a subring/subfield (defaults to the base ring).

**EXAMPLES:**
```python
sage: R.<a> = Zq(125); R.is_galois()
True
```

**residue_class_field()**

Returns the residue class field.

**EXAMPLES:**

```python
sage: R.<a> = Zq(125); R.residue_class_field()
Finite Field in a0 of size 5^3
```

**residue_ring(n)**

Return the quotient of the ring of integers by the nth power of its maximal ideal.

**EXAMPLES:**

```python
sage: R.<a> = Zq(125)
sage: R.residue_ring(1)
Finite Field in a0 of size 5^3
```

The following requires implementing more general Artinian rings:

```python
sage: R.residue_ring(2)
Traceback (most recent call last):
  ... Not Implemented
```

**uniformizer()**

Returns a uniformizer for this extension.

Since this extension is unramified, a uniformizer for the ground ring will also be a uniformizer for this extension.

**EXAMPLES:**

```python
sage: R.<a> = ZqCR(125)
sage: R.uniformizer()
5 + O(5^21)
```

**uniformizer_pow(n)**

Returns the nth power of the uniformizer of self (as an element of self).

**EXAMPLES:**

```python
sage: R.<a> = ZqCR(125)
sage: R.uniformizer_pow(5)
5^5 + O(5^25)
```
Implementations of $\mathbb{Z}_p$ and $\mathbb{Q}_p$

AUTHORS:
- David Roe
- Genya Zaytman: documentation
- David Harvey: doctests
- William Stein: doctest updates

EXAMPLES:
$p$-adic rings and fields are examples of inexact structures, as the reals are. That means that elements cannot generally be stored exactly: to do so would take an infinite amount of storage. Instead, we store an approximation to the elements with varying precision.

There are two types of precision for a $p$-adic element. The first is relative precision, which gives the number of known $p$-adic digits:

```
sage: R = Qp(5, 20, 'capped-rel', 'series'); a = R(675); a
2*5^2 + 5^4 + O(5^22)
sage: a.precision_relative()
20
```

The second type of precision is absolute precision, which gives the power of $p$ that this element is stored modulo:

```
sage: a.precision_absolute()
22
```

The number of times that $p$ divides the element is called the valuation, and can be accessed with the functions `valuation()` and `ordp()`:

```
sage: a.valuation()
2
```

The following relationship holds:

```
self.valuation() + self.precision_relative() == self.precision_absolute().
sage: a.valuation() + a.precision_relative() == a.precision_absolute() True
```

In the capped relative case, the relative precision of an element is restricted to be at most a certain value, specified at the creation of the field. Individual elements also store their own precision, so the effect of various arithmetic operations on precision is tracked. When you cast an exact element into a capped relative field, it truncates it to the precision cap of the field.
```python
sage: R = Qp(5, 5); a = R(4006); a
1 + 5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(17/3); b
4 + 2*5 + 3*5^2 + 5^3 + 3*5^4 + O(5^5)
sage: c = R(4025); c
5*2 + 2*5^3 + 5^4 + 5^5 + O(5^7)
sage: a + b
4*5 + 3*5^2 + 3*5^3 + 4*5^4 + O(5^5)
sage: a + b + c
4*5 + 4*5^2 + 5^4 + O(5^5)
```

In the capped absolute type, instead of having a cap on the relative precision of an element there is instead a cap on the absolute precision. Elements still store their own precisions, and as with the capped relative case, exact elements are truncated when cast into the ring:

```python
sage: R = ZpCA(5, 5, 'capped-rel', 'series'); a = R(4006); a
5 + 2*5^3 + 5^4 + O(5^5)
sage: b = R(4025); b
5^2 + 2*5^3 + 5^4 + O(5^5)
sage: a * b
5^3 + 2*5^4 + O(5^5)
sage: (a * b) // 5^3
1 + 2*5 + O(5^2)
sage: type((a * b) // 5^3)
<class 'sage.rings.padics.padic_capped_absolute_element.pAdicCappedAbsoluteElement'>
sage: (a * b) / 5^3
1 + 2*5 + O(5^2)
sage: type((a * b) / 5^3)
<class 'sage.rings.padics.padic_capped_relative_element.pAdicCappedRelativeElement'>
```

The fixed modulus type is the leanest of the p-adic rings: it is basically just a wrapper around $\mathbb{Z}/p^n\mathbb{Z}$ providing a unified interface with the rest of the p-adics. This is the type you should use if your primary interest is in speed (though it’s not all that much faster than other p-adic types). It does not track precision of elements:

```python
sage: R = ZpFM(5, 5); a = R(4005); a
5 + 2*5^3 + 5^4
sage: a // 5
1 + 2*5 + 0(5^2)
sage: type(a // 5)
<class 'sage.rings.padics.padic_fixed_modulus_element.pAdicFixedModulusElement'>
```

p-adic rings and fields should be created using the creation functions `Zp` and `Qp` as above. This will ensure that there is only one instance of $\mathbb{Z}_p$ and $\mathbb{Q}_p$ of a given type, $p$, print mode and precision. It also saves typing very long class names:
Once one has a $p$-adic ring or field, one can cast elements into it in the standard way. Integers, ints, longs, Rationals, other $p$-adic types, pari $p$-adics and elements of $\mathbb{Z}/p^n\mathbb{Z}$ can all be cast into a $p$-adic field:

```sage
R = Qp(5, 5, 'capped-rel', 'series'); a = R(16); a
1 + 3*5 + O(5^5)
```

In the previous example, since fixed-mod elements don’t keep track of their precision, we assume that it has the full precision of the ring. This is why you have to cast manually here.

While you can cast explicitly as above, the chains of automatic coercion are more restricted. As always in Sage, the following arrows are transitive and the diagram is commutative:

```
text
```

In addition, there are arrows within each type. For capped relative and capped absolute rings and fields, these arrows go from lower precision cap to higher precision cap. This works since elements track their own precision: choosing the parent with higher precision cap means that precision is less likely to be truncated unnecessarily. For fixed modulus parents, the arrow goes from higher precision cap to lower. The fact that elements do not track precision necessitates this choice in order to not produce incorrect results.

```sage
class sage.rings.padics.padic_base_leaves.pAdicFieldCappedRelative(p, prec, print_mode, names)
Bases: sage.rings.padics.generic_nodes.pAdicFieldBaseGeneric, sage.rings.padics.generic_nodes.pAdicCappedRelativeFieldGeneric
An implementation of $p$-adic fields with capped relative precision.

class sage.rings.padics.padic_base_leaves.pAdicFieldFloatingPoint(p, prec, print_mode, names)
Bases: sage.rings.padics.generic_nodes.pAdicFieldBaseGeneric, sage.rings.padics.generic_nodes.pAdicFloatingPointFieldGeneric
An implementation of the $p$-adic rationals with floating point precision.

class sage.rings.padics.padic_base_leaves.pAdicFieldLattice(p, prec, subtype, print_mode, names, label=None)
Bases: sage.rings.padics.generic_nodes.pAdicLatticeGeneric, sage.rings.padics.generic_nodes.pAdicFieldBaseGeneric
An implementation of the $p$-adic numbers with lattice precision.

INPUT:
- $p$ – prime
- prec – precision cap, given as a pair (relative_cap, absolute_cap)
- subtype – either 'cap' or 'float'
- print_mode – dictionary with print options
- names – how to print the prime
- label – the label of this ring

See also:
- label()

EXAMPLES:

sage: R = QpLC(next_prime(10^60))  # indirect doctest
doctest:...: FutureWarning: This class/method/function is marked as experimental. Its functionality or its interface might change without a formal deprecation. See http://trac.sagemath.org/23505 for details.
sage: type(R)
<class 'sage.rings.padics.padic_base_leaves.pAdicFieldLattice_with_category'>
sage: R = QpLC(2,label='init')  # indirect doctest
sage: R
2-adic Field with lattice-cap precision (label: init)

random_element(prec=None, integral=False)
Return a random element of this ring.

INPUT:
- prec – an integer or None (the default): the absolute precision of the generated random element
- integral – a boolean (default: False); if true return an element in the ring of integers

EXAMPLES:

sage: K = QpLC(2)
sage: K.random_element()  # not tested, known bug (see :trac:`32126`)
sage: K.random_element(integral=True)  # random
2^3 + 2^4 + 2^5 + 2^6 + 2^7 + 2^10 + 2^11 + 2^14 + 2^15 + 2^16 + 2^17 + 2^18 + \ldots
\approx 2^{19} + O(2^{20})

sage: K.random_element(prec=10)  # random
2^{(-3)} + 1 + 2 + 2^4 + 2^8 + O(2^{10})

If the given precision is higher than the internal cap of the parent, then the cap is used:

sage: K.precision_cap_relative()
20
sage: K.random_element(prec=100)  # random
2^5 + 2^8 + 2^{11} + 2^{12} + 2^{14} + 2^{18} + 2^{20} + 2^{24} + O(2^{25})

class sage.rings.padics.padic_base_leaves.pAdicFieldRelaxed(p, prec, print_mode, names)
    Bases: sage.rings.padics.generic_nodes.pAdicRelaxedGeneric, sage.rings.padics.
generic_nodes.pAdicFieldBaseGeneric

An implementation of relaxed arithmetics over \( \mathbb{Q}_p \).

INPUT:

- \( p \) – prime
- \( \text{prec} \) – default precision
- \( \text{print\_mode} \) – dictionary with print options
- \( \text{names} \) – how to print the prime

EXAMPLES:

sage: R = QpER(5)  # indirect doctest
sage: type(R)
<class 'sage.rings.padics.padic_base_leaves.pAdicFieldRelaxed_with_category'>

class sage.rings.padics.padic_base_leaves.pAdicRingCappedAbsolute(p, prec, print_mode, names)
    Bases: sage.rings.padics.generic_nodes.pAdicRingBaseGeneric

An implementation of the \( p \)-adic integers with capped absolute precision.

class sage.rings.padics.padic_base_leaves.pAdicRingCappedRelative(p, prec, print_mode, names)
    Bases: sage.rings.padics.generic_nodes.pAdicRingBaseGeneric

An implementation of the \( p \)-adic integers with capped relative precision.

class sage.rings.padics.padic_base_leaves.pAdicRingFixedMod(p, prec, print_mode, names)
    Bases: sage.rings.padics.generic_nodes.pAdicRingBaseGeneric

An implementation of the \( p \)-adic integers using fixed modulus.

class sage.rings.padics.padic_base_leaves.pAdicRingFloatingPoint(p, prec, print_mode, names)
    Bases: sage.rings.padics.generic_nodes.pAdicRingBaseGeneric

An implementation of the \( p \)-adic integers with floating point precision.
class sage.rings.padics.padic_base_leaves.pAdicRingLattice(p, prec, subtype, print_mode, names, label=None)

Bases: sage.rings.padics.generic_nodes.pAdicLatticeGeneric, sage.rings.padics.generic_nodes.pAdicRingBaseGeneric

An implementation of the $p$-adic integers with lattice precision.

INPUT:

- $p$ – prime
- $\text{prec}$ – precision cap, given as a pair $(\text{relative\_cap}, \text{absolute\_cap})$
- $\text{subtype}$ – either 'cap' or 'float'
- $\text{print\_mode}$ – dictionary with print options
- $\text{names}$ – how to print the prime
- $\text{label}$ – the label of this ring

See also:

label()

EXAMPLES:

```
sage: R = ZpLC(next_prime(10^60)) \ # indirect doctest
doctest:...: FutureWarning: This class/method/function is marked as experimental.
:\it, its functionality or its interface might change without a formal deprecation.
See http://trac.sagemath.org/23505 for details.
sage: type(R)
<class 'sage.rings.padics.padic_base_leaves.pAdicRingLattice_with_category'>
sage: R = ZpLC(2, label='init') \ # indirect doctest
sage: R
2-adic Ring with lattice-cap precision (label: init)
```

random_element(prec=None)

Return a random element of this ring.

INPUT:

- $\text{prec}$ – an integer or None (the default): the absolute precision of the generated random element

EXAMPLES:

```
sage: R = ZpLC(2)
sage: R.random_element() \ # random
2^3 + 2^4 + 2^5 + 2^6 + 2^7 + 2^10 + 2^11 + 2^14 + 2^15 + 2^16 + 2^17 + 2^18 +\n:\rightarrow 2^19 + 2^21 + O(2^23)
sage: R.random_element(prec=10) \ # random
1 + 2^3 + 2^4 + 2^7 + O(2^10)
```

class sage.rings.padics.padic_base_leaves.pAdicRingRelaxed(p, prec, print_mode, names)

Bases: sage.rings.padics.generic_nodes.pAdicRelaxedGeneric, sage.rings.padics.generic_nodes.pAdicRingBaseGeneric

An implementation of relaxed arithmetics over $\mathbb{Z}_p$.

INPUT:
• $p$ – prime
• $\text{prec}$ – default precision
• $\text{print\_mode}$ – dictionary with print options
• $\text{names}$ – how to print the prime

**EXAMPLES:**

```python
sage: R = ZpER(5)  # indirect doctest
sage: type(R)
<class 'sage.rings.padic_base_leaves.pAdicRingRelaxed_with_category'>
```
The final classes for extensions of \( \mathbb{Z}_p \) and \( \mathbb{Q}_p \) (i.e., classes that are not just designed to be inherited from).

**AUTHORS:**

- David Roe: initial version

```python
class sage.rings.padics.local_generic_element.LocalGenericElement
    Bases: sage.structure.element.CommutativeRingElement

    add_bigoh(absprec)
    Return a copy of this element with absolute precision decreased to absprec.

    INPUT:
    • absprec – an integer or positive infinity

    EXAMPLES:

    sage: K = QpCR(3,4)
sage: o = K(1); o
1 + O(3^4)
sage: o.add_bigoh(2)
1 + O(3^2)
sage: o.add_bigoh(-5)
O(3^-5)
```

One cannot use add_bigoh to lift to a higher precision; this can be accomplished with lift_to_precision():

```python
sage: o.add_bigoh(5)
1 + O(3^4)
```

Negative values of absprec return an element in the fraction field of the element’s parent:

```python
sage: R = ZpCA(3,4)
sage: R(3).add_bigoh(-5)
O(3^-5)
```

For fixed-mod elements this method truncates the element:
If `absprec` exceeds the precision of the element, then this method has no effect:

```
sage: R(3).add_bigoh(5)
sage: 3
```

A negative value for `absprec` returns an element in the fraction field:

```
sage: R(3).add_bigoh(-1).parent()
sage: 3-adic Field with floating precision 4
```

**euclidean_degree()**

Return the degree of this element as an element of an Euclidean domain.

**EXAMPLES:**

For a field, this is always zero except for the zero element:

```
sage: K = Qp(2)
sage: K.one().euclidean_degree()
sage: 0
sage: K.gen().euclidean_degree()
sage: 0
sage: K.zero().euclidean_degree()
Traceback (most recent call last):
  ... ValueError: euclidean degree not defined for the zero element
```

For a ring which is not a field, this is the valuation of the element:

```
sage: R = Zp(2)
sage: R.one().euclidean_degree()
0
sage: R.gen().euclidean_degree()
1
sage: R.zero().euclidean_degree()
Traceback (most recent call last):
  ... ValueError: euclidean degree not defined for the zero element
```

**inverse_of_unit()**

Returns the inverse of `self` if `self` is a unit.

**OUTPUT:**

- an element in the same ring as `self`

**EXAMPLES:**

```
sage: R = ZpCA(3,5)
sage: a = R(2); a
2 + O(3^5)
sage: b = a.inverse_of_unit(); b
2 + 3 + 3^2 + 3^3 + 3^4 + O(3^5)
```

122 Chapter 12. Local Generic Element
A \texttt{ZeroDivisionError} is raised if an element has no inverse in the ring:

```
sage: R(3).inverse_of_unit()
Traceback (most recent call last):...
ZeroDivisionError: inverse of 3 + O(3^5) does not exist
```

Unlike the usual inverse of an element, the result is in the same ring as \texttt{self} and not just in its fraction field:

```
sage: c = ~a; c
2 + 3 + 3^2 + 3^3 + 3^4 + O(3^5)
sage: a.parent()
3-adic Ring with capped absolute precision 5
sage: b.parent()
3-adic Ring with capped absolute precision 5
sage: c.parent()
3-adic Field with capped relative precision 5
```

For fields this does of course not make any difference:

```
sage: R = QpCR(3,5)
sage: a = R(2)
sage: b = a.inverse_of_unit()
sage: c = ~a
sage: a.parent()
3-adic Field with capped relative precision 5
sage: b.parent()
3-adic Field with capped relative precision 5
sage: c.parent()
3-adic Field with capped relative precision 5
```

\texttt{is_integral()}  
Returns whether self is an integral element.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{self} – a local ring element
\end{itemize}

\textbf{OUTPUT:}

\begin{itemize}
  \item boolean – whether \texttt{self} is an integral element.
\end{itemize}

\textbf{EXAMPLES:}

```
sage: R = Qp(3,20)
sage: a = R(7/3); a.is_integral()
False
sage: b = R(7/5); b.is_integral()
True
```

\texttt{is_padic_unit()}  
Returns whether self is a $p$-adic unit. That is, whether it has zero valuation.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{self} – a local ring element
\end{itemize}

\textbf{OUTPUT:}
• boolean – whether \texttt{self} is a unit

**EXAMPLES:**

```python
sage: R = Zp(3,20,'capped-rel'); K = Qp(3,20,'capped-rel')
sage: R(0).is_padic_unit()
False
sage: R(1).is_padic_unit()
True
sage: R(2).is_padic_unit()
True
sage: R(3).is_padic_unit()
False
sage: Qp(5,5)(5).is_padic_unit()
False
```

\texttt{is\_unit()}

Returns whether \texttt{self} is a unit

**INPUT:**

• \texttt{self} – a local ring element

**OUTPUT:**

• boolean – whether \texttt{self} is a unit

**Note:** For fields all nonzero elements are units. For DVR’s, only those elements of valuation 0 are. An older implementation ignored the case of fields, and returned always the negation of \texttt{self.valuation()==0}. This behavior is now supported with \texttt{self.is_padic_unit()}.

**EXAMPLES:**

```python
sage: R = Zp(3,20,'capped-rel'); K = Qp(3,20,'capped-rel')
sage: R(0).is_unit()
False
sage: R(1).is_unit()
True
sage: R(2).is_unit()
True
sage: R(3).is_unit()
False
sage: Qp(5,5)(5).is_unit()  # Note that 5 is invertible in `QQ_5`, even if it has
                        # positive valuation!
True
sage: Qp(5,5)(5).is_padic_unit()
False
```

\texttt{normalized\_valuation()}

Returns the normalized valuation of this local ring element, i.e., the valuation divided by the absolute ramification index.

**INPUT:**

\texttt{self} – a local ring element.

**OUTPUT:**
rational – the normalized valuation of self.

EXAMPLES:

```
sage: Q7 = Qp(7)
sage: R.<x> = Q7[]
sage: F.<z> = Q7.ext(x^3+7*x+7)
sage: z.normalized_valuation()
1/3
```

\textbf{quo\_rem(}other, integral=False\textbf{)}

Return the quotient with remainder of the division of this element by other.

INPUT:

• other – an element in the same ring
• integral – if True, use integral-style remainders even when the parent is a field. Namely, the remainder will have no terms in its p-adic expansion above the valuation of other.

EXAMPLES:

```
sage: R = Zp(3, 5)
sage: R(12).quo_rem(R(2))
(2^3 + 0(3^6), 0)
sage: R(2).quo_rem(R(12))
(0(3^4), 2 + 0(3^5))
```

You can get the same behavior for fields as for rings by using integral=True:

```
sage: K = Qp(3, 5)
sage: K(12).quo_rem(K(2), integral=True)
(2^3 + 0(3^6), 0)
sage: K(2).quo_rem(K(12), integral=True)
(0(3^4), 2 + 0(3^5))
```

\textbf{slice(}i, j, k=1, lift\_mode='\text{simple}'\textbf{)}

Returns the sum of the $p^{i+i\cdot k}$ terms of the series expansion of this element, where $p$ is the uniformizer, for $i + l \cdot k$ between $i$ and $j-1$ inclusive, and nonnegative integers $l$. Behaves analogously to the slice function for lists.

INPUT:

• $i$ – an integer; if set to None, the sum will start with the first non-zero term of the series.
• $j$ – an integer; if set to None or $\infty$, this method behaves as if it was set to the absolute precision of this element.
• $k$ – (default: 1) a positive integer

EXAMPLES:

```
sage: R = Zp(5, 6, 'capped-rel')
sage: a = R(1/2); a
```

(continues on next page)
\[3 + 2 \cdot 5 + 2 \cdot 5^2 + 2 \cdot 5^3 + 2 \cdot 5^4 + 2 \cdot 5^5 + O(5^6)\]

```
sage: a.slice(2, 4)
2 \cdot 5^2 + 2 \cdot 5^4 + O(5^6)
```

The step size \(k\) has to be positive:

```
sage: a.slice(0, 3, 0)
Traceback (most recent call last):
...
ValueError: slice step must be positive
```

```
sage: a.slice(0, 3, -1)
Traceback (most recent call last):
...
ValueError: slice step must be positive
```

If \(i\) exceeds \(j\), then the result will be zero, with the precision given by \(j\):

```
sage: a.slice(1, 6, 2)
2 \cdot 5^2 + 2 \cdot 5^3 + O(5^6)
```

```
sage: a.slice(0, 7, 2)
3 + 2 \cdot 5^2 + 2 \cdot 5^4 + O(5^6)
```

However, the precision cannot exceed the precision of the element:

```
sage: a.slice(101, 100)
O(5^6)
```

```
sage: a.slice(0, 7, 2)
3 + 2 \cdot 5^2 + 2 \cdot 5^4 + O(5^6)
```

If start is left blank, it is set to the valuation:

```
sage: K = Qp(5, 6)
sage: x = K(1/25 + 5); x
5^-2 + 5 + O(5^4)
sage: x.slice(None, 3)
5^-2 + 5 + O(5^3)
sage: x[:3]
doctest:warning
...
DeprecationWarning: __getitem__ is changing to match the behavior of number_fields. Please use expansion instead.
See http://trac.sagemath.org/14825 for details.
5^-2 + 5 + O(5^3)
sage: x[:3]
```

```
sqrt(extend=True, all=False, algorithm=None)
```

Return the square root of this element.

INPUT:
• **self** – a $p$-adic element.

• **extend** – a boolean (default: **True**); if **True**, return a square root in an extension if necessary; if **False** and no root exists in the given ring or field, raise a `ValueError`.

• **all** – a boolean (default: **False**); if **True**, return a list of all square roots.

• **algorithm** – "pari", "sage" or `None` (default: `None`); Sage provides an implementation for any extension of $Q_p$, whereas only square roots over $Q_p$ is implemented in Pari; the default is "pari" if the ground field is $Q_p$, "sage" otherwise.

**OUTPUT:**

The square root or the list of all square roots of this element.

**NOTE:**

The square root is chosen (resp. the square roots are ordered) in a deterministic way, which is compatible with change of precision.

**EXAMPLES:**

```sage
sage: R = Zp(3, 20)
sage: sqrt(R(0))
0

sage: sqrt(R(1))
1 + O(3^20)

sage: R(2).sqrt(extend=False)
Traceback (most recent call last):
  ...
ValueError: element is not a square

sage: s = sqrt(R(4)); -s
2 + O(3^20)

sage: s = sqrt(R(9)); s
3 + O(3^21)
```

Over the 2-adics, the precision of the square root is less than the input:

```sage
sage: R2 = Zp(2, 20)
sage: sqrt(R2(1))
1 + O(2^19)

sage: sqrt(R2(4))
2 + O(2^20)

sage: R.<t> = Zq(2^10, 10)
sage: u = 1 + 8*t
sage: sqrt(u)
1 + t*2^2 + t*2*2*3 + t*2*2^4 + (t*4 + t*3 + t*2)*2*5 + (t*4 + t*2)*2*6 + (t*5 + t*2)*2*7 + (t*6 + t*5 + t*4 + t*2)*2*8 + O(2^9)

sage: R.<a> = Zp(2).extension(x^3 - 2)
sage: u = R(1 + a^4 + a^5 + a^7 + a^8, 10); u
1 + a^4 + a^5 + a^7 + a^8 + O(a^10)
```

(continues on next page)
However, observe that the precision increases to its original value when we recompute the square of the square root:

sage: v^2
1 + a^4 + a^5 + a^7 + a^8 + O(a^10)

If the input does not have enough precision in order to determine if the given element has a square root in the ground field, an error is raised:

sage: R(1, 6).sqrt()
Traceback (most recent call last):
...  
PrecisionError: not enough precision to be sure that this element has a square root

sage: R(1, 7).sqrt()
1 + O(a^4)

sage: R(1+a^6, 7).sqrt(extend=False)
Traceback (most recent call last):
...  
ValueError: element is not a square

In particular, an error is raised when we try to compute the square root of an inexact

`sage.rings.padics.padic_generic_element.dwork_mahler_coeffs(R, bd=20)`

Compute Dwork’s formula for Mahler coefficients of $p$-adic Gamma.

This is called internally when one computes Gamma for a $p$-adic integer. Normally there is no need to call it directly.

INPUT:

- $R$ – $p$-adic ring in which to compute
- $bd$ – integer. Number of terms in the expansion to use

OUTPUT:

A list of $p$-adic integers.

EXAMPLES:

```python
sage: from sage.rings.padics.padic_generic_element import dwork_mahler_coeffs,
    evaluate_dwork_mahler
sage: R = Zp(3)
sage: v = dwork_mahler_coeffs(R)
sage: x = R(1/7)
sage: evaluate_dwork_mahler(v, x, 3, 20, 1)
2 + 2*3 + 3^2 + 3^3 + 3^4 + 3^5 + 2*3^6 + 2*3^7 + 2*3^8 + 2*3^9 + 2*3^11 + 2*3^12 +
     3^13 + 3^14 + 2*3^16 + 3^17 + 3^19 + O(3^20)
sage: x.dwork_expansion(a=1)  # Same result
2 + 2*3 + 3^2 + 3^3 + 3^4 + 3^5 + 2*3^6 + 2*3^7 + 2*3^8 + 2*3^9 + 2*3^11 + 2*3^12 +
     3^13 + 3^14 + 2*3^16 + 3^17 + 3^19 + O(3^20)
```

`sage.rings.padics.padic_generic_element.evaluate_dwork_mahler(v, x, p, bd, a)`

Evaluate Dwork’s Mahler series for $p$-adic Gamma.

EXAMPLES:
```python
sage: from sage.rings.padics.padic_generic_element import dwork_mahler_coeffs,
    evaluate_dwork_mahler
sage: R = Zp(3)
sage: v = dwork_mahler_coeffs(R)
sage: x = R(1/7)
sage: evaluate_dwork_mahler(v, x, 3, 20, 1)
2 + 2*3 + 3^2 + 3^3 + 3^4 + 3^5 + 2*3^6 + 2*3^7 + 2*3^8 + 2*3^9 + 2*3^11 + 2*3^12 +
   3^13 + 3^14 + 2*3^16 + 3^17 + 3^19 + O(3^20)
sage: x.dwork_expansion(a=1)  # Same result
2 + 2*3 + 3^2 + 3^3 + 3^4 + 3^5 + 2*3^6 + 2*3^7 + 2*3^8 + 2*3^9 + 2*3^11 + 2*3^12 +
   3^13 + 3^14 + 2*3^16 + 3^17 + 3^19 + O(3^20)
```

sage.rings.padics.padic_generic_element.gauss_table($p, f, prec, use_longs$)

Compute a table of Gauss sums using the Gross-Koblitz formula.

This is used in the computation of $L$-functions of hypergeometric motives. The Gross-Koblitz formula is used as in sage.rings.padics.misc.gauss_sum, but further unpacked for efficiency.

**INPUT:**
- $p$ - prime
- $f, prec$ - positive integers
- $use_longs$ - boolean; if True, computations are done in C long long integers rather than Sage $p$-adics, and the results are returned as a Python array rather than a list.

**OUTPUT:**
A list of length $q - 1 = p^f - 1$. The entries are $p$-adic units created with absolute precision $prec$.

**EXAMPLES:**

```python
sage: from sage.rings.padics.padic_generic_element import gauss_table
sage: gauss_table(2,2,4,True)
[1 + 2 + 2^2 + 2^3, 1 + 2 + 2^2 + 2^3, 1 + 2 + 2^2 + 2^3]
sage: gauss_table(3,2,4,True)[3]
2 + 3 + 2*3^2
```

class sage.rings.padics.padic_generic_element.pAdicGenericElement

**Bases:** sage.rings.padics.local_generic_element.LocalGenericElement

**abs**($prec=None$)

Return the $p$-adic absolute value of **self**.

This is normalized so that the absolute value of $p$ is $1/p$.

**INPUT:**
- $prec$ – Integer. The precision of the real field in which the answer is returned. If None, returns a rational for absolutely unramified fields, or a real with 53 bits of precision for ramified fields.

**EXAMPLES:**

```python
sage: a = Qp(5)(15); a.abs()
1/5
sage: a.abs(53)
0.200000000000000
sage: Qp(7)(0).abs()
0
```

(continues on next page)
An unramified extension:

```python
sage: R = Zp(5, 5)
sage: P.<x> = PolynomialRing(R)
sage: Z25.<u> = R.ext(x^2 - 3)
sage: u.abs()
1
sage: (u^24 - 1).abs()
1/5
```

A ramified extension:

```python
sage: W.<w> = R.ext(x^5 + 75*x^3 - 15*x^2 + 125*x - 5)
sage: w.abs()
0.724779663677696
sage: W(0).abs()
0.000000000000000
```

**additive_order**(prec=None)

Returns the additive order of this element truncated at precision prec

**INPUT:**

- prec – an integer or None (default: None)

**OUTPUT:**

The additive order of this element

**EXAMPLES:**

```python
sage: R = Zp(7, 4, 'capped-rel', 'series'); a = R(7^3); a.additive_order(3)
1
sage: a.additive_order(4)
+Infinity
sage: R = Zp(7, 4, 'fixed-mod', 'series'); a = R(7^5); a.additive_order(6)
1
```

**algdep**(n)

Returns a polynomial of degree at most $n$ which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won’t be if this number is a good approximation to an algebraic number of degree less than $n$.

**ALGORITHM:** Uses the PARI C-library `algdep` command.

**INPUT:**

- self – a p-adic element
- n – an integer

**OUTPUT:**

polynomial – degree $n$ polynomial approximately satisfied by self
EXAMPLES:

```plaintext
sage: K = Qp(3,20,'capped-rel','series'); R = Zp(3,20,'capped-rel','series')
sage: a = K(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2*3^19 + O(3^20)
sage: a.algebraic_dependency(1)
19*x - 7
```

```plaintext
sage: K2 = Qp(7,20,'capped-rel')
sage: b = K2.zeta(); b.algebraic_dependency(2)
x^2 - x + 1
```

```plaintext
sage: K2 = Qp(11,20,'capped-rel')
sage: b = K2.zeta(); b.algebraic_dependency(4)
x^4 - x^3 + x^2 - x + 1
```

```plaintext
sage: a = R(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2*3^19 + O(3^20)
sage: a.algebraic_dependency(1)
19*x - 7
```

```plaintext
sage: R2 = Zp(7,20,'capped-rel')
sage: b = R2.zeta(); b.algebraic_dependency(2)
x^2 - x + 1
```

```plaintext
sage: R2 = Zp(11,20,'capped-rel')
sage: b = R2.zeta(); b.algebraic_dependency(4)
x^4 - x^3 + x^2 - x + 1
```

**algebraic_dependency(n)**

Returns a polynomial of degree at most $n$ which is approximately satisfied by this number. Note that the returned polynomial need not be irreducible, and indeed usually won’t be if this number is a good approximation to an algebraic number of degree less than $n$.

ALGORITHM: Uses the PARI C-library algdep command.

INPUT:

• self – a p-adic element

• n – an integer

OUTPUT:

polynomial – degree $n$ polynomial approximately satisfied by self

EXAMPLES:

```plaintext
sage: K = Qp(3,20,'capped-rel','series'); R = Zp(3,20,'capped-rel','series')
sage: a = K(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2*3^19 + O(3^20)
sage: a.algebraic_dependency(1)
19*x - 7
```

```plaintext
sage: K2 = Qp(7,20,'capped-rel')
sage: b = K2.zeta(); b.algebraic_dependency(2)
x^2 - x + 1
```

```plaintext
sage: K2 = Qp(11,20,'capped-rel')
sage: b = K2.zeta(); b.algebraic_dependency(4)
x^4 - x^3 + x^2 - x + 1
```

(continues on next page)
\texttt{sage}: \ a = R(7/19); \ a
g1 + 2\cdot3 + 3\cdot2 + 3\cdot3 + 2\cdot3^4 + 2\cdot3^5 + 3\cdot8 + 2\cdot3^9 + 3\cdot11 + 3\cdot12 + 2\cdot3^15 + 2\cdot3^16 + 3\cdot17 + 2\cdot3^19 + O(3^20)
\texttt{sage}: \ a.algebraic_dependency(1)
19^x - 7
\texttt{sage}: \ R2 = Zp(7,20,'capped-rel')
\texttt{sage}: \ b = R2.zeta(); \ b.algebraic_dependency(2)
x^2 - x + 1
\texttt{sage}: \ R2 = Zp(11,20,'capped-rel')
\texttt{sage}: \ b = R2.zeta(); \ b.algebraic_dependency(4)
x^4 - x^3 + x^2 - x + 1

\texttt{artin_hasse_exp}(\texttt{prec=none, algorithm=None})

Return the Artin-Hasse exponential of this element.

\textbf{INPUT}:

- \texttt{prec} – an integer or \texttt{None} (default: \texttt{None}) the desired precision on the result; if \texttt{None}, the precision is derived from the precision on the input
- \texttt{algorithm} – \texttt{direct}, \texttt{series}, \texttt{newton} or \texttt{None} (default)

The direct algorithm computes the Artin-Hasse exponential of \(x\), namely \(AH(x)\) as

\[
AH(x) = \exp\left(x + \frac{x^p}{p} + \frac{x^{p^2}}{p^2} + \ldots\right)
\]

It runs roughly as fast as the computation of the exponential (since the computation of the argument is not that costly).

The series algorithm computes the series defining the Artin-Hasse exponential and evaluates it.

The Newton algorithm solves the equation

\[
\log(AH(x)) = x + \frac{x^p}{p} + \frac{x^{p^2}}{p^2} + \ldots
\]

using a Newton scheme. It runs roughly as fast as the computation of the logarithm.

By default, we use the direct algorithm if a fast algorithm for computing the exponential is available. If not, we use the Newton algorithm if a fast algorithm for computing the logarithm is available. Otherwise we switch to the series algorithm.

\textbf{OUTPUT}:

The Artin-Hasse exponential of this element.

See Wikipedia article Artin-Hasse_exponential for more information.

\textbf{EXAMPLES}:

\texttt{sage}: \ x = Zp(5)(45/7)
\texttt{sage}: \ y = x.artin_hasse_exp(); \ y
1 + 2\cdot5 + 4\cdot5\cdot2 + 3\cdot5\cdot3 + 5\cdot7 + 2\cdot5\cdot8 + 3\cdot5\cdot10 + 2\cdot5\cdot11 + 2\cdot5\cdot12 + 2\cdot5\cdot13 + 5\cdot14 + 3\cdot5\cdot17 + 2\cdot5\cdot18 + 2\cdot5\cdot19 + O(5^20)
\texttt{sage}: \ y * (-x).artin_hasse_exp()
1 + O(5^20)

The function respects your precision:
Unless you tell it not to:

```
sage: x = Zp(3)(45/7)
sage: x.artin_hasse_exp()
1 + 2*3^2 + 3^4 + 2*3^5 + 3^6 + 2*3^7 + 2*3^8 + 3^9 + 2*3^10 + 3^11 +
3^13 + 2*3^15 + 2*3^16 + 2*3^17 + 3^19 + 3^20 + 2*3^21 + 3^23 + 3^24 +
3^26 + 3^27 + 2*3^28 + O(3^30)
sage: x.artin_hasse_exp(10)
1 + 2*3^2 + 3^4 + 2*3^5 + 3^6 + 2*3^7 + 2*3^8 + 3^9 + O(3^10)
```

For precision 1 the function just returns 1 since the exponential is always a 1-unit:

```
sage: x = Zp(3).random_element()
sage: while x.dist(0) >= 1:
    ....:    x = Zp(3).random_element()
sage: x.artin_hasse_exp(1)
1 + O(3)
```

AUTHORS:
- Xavier Caruso (2018-08): extend to any p-adic rings and fields and implement several algorithms.

**dwork_expansion** *(bd=20, a=0)*

Return the value of a function defined by Dwork.

Used to compute the p-adic Gamma function, see `gamma()`.

**INPUT:**
- `bd` – integer. Precision bound, defaults to 20
- `a` – integer. Offset parameter, defaults to 0

**OUTPUT:**
A p-adic integer.

**Note:** This is based on GP code written by Fernando Rodriguez Villegas (http://www.ma.utexas.edu/cnt/cnt-frames.html). William Stein sped it up for GP (http://sage.math.washington.edu/home/wstein/www/home/wbhart/pari-2.4.2.alpha/src/basemath/trans2.c). The output is a p-adic integer from Dwork’s expansion, used to compute the p-adic gamma function as in [RV2007] section 6.2. The coefficients of the expansion are now cached to speed up multiple evaluation, as in the trace formula for hypergeometric motives.

**EXAMPLES:**

```
sage: R = Zp(17)
sage: x = R(5*3*17+13*17^2+6*17^3+12*17^5+10*17^14+5*17^17+0(17^19))
sage: x.dwork_expansion(18)
```
\[
16 + 7 \cdot 17 + 11 \cdot 17^2 + 4 \cdot 17^3 + 8 \cdot 17^4 + 10 \cdot 17^5 + 11 \cdot 17^6 + 6 \cdot 17^7 + 17^8 + 8 \cdot 17^9 + 13 \cdot 17^{11} + 9 \cdot 17^{12} + 15 \cdot 17^{13} + 2 \cdot 17^{14} + 6 \cdot 17^{15} + 7 \cdot 17^{16} + 6 \cdot 17^{17} + O(17^{18})
\]

```
sage: R = Zp(5)
sage: x = R(3*5^2+4*5^3+1*5^4+2*5^5+1*5^(10)+O(5^(20)))
sage: x.dwork_expansion()
4 + 4*5 + 4*5^2 + 4*5^3 + 2*5^4 + 4*5^5 + 5^7 + 3*5^9 + 4*5^10 + 3*5^11 + 5^13 + 4*5^14 + 2*5^15 + 2*5^16 + 2*5^17 + 3*5^18 + O(5^20)
```

\textit{exp}(\text{aprec=None, algorithm=None})

Compute the \( p \)-adic exponential of this element if the exponential series converges.

**INPUT:**

- \text{aprec} – an integer or \text{None} (default: \text{None}); if specified, computes only up to the indicated precision
- \text{algorithm} – \text{generic}, \text{binary_splitting}, \text{newton} or \text{None} (default)

The generic algorithm evaluates naively the series defining the exponential, namely

\[
\exp(x) = 1 + x + x^2/2 + x^3/6 + x^4/24 + \cdots.
\]

Its binary complexity is quadratic with respect to the precision.

The binary splitting algorithm is faster, it has a quasi-linear complexity.

The Newton algorithms solve the equation \( \log(x) = \text{self} \) using a Newton scheme. It runs roughly as fast as the computation of the logarithm.

By default, we use the binary splitting if it is available. If it is not, we use the Newton algorithm if a fast algorithm for computing the logarithm is available. Otherwise we switch to the generic algorithm.

**EXAMPLES:**

\textit{log()} and \textit{exp()} are inverse to each other:

```
sage: Z13 = Zp(13, 10)
sage: a = Z13(14); a
1 + 13 + O(13^10)
sage: a.log().exp()
1 + 13 + O(13^10)
```

An error occurs if this is called with an element for which the exponential series does not converge:

```
sage: Z13.one().exp()
Traceback (most recent call last):
...
ValueError: Exponential does not converge for that input.
```

The next few examples illustrate precision when computing \( p \)-adic exponentials:

```
sage: R = Zp(5,10)
sage: e = R(2*5 + 2*5^2 + 4*5^3 + 3*5^4 + 2*5^5 + 4*5^7 + 2*5^8 + 4*5^9 + 2*5^10 + 3*5^11 + 2*5^12 + 3*5^13 + 2*5^14 + 2*5^15 + 3*5^16 + 2*5^17 + 3*5^18 + 0(5^20)).add_bigoh(10); e
2*5 + 2*5^2 + 4*5^3 + 3*5^4 + 5^5 + 3*5^7 + 2*5^8 + 4*5^9 + 0(5^10)
sage: e.exp()*R.teichmuller(4)
4 + 2*5 + 3*5^3 + O(5^10)
```
Logarithms and exponentials in extension fields. First, in an Eisenstein extension:

```
sage: R = Zp(5, 5)
sage: S.<x> = R[]
sage: f = x^4 + 15*x^2 + 625*x - 5
sage: W.<w> = R.ext(f)
sage: z = 1 + w^2 + 4*w^7; z
1 + w^2 + 4*w^7 + O(w^20)
sage: z.log().exp()
1 + w^2 + 4*w^7 + O(w^20)
```

Now an unramified example:

```
sage: R = Zp(5, 5)
sage: S.<x> = R[]
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: b = 1 + 5*(1 + a^2) + 5^3*(3 + 2*a); b
1 + (a^2 + 1)*5 + (2*a + 3)*5^3 + O(5^5)
sage: b.log().exp()
1 + (a^2 + 1)*5 + (2*a + 3)*5^3 + O(5^5)
```

**AUTHORS:**

- Genya Zaytman (2007-02-15)
- Amnon Besser, Marc Masdeu (2012-02-23): Complete rewrite
- Julian Rueth (2013-02-14): Added doctests, fixed some corner cases
- Xavier Caruso (2017-06): Added binary splitting and Newton algorithms

**gamma(algorithm='pari')**

Return the value of the $p$-adic Gamma function.

**INPUT:**

- `algorithm` – string. Can be set to 'pari' to call the pari function, or 'sage' to call the function implemented in sage. The default is 'pari' since pari is about 10 times faster than sage.

**OUTPUT:**

- a $p$-adic integer

**Note:** This is based on GP code written by Fernando Rodriguez Villegas (http://www.ma.utexas.edu/cnt/cnt-frames.html). William Stein sped it up for GP (http://sage.math.washington.edu/home/wstein/www/home/wbhart/pari-2.4.2.alpha/src/basemath/trans2.c). The 'sage' version uses dwork_expansion() to compute the $p$-adic gamma function of self as in [RV2007] section 6.2.
This example illustrates x.gamma() for x a p-adic unit:

```
sage: R = Zp(7)
sage: x = R(2+3*7^2+4*7^3+O(7^20))
sage: x.gamma('pari')
1 + 2*7^2 + 4*7^3 + 5*7^4 + 3*7^5 + 7^8 + 7^9 + 4*7^10 + 3*7^12 + 7^13 + 5*7^14 + 3*7^15 + 2*7^16 + 2*7^17 + 5*7^18 + 4*7^19 + O(7^20)
sage: x.gamma('sage')
1 + 2*7^2 + 4*7^3 + 5*7^4 + 3*7^5 + 7^8 + 7^9 + 4*7^10 + 3*7^12 + 7^13 + 5*7^14 + 3*7^15 + 2*7^16 + 2*7^17 + 5*7^18 + 4*7^19 + O(7^20)
sage: x.gamma('pari') == x.gamma('sage')
True
```

Now x.gamma() for x a p-adic integer but not a unit:

```
sage: R = Zp(17)
sage: x = R(17+17^2+3*17^3+12*17^8+O(17^13))
sage: x.gamma('pari')
1 + 12*17 + 13*17^2 + 13*17^3 + 10*17^4 + 7*17^5 + 16*17^7 + 13*17^9 + 4*17^10 + 9*17^11 + 17^12 + O(17^13)
sage: x.gamma('sage')
1 + 12*17 + 13*17^2 + 13*17^3 + 10*17^4 + 7*17^5 + 16*17^7 + 13*17^9 + 4*17^10 + 9*17^11 + 17^12 + O(17^13)
sage: x.gamma('pari') == x.gamma('sage')
True
```

Finally, this function is not defined if x is not a p-adic integer:

```
sage: K = Qp(7)
sage: x = K(7^-5 + 2*7^-4 + 5*7^-3 + 2*7^-2 + 3*7^-1 + 3 + 3*7 + 7^3 + 4*7^4 + 5*7^5 + 6*7^8 + 3*7^9 + 6*7^10 + 5*7^11 + 6*7^12 + 3*7^13 + 5*7^14 + O(7^15))
sage: x.gamma()
Traceback (most recent call last):
  ...
ValueError: The p-adic gamma function only works on elements of Zp
```

```
```

\textbf{gcd}(\textit{other})

Return a greatest common divisor of \textit{self} and \textit{other}.

\textbf{INPUT:}

- \textit{other} – an element in the same ring as \textit{self}

\textbf{AUTHORS:}

- Julian Rueth (2012-10-19): initial version

\textbf{Note:} Since the elements are only given with finite precision, their greatest common divisor is in general not unique (not even up to units). For example \(O(3)\) is a representative for the elements 0 and 3 in the 3-adic ring \(\mathbb{Z}_3\). The greatest common divisor of \(O(3)\) and \(O(3)\) could be (among others) 3 or 0 which have different valuation. The algorithm implemented here, will return an element of minimal valuation among the possible greatest common divisors.

\textbf{EXAMPLES:}
The greatest common divisor is either zero or a power of the uniformizing parameter:

```
sage: R = Zp(3)
sage: R.zero().gcd(R.zero())
0
sage: R(3).gcd(9)
3 + O(3^21)
```

A non-zero result is always lifted to the maximal precision possible in the ring:

```
sage: a = R(3,2); a
3 + O(3^2)
sage: b = R(9,3); b
3^2 + O(3^3)
sage: a.gcd(b)
3 + O(3^21)
sage: a.gcd(0)
3 + O(3^21)
```

If both elements are zero, then the result is zero with the precision set to the smallest of their precisions:

```
sage: a = R.zero(); a
0
sage: b = R(0,2); b
O(3^2)
sage: a.gcd(b)
O(3^2)
```

One could argue that it is mathematically correct to return $9 + O(3^{22})$ instead. However, this would lead to some confusing behaviour:

```
sage: alternative_gcd = R(9,22); alternative_gcd
3^2 + O(3^{22})
sage: a.is_zero()
True
sage: b.is_zero()
True
sage: alternative_gcd.is_zero()
False
```

If exactly one element is zero, then the result depends on the valuation of the other element:

```
sage: R(0,3).gcd(3^4)
0(3^3)
sage: R(0,4).gcd(3^4)
0(3^4)
sage: R(0,5).gcd(3^4)
3^4 + O(3^{24})
```

Over a field, the greatest common divisor is either zero (possibly with finite precision) or one:

```
sage: K = Qp(3)
sage: K(3).gcd(0)
1 + O(3^{20})
```

(continues on next page)
\texttt{sage}: \texttt{K.zero().gcd(0)}
\[
0
\]
\texttt{sage}: \texttt{K.zero().gcd(K(0,2))}
\[
O(3^2)
\]
\texttt{sage}: \texttt{K(3).gcd(4)}
\[
1 + 0(3^20)
\]

\texttt{is\_prime()}
Return whether this element is prime in its parent

\textbf{EXAMPLES:}

\texttt{sage}: \texttt{A = Zp(2)}
\texttt{sage}: \texttt{A(1).is\_prime()}
\quad\text{False}
\texttt{sage}: \texttt{A(2).is\_prime()}
\quad\text{True}
\texttt{sage}: \texttt{K = A.fraction\_field()}
\texttt{sage}: \texttt{K(2).is\_prime()}
\quad\text{False}
\texttt{sage}: \texttt{B.<pi> = A.extension(x^5 - 2)}
\texttt{sage}: \texttt{pi.is\_prime()}
\quad\text{True}
\texttt{sage}: \texttt{B(2).is\_prime()}
\quad\text{False}

\texttt{is\_square()}
Returns whether this element is a square

\textbf{INPUT:}
\begin{itemize}
\item \texttt{self} – a \texttt{p-adic} element
\end{itemize}

\textbf{EXAMPLES:}

\texttt{sage}: \texttt{R = Zp(3,20,'capped-rel')}
\texttt{sage}: \texttt{R(0).is\_square()}
\quad\text{True}
\texttt{sage}: \texttt{R(1).is\_square()}
\quad\text{True}
\texttt{sage}: \texttt{R(2).is\_square()}
\quad\text{False}

\texttt{is\_squarefree()}
Return whether this element is squarefree, i.e., whether there exists no non-unit \(g\) such that \(g^2\) divides this element.

\textbf{EXAMPLES:}

The zero element is never squarefree:

\texttt{sage}: \texttt{K = Qp(2)}
\texttt{sage}: \texttt{K.zero().is\_squarefree()}
\quad\text{False}
In $p$-adic rings, only elements of valuation at most 1 are squarefree:

```
R = Zp(2)
sage: R(1).is_squarefree()
True
sage: R(2).is_squarefree()
True
sage: R(4).is_squarefree()
False
```

This works only if the precision is known sufficiently well:

```
R(0,1).is_squarefree()
Traceback (most recent call last):
  ...                  ← squarefreeness
R(0,2).is_squarefree()
False
sage: R(1,1).is_squarefree()
True
```

For fields we are not so strict about the precision and treat inexact zeros as the zero element:

```
K(0,0).is_squarefree()
False
```

\[ \log(p_{\text{branch}}=\text{None},\, \pi_{\text{branch}}=\text{None},\, \text{aprec}=\text{None},\, \text{change_frac}=\text{False},\, \text{algorithm}=\text{None}) \]

Compute the $p$-adic logarithm of this element.

The usual power series for the logarithm with values in the additive group of a $p$-adic ring only converges for 1-units (units congruent to 1 modulo $p$). However, there is a unique extension of the logarithm to a homomorphism defined on all the units: If $u = a \cdot v$ is a unit with $v \equiv 1 \pmod{p}$ and $a$ a Teichmuller representative, then we define $\log(u) = \log(v)$. This is the correct extension because the units $U$ split as a product $U = V \times \langle w \rangle$, where $V$ is the subgroup of 1-units and $w$ is a fundamental root of unity. The $\langle w \rangle$ factor is torsion, so must go to 0 under any homomorphism to the fraction field, which is a torsion free group.

INPUT:

- \text{p\_branch} – an element in the base ring or its fraction field; the implementation will choose the branch of the logarithm which sends $p$ to branch
- \text{pi\_branch} – an element in the base ring or its fraction field; the implementation will choose the branch of the logarithm which sends the uniformizer to branch; you may specify at most one of \text{p\_branch} and \text{pi\_branch}, and must specify one of them if this element is not a unit
- \text{aprec} – an integer or \text{None} (default: \text{None}); if not \text{None}, then the result will only be correct to precision \text{aprec}
- \text{change_frac} – In general the codomain of the logarithm should be in the $p$-adic field, however, for most neighborhoods of 1, it lies in the ring of integers. This flag decides if the codomain should be the same as the input (default) or if it should change to the fraction field of the input.
- \text{algorithm} – \text{generic}, \text{binary\_splitting} or \text{None} (default) The generic algorithm evaluates naively the series defining the log, namely

\[
\log(1 - x) = -x - 1/2x^2 - 1/3x^3 - 1/4x^4 - 1/5x^5 - \ldots
\]
Its binary complexity is quadratic with respect to the precision.

The binary splitting algorithm is faster, it has a quasi-linear complexity. By default, we use the binary splitting if it is available. Otherwise we switch to the generic algorithm.

**Note:** What some other systems do:
- PARI: Seems to define the logarithm for units not congruent to 1 as we do.
- MAGMA: Only implements logarithm for 1-units (version 2.19-2)

**Todo:** There is a soft-linear time algorithm for logarithm described by Dan Berstein at [http://cr.yp.to/lineartime/multapps-20041007.pdf](http://cr.yp.to/lineartime/multapps-20041007.pdf)

**EXAMPLES:**

```python
sage: Z13 = Zp(13, 10)
sage: a = Z13(14); a
1 + 13 + O(13^10)
sage: a.log()
13 + 6*13^2 + 2*13^3 + 5*13^4 + 10*13^6 + 13^7 + 11*13^8 + 8*13^9 + O(13^10)

sage: Q13 = Qp(13, 10)
sage: a = Q13(14); a
1 + 13 + O(13^10)
sage: a.log()
13 + 6*13^2 + 2*13^3 + 5*13^4 + 10*13^6 + 13^7 + 11*13^8 + 8*13^9 + O(13^10)
```

Note that the relative precision decreases when we take log. Precisely the absolute precision on \( \log(a) \) agrees with the relative precision on \( a \) thanks to the relation \( d \log(a) = \frac{da}{a} \).

The call \( \log(a) \) works as well:

```python
sage: log(a)
13 + 6*13^2 + 2*13^3 + 5*13^4 + 10*13^6 + 13^7 + 11*13^8 + 8*13^9 + O(13^10)
sage: log(a) == a.log()
True
```

The logarithm is not only defined for 1-units:

```python
sage: R = Zp(5, 10)
sage: a = R(2)
sage: a.log()
2*5 + 3*5^2 + 2*5^3 + 4*5^4 + 2*5^6 + 2*5^7 + 4*5^8 + 2*5^9 + O(5^10)
```

If you want to take the logarithm of a non-unit you must specify either \( p\_branch \) or \( \pi\_branch \):

```python
sage: b = R(5)
sage: b.log()
Traceback (most recent call last):
...
ValueError: you must specify a branch of the logarithm for non-units
sage: b.log(p_branch=4)
```

(continues on next page)
\(4 + O(5^{10})\)

\[
sage: c = R(10)
sage: c.log(p_branch=4)
4 + 2\times 5 + 3\times 5^2 + 2\times 5^3 + 4\times 5^4 + 2\times 5^6 + 2\times 5^7 + 4\times 5^8 + 2\times 5^9 + O(5^{10})
\]

The branch parameters are only relevant for elements of non-zero valuation:

\[
sage: a.log(p_branch=0)
2\times 5 + 3\times 5^2 + 2\times 5^3 + 4\times 5^4 + 2\times 5^6 + 2\times 5^7 + 4\times 5^8 + 2\times 5^9 + O(5^{10})
\]

Logarithms can also be computed in extension fields. First, in an Eisenstein extension:

\[
sage: R = Zp(5,5)
sage: S.<x> = ZZ[]
sage: f = x^4 + 15\times x^2 + 625\times x - 5
sage: W.<w> = R.ext(f)
sage: z = 1 + w^2 + 4\times w^7; z
1 + w^2 + 4\times w^7 + O(w^{20})
sage: z.log()
w^2 + 2\times w^4 + 3\times w^6 + 4\times w^7 + w^9 + 4\times w^{10} + 4\times w^{11} + 4\times w^{12} + 3\times w^{14} + w^{15} + w^{17} + 3\times w^{18} + 3\times w^{19} + O(w^{20})
\]

In an extension, there will usually be a difference between specifying \(p\_branch\) and \(pi\_branch\):

\[
sage: b = W(5)
sage: b.log()
Traceback (most recent call last):
...
ValueError: you must specify a branch of the logarithm for non-units
sage: b.log(p_branch=0)
0(w^{20})
sage: b.log(p_branch=w)
w + O(w^{20})
sage: b.log(pi_branch=0)
3\times w^2 + 2\times w^4 + 2\times w^6 + 3\times w^8 + 4\times w^{10} + w^{13} + w^{14} + 2\times w^{15} + 2\times w^{16} + w^{18} + 4\times w^{19} + O(w^{20})
sage: b.unit_part().log()
3\times w^2 + 2\times w^4 + 2\times w^6 + 3\times w^8 + 4\times w^{10} + w^{13} + w^{14} + 2\times w^{15} + 2\times w^{16} + w^{18} + 4\times w^{19} + O(w^{20})
sage: y = w^2 * 4\times w^7; y
4\times w^9 + O(w^{29})
sage: y.log(p_branch=0)
2\times w^2 + 2\times w^4 + 2\times w^6 + 2\times w^8 + w^{10} + w^{12} + 4\times w^{13} + 4\times w^{14} + 3\times w^{15} + 4\times w^{16} + 4\times w^{17} + w^{18} + 4\times w^{19} + O(w^{20})
sage: y.log(p_branch=w)
w + 2\times w^2 + 2\times w^4 + 4\times w^5 + 2\times w^6 + 2\times w^7 + 2\times w^8 + 4\times w^9 + w^{10} + 3\times w^{11} + w^{12} + 4\times w^{14} + 4\times w^{16} + 2\times w^{17} + w^{19} + O(w^{20})
\]

Check that \(\log\) is multiplicative:
Now an unramified example:

```python
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
```
```python
sage: b = 1 + 5*(1 + a^2) + 5^3*(3 + 2*a)
```
```python
sage: b.log()
```

```python
(a^2 + 1)*5 + (3*a^2 + 4*a + 2)*5^2 + (3*a^2 + 2*a)*5^3 + (3*a^2 + 2*a + 2)*5^4 + O(5^5)
```

We illustrate the effect of the precision argument:

```python
sage: R = ZpCA(7,10)
```
```python
sage: x = R(41152263); x
```
```
5 + 3*7^2 + 4*7^3 + 3*7^4 + 5*7^5 + 6*7^6 + 7^9 + O(7^10)
```
```python
sage: x.log(aprec = 5)
```
```
7 + 3*7^2 + 4*7^3 + 3*7^4 + O(7^5)
```
```python
sage: x.log(aprec = 7)
```
```
7 + 3*7^2 + 4*7^3 + 3*7^4 + 7*5 + 3*7^6 + O(7^7)
```
```python
sage: x.log(p_branch=0)
```
```
7 + 3*7^2 + 4*7^3 + 3*7^4 + 7*5 + 3*7^6 + 7*7 + 3*7^8 + 4*7^9 + O(7^10)
```

The logarithm is not defined for zero:

```python
sage: R.zero().log()
```
```
Traceback (most recent call last):
... ValueError: logarithm is not defined at zero
```

For elements in a $p$-adic ring, the logarithm will be returned in the same ring:

```python
sage: x = R(2)
```
```python
sage: x.log().parent() 7-adic Ring with capped absolute precision 10
```
```python
sage: x = R(14)
```
```python
sage: x.log(p_branch=0).parent() 7-adic Ring with capped absolute precision 10
```

This is not possible if the logarithm has negative valuation:

```python
sage: R = ZpCA(3,10)
```
```python
sage: S.<x> = R[]
```
```python
sage: f = x^3 - 3
```
```python
sage: W.<w> = R.ext(f)
```
```python
sage: w.log(p_branch=2)
```
```
Traceback (most recent call last):
```
ValueError: logarithm is not integral, use change_frac=True to obtain a result in the fraction field

```
sage: w.log(p_branch=2, change_frac=True)
2^w^-3 + O(w^24)
```

AUTHORS:
- William Stein: initial version
- David Harvey (2006-09-13): corrected subtle precision bug (need to take denominators into account! – see trac ticket #53)
- Genya Zaytman (2007-02-14): adapted to new \( p \)-adic class
- Amnon Besser, Marc Masdeu (2012-02-21): complete rewrite, valid for generic \( p \)-adic rings.
- Soroosh Yazdani (2013-02-01): Fixed a precision issue in \_log\_generic(). This should really fix the issue with divisions.
- Xavier Caruso (2017-06): Added binary splitting type algorithms over \( \mathbb{Q}_p \)

```python
minimal_polynomial(name='x', base=None)
```

Returns the minimal polynomial of this element over \( base \)

**INPUT:**
- name – string (default: \( x \)): the name of the variable
- base – a ring (default: the base ring of the parent): the base ring over which the minimal polynomial is computed

**EXAMPLES:**
```
sage: Zp(5,5)(1/3).minimal_polynomial('x')
(1 + O(5^5))*x + 3 + 5 + 3*5^2 + 5^3 + 3*5^4 + O(5^5)

sage: Zp(5,5)(1/3).minimal_polynomial('foo')
(1 + O(5^5))*foo + 3 + 5 + 3*5^2 + 5^3 + 3*5^4 + O(5^5)
```

```
sage: K.<a> = QqCR(2^3,5)
sage: S.<x> = K[]
sage: L.<pi> = K.extension(x^4 - 2^a)

sage: pi.minimal_polynomial()
(1 + O(2^5))*x^4 + a*2 + a*2^2 + a*2^3 + a*2^4 + a*2^5 + O(2^6)

sage: (pi^2).minimal_polynomial()
(1 + O(2^5))*x^2 + a*2 + a*2^2 + a*2^3 + a*2^4 + a*2^5 + O(2^6)

sage: (1/pi).minimal_polynomial()
(1 + O(2^5))*x^4 + (a^2 + 1)*2^-1 + O(2^4)

sage: elt = L.random_element()
sage: P = elt.minimal_polynomial()  # not tested, known bug (see :trac:`32111`)
sage: P(elt) == 0  # not tested
True
```
**multiplicative_order**(prec=None)

Returns the multiplicative order of self, where self is considered to be one if it is one modulo \( p^{\text{prec}} \).

**INPUT:**

- self – a p-adic element
- prec – an integer

**OUTPUT:**

- integer – the multiplicative order of self

**EXAMPLES:**

```plaintext
sage: K = Qp(5,20,'capped-rel')
sage: K(-1).multiplicative_order(20)
2
sage: K(1).multiplicative_order(20)
1
sage: K(2).multiplicative_order(20)
+Infinity
sage: K(5).multiplicative_order(20)
+Infinity
sage: K(1/5).multiplicative_order(20)
+Infinity
sage: K.zeta().multiplicative_order(20)
4
```

Over unramified extensions:

```plaintext
sage: L1.<a> = Qq(5^3)
sage: c = L1.teichmuller(a)
sage: c.multiplicative_order()
124
sage: c^124
1 + O(5^20)
```

Over totally ramified extensions:

```plaintext
sage: L2.<pi> = Qp(5).extension(x^4 + 5^3*x + 10^5*x^2 + 10^6*x + 5)
sage: u = 1 + pi
sage: u.multiplicative_order()
5
sage: v = L2.teichmuller(2)
sage: v.multiplicative_order()
4
sage: (u*v).multiplicative_order()
20
```

**norm**(base=None)

Returns the norm of this p-adic element over base.

**Warning:** This is not the p-adic absolute value. This is a field theoretic norm down to a base ring. If you want the p-adic absolute value, use the abs() function instead.
\textbf{INPUT:}

- \textit{base} – a subring of the parent (default: base ring)

\textbf{OUTPUT:}

The norm of this \(p\)-adic element over the given base.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Zp(5)(5).norm()
sage: K.<a> = QqCR(2^3,5)
sage: S.<x> = K[]
sage: L.<pi> = K.extension(x^4 - 2*a)
sage: pi.norm()  # norm over K
sage: (pi^2).norm()
sage: pi.norm()^2
sage: nth_root(n, all=False)
Return the nth root of this element.

\textbf{INPUT:}

- \textit{n} – an integer
- \textit{all} – a boolean (default: False): if True, return all ntn roots of this element, instead of just one.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A = Zp(5,10)
sage: x = A(61376); x
1 + 5^3 + 3*5^4 + 4*5^5 + 3*5^6 + O(5^10)
sage: y = x.nth_root(4); y
2 + 5 + 2*5^2 + 4*5^3 + 3*5^4 + 5^6 + O(5^10)
sage: y^4 == x
True
sage: x.nth_root(4, all=True)
[2 + 5 + 2*5^2 + 4*5^3 + 3*5^4 + 5^6 + O(5^10),
4 + 4*5 + 4*5^2 + 4*5^4 + 3*5^5 + 5^6 + 3*5^7 + 5^8 + 5^9 + O(5^10),
1 + 4*5^3 + 5^5 + 3*5^6 + 5^7 + 3*5^8 + 3*5^9 + O(5^10)]
\end{verbatim}

When \(n\) is divisible by the underlying prime \(p\), we are losing precision (which is consistent with the fact that raising to the \(p\)th power increases precision):

\begin{verbatim}
sage: z = x.nth_root(5); z
1 + 5^2 + 3*5^3 + 2*5^4 + 5^5 + 3*5^7 + 2*5^8 + O(5^9)
sage: z^5
1 + 5^3 + 3*5^4 + 4*5^5 + 3*5^6 + O(5^10)
\end{verbatim}

Everything works over extensions as well:
sage: \texttt{W.<a> = Zq(5^3)}
sage: \texttt{S.<x> = W[]}
sage: \texttt{R.<pi> = W.extension(x^7 - 5)}
sage: \texttt{R(5).nth_root(7)}
\texttt{pi + O(pi^{141})}
sage: \texttt{R(5).nth_root(7, all=True)}
\texttt{[pi + O(pi^{141})]}

An error is raised if the given element is not a nth power in the ring:

sage: \texttt{R(5).nth_root(11)}
Traceback (most recent call last):
... 
ValueError: this element is not a nth power

Similarly, when precision on the input is too small, an error is raised:

sage: \texttt{x = R(1,6); x}
1 + O(pi^6)
sage: \texttt{x.nth_root(5)}
Traceback (most recent call last):
...
PrecisionError: not enough precision to be sure that this element is a nth power

Check that trac ticket \#30314 is fixed:

sage: \texttt{K = Qp(29)}
sage: \texttt{x = polygen(K)}
sage: \texttt{L.<a> = K.extension(x^2 -29)}
sage: \texttt{L(4).nth_root(2)}
2 + O(a^{40})

\texttt{ordp}(p=None)
Returns the valuation of self, normalized so that the valuation of p is 1

INPUT:

• self – a p-adic element

• p – a prime (default: None). If specified, will make sure that \texttt{p == self.parent().prime()}

NOTE: The optional argument p is used for consistency with the valuation methods on integer and rational.

OUTPUT:

integer – the valuation of self, normalized so that the valuation of p is 1

EXAMPLES:

sage: \texttt{R = Zp(5,20,}'capped-rel'\texttt{)}
sage: \texttt{R(0).ordp()} +Infinity
sage: \texttt{R(1).ordp()} 0
sage: \texttt{R(2).ordp()} 0
sage: \texttt{R(5).ordp()}
(continues on next page)
polylog\((n, p\_branch=0)\)

Return \(Li_n(self)\), the \(n\)-th \(p\)-adic polylogarithm of this element.

INPUT:

• \(n\) – a non-negative integer

• \(p\_branch\) – an element in the base ring or its fraction field; the implementation will choose the branch of the logarithm which sends \(p\) to \(branch\)

EXAMPLES:

The \(n\)-th polylogarithm of \(-1\) is 0 for even \(n\):

```
sage: Qp(13)(-1).polylog(6) == 0
True
```

We can check some identities, for example those mentioned in [DCW2016]:

```
sage: x = Qp(7, prec=30)(1/3)
sage: (x^2).polylog(4) - 8*x.polylog(4) - 8*(-x).polylog(4) == 0
True
```

```
sage: x = Qp(5, prec=30)(4)
sage: x.polylog(2) + (1/x).polylog(2) + x.log(0)**2/2 == 0
True
```

```
sage: x = Qp(11, prec=30)(2)
sage: x.polylog(2) + (1-x).polylog(2) + x.log(0)**2*(1-x).log(0) == 0
True
```

\(Li_1(z) = -\log(1 - z)\) for \(|z| < 1\):

```
sage: Qp(5)(10).polylog(1) == -Qp(5)(1-10).log(0)
True
```

The dilogarithm of 1 is zero:

```
sage: Qp(5)(1).polylog(2)
0(5^20)
```

The cubing relation holds for the trilogarithm at 1:

```
sage: K = Qp(7)
sage: z = K.zeta(3)
```
sage: -8*K(1).polylog(3) == 9*(K(z).polylog(3) + K(z^2).polylog(3))
True

The polylogarithm of 0 is 0:

sage: Qp(11)(0).polylog(7)
0

Only polylogarithms for positive $n$ are defined:

sage: Qp(11)(2).polylog(-1)
Traceback (most recent call last):
...
ValueError: polylogarithm only implemented for n at least 0

Check that trac ticket #29222 is fixed:

sage: K = Qp(7)
sage: print(K(1 + 7^11).polylog(4))
6*7^14 + 3*7^15 + 7^16 + 7^17 + O(7^18)

ALGORITHM:
The algorithm of Besser-de Jeu, as described in [BdJ2008] is used.

AUTHORS:
• Jennifer Balakrishnan - Initial implementation
• Alex J. Best (2017-07-21) - Extended to other residue disks

Todo:
• Implement for extensions.
• Use the change method to create $K$ from self.parent().

rational_reconstruction()
Returns a rational approximation to this $p$-adic number
This will raise an ArithmeticError if there are no valid approximations to the unit part with numerator and denominator bounded by $\sqrt{p^{\text{absprec}}/2}$.

See also:
._rational_()

OUTPUT:
	rational – an approximation to self

EXAMPLES:

sage: R = Zp(5,20,'capped-rel')
sage: for i in range(11):
    ....:     for j in range(1,10):
    ....:         if j == 5: (continues on next page)
square_root(extend=True, all=False, algorithm=None)

Return the square root of this $p$-adic number.

INPUT:

- `self` – a $p$-adic element.
- `extend` – a boolean (default: True); if True, return a square root in an extension if necessary; if False and no root exists in the given ring or field, raise a ValueError.
- `all` – a boolean (default: False); if True, return a list of all square roots.
- `algorithm` – "pari", "sage" or None (default: None); Sage provides an implementation for any extension of $\mathbb{Q}_p$ whereas only square roots over $\mathbb{Q}_p$ is implemented in Pari; the default is "pari" if the ground field is $\mathbb{Q}_p$, "sage" otherwise.

OUTPUT:

The square root or the list of all square roots of this $p$-adic number.

NOTE:

The square root is chosen (resp. the square roots are ordered) in a deterministic way.

EXAMPLES:

```
sage: R = Zp(3, 20)
sage: R(0).square_root()
0

sage: R(1).square_root()
1 + O(3^20)

sage: R(2).square_root(extend=False)
Traceback (most recent call last):
  ...
ValueError: element is not a square

sage: -R(4).square_root()
2 + O(3^20)

sage: R(9).square_root()
3 + O(3^21)
```

When $p = 2$, the precision of the square root is less than the input:

```
sage: R2 = Zp(2, 20)
sage: R2(1).square_root()
1 + O(2^19)

sage: R2(4).square_root()
2 + O(2^20)

sage: R.<t> = Zq(2^10, 10)
sage: u = 1 + 8*t
```

(continues on next page)
However, observe that the precision increases to its original value when we recompute the square of the square root:

\[
\text{sage: } v^2 \\
1 + a^4 + a^5 + a^7 + 0(a^8)
\]

If the input does not have enough precision in order to determine if the given element has a square root in the ground field, an error is raised:

\[
\text{sage: } R(1, 6).\text{square_root()}
\]
Traceback (most recent call last):
... 
PrecisionError: not enough precision to be sure that this element has a square_root

\[
\text{sage: } R(1, 7).\text{square_root()}
\]
1 + 0(a^4)

\[
\text{sage: } R(1+a^6, 7).\text{square_root(extend=False)}
\]
Traceback (most recent call last):
... 
ValueError: element is not a square

In particular, an error is raised when we try to compute the square root of an inexact zero.

\[
\text{str(mode=}\text{None})
\]
Returns a string representation of self.

**EXAMPLES:**

\[
\text{sage: } \text{Zp(5,5,print_mode=’bars’)}(1/3).\text{str()[3:]} \\
’1|3|1|3|2’
\]

\[
\text{trace(base=}\text{None})
\]
Returns the trace of this \(p\)-adic element over the base ring

**INPUT:**

- base – a subring of the parent (default: base ring)

**OUTPUT:**

The trace of this \(p\)-adic element over the given base.

**EXAMPLES:**
sage: Zp(5, 5)(5).trace()
5 + O(5^6)
sage: K.<a> = QqCR(2^3, 7)
sage: S.<x> = K[]
sage: L.<pi> = K.extension(x^4 - 4*a*x^3 + 2*a)

sage: pi.trace()  # trace over K
a*2^2 + O(2^8)
sage: (pi+1).trace()
(a + 1)*2^2 + O(2^7)

val_unit()
Return (self.valuation(), self.unit_part()). To be overridden in derived classes.

EXAMPLES:

sage: Zp(5, 5)(5).val_unit()
(1, 1 + O(5^5))

valuation(p=None)
Returns the valuation of this element.

INPUT:

• self – a p-adic element
  • p – a prime (default: None). If specified, will make sure that p==self.parent().prime()

NOTE: The optional argument p is used for consistency with the valuation methods on integer and rational.

OUTPUT:

integer – the valuation of self

EXAMPLES:

sage: R = Zp(17, 4, 'capped-rel')
sage: a = R(2*17^2)
sage: a.valuation()
2
sage: R = Zp(5, 4, 'capped-rel')
sage: R(8).valuation()
+Infinity

xgcd(other)
Compute the extended gcd of this element and other.

INPUT:

• other – an element in the same ring

OUTPUT:

A tuple r, s, t such that r is a greatest common divisor of this element and other and r = s*self + t*other.

AUTHORS:

• Julian Rueth (2012-10-19): initial version
Note: Since the elements are only given with finite precision, their greatest common divisor is in general not unique (not even up to units). For example $O(3)$ is a representative for the elements 0 and 3 in the 3-adic ring $\mathbb{Z}_3$. The greatest common divisor of $O(3)$ and $O(3)$ could be (among others) 3 or 0 which have different valuation. The algorithm implemented here, will return an element of minimal valuation among the possible greatest common divisors.

EXAMPLES:

The greatest common divisor is either zero or a power of the uniformizing parameter:

```
sage: R = Zp(3)
sage: R.zero().xgcd(R.zero())
(0, 1 + O(3^20), 0)
sage: R(3).xgcd(9)
(3 + O(3^21), 1 + O(3^20), 0)
```

Unlike for \texttt{gcd()}, the result is not lifted to the maximal precision possible in the ring; it is such that $r = s*\text{self} + t*\text{other}$ holds true:

```
sage: a = R(3,2); a
3 + O(3^2)
sage: b = R(9,3); b
3^2 + O(3^3)
sage: a.xgcd(b)
(3 + O(3^2), 1 + O(3), 0)
sage: a.xgcd(0)
(3 + O(3^2), 1 + O(3), 0)
```

If both elements are zero, then the result is zero with the precision set to the smallest of their precisions:

```
sage: a = R.zero(); a
0
sage: b = R(0,2); b
O(3^2)
sage: a.xgcd(b)
(0(3^2), 0, 1 + O(3^20))
```

If only one element is zero, then the result depends on its precision:

```
sage: R(9).xgcd(R(0,1))
(0(3), 0, 1 + 0(3^20))
sage: R(9).xgcd(R(0,2))
(0(3^2), 0, 1 + 0(3^20))
sage: R(9).xgcd(R(0,3))
(3^2 + 0(3^22), 1 + 0(3^20), 0)
sage: R(9).xgcd(R(0,4))
(3^2 + 0(3^22), 1 + 0(3^20), 0)
```

Over a field, the greatest common divisor is either zero (possibly with finite precision) or one:

```
sage: K = Qp(3)
sage: K(3).xgcd(0)
(1 + 0(3^20), 3^-1 + 0(3^19), 0)
```

(continues on next page)
\begin{verbatim}
sage: K.zero().xgcd(0)
(0, 1 + O(3^20), 0)
sage: K.zero().xgcd(K(0,2))
(0(3^2), 0, 1 + O(3^20))
sage: K(3).xgcd(4)
(1 + O(3^20), 3^-1 + O(3^19), 0)
\end{verbatim}
Elements of $p$-adic Rings with Capped Relative Precision

AUTHORS:

- David Roe: initial version, rewriting to use templates (2012-3-1)
- Genya Zaytman: documentation
- David Harvey: doctests

```python
class sage.rings.padics.padic_capped_relative_element.CRElement
    Bases: sage.rings.padics.padic_capped_relative_element.pAdicTemplateElement

    add_bigoh(absprec)
    Returns a new element with absolute precision decreased to absprec.
    INPUT:
    • absprec – an integer or infinity
    OUTPUT:
    an equal element with precision set to the minimum of self’s precision and absprec

    EXAMPLES:
```

```python
sage: R = Zp(7,4,'capped-rel','series'); a = R(8); a.add_bigoh(1)
1 + O(7)
sage: b = R(0); b.add_bigoh(3)
O(7^3)
sage: R = Qp(7,4); a = R(8); a.add_bigoh(1)
1 + O(7)
sage: b = R(0); b.add_bigoh(3)
O(7^3)
```

The precision never increases::

```python
sage: R(4).add_bigoh(2).add_bigoh(4)  
4 + O(7^2)
```

Another example that illustrates that the precision does not increase::

```python
sage: k = Qp(3,5)
sage: a = k(1234123412/3^70); a
2*3^-70 + 3^-69 + 3^-68 + 3^-67 + 0(3^-65)
```

(continues on next page)
\[
sage: \text{a.add_bigoh}(2) \\
2^*3^{^70} + 3^{^69} + 3^{^68} + 3^{^67} + O(3^{^65}) \\
\]

\[
sage: \text{k = Qp}(5,10) \\
sage: \text{a = k}(1/5^{^3} + 5^{^2}); \text{a} \\
5^{^3} - 3 + 5^{^2} + O(5^{^7}) \\
sage: \text{a.add_bigoh}(2) \\
5^{^3} + O(5^{^2}) \\
sage: \text{a.add_bigoh}(-1) \\
5^{^3} + O(5^{^1}) \\
\]

**is\_equal\_to(right, absprec=None)**

Returns whether self is equal to right modulo \(\pi^{\text{absprec}}\).

If \(\text{absprec}\) is None, returns True if self and right are equal to the minimum of their precisions.

**INPUT:**

- right – a \(p\)-adic element
- absprec – an integer, infinity, or None

**EXAMPLES:**

\[
\begin{align*}
sage: \text{R = Zp}(5, 10); \text{a} = \text{R}(0); \text{b} = \text{R}(0, 3); \text{c} = \text{R}(75, 5) \\
sage: \text{aa} = \text{a} + 625; \text{bb} = \text{b} + 625; \text{cc} = \text{c} + 625 \\
sage: \text{a.is\_equal\_to(aa)}, \text{a.is\_equal\_to(aa, 4)}, \text{a.is\_equal\_to(aa, 5)} \\
(False, True, False) \\
sage: \text{a.is\_equal\_to(aa, 15)} \\
Traceback (most recent call last): \\
... \\
PrecisionError: elements not known to enough precision \\
sage: \text{a.is\_equal\_to(a, 50000)} \\
True \\
sage: \text{a.is\_equal\_to(b)}, \text{a.is\_equal\_to(b, 2)} \\
(True, True) \\
sage: \text{a.is\_equal\_to(b, 5)} \\
Traceback (most recent call last): \\
... \\
PrecisionError: elements not known to enough precision \\
sage: \text{b.is\_equal\_to(b, 5)} \\
Traceback (most recent call last): \\
... \\
PrecisionError: elements not known to enough precision \\
sage: \text{b.is\_equal\_to(bb, 3)} \\
True \\
sage: \text{b.is\_equal\_to(bb, 4)} \\
Traceback (most recent call last): \\
... \\
PrecisionError: elements not known to enough precision \\
\end{align*}
\]
\texttt{sage:} \texttt{c.is\_equal\_to(b, 2), c.is\_equal\_to(b, 3)}
(True, False)
\texttt{sage:} \texttt{c.is\_equal\_to(b, 4)}
Traceback (most recent call last):
... 
\text{PrecisionError: elements not known to enough precision}
\texttt{sage:} \texttt{c.is\_equal\_to(cc, 2), c.is\_equal\_to(cc, 4), c.is\_equal\_to(cc, 5)}
(True, True, False)

\textbf{is\_zero}(\textit{absprec}=None)

Determines whether this element is zero modulo \(\pi^{\text{absprec}}\).

If \textit{absprec} is None, returns True if this element is indistinguishable from zero.

\textbf{INPUT:}

- \textit{absprec} – an integer, infinity, or None

\textbf{EXAMPLES:}

\texttt{sage:} \texttt{R = Zp(5); a = R(0); b = R(0,5); c = R(75)}
\texttt{sage:} \texttt{a.is\_zero(), a.is\_zero(6)}
(True, True)
\texttt{sage:} \texttt{b.is\_zero(), b.is\_zero(5)}
(True, True)
\texttt{sage:} \texttt{c.is\_zero(), c.is\_zero(2), c.is\_zero(3)}
(False, True, False)
\texttt{sage:} \texttt{b.is\_zero(6)}
Traceback (most recent call last):
... 
\text{PrecisionError: not enough precision to determine if element is zero}

\textbf{polynomial}(\textit{var}='x')

Return a polynomial over the base ring that yields this element when evaluated at the generator of the parent.

\textbf{INPUT:}

- \textit{var} – string, the variable name for the polynomial

\textbf{EXAMPLES:}

\texttt{sage:} \texttt{K.<a> = Qq(5^3)}
\texttt{sage:} \texttt{a.polynomial()} 
(1 + O(5^20))*x + O(5^20)
\texttt{sage:} \texttt{a.polynomial(var='y')} 
(1 + O(5^20))*y + O(5^20)
\texttt{sage:} \texttt{(5*a\^2 + K(25, 4)).polynomial()} 
(5 + O(5^4))*x^2 + O(5^4)*x + 5^2 + O(5^4)

\textbf{precision\_absolute}()

Returns the absolute precision of this element.

This is the power of the maximal ideal modulo which this element is defined.

\textbf{EXAMPLES:}
The `sage: R = Zp(7,3,'capped-rel'); a = R(7); a.precision_absolute()` example shows how to work with precision using the `precision_absolute()` method. It returns the absolute precision of the element, which is the power of the maximal ideal modulo which the unit part of the element is defined.

```
sage: R = Zp(7,3,'capped-rel'); a = R(7); a.precision_absolute() 4
sage: R = Qp(7,3); a = R(7); a.precision_absolute() 4
sage: R(7^-3).precision_absolute() 0
sage: R(0).precision_absolute() +Infinity
sage: R(0,7).precision_absolute() 7
```

### precision_relative()

Returns the relative precision of this element. This is the power of the maximal ideal modulo which the unit part of self is defined.

```
sage: R = Zp(7,3,'capped-rel'); a = R(7); a.precision_relative() 3
sage: R = Qp(7,3); a = R(7); a.precision_relative() 3
sage: a = R(7^-2, -1); a.precision_relative() 1
sage: a 7^-2 + O(7^-1)
sage: R(0).precision_relative() 0
sage: R(0,7).precision_relative() 0
```

### unit_part()

Returns $u$, where this element is $\pi^nu$.

```
sage: R = Zp(17,4,'capped-rel')
sage: a = R(18*17)
sage: a.unit_part() 1 + 17 + O(17^4)
sage: type(a) <class 'sage.rings.padics.padic_capped_relative_element.pAdicCappedRelativeElement'>
sage: R = Qp(17,4,'capped-rel')
sage: a = R(18*17)
sage: a.unit_part() 1 + 17 + O(17^4)
sage: type(a) <class 'sage.rings.padics.padic_capped_relative_element.pAdicCappedRelativeElement'>
sage: a = R(2*17^2); a 2*17^2 + O(17^6)
```

(continues on next page)
sage: a.unit_part()
2 + O(17^4)
sage: b=1/a; b
9*17^-2 + 8*17^-1 + 8 + 8*17 + O(17^2)
sage: b.unit_part()
9 + 8*17 + 8*17^2 + 8*17^3 + O(17^4)
sage: Zp(5)(75).unit_part()
3 + O(5^20)
sage: R(0).unit_part()
Traceback (most recent call last):
  ... ValueError: unit part of 0 not defined
sage: R(0,7).unit_part()
O(17^0)

val_unit(p=None)
Returns a pair (self.valuation(), self.unit_part()).

INPUT:
• p – a prime (default: None). If specified, will make sure that p==self.parent().prime()

Note: The optional argument p is used for consistency with the valuation methods on integer and rational.

class sage.rings.padics.padic_capped_relative_element.ExpansionIter
Bases: object
An iterator over a $p$-adic expansion.
This class should not be instantiated directly, but instead using expansion().

INPUT:
• elt – the $p$-adic element
• prec – the number of terms to be emitted
• mode – either simple_mode, smallest_mode or teichmuller_mode

EXAMPLES:
\begin{Verbatim}[commandchars=\|]
sage: E = Zp(5,4)(373).expansion()
sage: I = iter(E)  # indirect doctest
sage: type(I)
<class 'sage.rings.padics.padic_capped_relative_element.ExpansionIter'>
\end{Verbatim}

class \texttt{sage.rings.padics.padic\_capped\_relative\_element.ExpansionIterable}  
\texttt{ExpansionIterable} \texttt{Bases: object}

An iterable storing a \( p \)-adic expansion of an element.

This class should not be instantiated directly, but instead using \texttt{expansion()}.

INPUT:

- \texttt{elt} – the \( p \)-adic element
- \texttt{prec} – the number of terms to be emitted
- \texttt{val\_shift} – how many zeros to add at the beginning of the expansion, or the number of initial terms to truncate (if negative)
- \texttt{mode} – one of the following:
  - \texttt{'simple\_mode'}
  - \texttt{'smallest\_mode'}
  - \texttt{'teichmuller\_mode'}

EXAMPLES:

\begin{Verbatim}[commandchars=\|]
sage: E = Zp(5,4)(373).expansion()  # indirect doctest
tsage: type(E)
<class 'sage.rings.padics.padic\_capped\_relative\_element.ExpansionIterable'>
\end{Verbatim}

class \texttt{sage.rings.padics.padic\_capped\_relative\_element.PowComputer}_

\texttt{PowComputer} \texttt{Bases: sage.rings.padics.pow\_computer.PowComputer\_base}

A PowComputer for a capped-relative padic ring or field.

\texttt{sage.rings.padics.padic\_capped\_relative\_element.base\_p\_list}(n, pos, prime\_pow)  
\texttt{base\_p\_list} \texttt{Return a base-\( p \) list of digits of \( n \).}

INPUT:

- \texttt{n} – a positive \texttt{Integer}
- \texttt{pos} – a boolean; if \texttt{True}, then returns the standard base \( p \) expansion, otherwise the digits lie in the range \(-p/2\) to \( p/2\).
- \texttt{prime\_pow} – a \texttt{PowComputer} giving the prime

EXAMPLES:

\begin{Verbatim}[commandchars=\|]
sage: from sage.rings.padics.padic\_capped\_relative\_element import base\_p\_list
tsage: base\_p\_list(192837, true, Zp(5).prime\_pow)
[2, 2, 3, 3, 1, 2, 2]
sage: 2 + 2*5 + 3*5^2 + 2*5^3 + 3*5^4 + 5^5 + 2*5^6 + 2*5^7
192837
\end{Verbatim}
class sage.rings.padics.padic_capped_relative_element.pAdicCappedRelativeElement
Bases: sage.rings.padics.padic_capped_relative_element.CRElement

Constructs new element with given parent and value.

INPUT:
- x – value to coerce into a capped relative ring or field
- absprec – maximum number of digits of absolute precision
- relprec – maximum number of digits of relative precision

EXAMPLES:

sage: R = Zp(5, 10, 'capped-rel')

Construct from integers:

sage: R(3)
3 + O(5^10)
sage: R(75)
3*5^2 + O(5^12)
sage: R(0)
0
sage: R(-1)
4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + 4*5^6 + 4*5^7 + 4*5^8 + 4*5^9 + O(5^10)
sage: R(-5)
4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + 4*5^6 + 4*5^7 + 4*5^8 + 4*5^9 + 4*5^10 + O(5^11)
sage: R(-7*25)
3*5^2 + 3*5^3 + 4*5^4 + 4*5^5 + 4*5^6 + 4*5^7 + 4*5^8 + 4*5^9 + 4*5^10 + 4*5^11 +
   O(5^12)

Construct from rationals:

sage: R(1/2)
3 + 2*5 + 2*5^2 + 2*5^3 + 2*5^4 + 2*5^5 + 2*5^6 + 2*5^7 + 2*5^8 + 2*5^9 + O(5^10)
sage: R(-7875/874)
3*5^3 + 2*5^4 + 2*5^5 + 5^6 + 3*5^7 + 2*5^8 + 3*5^10 + 3*5^11 + 3*5^12 + O(5^13)
sage: R(15/425)
Traceback (most recent call last):
...
ValueError: p divides the denominator

Construct from IntegerMod:

sage: R(Integers(125)(3))
3 + O(5^3)
sage: R(Integers(5)(3))
3 + O(5)
sage: R(Integers(5^30)(3))
3 + O(5^10)
Some other conversions:

```
sage: R(R(5))
5 + O(5^11)
```

Construct from Pari objects:

```
sage: R = Zp(5)
sage: x = pari(123123) ; R(x)
3 + 4*5 + 4*5^2 + 4*5^3 + 5^4 + 4*5^3 + 2*5^6 + 5^7 + O(5^20)
sage: R(pari(R(5252)))
2 + 2*5^3 + 3*5^4 + 5^5 + O(5^20)
sage: R = Zp(5, prec=5)
sage: R(pari(-1))
4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 0(5^5)
sage: pari(R(-1))
4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 0(5^5)
sage: pari(R(0))
0
sage: R(pari(R(0,5)))
0(5^5)
```

**Todo:** doctests for converting from other types of p-adic rings

**lift()**

Return an integer or rational congruent to self modulo self's precision. If a rational is returned, its denominator will equal \( p^{\text{ordp}(self)} \).

**EXAMPLES:**

```
sage: R = Zp(7, 4, 'capped-rel'); a = R(8); a.lift()
8
sage: R = Qp(7, 4); a = R(8); a.lift()
8
sage: R = Qp(7, 4); a = R(8/7); a.lift()
8/7
```

**residue(absprec=1, field=None, check_prec=True)**

Reduce this element modulo \( p^{\text{absprec}} \).

**INPUT:**
• absprec – a non-negative integer (default: 1)
• field – boolean (default None); whether to return an element of \( \mathbf{F}_p \) or \( \mathbf{Z}/p\mathbf{Z} \)
• check_prec – boolean (default True); whether to raise an error if this element has insufficient precision to determine the reduction

OUTPUT:
This element reduced modulo \( p^{\text{absprec}} \) as an element of \( \mathbf{Z}/p^{\text{absprec}}\mathbf{Z} \).

EXAMPLES:

```
sage: R = Zp(7,4)
sage: a = R(8)
sage: a.residue(1)
1
```

This is different from applying \( \% p^n \) which returns an element in the same ring:

```
sage: b = a.residue(2); b
8
sage: b.parent()
Ring of integers modulo 49
sage: c = a \% 7^2; c
1 + 7 + O(7^4)
sage: c.parent()
7-adic Ring with capped relative precision 4
```

For elements in a field, application of \( \% p^n \) always returns zero, the remainder of the division by \( p^n \):

```
sage: K = Qp(7,4)
sage: a = K(8)
sage: a.residue(2)
8
sage: a % 7^2
1 + 7 + O(7^4)
sage: b = K(1/7)
sage: b.residue()
Traceback (most recent call last):
...
ValueError: element must have non-negative valuation in order to compute residue
```

See also:
_\_mod\_()

class sage.rings.padics.padic_capped_relative_element.pAdicCoercion_CR_frac_field
Bases: sage.rings.morphism.RingHomomorphism

The canonical inclusion of \( \mathbf{Z}_q \) into its fraction field.

EXAMPLES:

```
sage: R.<a> = ZqCR(27, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R); f
```

(continues on next page)
Ring morphism:
From: 3-adic Unramified Extension Ring in a defined by x^3 + 2*x + 1
To: 3-adic Unramified Extension Field in a defined by x^3 + 2*x + 1

**is_injective()**
Return whether this map is injective.

**EXAMPLES:**
```
sage: R.<a> = ZqCR(9, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R)
sage: f.is_injective()
True
```

**is_surjective()**
Return whether this map is surjective.

**EXAMPLES:**
```
sage: R.<a> = ZqCR(9, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R)
sage: f.is_surjective()
False
```

**section()**
Returns a map back to the ring that converts elements of non-negative valuation.

**EXAMPLES:**
```
sage: R.<a> = ZqCR(27, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R)
sage: f(K.gen())
a + O(3^20)
sage: f.section()
Generic morphism:
From: 3-adic Unramified Extension Field in a defined by x^3 + 2*x + 1
To: 3-adic Unramified Extension Ring in a defined by x^3 + 2*x + 1
```

```
class sage.rings.padics.padic_capped_relative_element.pAdicCoercion_QQ_CR
Bases: sage.rings.morphism.RingHomomorphism

The canonical inclusion from the rationals to a capped relative field.

**EXAMPLES:**
```
sage: f = Qp(5).coerce_map_from(QQ); f
Ring morphism:
From: Rational Field
To: 5-adic Field with capped relative precision 20
sage: f.section()
```

Returns a map back to the rationals that approximates an element by a rational number.

**EXAMPLES:**
```python
sage: f = Qp(5).coerce_map_from(QQ).section()
sage: f(Qp(5)(1/4))
1/4
sage: f(Qp(5)(1/5))
1/5
```

**class** `sage.rings.padics.padic_capped_relative_element.pAdicCoercion_ZZ_CR`

**Bases:** `sage.rings.morphism.RingHomomorphism`

The canonical inclusion from the integer ring to a capped relative ring.

**EXAMPLES:**

```python
sage: f = Zp(5).coerce_map_from(ZZ); f
Ring morphism:
  From: Integer Ring
  To: 5-adic Ring with capped relative precision 20

sage: f(Zp(5)(-1)) - 5^20
-1
```

**class** `sage.rings.padics.padic_capped_relative_element.pAdicConvert_CR_QQ`

**Bases:** `sage.rings.morphism.RingMap`

The map from the capped relative ring back to the rationals that returns a rational approximation of its input.

**EXAMPLES:**

```python
sage: f = Qp(5).coerce_map_from(QQ).section(); f
Set-theoretic ring morphism:
  From: 5-adic Field with capped relative precision 20
  To:  Rational Field
```

**class** `sage.rings.padics.padic_capped_relative_element.pAdicConvert_CR_ZZ`

**Bases:** `sage.rings.morphism.RingMap`

The map from a capped relative ring back to the ring of integers that returns the smallest non-negative integer approximation to its input which is accurate up to the precision.

Raises a `ValueError`, if the input is not in the closure of the image of the integers.

**EXAMPLES:**

```python
sage: f = Zp(5).coerce_map_from(ZZ).section(); f
Set-theoretic ring morphism:
  From: 5-adic Ring with capped relative precision 20
  To:  Integer Ring
```

**class** `sage.rings.padics.padic_capped_relative_element.pAdicConvert_CR_frac_field`

**Bases:** `sage.categories.morphism.Morphism`

The section of the inclusion from $\mathbb{Z}_q$ to its fraction field.
EXAMPLES:

```python
sage: R.<a> = ZqCR(27, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = R.convert_map_from(K); f
Generic morphism:
   From: 3-adic Unramified Extension Field in a defined by x^3 + 2*x + 1
   To: 3-adic Unramified Extension Ring in a defined by x^3 + 2*x + 1
```

class sage.rings.padics.padic_capped_relative_element.pAdicConvert_QQ_CR

Bases: sage.categories.morphism.Morphism

The inclusion map from the rationals to a capped relative ring that is defined on all elements with non-negative $p$-adic valuation.

EXAMPLES:

```python
sage: f = Zp(5).convert_map_from(QQ); f
Generic morphism:
   From: Rational Field
   To: 5-adic Ring with capped relative precision 20

section()

Returns the map back to the rationals that returns the smallest non-negative integer approximation to its input which is accurate up to the precision.

EXAMPLES:

```python
sage: f = Zp(5,4).convert_map_from(QQ).section()
sage: f(Zp(5,4)(-1))
-1
```

class sage.rings.padics.padic_capped_relative_element.pAdicTemplateElement

Bases: sage.rings.padics.padic_generic_element.pAdicGenericElement

A class for common functionality among the $p$-adic template classes.

INPUT:

- `parent` – a local ring or field
- `x` – data defining this element. Various types are supported, including ints, Integers, Rationals, PARI $p$-adics, integers mod $p^k$ and other Sage $p$-adics.
- `absprec` – a cap on the absolute precision of this element
- `relprec` – a cap on the relative precision of this element

EXAMPLES:

```python
sage: Zp(17)(17^3, 8, 4)
17^3 + O(17^7)
```

`expansion(n=None, lift_mode='simple', start_val=None)`

Return the coefficients in a $\pi$-adic expansion. If this is a field element, start at $\pi^{\text{valuation}}$, if a ring element at $\pi^0$. 

For each lift mode, this function returns a list of $a_i$ so that this element can be expressed as

$$\pi^v \cdot \sum_{i=0}^{\infty} a_i \pi^i,$$

where $v$ is the valuation of this element when the parent is a field, and $v = 0$ otherwise.

Different lift modes affect the choice of $a_i$. When lift_mode is 'simple', the resulting $a_i$ will be non-negative: if the residue field is $\mathbb{F}_p$, then they will be integers with $0 \leq a_i < p$; otherwise they will be a list of integers in the same range giving the coefficients of a polynomial in the indeterminant representing the maximal unramified subextension.

Choosing lift_mode as 'smallest' is similar to 'simple', but uses a balanced representation $-p/2 < a_i \leq p/2$.

Finally, setting lift_mode = 'teichmuller' will yield Teichmuller representatives for the $a_i$: $a_i^q = a_i$.

In this case the $a_i$ will lie in the ring of integers of the maximal unramified subextension of the parent of this element.

**INPUT:**

- n – integer (default None). If given, returns the corresponding entry in the expansion. Can also accept a slice (see slice())
- lift_mode – 'simple', 'smallest' or 'teichmuller' (default: 'simple')
- start_val – start at this valuation rather than the default (0 or the valuation of this element).

**OUTPUT:**

- If n is None, an iterable giving a $\pi$-adic expansion of this element. For base elements the contents will be integers if lift_mode is 'simple' or 'smallest', and elements of self.parent() if lift_mode is 'teichmuller'.
- If n is an integer, the coefficient of $\pi^n$ in the $\pi$-adic expansion of this element.

**Note:** Use slice operators to get a particular range.

**EXAMPLES:**

```sage
sage: R = Zp(7,6); a = R(12837162817); a
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: E = a.expansion(); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: list(E)
[3, 4, 4, 0, 4, 0]
sage: sum([c * 7^i for i, c in enumerate(E)]) == a
True
sage: E = a.expansion(lift_mode='smallest'); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6) (balanced)
sage: list(E)
[3, -3, -2, 1, -3, 1]
sage: sum([c * 7^i for i, c in enumerate(E)]) == a
True
sage: E = a.expansion(lift_mode='teichmuller'); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6) (teichmuller)
sage: list(E)
```

(continues on next page)
If the element has positive valuation then the list will start with some zeros:

```
sage: a = R(7^3 * 17)
sage: E = a.expansion(); E
7-adic expansion of 3*7^3 + 2*7^4 + O(7^9)
sage: list(E)
[0, 0, 0, 3, 2, 0, 0, 0, 0]
```

The expansion of 0 is truncated:

```
sage: E = R(0, 7).expansion(); E
7-adic expansion of O(7^7)
sage: len(E)
0
sage: list(E)
[]
```

In fields, on the other hand, the expansion starts at the valuation:

```
sage: R = Qp(7,4); a = R(6*7+7**2); E = a.expansion(); E
7-adic expansion of 6^7 + 7^2 + O(7^5)
sage: list(E)
[6, 1, 0, 0]
sage: list(a.expansion(lift_mode='smallest'))
[-1, 2, 0, 0]
sage: list(a.expansion(lift_mode='teichmuller'))
[6 + 6*7 + 6*7^2 + 6*7^3 + O(7^4),
  2 + 4*7 + 6*7^2 + 0(7^3),
  3 + 4*7 + 0(7^2),
  3 + 0(7)]
```

You can ask for a specific entry in the expansion:

```
sage: a.expansion(1)
6
sage: a.expansion(1, lift_mode='smallest')
-1
sage: a.expansion(2, lift_mode='teichmuller')
2 + 4*7 + 6*7^2 + 0(7^3)
```

**lift_to_precision** (*absprec=None*)

Return another element of the same parent with absolute precision at least *absprec*, congruent to this *p*-adic element modulo the precision of this element.

**INPUT:**
- absprec – an integer or None (default: None); the absolute precision of the result. If None, lifts to the maximum precision allowed

Note: If setting absprec that high would violate the precision cap, raises a precision error. Note that the new digits will not necessarily be zero.

EXAMPLES:

```
sage: R = ZpCA(17)
sage: R(-1,2).lift_to_precision(10)
16 + 16*17 + O(17^10)
sage: R(1,15).lift_to_precision(10)
1 + 0(17^15)
sage: R(1,15).lift_to_precision(30)
Traceback (most recent call last):
  ...  
  PrecisionError: precision higher than allowed by the precision cap
sage: R(-1,2).lift_to_precision().precision_absolute() == R.precision_cap()
True
sage: R = Zp(5); c = R(17,3); c.lift_to_precision(8)
2 + 3*5 + O(5^8)
sage: c.lift_to_precision().precision_relative() == R.precision_cap()
True
```

Fixed modulus elements don't raise errors:

```
sage: R = ZpFM(5); a = R(5); a.lift_to_precision(7)
5
sage: a.lift_to_precision(10000)
5
```

residue(absprec=1, field=None, check_prec=True)
Reduce this element modulo $p^{absprec}$.  

INPUT:

- absprec – 0 or 1.
- field – boolean (default None). For precision 1, whether to return an element of the residue field or a residue ring. Currently unused.
- check_prec – boolean (default True). Whether to raise an error if this element has insufficient precision to determine the reduction. Errors are never raised for fixed-mod or floating-point types.

OUTPUT:
This element reduced modulo $p^{absprec}$ as an element of the residue field or the null ring.

EXAMPLES:

```
sage: R.<a> = Zq(27, 4)
sage: (3 + 3*a).residue()  
0
sage: (a + 1).residue()  
a0 + 1
```
\textbf{teichmuller\_expansion}(n=None)

Returns an iterator over coefficients \(a_0, a_1, \ldots, a_n\) such that

- \(a_i^q = a_i\), where \(q\) is the cardinality of the residue field,
- this element can be expressed as

\[\pi^v \sum_{i=0}^{\infty} a_i \pi^i\]

where \(v\) is the valuation of this element when the parent is a field, and \(v = 0\) otherwise.

- if \(a_i \neq 0\), the precision of \(a_i\) is \(i\) less than the precision of this element (relative in the case that the parent is a field, absolute otherwise)

\textbf{Note}: The coefficients will lie in the ring of integers of the maximal unramified subextension.

\textbf{INPUT}:

- \(n\) – integer (default None). If given, returns the coefficient of \(\pi^n\) in the expansion.

\textbf{EXAMPLES}:

For fields, the expansion starts at the valuation:

\begin{verbatim}
sage: R = Qp(5,5); list(R(70).teichmuller_expansion()) [4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + O(5^5),
3 + 3*5 + 2*5^2 + 3*5^3 + O(5^4),
2 + 5 + 2*5^2 + O(5^3),
1 + O(5^2),
4 + O(5)]
\end{verbatim}

But if you specify \(n\), you get the coefficient of \(\pi^n\):

\begin{verbatim}
sage: R(70).teichmuller_expansion(2)
3 + 3*5 + 2*5^2 + 3*5^3 + O(5^4)
\end{verbatim}

\textbf{unit\_part}()

Returns the unit part of this element.

This is the \(p\)-adic element \(u\) in the same ring so that this element is \(\pi^v u\), where \(\pi\) is a uniformizer and \(v\) is the valuation of this element.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: R.<a> = Zq(125)
sage: (5*a).unit_part()
a + O(5^20)
\end{verbatim}
True
sage: a.precision_relative() == b.precision_relative()
True

sage.rings.padics.padic_capped_relative_element.unpickle_pcre_v1(R, unit, ordp, relprec)
Unpickles a capped relative element.

EXAMPLES:

sage: from sage.rings.padics.padic_capped_relative_element import unpickle_pcre_v1
sage: R = Zp(5)
sage: a = unpickle_pcre_v1(R, 17, 2, 5); a
2*5^2 + 3*5^3 + O(5^7)
Elements of $p$-adic Rings with Absolute Precision Cap

AUTHORS:

• David Roe

• Genya Zaytman: documentation

• David Harvey: doctests

```python
class sage.rings.padics.padic_capped_absolute_element.CAElement
    Bases: sage.rings.padics.padic_capped_absolute_element.pAdicTemplateElement

    add_bigoh(absprec)
        Return a new element with absolute precision decreased to absprec. The precision never increases.
        INPUT:
            • absprec – an integer or infinity
        OUTPUT:
            self with precision set to the minimum of self's precision and prec
        EXAMPLES:
          sage: R = Zp(7,4,'capped-abs','series'); a = R(8); a.add_bigoh(1)
          1 + O(7)
          sage: k = ZpCA(3,5)
          sage: a = k(41); a
          2 + 3 + 3^2 + 3^3 + O(3^5)
          sage: a.add_bigoh(7)
          2 + 3 + 3^2 + 3^3 + O(3^5)
          sage: a.add_bigoh(3)
          2 + 3 + 3^2 + O(3^3)

difficult

    is_equal_to(_right, absprec=None)
        Determine whether the inputs are equal modulo $\pi^{\text{absprec}}$.
        INPUT:
            • right – a $p$-adic element with the same parent
            • absprec – an integer, infinity, or None
        EXAMPLES:
```
```python
sage: R = ZpCA(2, 6)
sage: R(13).is_equal_to(R(13))
True
sage: R(13).is_equal_to(R(13+2^10))
True
sage: R(13).is_equal_to(R(17), 2)
True
sage: R(13).is_equal_to(R(17), 5)
False
sage: R(13).is_equal_to(R(13+2^10), absprec=10)
Traceback (most recent call last):
...  
PrecisionError: elements not known to enough precision
```

### is_zero(absprec=None)

Determine whether this element is zero modulo \( \pi^{\text{absprec}} \).

If \text{absprec} is None, returns True if this element is indistinguishable from zero.

**INPUT:**

- absprec – an integer, infinity, or None

**EXAMPLES:**

```python
sage: R = ZpCA(17, 6)
sage: R(0).is_zero()
True
sage: R(17^6).is_zero()
True
sage: R(17^2).is_zero(absprec=2)
True
sage: R(17^6).is_zero(absprec=10)
Traceback (most recent call last):
...  
PrecisionError: not enough precision to determine if element is zero
```

### polynomial(var='x')

Return a polynomial over the base ring that yields this element when evaluated at the generator of the parent.

**INPUT:**

- var – string; the variable name for the polynomial

**EXAMPLES:**

```python
sage: R.<a> = ZqCA(5^3)
sage: a.polynomial()
(1 + O(5^20))*x + O(5^20)
sage: a.polynomial(var='y')
(1 + O(5^20))*y + O(5^20)
sage: (5*a^2 + R(25, 4)).polynomial()
(5 + O(5^4))*x^2 + 0(5^4)*x + 5^2 + O(5^4)
```

### precision_absolute()

The absolute precision of this element.

This is the power of the maximal ideal modulo which this element is defined.
EXAMPLES:

```
sage: R = Zp(7,4,'capped-abs'); a = R(7); a.precision_absolute()
sage: a.precision_absolute()
sage: a = R(7); a.precision_relative()
sage: a = R(7); a.precision_relative()
```

**precision_relative()**
The relative precision of this element.

This is the power of the maximal ideal modulo which the unit part of this element is defined.

**EXAMPLES:**

```
sage: R = Zp(7,4,'capped-abs'); a = R(7); a.precision_relative()
sage: a = R(7); a.precision_relative()
```

**unit_part()**
Return the unit part of this element.

**EXAMPLES:**

```
sage: R = Zp(17,4,'capped-abs','val-unit')
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)

sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)
sage: a = R(18*17)```
```python
sage: E = Zp(5,4)(373).expansion()
sage: I = iter(E)  # indirect doctest
sage: type(I)
<class 'sage.rings.padics.padic_capped_relative_element.ExpansionIter'>
```

```python
class sage.rings.padics.padic_capped_absolute_element.ExpansionIterable
Bases: object

An iterable storing a $p$-adic expansion of an element.

This class should not be instantiated directly, but instead using `expansion()`.

INPUT:

- `elt` – the $p$-adic element
- `prec` – the number of terms to be emitted
- `val_shift` – how many zeros to add at the beginning of the expansion, or the number of initial terms to truncate (if negative)
- `mode` – one of the following:
  - `'simple_mode'`
  - `'smallest_mode'`
  - `'teichmuller_mode'`

EXAMPLES:

```python
sage: E = Zp(5,4)(373).expansion()  # indirect doctest
sage: type(E)
<class 'sage.rings.padics.padic_capped_relative_element.ExpansionIterable'>
```

```python
class sage.rings.padics.padic_capped_absolute_element.PowComputer_
Bases: sage.rings.padics.pow_computer.PowComputer_base

A PowComputer for a capped-absolute padic ring.

`sage.rings.padics.padic_capped_absolute_element.make_pAdicCappedAbsoluteElement` (parent, x, absprec)

Unpickles a capped absolute element.

EXAMPLES:

```python
sage: from sage.rings.padics.padic_capped_absolute_element import make_ 
    pAdicCappedAbsoluteElement
sage: R = ZpCA(5)
sage: a = make_pAdicCappedAbsoluteElement(R, 17*25, 5); a
2*5^2 + 3*5^3 + O(5^5)
```

```python
class sage.rings.padics.padic_capped_absolute_element.pAdicCappedAbsoluteElement
Bases: sage.rings.padics.padic_capped_absolute_element.CAEElement

Constructs new element with given parent and value.

INPUT:

- `x` – value to coerce into a capped absolute ring
- `absprec` – maximum number of digits of absolute precision
```

Chapter 15. $p$-adic Capped Absolute Elements
• relprec – maximum number of digits of relative precision

EXAMPLES:

```
sage: R = ZpCA(3, 5)
sage: R(2)
2 + 0(3^5)
sage: R(2, absprec=2)
2 + 0(3^2)
sage: R(3, relprec=2)
3 + 0(3^3)
sage: R(Qp(3)(10))
1 + 3^2 + 0(3^5)
sage: R(pari(6))
2*3 + 0(3^5)
sage: R(pari(1/2))
2 + 3 + 3^2 + 3^3 + 3^4 + 0(3^5)
sage: R(1/2)
2 + 3 + 3^2 + 3^3 + 3^4 + 0(3^5)
sage: R(mod(-1, 3^7))
2 + 2*3 + 2*3^2 + 2*3^3 + 2*3^4 + 0(3^5)
sage: R(mod(-1, 3^2))
2 + 2*3 + 0(3^2)
sage: R(3 + 0(3^2))
3 + 0(3^2)
```

`lift()`

```
sage: R = ZpCA(3) sage: R(10).lift() 10 sage: R(-1).lift() 3486784400
```

`multiplicative_order()`

Return the minimum possible multiplicative order of this element.

OUTPUT:

The multiplicative order of self. This is the minimum multiplicative order of all elements of \( \mathbb{Z}_p \) lifting self to infinite precision.

EXAMPLES:

```
sage: R = ZpCA(7, 6)
sage: R(1/3)
5 + 4*7 + 4*7^2 + 4*7^3 + 4*7^4 + 4*7^5 + 0(7^6)
sage: R(1/3).multiplicative_order()
+Infinity
sage: R(7).multiplicative_order()
+Infinity
sage: R(1).multiplicative_order()
1
sage: R(-1).multiplicative_order()
2
sage: R.teichmuller(3).multiplicative_order()
6
```

`residue(absprec=1, field=None, check_prec=True)`

Reduces self modulo \( p^{\text{absprec}} \).

INPUT:
• absprec – a non-negative integer (default: 1)
• field – boolean (default None). Whether to return an element of GF(p) or Zmod(p).
• check_prec – boolean (default True). Whether to raise an error if this element has insufficient precision to determine the reduction.

OUTPUT:
This element reduced modulo \( p^{\text{absprec}} \) as an element of \( \mathbb{Z}/p^{\text{absprec}}\mathbb{Z} \)

EXAMPLES:

```
sage: R = Zp(7,10,'capped-abs')
sage: a = R(8)
sage: a.residue(1)
1
```

This is different from applying \( \% p^n \) which returns an element in the same ring:

```
sage: b = a.residue(2); b
8
sage: b.parent()
Ring of integers modulo 49
sage: c = a % 7^2; c
1 + 7 + O(7^10)
sage: c.parent()
7-adic Ring with capped absolute precision 10
```

Note that reduction of \( c \) dropped to the precision of the unit part of \( 7^2 \), see \( \_\text{mod}() \):

```
sage: R(7^2).unit_part()
1 + O(7^8)
```

See also:

\( \_\text{mod}() \)

```python
class sage.rings.padics.padic_capped_absolute_element.pAdicCoercion_CA_frac_field
bases: sage.rings.morphism.RingHomomorphism
```

The canonical inclusion of \( \mathbb{Z}q \) into its fraction field.

EXAMPLES:

```
sage: R.<a> = ZqCA(27, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R); f
Ring morphism:
  From: 3-adic Unramified Extension Ring in a defined by x^3 + 2*x + 1
  To:  3-adic Unramified Extension Field in a defined by x^3 + 2*x + 1
```

```python
is_injective()
Return whether this map is injective.
```

EXAMPLES:

```
sage: R.<a> = ZqCA(9, implementation='FLINT')
sage: K = R.fraction_field()
```
sage: f = K.coerce_map_from(R)
sage: f.is_injective()
True

is_surjective()
  Return whether this map is surjective.

EXAMPLES:

sage: R.<a> = ZqCA(9, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R)
sage: f.is_surjective()
False

section()
  Return a map back to the ring that converts elements of non-negative valuation.

EXAMPLES:

sage: R.<a> = ZqCA(27, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R)
sage: f(K.gen())
a + O(3^20)
sage: f.section()
Generic morphism:
  From: 3-adic Unramified Extension Field in a defined by x^3 + 2*x + 1
  To: 3-adic Unramified Extension Ring in a defined by x^3 + 2*x + 1

class sage.rings.padics.padic_capped_absolute_element.pAdicCoercion_ZZ_CA
  Bases: sage.rings.morphism.RingHomomorphism

  The canonical inclusion from the ring of integers to a capped absolute ring.

EXAMPLES:

sage: f = ZpCA(5).coerce_map_from(ZZ); f
Ring morphism:
  From: Integer Ring
  To: 5-adic Ring with capped absolute precision 20

section()
  Return a map back to the ring of integers that approximates an element by an integer.

EXAMPLES:

sage: f = ZpCA(5).coerce_map_from(ZZ).section()
sage: f(ZpCA(5)(-1)) - 5^20
-1

class sage.rings.padics.padic_capped_absolute_element.pAdicConvert_CA_ZZ
  Bases: sage.rings.morphism.RingMap

  The map from a capped absolute ring back to the ring of integers that returns the smallest non-negative integer approximation to its input which is accurate up to the precision.
Raises a \texttt{ValueError} if the input is not in the closure of the image of the ring of integers.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: f = ZpCA(5).coerce_map_from(ZZ).section(); f
Set-theoretic ring morphism:
  From: 5-adic Ring with capped absolute precision 20
  To:   Integer Ring
\end{verbatim}

\begin{class}
sage.rings.padics.padic_capped_absolute_element.pAdicConvert_CA_frac_field
\end{class}

Bases: \texttt{sage.categories.morphism.Morphism}

The section of the inclusion from $\mathbb{Z}_q$ to its fraction field.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: R.<a> = ZqCA(27, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = R.convert_map_from(K); f
Generic morphism:
  From: 3-adic Unramified Extension Field in a defined by x^3 + 2*x + 1
  To:   3-adic Unramified Extension Ring in a defined by x^3 + 2*x + 1
\end{verbatim}

\begin{class}
sage.rings.padics.padic_capped_absolute_element.pAdicConvert_QQ_CA
\end{class}

Bases: \texttt{sage.categories.morphism.Morphism}

The inclusion map from the rationals to a capped absolute ring that is defined on all elements with non-negative $p$-adic valuation.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: f = ZpCA(5).convert_map_from(QQ); f
Generic morphism:
  From: Rational Field
  To:   5-adic Ring with capped absolute precision 20
\end{verbatim}

\begin{class}
sage.rings.padics.padic_capped_absolute_element.pAdicTemplateElement
\end{class}

Bases: \texttt{sage.rings.padics.padic_generic_element.pAdicGenericElement}

A class for common functionality among the $p$-adic template classes.

\textbf{INPUT:}

- parent – a local ring or field
- x – data defining this element. Various types are supported, including ints, Integers, Rationals, PARI \texttt{p}-adics, integers mod $p^k$ and other Sage \texttt{p}-adics.
- absprec – a cap on the absolute precision of this element
- relprec – a cap on the relative precision of this element

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Zp(17)(17^3, 8, 4)
17^3 + O(17^7)
\end{verbatim}

\begin{verbatim}
expansion(n=None, lift_mode='simple', start_val=None)

Return the coefficients in a $\pi$-adic expansion. If this is a field element, start at $\pi^{\text{valuation}}$, if a ring element at $\pi^0$.
\end{verbatim}
For each lift mode, this function returns a list of \(a_i\) so that this element can be expressed as

\[
\pi^v \cdot \sum_{i=0}^{\infty} a_i \pi^i,
\]

where \(v\) is the valuation of this element when the parent is a field, and \(v = 0\) otherwise.

Different lift modes affect the choice of \(a_i\). When \(\text{lift\_mode}\) is 'simple', the resulting \(a_i\) will be non-negative: if the residue field is \(\mathbb{F}_p\), then they will be integers with \(0 \leq a_i < p\); otherwise they will be a list of integers in the same range giving the coefficients of a polynomial in the indeterminant representing the maximal unramified subextension.

Choosing \(\text{lift\_mode}\) as 'smallest' is similar to 'simple', but uses a balanced representation \(-p/2 < a_i \leq p/2\).

Finally, setting \(\text{lift\_mode} = \text{'teichmuller'}\) will yield Teichmuller representatives for the \(a_i\): \(a^q_i = a_i\). In this case the \(a_i\) will lie in the ring of integers of the maximal unramified subextension of the parent of this element.

**INPUT:**
- \(n\) – integer (default None). If given, returns the corresponding entry in the expansion. Can also accept a slice (see slice())
- \(\text{lift\_mode}\) – 'simple', 'smallest' or 'teichmuller' (default: 'simple')
- \(\text{start\_val}\) – start at this valuation rather than the default (0 or the valuation of this element).

**OUTPUT:**
- If \(n\) is None, an iterable giving a \(\pi\)-adic expansion of this element. For base elements the contents will be integers if \(\text{lift\_mode}\) is 'simple' or 'smallest', and elements of \(\text{self.parent()}\) if \(\text{lift\_mode}\) is 'teichmuller'.
- If \(n\) is an integer, the coefficient of \(\pi^n\) in the \(\pi\)-adic expansion of this element.

**Note:** Use slice operators to get a particular range.

**EXAMPLES:**

```python
sage: R = Zp(7, 6); a = R(12837162817); a
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: E = a.expansion(); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: list(E)
[3, 4, 4, 0, 4, 0]
sage: sum([c * 7^i for i, c in enumerate(E)]) == a
True
sage: E = a.expansion(lift_mode='smallest'); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + 0(7^6) (balanced)
sage: list(E)
[3, -3, -2, 1, -3, 1]
sage: sum([c * 7^i for i, c in enumerate(E)]) == a
True
sage: E = a.expansion(lift_mode='teichmuller'); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + 0(7^6) (teichmuller)
sage: list(E)
```

(continues on next page)
If the element has positive valuation then the list will start with some zeros:

```
sage: a = R(7^3 * 17)
sage: E = a.expansion(); E
7-adic expansion of 3*7^3 + 2*7^4 + O(7^9)
sage: list(E)
[0, 0, 0, 3, 2, 0, 0, 0, 0]
```

The expansion of 0 is truncated:

```
sage: E = R(0, 7).expansion(); E
7-adic expansion of O(7^7)
sage: len(E)
0
sage: list(E)
[]
```

In fields, on the other hand, the expansion starts at the valuation:

```
sage: R = Qp(7, 4); a = R(6*7+7**2); E = a.expansion(); E
7-adic expansion of 6*7 + 7^2 + O(7^5)
sage: list(E)
[6, 1, 0, 0]
sage: list(a.expansion(lift_mode='smallest'))
[-1, 2, 0, 0]
sage: list(a.expansion(lift_mode='teichmuller'))
[6 + 6*7 + 6*7^2 + 6*7^3 + O(7^4),
  2 + 4*7 + 6*7^2 + O(7^3),
  3 + 4*7 + O(7^2),
  3 + O(7)]
```

You can ask for a specific entry in the expansion:

```
sage: a.expansion(1)
6
sage: a.expansion(1, lift_mode='smallest')
-1
sage: a.expansion(2, lift_mode='teichmuller')
2 + 4*7 + 6*7^2 + O(7^3)
```

`lift_to_precision(absprec=None)`

Return another element of the same parent with absolute precision at least `absprec`, congruent to this `p`-adic element modulo the precision of this element.

INPUT:
• absprec – an integer or None (default: None); the absolute precision of the result. If None, lifts to the maximum precision allowed

Note: If setting absprec that high would violate the precision cap, raises a precision error. Note that the new digits will not necessarily be zero.

EXAMPLES:

```sage
sage: R = ZpCA(17)
sage: R(-1,2).lift_to_precision(10)
16 + 16*17 + O(17^10)
sage: R(1,15).lift_to_precision(10)
1 + 0(17^15)
sage: R(1,15).lift_to_precision(30)
Traceback (most recent call last):
  ...  
PrecisionError: precision higher than allowed by the precision cap
```

```sage
sage: R(-1,2).lift_to_precision().precision_absolute() == R.precision_cap()  
True
```

```sage
sage: R = Zp(5); c = R(17,3); c.lift_to_precision(8)
2 + 3*5 + O(5^8)
sage: c.lift_to_precision().precision_relative() == R.precision_cap()  
True
```

Fixed modulus elements don't raise errors:

```sage
sage: R = ZpFM(5); a = R(5); a.lift_to_precision(7)
5
sage: a.lift_to_precision(10000)
5
```

`residue(absprec=1, field=None, check_prec=True)`
Reduce this element modulo \(p^{\text{absprec}}\).

INPUT:

• absprec – 0 or 1.
• field – boolean (default None). For precision 1, whether to return an element of the residue field or a residue ring. Currently unused.
• check_prec – boolean (default True). Whether to raise an error if this element has insufficient precision to determine the reduction. Errors are never raised for fixed-mod or floating-point types.

OUTPUT:
This element reduced modulo \(p^{\text{absprec}}\) as an element of the residue field or the null ring.

EXAMPLES:

```sage
sage: R.<a> = Zq(27, 4)
sage: (3 + 3*a).residue()  
0
sage: (a + 1).residue()  
a0 + 1
```
teichmuller_expansion\((n=\text{None})\)
Returns an iterator over coefficients \(a_0, a_1, \ldots, a_n\) such that
- \(a^q = a_i\), where \(q\) is the cardinality of the residue field,
- this element can be expressed as
\[
\pi^v \sum_{i=0}^{\infty} a_i \pi^i
\]
where \(v\) is the valuation of this element when the parent is a field, and \(v = 0\) otherwise.
- if \(a_i \neq 0\), the precision of \(a_i\) is \(i\) less than the precision of this element (relative in the case that the parent is a field, absolute otherwise)

**Note:** The coefficients will lie in the ring of integers of the maximal unramified subextension.

**INPUT:**
- \(n\) – \text{integer (default None)}. If given, returns the coefficient of \(\pi^n\) in the expansion.

**EXAMPLES:**
For fields, the expansion starts at the valuation:

```
sage: R = Qp(5, 5); list(R(70).teichmuller_expansion())
[4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + O(5^5),
 3 + 3*5 + 2*5^2 + 3*5^3 + O(5^4),
 2 + 5 + 2*5^2 + O(5^3),
 1 + O(5^2),
 4 + O(5)]
```

But if you specify \(n\), you get the coefficient of \(\pi^n\):

```
sage: R(70).teichmuller_expansion(2)
3 + 3*5 + 2*5^2 + 3*5^3 + O(5^4)
```

unit_part()
Returns the unit part of this element.
This is the \(p\)-adic element \(u\) in the same ring so that this element is \(\pi^v u\), where \(\pi\) is a uniformizer and \(v\) is the valuation of this element.

**EXAMPLES:**
```
sage: R.<a> = Zq(125)
sage: (5*a).unit_part()
a + O(5^20)
```

`sage.rings.padics.padic_capped_absolute_element.unpickle_cae_v2\((cls, parent, value, absprec)\)`
Unpickle capped absolute elements.

**INPUT:**
- \(cls\) – the class of the capped absolute element
- \(parent\) – a \(p\)-adic ring
- \(value\) – a Python object wrapping a celement, of the kind accepted by the cunpickle function
- \(absprec\) – a Python int or Sage integer
EXAMPLES:

```python
sage: from sage.rings.padics.padic_capped_absolute_element import unpickle_cae_v2,
    pAdicCappedAbsoluteElement
sage: R = ZpCA(5,8)

sage: a = unpickle_cae_v2(pAdicCappedAbsoluteElement, R, 42, int(6)); a
2 + 3*5 + 5^2 + O(5^6)

sage: a.parent() is R
True
```
Elements of $p$-adic Rings with Fixed Modulus

AUTHORS:
- David Roe
- Genya Zaytman: documentation
- David Harvey: doctests

class sage.rings.padics.padic_fixed_mod_elementExpansionIter
Bases: object

An iterator over a $p$-adic expansion.

This class should not be instantiated directly, but instead using expansion().

INPUT:
- elt – the $p$-adic element
- prec – the number of terms to be emitted
- mode – either simple_mode, smallest_mode or teichmuller_mode

EXAMPLES:

```python
sage: E = Zp(5,4)(373).expansion()
sage: I = iter(E) # indirect doctest
sage: type(I)
<class 'sage.rings.padics.padic_capped_relative_element.ExpansionIter'>
```

class sage.rings.padics.padic_fixed_mod_elementExpansionIterable
Bases: object

An iterable storing a $p$-adic expansion of an element.

This class should not be instantiated directly, but instead using expansion().

INPUT:
- elt – the $p$-adic element
- prec – the number of terms to be emitted
- val_shift – how many zeros to add at the beginning of the expansion, or the number of initial terms to truncate (if negative)
- mode – one of the following:
  - 'simple_mode'
Examples:

```python
sage: E = Zp(5,4)(373).expansion()  # indirect doctest
sage: type(E)
<class 'sage.rings.padics.padic_capped_relative_element.ExpansionIterable'>
```

class `sage.rings.padics.padic_fixed_mod_element.FMElement`

Bases: `sage.rings.padics.padic_fixed_mod_element.pAdicTemplateElement`

**add_bigoh** (*absprec*)

Returns a new element truncated modulo $\pi^{\text{absprec}}$.

**INPUT:**
- *absprec* – an integer or infinity

**OUTPUT:**
- a new element truncated modulo $\pi^{\text{absprec}}$.

**EXAMPLES:**

```python
sage: R = Zp(7,4,'fixed-mod','series'); a = R(8); a.add_bigoh(1)
1
```

**is_equal_to** (*right*, *absprec=None*)

Returns whether this element is equal to *right* modulo $p^{\text{absprec}}$.

If *absprec* is None, returns if self == 0.

**INPUT:**
- *right* – a p-adic element with the same parent
- *absprec* – a positive integer or None (default: None)

**EXAMPLES:**

```python
sage: R = ZpFM(2, 6)
sage: R(13).is_equal_to(R(13))
True
sage: R(13).is_equal_to(R(13+2^10))
True
sage: R(13).is_equal_to(R(17), 2)
True
sage: R(13).is_equal_to(R(17), 5)
False
```

**is_zero** (*absprec=None*)

Returns whether self is zero modulo $\pi^{\text{absprec}}$.

**INPUT:**
- *absprec* – an integer

**EXAMPLES:**
polynomial(var='x')
Return a polynomial over the base ring that yields this element when evaluated at the generator of the parent.

INPUT:

• var – string, the variable name for the polynomial

EXAMPLES:

```sage
sage: R.<a> = ZqFM(5^3)
sage: a.polynomial()
x
sage: a.polynomial(var='y')
y
sage: (5*a^2 + 25).polynomial()
5*x^2 + 5^2
```

precision_absolute()
The absolute precision of this element.

EXAMPLES:

```sage
sage: R = Zp(7,4,'fixed-mod'); a = R(7); a.precision_absolute()
4
```

precision_relative()
The relative precision of this element.

EXAMPLES:

```sage
sage: R = Zp(7,4,'fixed-mod'); a = R(7); a.precision_relative()
3
sage: a = R(0); a.precision_relative()
0
```

unit_part()
Returns the unit part of self.

If the valuation of self is positive, then the high digits of the result will be zero.

EXAMPLES:

```sage
sage: R = Zp(17, 4, 'fixed-mod')
sage: R(5).unit_part()
5
sage: R(18*17).unit_part()
1 + 17
sage: R(0).unit_part()
0
```
\begin{verbatim}
sage: type(R(5).unit_part())
<class 'sage.rings.padics.padic_fixed_mod_element.pAdicFixedModElement'>
sage: R = ZpFM(5, 5); a = R(75); a.unit_part()
3

val_unit()
Returns a 2-tuple, the first element set to the valuation of self, and the second to the unit part of self.
If self == 0, then the unit part is O(p^self.parent().precision_cap()).

EXAMPLES:

sage: R = ZpFM(5, 5)
sage: a = R(75); b = a - a
sage: a.val_unit()
(2, 3)
sage: b.val_unit()
(5, 0)
\end{verbatim}

\begin{verbatim}
class sage.rings.padics.padic_fixed_mod_element.PowComputer_
Bases: sage.rings.padics.pow_computer.PowComputer_base
A PowComputer for a fixed-modulus padic ring.
sage.rings.padics.padic_fixed_mod_element.make_pAdicFixedModElement(parent, value)
Unpickles a fixed modulus element.

EXAMPLES:

sage: from sage.rings.padics.padic_fixed_mod_element import make_
    \_pAdicFixedModElement
sage: R = ZpFM(5)
sage: a = make_pAdicFixedModElement(R, 17*25); a
2*5^2 + 3*5^3
\end{verbatim}

\begin{verbatim}
class sage.rings.padics.padic_fixed_mod_element.pAdicCoercion_FM_frac_field
Bases: sage.rings.morphism.RingHomomorphism
The canonical inclusion of \(\mathbb{Z}_q\) into its fraction field.

EXAMPLES:

sage: R.<a> = ZqFM(27, implementation='FLINT')
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R); f
Ring morphism:
    From: 3-adic Unramified Extension Ring in a defined by x^3 + 2*x + 1
    To: 3-adic Unramified Extension Field in a defined by x^3 + 2*x + 1

is_injective()
Return whether this map is injective.

EXAMPLES:

sage: R.<a> = ZqFM(9)
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R)
\end{verbatim}
sage: f.is_injective()
True

is_surjective()
Return whether this map is surjective.

EXAMPLES:

sage: R.<a> = ZqFM(9)
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R)
sage: f.is_surjective()
False

section()
Returns a map back to the ring that converts elements of non-negative valuation.

EXAMPLES:

sage: R.<a> = ZqFM(27)
sage: K = R.fraction_field()
sage: f = K.coerce_map_from(R)
sage: f.section()(K.gen())
a

class sage.rings.padics.padic_fixed_mod_element.pAdicCoercion_ZZ_FM
Bases: sage.rings.morphism.RingHomomorphism

The canonical inclusion from ZZ to a fixed modulus ring.

EXAMPLES:

sage: f = ZpFM(5).coerce_map_from(ZZ); f
Ring morphism:
  From: Integer Ring
  To:   5-adic Ring of fixed modulus 5^20

section()
Returns a map back to ZZ that approximates an element of this $p$-adic ring by an integer.

EXAMPLES:

sage: f = ZpFM(5).coerce_map_from(ZZ).section()
sage: f(ZpFM(5)(-1)) - 5^20
-1

class sage.rings.padics.padic_fixed_mod_element.pAdicConvert_FM_ZZ
Bases: sage.rings.morphism.RingMap

The map from a fixed modulus ring back to ZZ that returns the smallest non-negative integer approximation to its input which is accurate up to the precision.

If the input is not in the closure of the image of ZZ, raises a ValueError.

EXAMPLES:
sage: f = ZpFM(5).coerce_map_from(ZZ).section(); f
Set-theoretic ring morphism:
   From: 5-adic Ring of fixed modulus 5^20
   To:   Integer Ring

class sage.rings.padics.padic_fixed_mod_element.pAdicConvert_FM_frac_field
Bases: sage.categories.morphism.Morphism

The section of the inclusion from \( \mathbb{Z}_p \) to its fraction field.

EXAMPLES:

sage: R.<a> = ZqFM(27)
sage: K = R.fraction_field()
sage: f = R.convert_map_from(K); f
Generic morphism:
   From: 3-adic Unramified Extension Field in a defined by x^3 + 2*x + 1
   To:   3-adic Unramified Extension Ring in a defined by x^3 + 2*x + 1

class sage.rings.padics.padic_fixed_mod_element.pAdicConvert_QQ_FM
Bases: sage.categories.morphism.Morphism

The inclusion map from \( \mathbb{Q} \) to a fixed modulus ring that is defined on all elements with non-negative \( p \)-adic valuation.

EXAMPLES:

sage: f = ZpFM(5).convert_map_from(QQ); f
Generic morphism:
   From: Rational Field
   To:   5-adic Ring of fixed modulus 5^20

class sage.rings.padics.padic_fixed_mod_element.pAdicFixedModElement
Bases: sage.rings.padics.padic_fixed_mod_element.FMElement

INPUT:

- parent – a \( p \)-adicRingFixedMod object.
- \( x \) – input data to be converted into the parent.
- absprec – ignored; for compatibility with other \( p \)-adic rings
- relprec – ignored; for compatibility with other \( p \)-adic rings

Note: The following types are currently supported for \( x \):

- Integers
- Rationals – denominator must be relatively prime to \( p \)
- FixedMod \( p \)-adics
- Elements of \( \text{IntegerModRing}(p^k) \) for \( k \) less than or equal to the modulus

The following types should be supported eventually:

- Finite precision \( p \)-adics
- Lazy \( p \)-adics
- Elements of local extensions of THIS \( p \)-adic ring that actually lie in \( \mathbb{Z}_p \)
EXAMPLES:

```python
sage: R = Zp(5, 20, 'fixed-mod', 'terse')
```

Construct from integers:

```python
sage: R(3)
3
sage: R(75)
75
sage: R(0)
0
sage: R(-1)
95367431640624
sage: R(-5)
95367431640620
```

Construct from rationals:

```python
sage: R(1/2)
47683715820313
sage: R(-7875/874)
9493096742250
sage: R(15/425)
Traceback (most recent call last):
  ...  
ValueError: p divides denominator
```

Construct from IntegerMod:

```python
sage: R(Integers(125)(3))
3
sage: R(Integers(5)(3))
3
sage: R(Integers(5^30)(3))
3
sage: R(Integers(5^30)(1+5^23))
1
sage: R(Integers(49)(3))
Traceback (most recent call last):
  ... 
TypeError: p does not divide modulus 49
```

Some other conversions:

```python
sage: R(R(5))
5
```
Todo: doctests for converting from other types of \( p \)-adic rings

**lift()**

Return an integer congruent to \self\ modulo the precision.

| Warning: | Since fixed modulus elements don’t track their precision, the result may not be correct modulo \( i^\text{prec} \cdot \mathbb{F}_p \) if the element was defined by constructions that lost precision. |

**EXAMPLES:**

```
sage: R = Zp(7,4,’fixed-mod’); a = R(8); a.lift()
sage: type(a.lift())
<class 'sage.rings.integer.Integer'>
```

**multiplicative_order()**

Return the minimum possible multiplicative order of \self\.

**OUTPUT:**

an integer – the multiplicative order of this element. This is the minimum multiplicative order of all elements of \( \mathbb{Z}_p \) lifting this element to infinite precision.

**EXAMPLES:**

```
sage: R = ZpFM(7, 6)
sage: R(1/3)
5 + 4*7 + 4*7^2 + 4*7^3 + 4*7^4 + 4*7^5
sage: R(1/3).multiplicative_order()
+Infinity
sage: R(7).multiplicative_order()
+Infinity
sage: R(1).multiplicative_order()
1
sage: R(-1).multiplicative_order()
2
sage: R.teichmuller(3).multiplicative_order()
6
```

**residue(absprec=1, field=None, check_prec=False)**

Reduce \self\ modulo \( p^{\text{absprec}} \).

**INPUT:**

- \text{absprec} – an integer (default: 1)
- \text{field} – boolean (default \text{None}). Whether to return an element of GF(p) or Zmod(p).
- \text{check_prec} – boolean (default False). No effect (for compatibility with other types).

**OUTPUT:**

This element reduced modulo \( p^{\text{absprec}} \) as an element of \( \mathbb{Z}/p^{\text{absprec}}\mathbb{Z} \).

**EXAMPLES:**
\begin{verbatim}
sage: R = Zp(7, 4, 'fixed-mod')
sage: a = R(8)
sage: a.residue(1)
1
\end{verbatim}

This is different from applying \% \( p^n \) which returns an element in the same ring:

\begin{verbatim}
sage: b = a.residue(2); b
8
sage: b.parent()
Ring of integers modulo 49
sage: c = a \% 7^2; c
1 + 7
sage: c.parent()
7-adic Ring of fixed modulus 7^4
\end{verbatim}

See also:

\_mod\_()

class sage.rings.padics.padic_fixed_mod_element.PAdicTemplateElement
Bases: sage.rings.padics.padic_generic_element.PAdicGenericElement

A class for common functionality among the \( p \)-adic template classes.

INPUT:

- parent – a local ring or field
- x – data defining this element. Various types are supported, including \( \text{ints, Integers, Rationals, pari } p \)-adics, \( \text{integers mod } p^k \) and other Sage \( p \)-adics.
- absprec – a cap on the absolute precision of this element
- relprec – a cap on the relative precision of this element

EXAMPLES:

\begin{verbatim}
sage: Zp(17)(17^3, 8, 4)
17^3 + O(17^7)
\end{verbatim}

expansion(n=None, lift_mode='simple', start_val=None)

Return the coefficients in a \( \pi \)-adic expansion. If this is a field element, start at \( \pi \)\text{valuation}, if a ring element at \( \pi^0 \).

For each lift mode, this function returns a list of \( a_i \) so that this element can be expressed as

\[ \pi^v \cdot \sum_{i=0}^{\infty} a_i \pi^i, \]

where \( v \) is the valuation of this element when the parent is a field, and \( v = 0 \) otherwise.

Different lift modes affect the choice of \( a_i \). When lift_mode is 'simple', the resulting \( a_i \) will be non-negative: if the residue field is \( \mathbb{F}_p \) then they will be integers with \( 0 \leq a_i < p \); otherwise they will be a list of integers in the same range giving the coefficients of a polynomial in the indeterminant representing the maximal unramified subextension.

Choosing lift_mode as 'smallest' is similar to 'simple', but uses a balanced representation \(-p/2 < a_i \leq p/2\).
Finally, setting \( \text{lift\_mode} = \text{'teichmuller'} \) will yield Teichmuller representatives for the \( a_i: a_i^q = a_i \).
In this case the \( a_i \) will lie in the ring of integers of the maximal unramified subextension of the parent of this element.

**INPUT:**

- \( n \) – integer (default None). If given, returns the corresponding entry in the expansion. Can also accept a slice (see slice()).
- \( \text{lift\_mode} \) – 'simple', 'smallest' or 'teichmuller' (default: 'simple')
- \( \text{start\_val} \) – start at this valuation rather than the default (0 or the valuation of this element).

**OUTPUT:**

- If \( n \) is None, an iterable giving a \( \pi \)-adic expansion of this element. For base elements the contents will be integers if \( \text{lift\_mode} \) is 'simple' or 'smallest', and elements of self.parent() if \( \text{lift\_mode} \) is 'teichmuller'.
- If \( n \) is an integer, the coefficient of \( \pi^n \) in the \( \pi \)-adic expansion of this element.

**Note:** Use slice operators to get a particular range.

**EXAMPLES:**

```
sage: R = Zp(7,6); a = R(12837162817); a
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: E = a.expansion(); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
sage: list(E)
[3, 4, 4, 0, 4, 0]
sage: sum([c * 7^i for i, c in enumerate(E)]) == a
True
sage: E = a.expansion(lift_mode='smallest'); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6) (balanced)
sage: list(E)
[3, -3, -2, 1, -3, 1]
sage: sum([c * 7^i for i, c in enumerate(E)]) == a
True
sage: E = a.expansion(lift_mode='teichmuller'); E
7-adic expansion of 3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6) (teichmuller)
sage: list(E)
[3 + 4*7 + 6*7^2 + 3*7^3 + 2*7^5 + O(7^6),
0,
5 + 2*7 + 3*7^3 + 0(7^4),
1 + 0(7^3),
3 + 4*7 + 0(7^2),
5 + 0(7)]
sage: sum(c * 7^i for i, c in enumerate(E))
3 + 4*7 + 4*7^2 + 4*7^4 + O(7^6)
```

If the element has positive valuation then the list will start with some zeros:

```
sage: a = R(7^3 * 17)
sage: E = a.expansion(); E
7-adic expansion of 3*7^3 + 2*7^4 + O(7^9)
```

(continues on next page)
The expansion of 0 is truncated:

```sage
sage: E = R(0, 7).expansion(); E
7-adic expansion of O(7^7)
sage: len(E)
0
sage: list(E)
[]
```

In fields, on the other hand, the expansion starts at the valuation:

```sage
sage: R = Qp(7,4); a = R(6*7+7**2); E = a.expansion(); E
7-adic expansion of 6*7 + 7^2 + O(7^5)
sage: list(E)
[6, 1, 0, 0]
sage: list(a.expansion(lift_mode='smallest'))
[-1, 2, 0, 0]
sage: list(a.expansion(lift_mode='teichmuller'))
[6 + 6*7 + 6*7^2 + 6*7^3 + O(7^4),
 2 + 4*7 + 6*7^2 + O(7^3),
 3 + 4*7 + O(7^2),
 3 + O(7)]
```

You can ask for a specific entry in the expansion:

```sage
sage: a.expansion(1)
6
sage: a.expansion(1, lift_mode='smallest')
-1
sage: a.expansion(2, lift_mode='teichmuller')
2 + 4*7 + 6*7^2 + O(7^3)
```

**lift_to_precision**(absprec=None)

Return another element of the same parent with absolute precision at least absprec, congruent to this $p$-adic element modulo the precision of this element.

**INPUT:**

- absprec – an integer or None (default: None); the absolute precision of the result. If None, lifts to the maximum precision allowed

**Note:** If setting absprec that high would violate the precision cap, raises a precision error. Note that the new digits will not necessarily be zero.

**EXAMPLES:**

```sage
sage: R = ZpCA(17)
sage: R(-1,2).lift_to_precision(10)
16 + 16*17 + O(17^10)
sage: R(1,15).lift_to_precision(10)
```

(continues on next page)
\[ 1 + O(17^{15}) \]
\[
\text{sage: } R(1,15).lift_to_precision(30)
\]
Traceback (most recent call last):
...
PrecisionError: precision higher than allowed by the precision cap
\[
\text{sage: } R(-1,2).lift_to_precision().precision_absolute() == R.precision_cap()
\]
True
\[
\text{sage: } R = \mathbb{Z}_p(5); c = R(17,3); c.lift_to_precision(8)
2 + 3*5 + O(5^8)
\]
\[
\text{sage: } c.lift_to_precision().precision_relative() == R.precision_cap()
\]
True

Fixed modulus elements don’t raise errors:
\[
\text{sage: } R = \mathbb{Z}_pFM(5); a = R(5); a.lift_to_precision(7)
5
\]
\[
\text{sage: } a.lift_to_precision(10000)
5
\]

**residue** (*absprec=*1, *field=*None, *check_prec=*True)
Reduce this element modulo \( p^{\text{absprec}} \).

**INPUT:**
- \( \text{absprec} \) – 0 or 1.
- \( \text{field} \) – boolean (default None). For precision 1, whether to return an element of the residue field or a residue ring. Currently unused.
- \( \text{check_prec} \) – boolean (default True). Whether to raise an error if this element has insufficient precision to determine the reduction. Errors are never raised for fixed-mod or floating-point types.

**OUTPUT:**
This element reduced modulo \( p^{\text{absprec}} \) as an element of the residue field or the null ring.

**EXAMPLES:**
\[
\text{sage: } R.<a> = \mathbb{Z}_q(27, 4)
\]
\[
\text{sage: } (3 + 3*a).residue()
\]
0
\[
\text{sage: } (a + 1).residue()
\]
a0 + 1

**teichmuller_expansion** (*n=*None)
Returns an iterator over coefficients \( a_0, a_1, \ldots, a_n \) such that

- \( a_i^q = a_i \), where \( q \) is the cardinality of the residue field,
- this element can be expressed as

\[
\pi^v \cdot \sum_{i=0}^{\infty} a_i \pi^i
\]

where \( v \) is the valuation of this element when the parent is a field, and \( v = 0 \) otherwise.

- if \( a_i \neq 0 \), the precision of \( a_i \) is \( i \) less than the precision of this element (relative in the case that the parent is a field, absolute otherwise)
Note: The coefficients will lie in the ring of integers of the maximal unramified subextension.

INPUT:

- `n` – integer (default None). If given, returns the coefficient of $\pi^n$ in the expansion.

EXAMPLES:

For fields, the expansion starts at the valuation:

```python
sage: R = Qp(5,5); list(R(70).teichmuller_expansion())
[4 + 4*5 + 4*5^2 + 4*5^3 + 4*5^4 + O(5^5),
 3 + 3*5 + 2*5^2 + 3*5^3 + O(5^4),
 2 + 5 + 2*5^2 + O(5^3),
 1 + 0(5^2),
 4 + 0(5)]
```

But if you specify `n`, you get the coefficient of $\pi^n$:

```python
sage: R(70).teichmuller_expansion(2)
3 + 3*5 + 2*5^2 + 3*5^3 + O(5^4)
```

```
unit_part()
```

Returns the unit part of this element.

This is the $p$-adic element $u$ in the same ring so that this element is $\pi^vu$, where $\pi$ is a uniformizer and $v$ is the valuation of this element.

EXAMPLES:

```python
sage: R.<a> = Zq(125)
```

```python
sage: (5*a).unit_part()
a + O(5^20)
```

```
unit_part()
```

Returns the unit part of this element.

This is the $p$-adic element $u$ in the same ring so that this element is $\pi^vu$, where $\pi$ is a uniformizer and $v$ is the valuation of this element.

EXAMPLES:

```python
sage: R.<a> = Zq(125)
```

```python
sage: (5*a).unit_part()
a + O(5^20)
```

```
unit_part()
```

Returns the unit part of this element.

This is the $p$-adic element $u$ in the same ring so that this element is $\pi^vu$, where $\pi$ is a uniformizer and $v$ is the valuation of this element.

EXAMPLES:

```python
sage: R.<a> = Zq(125)
```

```python
sage: (5*a).unit_part()
a + O(5^20)
```

```
unit_part()
```

Returns the unit part of this element.

This is the $p$-adic element $u$ in the same ring so that this element is $\pi^vu$, where $\pi$ is a uniformizer and $v$ is the valuation of this element.

EXAMPLES:

```python
sage: R.<a> = Zq(125)
```

```python
sage: (5*a).unit_part()
a + O(5^20)
```

```
unit_part()
```

Returns the unit part of this element.

This is the $p$-adic element $u$ in the same ring so that this element is $\pi^vu$, where $\pi$ is a uniformizer and $v$ is the valuation of this element.

EXAMPLES:

```python
sage: R.<a> = Zq(125)
```

```python
sage: (5*a).unit_part()
a + O(5^20)
```

```
unit_part()
```

Returns the unit part of this element.

This is the $p$-adic element $u$ in the same ring so that this element is $\pi^vu$, where $\pi$ is a uniformizer and $v$ is the valuation of this element.

EXAMPLES:

```python
sage: R.<a> = Zq(125)
```

```python
sage: (5*a).unit_part()
a + O(5^20)
```
A common superclass for all elements of extension rings and field of \( \mathbb{Z}_p \) and \( \mathbb{Q}_p \).

**AUTHORS:**

- David Roe (2007): initial version
- Julian Rueth (2012-10-18): added residue

**class** `sage.rings.padics.padic_ext_element.pAdicExtElement`

**Bases:** `sage.rings.padics.padic_generic_element.pAdicGenericElement`

**frobenius** `(arithmetic=True)`

Return the image of this element under the Frobenius automorphism applied to its parent.

**INPUT:**

- `arithmetic` – whether to apply the arithmetic Frobenius (acting by raising to the \( p \)-th power on the residue field). If `False` is provided, the image of geometric Frobenius (raising to the \( (1/p) \)-th power on the residue field) will be returned instead.

**EXAMPLES:**

```python
sage: R.<a> = Zq(5^4,3)
sage: a.frobenius()
(a^3 + a^2 + 3*a) + (3*a + 1)*5 + (2*a^3 + 2*a^2 + 2*a)*5^2 + O(5^3)
sage: f = R.defining_polynomial()
sage: f(a)
O(5^3)
sage: f(a.frobenius())
O(5^3)
sage: for i in range(4): a = a.frobenius()
sage: a
a + O(5^3)
sage: K.<a> = Qq(7^3,4)
sage: b = (a+1)/7
sage: c = b.frobenius(); c
(3*a^2 + 5*a + 1)*7^-1 + (6*a^2 + 6*a + 6) + (4*a^2 + 3*a + 4)*7 + (6*a^2 + a + 6)*7^2 + O(7^3)
sage: c.frobenius().frobenius()
(a + 1)*7^-1 + O(7^3)
```

An error will be raised if the parent of self is a ramified extension:
```python
sage: K.<a> = Qp(5).extension(x^2 - 5)
sage: a.frobenius()
Traceback (most recent call last):
...  
NotImplementedError: Frobenius automorphism only implemented for unramified_ ˓→extensions
```

### residue(absprec=1, field=None, check_prec=True)

Reduces this element modulo $\pi^{absprec}$.

**INPUT:**

- `absprec` – a non-negative integer (default: 1)
- `field` – boolean (default `None`). For precision 1, whether to return an element of the residue field or a residue ring. Currently unused.
- `check_prec` – boolean (default `True`). Whether to raise an error if this element has insufficient precision to determine the reduction. Errors are never raised for fixed-mod or floating-point types.

**OUTPUT:**

This element reduced modulo $\pi^{absprec}$.

If `absprec` is zero, then as an element of $\mathbb{Z}/(1)$.

If `absprec` is one, then as an element of the residue field.

**Note:** Only implemented for `absprec` less than or equal to one.

**AUTHORS:**

- Julian Rueth (2012-10-18): initial version

**EXAMPLES:**

#### Unramified case:

```python
sage: R = ZpCA(3,5)
sage: S.<a> = R[]
sage: W.<a> = R.extension(a^2 + 9*a + 1)
sage: (a + 1).residue(1)
     a0 + 1
```

#### Eisenstein case:

```python
sage: R = ZpCA(3,5)
sage: S.<a> = R[]
sage: W.<a> = R.extension(a^2 + 9*a + 3)
sage: (a + 1).residue(1)
     1
```

(continues on next page)
NotImplementedError: residue() not implemented in extensions for absprec larger than one
A common superclass implementing features shared by all elements that use NTL’s ZZ_pX as the fundamental data type.

AUTHORS:

• David Roe

```python
class sage.rings.padics.padic_ZZ_pX_element.pAdicZZpXElement
    Bases: sage.rings.padics.padic_ext_element.pAdicExtElement

Initialization

EXAMPLES:

```sage
A = Zp(next_prime(50000),10)
S.<x> = A[]
B.<t> = A.ext(x^2+next_prime(50000)) #indirect doctest
```

**norm(base=None)**

Return the absolute or relative norm of this element.

**Note:** This is not the $p$-adic absolute value. This is a field theoretic norm down to a ground ring. If you want the $p$-adic absolute value, use the abs() function instead.

If `base` is given then `base` must be a subfield of the parent $L$ of `self`, in which case the norm is the relative norm from $L$ to `base`.

In all other cases, the norm is the absolute norm down to $Q_p$ or $Z_p$.

**EXAMPLES:**

```sage
R = ZpCR(5,5)
S.<x> = R[]
f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
W.<w> = R.ext(f)
((1+2*w)^5).norm()
1 + 5^2 + O(5^5)
((1+2*w)).norm()^5
1 + 5^2 + O(5^5)
```

**trace(base=None)**

Return the absolute or relative trace of this element.
If base is given then base must be a subfield of the parent \( L \) of \( \text{self} \), in which case the norm is the relative norm from \( L \) to base.

In all other cases, the norm is the absolute norm down to \( \mathbb{Q}_p \) or \( \mathbb{Z}_p \).

EXAMPLES:

```python
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (2+3*w)^7
sage: b = (6+w^3)^5
sage: a.trace()
3*5 + 2*5^2 + 3*5^3 + 2*5^4 + O(5^5)
sage: a.trace() + b.trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
sage: (a+b).trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
```
This file implements elements of Eisenstein and unramified extensions of $\mathbb{Z}_p$ and $\mathbb{Q}_p$ with capped relative precision.

For the parent class see padic_extension_leaves.pyx.

The underlying implementation is through NTL's $\mathbb{Z}_p\mathbb{X}$ class. Each element contains the following data:

- **ordp (long)** – A power of the uniformizer to scale the unit by. For unramified extensions this uniformizer is $p$, for Eisenstein extensions it is not. A value equal to the maximum value of a long indicates that the element is an exact zero.

- **relprec (long)** – A signed integer giving the precision to which this element is defined. For nonzero relprec, the absolute value gives the power of the uniformizer modulo which the unit is defined. A positive value indicates that the element is normalized (ie $\text{unit}$ is actually a unit: in the case of Eisenstein extensions the constant term is not divisible by $p$, in the case of unramified extensions that there is at least one coefficient that is not divisible by $p$). A negative value indicates that the element may or may not be normalized. A zero value indicates that the element is zero to some precision. If so, ordp gives the absolute precision of the element. If ordp is greater than maxordp, then the element is an exact zero.

- **unit ($\mathbb{Z}_p\mathbb{X}$) – **An ntl $\mathbb{Z}_p\mathbb{X}$ storing the unit part. The variable $x$ is the uniformizer in the case of Eisenstein extensions. If the element is not normalized, the unit may or may not actually be a unit. This $\mathbb{Z}_p\mathbb{X}$ is created with global ntl modulus determined by the absolute value of relprec. If relprec is 0, unit is not initialized, or destructed if normalized and found to be zero. Otherwise, let $r$ be relprec and $e$ be the ramification index over $\mathbb{Q}_p$ or $\mathbb{Z}_p$. Then the modulus of unit is given by $p^{\lceil r/e \rceil}$. Note that all kinds of problems arise if you try to mix moduli. $\mathbb{Z}_p\mathbb{X}$\_conv\_modulus gives a semi-safe way to convert between different moduli without having to pass through ZZX.

- **prime\_pow (some subclass of PowComputer_ZZ\_pX) –** a class, identical among all elements with the same parent, holding common data.
  - prime\_pow.deg – The degree of the extension
  - prime\_pow.e – The ramification index
  - prime\_pow.f – The inertia degree
  - prime\_pow.prec\_cap – the unramified precision cap. For Eisenstein extensions this is the smallest power of $p$ that is zero.
  - prime\_pow.ram\_prec\_cap – the ramified precision cap. For Eisenstein extensions this will be the smallest power of $x$ that is indistinguishable from zero.
  - prime\_pow.pow\_ZZ\_tmp, prime\_pow.pow\_mpz\_t\_tmp, prime\_pow.pow\_Integer – functions for accessing powers of $p$. The first two return pointers. See sage/rings/padics/pow_computer_ext for examples and important warnings.
- `prime_pow.get_context`, `prime_pow.get_context_capdiv`, `prime_pow.get_top_context` — obtain an `ntl_ZZ_pContext_class` corresponding to \( p^n \). The capdiv version divides by `prime_pow.e` as appropriate. `top_context` corresponds to \( p^{\text{prec} - 1} \).

- `prime_pow.restore_context`, `prime_pow.restore_context_capdiv`, `prime_pow.restore_top_context` — restores the given context.

- `prime_pow.get_modulus`, `get_modulus_capdiv`, `get_top_modulus` — Returns a `ZZ_pX_Modulus_c*` pointing to a polynomial modulus defined modulo \( p^n \) (appropriately divided by `prime_pow.e` in the capdiv case).

EXEMPLARY:

An Eisenstein extension:

```sage
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f); W
5-adic Eisenstein Extension Ring in w defined by x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: z = (1+w)^5; z
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 + 4*w^20 + w^21 + 4*w^24 + O(w^25)
sage: y = z >> 1; y
w^4 + w^5 + 2*w^6 + 4*w^7 + 3*w^9 + w^11 + 4*w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^19 + w^20 + 4*w^23 + O(w^24)
sage: y.valuation()
4
sage: y.precision_relative()
20
sage: y.precision_absolute()
24
sage: z - (y << 1)
1 + O(w^25)
sage: (1/w)^12+w
w^-12 + w + O(w^13)
sage: (1/w).parent()
5-adic Eisenstein Extension Field in w defined by x^5 + 75*x^3 - 15*x^2 + 125*x - 5
```

Unramified extensions:

```sage
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: z = (1+a)^5; z
(2*a^2 + 4*a) + (3*a^2 + 3*a + 1)*5 + (4*a^2 + 3*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 + O(5^4)
sage: z - 1 - 5*a - 10*a^2 - 10*a^3 - 5*a^4 - a^5
0(5^5)
sage: y = z >> 1; y
(3*a^2 + 3*a + 1) + (4*a^2 + 3*a + 4)*5 + (4*a^2 + 4*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 + O(5^4)
sage: 1/a
(3*a^2 + 4) + (a^2 + 4)*5 + (3*a^2 + 4)*5^2 + (a^2 + 4)*5^3 + (3*a^2 + 4)*5^4 + O(5^5)
sage: FFP = R.residue_field()
sage: R(FFP(3))
3 + O(5)
```

(continues on next page)
Different printing modes:

```plaintext
sage: R = Zp(5, print_mode='digits'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -5;\n    W.<w> = R.ext(f)
sage: z = (1+w)^5; repr(z)
'...
   ...411040311321031044222131124200011011201102002023303214332011214403232013144001400444441030421100001
_'.
sage: R = Zp(5, print_mode='bars'); S.<x> = R[]; g = x^3 + 3*x + 3; A.<a> = R.ext(g)
sage: z = (1+a)^5; repr(z)
'...[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|[4, 4, 4]|\n   ...4, 4, 4]|[1, 3, 3]|[0, 4, 2]'\n    sage: R = Zp(5, print_mode='terse'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -5;\n    W.<w> = R.ext(f)
sage: z = (1+w)^5; z
6 + 95367431640505*w + 25*w^2 + 95367431640560*w^3 + 5*w^4 + O(w^100)
sage: R = Zp(5, print_mode='val-unit'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x -\n    ...5; W.<w> = R.ext(f)
sage: y = (1+w)^5 - 1; y
w^5 * (2090041 + 19073486126901*w + 1258902*w^2 + 674*w^3 + 16785*w^4) + O(w^100)
```

You can get at the underlying ntl unit:

```plaintext
sage: z._ntl_rep()\n[6 95367431640505 25 95367431640560 5]
sage: y._ntl_rep()\n[2090041 19073486126901 1258902 674 16785]
sage: y._ntl_rep_abs()\n([5 95367431640505 25 95367431640560 5], 0)
```

Note: If you get an error internal error: can't grow this _ntl_gbigint, it indicates that moduli are being mixed inappropriately somewhere.

For example, when calling a function with a ZZ_pX_c as an argument, it copies. If the modulus is not set to the modulus of the ZZ_pX_c, you can get errors.

AUTHORS:

- Julian Rueth (2014-05-09): enable caching through _cache_key
sage.rings.padics.padic_ZZ_pX_CR_element.make_ZZpXCRElement(parent, unit, ordp, relprec, version)

Unpickling.

EXAMPLES:

```python
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: y = W(775, 19); y
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: loads(dumps(y)) # indirect doctest
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: from sage.rings.padics.padic_ZZ_pX_CR_element import make_ZZpXCRElement
sage: make_ZZpXCRElement(W, y._ntl_rep(), 3, 9, 0)
w^3 + 4*w^5 + 2*w^7 + w^8 + 2*w^9 + 4*w^10 + w^11 + O(w^12)
```

class sage.rings.padics.padic_ZZ_pX_CR_element.pAdicZZpXCRElement

Bases: sage.rings.padics.padic_ZZ_pX_element.pAdicZZpXElement

Creates an element of a capped relative precision, unramified or Eisenstein extension of \( \mathbb{Z}_p \) or \( \mathbb{Q}_p \).

INPUT:

- \( \text{parent} \) – either an EisensteinRingCappedRelative or UnramifiedRingCappedRelative
- \( x \) – an integer, rational, \( p \)-adic element, polynomial, list, integer_mod, pari int/frac/poly_t/pol_mod, an ntl_ZZ_pX, an ntl ZZ, an ntl ZZ p, an ntl ZZX, or something convertible into parent.residue_field()
- \( \text{absprec} \) – an upper bound on the absolute precision of the element created
- \( \text{relprec} \) – an upper bound on the relative precision of the element created
- \( \text{empty} \) – whether to return after initializing to zero (without setting the valuation).

EXAMPLES:

```python
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: z = (1+w)^5; z
# indirect doctest
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + ...
+ 4*w^17 + 4*w^20 + w^21 + 4*w^24 + O(w^25)
sage: W(pari('3 + O(5^3)'))
3 + O(w^15)
sage: W(R(3,3))
3 + O(w^15)
sage: W.<w> = R.ext(x^625 + 915*x^17 - 95)
sage: W(3)
3 + O(w^3125)
sage: W(w, 14)
w + O(w^14)
```

expansion(n=None, lift_mode='simple')

Return a list giving a series representation of self.
• If lift_mode == 'simple' or 'smallest', the returned list will consist of integers (in the Eisenstein case) or a list of lists of integers (in the unramified case). self can be reconstructed as a sum of elements of the list times powers of the uniformiser (in the Eisenstein case), or as a sum of powers of the \( p \) times polynomials in the generator (in the unramified case).

  - If lift_mode == 'simple', all integers will be in the interval \([0, p - 1]\).
  - If lift_mode == 'smallest' they will be in the interval \([1 - p)/2, p/2]\).

• If lift_mode == 'teichmuller', returns a list of \( \mathbb{p} \text{Adic}\mathbb{Z}_pXCRElements \), all of which are Teichmuller representatives and such that self is the sum of that list times powers of the uniformizer.

Note that zeros are truncated from the returned list if self.parent() is a field, so you must use the valuation function to fully reconstruct self.

INPUT:

• n – integer (default None). If given, returns the corresponding entry in the expansion.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & R = \mathbb{Z}_p(5,5) \\
\text{sage: } & S.<x> = R[] \\
\text{sage: } & f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5 \\
\text{sage: } & W.<w> = R.<f> \\
\text{sage: } & y = W(775, 19); y \\
& w^{10} + 4*w^{12} + 2*w^{14} + w^{15} + 2*w^{16} + 4*w^{17} + w^{18} + O(w^{19}) \\
\text{sage: } & (y>>9).expansion() \\
& [0, 1, 0, 4, 0, 2, 1, 2, 4, 1] \\
\text{sage: } & (y>>9).expansion(lift_mode='smallest') \\
& [0, 1, 0, -1, 0, 2, 1, 2, 0, 1] \\
\text{sage: } & g = x^3 + 3*x + 3 \\
\text{sage: } & A.<a> = R.<g> \\
\text{sage: } & y = 75 + 45*a + 1200*a^2; y \\
& 4*a^5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4 + O(5^6) \\
\text{sage: } & E = y.expansion(); E \\

& [] \\
\text{sage: } & list(A(0,4).expansion()) \\
& []
\end{align*}
\]

is_equal_to(right, absprec=None)

Return whether this element is equal to right modulo self.uniformizer()^absprec.

If absprec is None, checks whether this element is equal to right modulo the lower of their two precisions.

EXAMPLES:
\begin{verbatim}
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(47); b = W(47 + 25)
sage: a.is_equal_to(b) False
sage: a.is_equal_to(b, 7) True

is_zero(absprec=None)
Return whether the valuation of this element is at least absprec. If absprec is None, checks if this element
is indistinguishable from zero.

If this element is an inexact zero of valuation less than absprec, raises a PrecisionError.

EXAMPLES:
\end{verbatim}

\begin{verbatim}
sage: R = Zp(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: O(w^189).is_zero() True
sage: W(0).is_zero() True
sage: a = W(675)
sage: a.is_zero() False
sage: a.is_zero(7) True
sage: a.is_zero(21) False

lift_to_precision(absprec=None)
Return a \texttt{pAdicZZpXCRElement} congruent to this element but with absolute precision at least absprec.

INPUT:

- absprec – (default None) the absolute precision of the result. If None, lifts to the maximum precision allowed.

\textbf{Note:} If setting absprec that high would violate the precision cap, raises a precision error. If self is an
inexact zero and absprec is greater than the maximum allowed valuation, raises an error.

Note that the new digits will not necessarily be zero.

EXAMPLES:
\end{verbatim}
\[ 4w^5 + 3w^7 + w^9 + 3w^{10} + 2w^{11} + 4w^{12} + w^{13} + 2w^{14} + 2w^{15} + O(w^{17}) \]

```sage
sage: b = a.lift_to_precision(19); b
4w^5 + 3w^7 + w^9 + 3w^{10} + 2w^{11} + 4w^{12} + w^{13} + 2w^{14} + 2w^{15} + w^{17} + 2w^{18} + O(w^{19})
```

```sage
c = a.lift_to_precision(24); c
4w^5 + 3w^7 + w^9 + 3w^{10} + 2w^{11} + 4w^{12} + w^{13} + 2w^{14} + 2w^{15} + w^{17} + 2w^{18} + 4w^{19} + 4w^{20} + 2w^{21} + 4w^{23} + O(w^{24})
```

```sage
sage: a._ntl_rep()
[19 35 118 60 121]
```

```sage
sage: b._ntl_rep()
[19 35 118 60 121]
```

```sage
sage: c._ntl_rep()
[19 35 118 60 121]
```

```sage
sage: a.lift_to_precision().precision_relative() == W.precision_cap()
True
```

**matrix_mod_pn()**

Return the matrix of right multiplication by the element on the power basis \(1, x, x^2, \ldots, x^{d-1}\) for this extension field. Thus the rows of this matrix give the images of each of the \(x^i\). The entries of the matrices are IntegerMod elements, defined modulo \(p^{\lfloor N/e \rfloor}\) where \(N\) is the absolute precision of this element (unless this element is zero to arbitrary precision; in that case the entries are integer zeros.)

Raises an error if this element has negative valuation.

**EXAMPLES:**

```sage
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (3+w)^7
sage: a.matrix_mod_pn()
[[2757 333 1068 725 2510]
 [ 50 1507 483 318 725]
 [ 500 50 3007 2358 318]
 [1590 1375 1695 1032 2358]
 [2415 590 2370 2970 1032]]
```

**polynomial(var='x')**

Return a polynomial over the base ring that yields this element when evaluated at the generator of the parent.

**INPUT:**

- var – string, the variable name for the polynomial

**EXAMPLES:**

```sage
sage: S.<x> = ZZ[]
sage: W.<w> = Zp(5).extension(x^2 - 5)
sage: (w + W(5, 7)).polynomial()
(1 + O(5^4))*x + 5 + O(5^4)
```

**precision_absolute()**

Return the absolute precision of this element, i.e the power of the uniformizer modulo which this element is defined.
EXAMPLES:

```
sage: R = Zp(5, 5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
sage: (a.unit_part() - 3).precision_absolute()
9
```

**precision_relative()**

Return the relative precision of this element, i.e., the power of the uniformizer modulo which the unit part of self is defined.

EXAMPLES:

```
sage: R = Zp(5, 5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```

**teichmuller_expansion(n=None)**

Return a list \([a_0, a_1, \ldots, a_n]\) such that

- \(a_i = a_i^q\)
- \(\text{self.unit_part()} = \sum_{i=0}^{n} a_i \pi^i\), where \(\pi\) is a uniformizer of \(\text{self.parent()}\)
- if \(a_i \neq 0\), the absolute precision of \(a_i\) is \(\text{self.precision_relative()} - i\)

**INPUT:**

- \(n\) – integer (default None). If given, returns the corresponding entry in the expansion.

**EXAMPLES:**

```
sage: R.<a> = ZqCR(5^4,4)
sage: E = a.teichmuller_expansion(); E
```

(continues on next page)
5-adic expansion of $a + O(5^4)$ (teichmuller)

```python
sage: list(E)
[(a + (2*a^3 + 2*a^2 + 3*a + 4)*5 + (4*a^3 + 3*a^2 + 3*a + 2)*5^2 + (4*a^2 + 2*a + 2)*5^3 + O(5^4), (a^3 + a^2 + a + 4) + O(5))
  + O(5^2), (a^3 + a^2 + a + 4)*5 + O(5^3), (4*a^3 + 3*a^2 + 3*a + 2)*5^2 + (4*a^2 + 2*a + 2)*5^3 + O(5^4), (a^3 + a^2 + a + 4)*5^2 + O(5^3), (4*a^3 + 3*a^2 + 3*a + 2)*5^2 + (4*a^2 + 2*a + 2)*5^3 + O(5^4), (a^3 + a^2 + a + 4) + O(5)]
```

```python
sage: sum([c * 5^i for i, c in enumerate(E)])
```

```python
a + O(5^4)
```

```python
sage: all(c^625 == c for c in E)
True
```

```python
sage: S.<x> = ZZ[]
sage: f = x^3 - 98*x + 7
sage: W.<w> = ZpCR(7,3).ext(f)
sage: b = (1+w)^5; L = b.teichmuller_expansion(); L
[1 + O(w^9), 5 + 5*w^3 + w^6 + 4*w^7 + O(w^8), 3 + 3*w^3 + O(w^7), 3 + 3*w^3 + O(w^6), 0(w^5), 4 + 5*w^3 + O(w^4), 3 + O(w^3), 6 + O(w^2), 6 + O(w)]
```

```python
sage: sum([w^i*L[i] for i in range(9)]) == b
True
sage: all(L[i]^(7^3) == L[i] for i in range(9))
True
```

```python
sage: L = W(3).teichmuller_expansion(); L
[3 + 3*w^3 + w^7 + O(w^9), 0(w^8), 0(w^7), 4 + 5*w^3 + O(w^6), 0(w^4), 3 + O(w^3), 6 + O(w^2)]
```

```python
sage: sum([w^i*L[i] for i in range(len(L))])
3 + O(w^9)
```

**unit_part()**

Return the unit part of this element, i.e. $\text{self} / \text{uniformizer}^{\text{self.valuation()}}$

**EXAMPLES:**

```python
sage: R = Zp(5,5)
```

```python
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: w.<w> = R.ext(f)
sage: a = W(75, 19); a
```

```python
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
```

```python
sage: a.valuation()
10
```

```python
sage: a.precision_absolute()
19
```

```python
sage: a.precision_relative()
9
```

```python
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```

```python
unit_part()
```

Return the unit part of this element, i.e self / uniformizer^(self.valuation())

**EXAMPLES:**

```python
sage: R = Zp(5,5)
```

```python
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: w.<w> = R.ext(f)
sage: a = W(75, 19); a
```

```python
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
```

```python
sage: a.valuation()
10
```

```python
sage: a.precision_absolute()
19
```

```python
sage: a.precision_relative()
9
```

```python
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```

```python
unit_part()
```

Return the unit part of this element, i.e self / uniformizer^(self.valuation())

**EXAMPLES:**

```python
sage: R = Zp(5,5)
```

```python
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: w.<w> = R.ext(f)
sage: a = W(75, 19); a
```

```python
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + O(w^19)
```
This file implements elements of Eisenstein and unramified extensions of \( \mathbb{Z}_p \) with capped absolute precision.

For the parent class see padic_extension_leaves.pyx.

The underlying implementation is through NTL's \( \mathbb{Z}_p \_pX \) class. Each element contains the following data:

- **absprec** (long) – An integer giving the precision to which this element is defined. This is the power of the uniformizer modulo which the element is well defined.

- **value** (\( \mathbb{Z}_p \_pX \_c \)) – An ntl \( \mathbb{Z}_p \_pX \) storing the value. The variable \( x \) is the uniformizer in the case of Eisenstein extensions. This \( \mathbb{Z}_p \_pX \) is created with global ntl modulus determined by absprec. Let \( a \) be absprec and \( e \) be the ramification index over \( \mathbb{Q}_p \) or \( \mathbb{Z}_p \). Then the modulus is given by \( p^{\lceil a/e \rceil} \). Note that all kinds of problems arise if you try to mix moduli. \( \mathbb{Z}_p \_pX \_conv \_modulus \) gives a semi-safe way to convert between different moduli without having to pass through \( \mathbb{Z}_pX \).

- **prime_pow** (some subclass of PowComputer\( \_Z_p \_pX \)) – a class, identical among all elements with the same parent, holding common data.
  - **prime_pow.deg** – The degree of the extension
  - **prime_pow.e** – The ramification index
  - **prime_pow.f** – The inertia degree
  - **prime_pow.prec_cap** – the unramified precision cap. For Eisenstein extensions this is the smallest power of \( p \) that is zero.
  - **prime_pow.ram_prec_cap** – the ramified precision cap. For Eisenstein extensions this will be the smallest power of \( x \) that is indistinguishable from zero.
  - **prime_pow.pow\_ZZ\_tmp, prime_pow.pow\_mpz\_t\_tmp, prime_pow.pow\_Integer** – functions for accessing powers of \( p \). The first two return pointers. See sage/rings/padics/pow_computer_ext for examples and important warnings.
  - **prime_pow.get\_context, prime_pow.get\_context\_capdiv, prime_pow.get\_top\_context** – obtain an ntl\( \_Z_p\_pContext\_class \) corresponding to \( p^n \). The capdiv version divides by \( p^{\lceil prec/e \rceil} \) as appropriate. top_context corresponds to \( p^{prec.cap} \).
  - **prime_pow.restore\_context, prime_pow.restore\_context\_capdiv, prime_pow.restore\_top\_context** – restores the given context.
  - **prime_pow.get\_modulus, get\_modulus\_capdiv, get\_modulus\_top** – Returns a \( \mathbb{Z}_p \_pX \_Modulus\_c* \) pointing to a polynomial modulus defined modulo \( p^n \) (appropriately divided by prime_pow.e in the capdiv case).

EXAMPLES:

An Eisenstein extension:
```plaintext
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f); W
5-adic Eisenstein Extension Ring in w defined by x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: z = (1+w)^5; z
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 + 4*w^20 + w^21 + 4*w^24 + O(w^25)
sage: y = z >> 1; y
w^4 + w^5 + 2*w^6 + 4*w^7 + 3*w^9 + w^11 + 4*w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^19 + w^20 + 4*w^23 + O(w^24)
sage: y.valuation()
4
sage: y.precision_relative()
20
sage: y.precision_absolute()
24
sage: z - (y << 1)
1 + O(w^25)
sage: (1/w)^12+w
w^-12 + w + O(w^12)
sage: (1/w).parent()
5-adic Eisenstein Extension Field in w defined by x^5 + 75*x^3 - 15*x^2 + 125*x - 5

An unramified extension:

sage: g = x^3 + 3*x^3 + 3
sage: A.<a> = R.ext(g)
sage: z = (1+a)^5; z
(2*a^2 + 4*a) + (3*a^2 + 3*a + 1)*5 + (4*a^2 + 3*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 + O(5^5)
sage: z - 1 - 5*a - 10*a^2 - 10*a^3 - 5*a^4 - a^5
0(5^5)
sage: y = z >> 1; y
(3*a^2 + 3*a + 1) + (4*a^2 + 3*a + 4)*5 + (4*a^2 + 4*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 + O(5^4)
sage: 1/a
(3*a^2 + 4) + (a^2 + 4)*5 + (3*a^2 + 4)*5^2 + (a^2 + 4)*5^3 + O(5^4)
sage: FFA = A.residue_field()
sage: a0 = FFA.gen(); A(a0^3)
(2*a + 2) + O(5)

Different printing modes:

sage: R = ZpCA(5, print_mode='digits'); S.<x> = ZZ[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5; W.<w> = R.ext(f)
sage: z = (1+w)^5; repr(z)
,...
4110403113210310442221311242000111011201102002023032143201121440323201314400140044441030421100001
...
```

(continues on next page)
You can get at the underlying ntl representation:

```
sage: z._ntl_rep()
[6 95367431640505 25 95367431640560 5]
sage: y._ntl_rep()
[5 95367431640505 25 95367431640560 5]
sage: y._ntl_rep_abs()
([5 95367431640505 25 95367431640560 5], 0)
```

Note: If you get an error `internal error: can't grow this _ntl_gbigin`, it indicates that moduli are being mixed inappropriately somewhere.

For example, when calling a function with a `ZZ_pX_c` as an argument, it copies. If the modulus is not set to the modulus of the `ZZ_pX_c`, you can get errors.

AUTHORS:

- David Roe (2008-01-01): initial version
- Robert Harron (2011-09): fixes/enhancements
- Julian Rueth (2012-10-15): fixed an initialization bug

```
sage.rings.padics.padic_ZZ_pX_CA_element.make_ZZpXCAElement(parent, value, absprec, version)
```

For pickling. Makes a `pAdicZZpXCAElement` with given `parent`, `value`, `absprec`.

EXAMPLES:

```
sage: from sage.rings.padics.padic_ZZ_pX_CA_element import make_ZZpXCAElement
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: make_ZZpXCAElement(W, ntl.ZZ_pX([3,2,4],5^3),13,0)
3 + 2*w + 4*w^2 + O(w^13)
```

```
class sage.rings.padics.padic_ZZ_pX_CA_element.pAdicZZpXCAElement
```

Bases: `sage.rings.padics.padic_ZZ_pX_element.pAdicZZpXElement`

Creates an element of a capped absolute precision, unramified or Eisenstein extension of Zp or Qp.

INPUT:

- `parent` – either an EisensteinRingCappedAbsolute or UnramifiedRingCappedAbsolute
- `x` – an integer, rational, p-adic element, polynomial, list, integer_mod, pari int/frac/poly_t/pol_mod, an `ntl_ZZ_pX`, an `ntl_ZZ`, an `ntl_ZZ_p`, an `ntl_ZZX`, or something convertible into parent.residue_field()
- `absprec` – an upper bound on the absolute precision of the element created
- `relprec` – an upper bound on the relative precision of the element created
- `empty` – whether to return after initializing to zero.

**EXAMPLES:**

```python
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: z = (1+w)^5; z
# indirect doctest
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + ...
-4*w^17 + 4*w^20 + w^21 + 4*w^24 + O(w^25)
sage: W(R(3,3))
3 + O(w^15)
sage: W(pari('3 + O(5^3)))
3 + O(w^15)
sage: W(w, 14)
w + O(w^14)
```

**expansion** *(n=None, lift_mode='simple')*

Return a list giving a series representation of `self`.

- If `lift_mode` == 'simple' or 'smallest', the returned list will consist of integers (in the Eisenstein case) or a list of lists of integers (in the unramified case). `self` can be reconstructed as a sum of elements of the list times powers of the uniformizer (in the Eisenstein case), or as a sum of powers of `p` times polynomials in the generator (in the unramified case).
  - If `lift_mode` == 'simple', all integers will be in the interval `[0, p - 1]`
  - If `lift_mode` == 'smallest', they will be in the interval `[(1 - p)/2, p/2]`.
- If `lift_mode` == 'teichmuller', returns a list of `pAdicZZpXCAElements`, all of which are Teichmuller representatives and such that `self` is the sum of that list times powers of the uniformizer.

**INPUT:**
- `n` – integer (default None). If given, returns the corresponding entry in the expansion.

**EXAMPLES:**

```python
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: y = W(775, 19); y
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: (y>>9).expansion()
[0, 1, 0, 4, 0, 2, 1, 2, 0, 1]
sage: (y>>9).expansion(lift_mode='smallest')
[0, 1, 0, -1, 0, 2, 1, 2, 0, 1]
sage: w^10 - w^12 + 2*w^14 + w^15 + 2*w^16 + w^18 + O(w^19)
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + O(w^19)
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: y = 75 + 45*a + 1200*a^2; y
4*a^5 + (3*a^2 + a + 3)*a^2 + 4*a^2*a^5 + a^2*a^5 + 4 + O(5^5)
```
sage: E = y.expansion(); E

Check that trac ticket #25879 has been resolved:

```python
sage: K = ZpCA(3,5)
sage: R.<a> = K[]
sage: L.<a> = K.extension(a^2 - 3)
sage: a.residue()
0
```

### is_equal_to(right, absprec=None)

Returns whether `self` is equal to `right` modulo `self.uniformizer()^absprec`.

If `absprec` is None, returns if `self` is equal to `right` modulo the lower of their two precisions.

**EXAMPLES:**

```python
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(47); b = W(47 + 25)
sage: a.is_equal_to(b)
False
sage: a.is_equal_to(b, 7)
True
```

### is_zero(absprec=None)

Return whether the valuation of `self` is at least `absprec`.

If `absprec` is None, returns if `self` is indistinguishable from zero.

If `self` is an inexact zero of valuation less than `absprec`, raises a `PrecisionError`.

**EXAMPLES:**

```python
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: O(w^189).is_zero()
True
sage: W(0).is_zero()
True
```

(continues on next page)
lift_to_precision(absprec=None)

Returns a \( p \)-Adic\( \mathbb{Z}_p \)CAElement congruent to self but with absolute precision at least absprec.

INPUT:

- absprec – (default None) the absolute precision of the result. If None, lifts to the maximum precision allowed.

**Note:** If setting absprec that high would violate the precision cap, raises a precision error.

Note that the new digits will not necessarily be zero.

**EXAMPLES:**

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(345, 17); a
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + O(w^17)
sage: b = a.lift_to_precision(19); b
# indirect doctest
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + w^17 + 2*w^18 + O(w^19)
sage: c = a.lift_to_precision(24); c
4*w^5 + 3*w^7 + w^9 + 3*w^10 + 2*w^11 + 4*w^12 + w^13 + 2*w^14 + 2*w^15 + w^17 + 2*w^18 + 4*w^19 + 4*w^20 + 2*w^21 + 4*w^23 + O(w^24)
sage: a._ntl_rep()
[345]
sage: b._ntl_rep()
[345]
sage: c._ntl_rep()
[345]
sage: a.lift_to_precision().precision_absolute() == W.precision_cap()
True
```

matrix_mod_pn()

Returns the matrix of right multiplication by the element on the power basis \( 1, x, x^2, \ldots, x^{d-1} \) for this extension field. Thus the rows of this matrix give the images of each of the \( x^i \). The entries of the matrices are \texttt{IntegerMod} elements, defined modulo \( p^\ast(self.absprec() / e) \).

**EXAMPLES:**

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
```
sage: \( f = x^5 + 75x^3 - 15x^2 + 125x - 5 \)
sage: W.<w> = R.ext(f)
sage: a = (3+w)^7
sage: a.matrix_mod_pn()
\[
\begin{bmatrix}
2757 & 333 & 1068 & 725 & 2510 \\
50 & 1507 & 483 & 318 & 725 \\
500 & 50 & 3007 & 2358 & 318 \\
1590 & 1375 & 1695 & 1032 & 2358 \\
2415 & 590 & 2370 & 2970 & 1032 \\
\end{bmatrix}
\]
polynomial(\textit{var}=\textquoteSingle{s}x\textquoteSingle{)}

Return a polynomial over the base ring that yields this element when evaluated at the generator of the parent.

**INPUT:**

- \textit{var} – string, the variable name for the polynomial

**EXAMPLES:**

sage: S.<x> = ZZ[]
sage: W.<w> = ZpCA(5).extension(x^2 - 5)
sage: (w + W(5, 7)).polynomial()
\((1 + O(5^3))*x + 5 + O(5^4)\)

**precision_absolute()**

Returns the absolute precision of \texttt{self}, i.e., the power of the uniformizer modulo which this element is defined.

**EXAMPLES:**

sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75x^3 - 15x^2 + 125x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
\(3w^{10} + 2w^{12} + w^{14} + w^{16} + w^{17} + 3w^{18} + O(w^{19})\)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2w^2 + w^4 + w^6 + w^7 + 3w^8 + O(w^9)

**precision_relative()**

Returns the relative precision of \texttt{self}, i.e., the power of the uniformizer modulo which the unit part of \texttt{self} is defined.

**EXAMPLES:**

sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75x^3 - 15x^2 + 125x - 5
sage: W.<w> = R.ext(f)
### sage

```python
sage: a = W(75, 19); a
3*ω^10 + 2*ω^12 + ω^14 + ω^16 + 3*ω^18 + O(ω^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*ω^2 + ω^4 + ω^6 + 3*ω^8 + O(ω^9)
```

### teichmuller_expansion(n=None)

Returns a list \[ [a_0, a_1, \ldots, a_n] \] such that:

- \[ a_q^i = a_i \]
- \[ \text{self.unit_part()} = \sum_{i=0}^{n} a_i \pi^i \]
- if \[ a_i \neq 0 \], the absolute precision of \[ a_i \] is \[ \text{self.precision_relative()} - i \]

**INPUT:**
- \( n \) – integer (default None). If given, returns the corresponding entry in the expansion.

**EXAMPLES:**

```python
sage: R.<a> = Zq(5^4,4)
sage: E = a.teichmuller_expansion(); E
5-adic expansion of a + O(5^4) (teichmuller)
sage: list(E)
[a + (2*a^3 + 2*a^2 + 3*a + 4)*5 + (4*a^3 + 3*a^2 + 3*a + 2)*5^2 + (4*a^2 + 2*a + 1)*5^3 + O(5^4),
 a^3 + a^2 + a + 4 + O(5^3),
 a^3 + a^2 + a + 4 + O(5^2),
 a + O(5^4)]
sage: all(c^625 == c for c in E)
True
sage: S.<x> = ZZ[]
sage: f = x^3 - 98*x + 7
sage: W.<w> = ZpCA(7,3).ext(f)
sage: b = (1+w)^5; L = b.teichmuller_expansion(); L
[1 + O(w^9), 5 + 5*w^3 + w^6 + 4*w^7 + O(w^8), 3 + 3*w^3 + 0(w^7), 3 + 3*w^3 + O(w^6),
 3 + 0(w^5), 4 + 5*w^3 + O(w^4), 3 + 0(w^3), 6 + 0(w^2), 6 + O(w)]
sage: all(L[i]^(7^3) == L[i] for i in range(9))
True
sage: L = W(3).teichmuller_expansion(); L
[3 + 3*w^3 + w^7 + O(w^9), 0(w^8), O(w^7), 4 + 5*w^3 + O(w^6), 0(w^5), O(w^4),
 3 + 0(w^3), 6 + 0(w^2)]
sage: all(L[i]^(3^3) == L[i] for i in range(len(L)))
True
```

224 Chapter 20. \( p \)-adic ZZ\_pX CA Element
to_fraction_field()
Returns self cast into the fraction field of self.parent().

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: z = (1 + w)^5; z
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 + 4*w^20 + w^21 + 4*w^24 + O(w^25)
sage: y = z.to_fraction_field(); y #indirect doctest
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + 4*w^17 + 4*w^20 + w^21 + 4*w^24 + O(w^25)
sage: y.parent()
5-adic Eisenstein Extension Field in w defined by x^5 + 75*x^3 - 15*x^2 + 125*x - 5
```

unit_part()
Returns the unit part of self, i.e. self / uniformizer^(self.valuation())

EXAMPLES:

```
sage: R = ZpCA(5,5)
sage: S.<x> = ZZ[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75, 19); a
3*w^10 + 2*w^12 + w^14 + w^16 + 3*w^18 + O(w^19)
sage: a.valuation()
10
sage: a.precision_absolute()
19
sage: a.precision_relative()
9
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + O(w^9)
```
Chapter 20. \( p \)-adic ZZ\_pX CA Element
This file implements elements of Eisenstein and unramified extensions of $\mathbb{Z}_p$ with fixed modulus precision.

For the parent class see `padic_extension_leaves.pyx`.

The underlying implementation is through NTL’s $\mathbb{Z}_pX$ class. Each element contains the following data:

- **value** ($\mathbb{Z}_pX_c$) – An ntl $\mathbb{Z}_pX$ storing the value. The variable $x$ is the uniformizer in the case of Eisenstein extensions. This $\mathbb{Z}_pX$ is created with global ntl modulus determined by the parent’s precision cap and shared among all elements.

- **prime_pow** (some subclass of PowComputer_$\mathbb{Z}_pX$) – a class, identical among all elements with the same parent, holding common data.
  - **prime_pow.deg** – the degree of the extension
  - **prime_pow.e** – the ramification index
  - **prime_pow.f** – the inertia degree
  - **prime_pow.prec_cap** – the unramified precision cap: for Eisenstein extensions this is the smallest power of $p$ that is zero
  - **prime_pow.ram_prec_cap** – the ramified precision cap: for Eisenstein extensions this will be the smallest power of $x$ that is indistinguishable from zero
  - **prime_pow.pow_ZZ_tmp**, **prime_pow.pow_mpz_t_tmp**, **prime_pow.pow_Integer** – functions for accessing powers of $p$. The first two return pointers. See `sage/rings/padics/pow_computer_ext` for examples and important warnings.
  - **prime_pow.get_context**, **prime_pow.get_context_capdiv**, **prime_pow.get_top_context** – obtain an ntl $\mathbb{Z}_p$Context_class corresponding to $p^n$. The capdiv version divides by $prime\_pow.e$ as appropriate. top_context corresponds to $p^{prec\_cap}$.
  - **prime_pow.restore_context**, **prime_pow.restore_context_capdiv**, **prime_pow.restore_top_context** – restores the given context
  - **prime_pow.get_modulus**, **get_modulus_capdiv**, **get_top_modulus** – Returns a $\mathbb{Z}_pX$Modulus_c* pointing to a polynomial modulus defined modulo $p^n$ (appropriately divided by $prime\_pow.e$ in the capdiv case).

EXAMPLES:

An Eisenstein extension:

```python
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f); W
```

(continues on next page)
An unramified extension:

```
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: z = (1+a)^5; z
(2*a^2 + 4*a) + (3*a^2 + 3*a + 1)*5 + (4*a^2 + 3*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3 +...
sage: z - 1 - 5*a - 10*a^2 - 10*a^3 - 5*a^4 - a^5
0
sage: y = z >> 1; y
(3*a^2 + 3*a + 1) + (4*a^2 + 3*a + 4)*5 + (4*a^2 + 4*a + 4)*5^2 + (4*a^2 + 4*a + 4)*5^3
sage: 1/a
(3*a^2 + 4) + (a^2 + 4)*5 + (3*a^2 + 4)*5^2 + (a^2 + 4)*5^3 + (3*a^2 + 4)*5^4
```

Different printing modes:

```
sage: R = ZpFM(5, print_mode='digits'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: R = ZpFM(5, print_mode='bars'); S.<x> = R[]; g = x^3 + 3*x + 3; A.<a> = R.ext(g)
sage: R = ZpFM(5, print_mode='terse'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: R = ZpFM(5, print_mode='val-unit'); S.<x> = R[]; f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
```

AUTHORS:
sage.rings.padics.padic ZZ_pX_FM_element.make_ZZpXFMElement(parent, f)
Create a new pAdicZZpXMElement out of an ntl ZZ_pX f, with parent parent. For use with pickling.

EXAMPLES:

```python
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: z = (1 + w)^5 - 1
sage: loads(dumps(z)) == z # indirect doctest
True
```

class sage.rings.padics.padic ZZ_pX_FM_element.pAdicZZpXFMElement
Bases: sage.rings.padics.padic ZZ_pX_element.pAdicZZpXElement

Creates an element of a fixed modulus, unramified or eisenstein extension of \( \mathbb{Z}_p \) or \( \mathbb{Q}_p \).

INPUT:

- `parent` – either an EisensteinRingFixedMod or UnramifiedRingFixedMod
- `x` – an integer, rational, \( p \)-adic element, polynomial, list, integer_mod, pari int/frac/poly_t/pol_mod, an ntl ZZ_pX, an ntl ZZX, an ntl ZZ, or an ntl ZZ_p
- `absprec` – not used
- `relprec` – not used
- `empty` – whether to return after initializing to zero (without setting anything)

EXAMPLES:

```python
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: z = (1+w)^5; z
# indirect doctest
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + ...
˓→ 4*w^17 + 4*w^20 + w^21 + 4*w^24
```

add_bigoh(absprec)
Return a new element truncated modulo \( p^{absprec} \).

This is only implemented for unramified extension at this point.

INPUT:

- `absprec` – an integer

OUTPUT:

A new element truncated modulo \( p^{absprec} \).

EXAMPLES:

```python
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: z = (1+w)^5; z
# indirect doctest
1 + w^5 + w^6 + 2*w^7 + 4*w^8 + 3*w^10 + w^12 + 4*w^13 + 4*w^14 + 4*w^15 + 4*w^16 + ...
˓→ 4*w^17 + 4*w^20 + w^21 + 4*w^24
```

```python
sage: R = ZpFM(7,5, 'fixed-mod')
sage: a = R(1+7+7^2)
sage: a.add_bigoh(1)
1
```
expansion($n$=None, $\text{lift\_mode}='$\text{simple}'$)

Return a list giving a series representation of this element.

- If lift_mode == 'simple' or 'smallest', the returned list will consist of
  - integers (in the eisenstein case) or
  - lists of integers (in the unramified case).

- this element can be reconstructed as
  - a sum of elements of the list times powers of the uniformiser (in the eisenstein case), or
  - as a sum of powers of the $p$ times polynomials in the generator (in the unramified case).

- If lift_mode == 'simple', all integers will be in the range $[0, p-1]$.
- If lift_mode == 'smallest' they will be in the range $[(1-p)/2, p/2]$.
- If lift_mode == 'teichmuller', returns a list of $\text{pAdicZZpXCRElements}$, all of which are Teichmuller representatives and such that this element is the sum of that list times powers of the uniformizer.

**INPUT:**

- $n$ – integer (default None); if given, returns the corresponding entry in the expansion

**EXAMPLES:**

```
sage: R = ZpFM(5, 5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 + 125*x - 5
sage: W.<w> = R.ext(f)
sage: y = W(775); y
w^10 + 4*w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + w^20 + 2*w^21 + 3*w^22
   →+ w^23 + w^24
sage: (y>>9).expansion()
[0, 1, 0, 4, 0, 2, 1, 2, 4, 1, 0, 1, 2, 3, 1, 1, 1, 2, 4, 1, 0, 0, 3]
sage: (y>>9).expansion(lift_mode='smallest')
[0, 1, 0, -1, 0, 2, 1, 2, 0, 1, 2, 1, 1, -1, 1, 2, -2, 0, 2, -2, -2, 0, -2, -2, -2]
sage: w^10 - w^12 + 2*w^14 + w^15 + 2*w^16 + 4*w^17 + w^18 + w^20 + 2*w^21 + 3*w^22
   →- w^23 + 2*w^24
sage: g = x^3 + 3*x + 3
sage: A.<a> = R.ext(g)
sage: y = 75 + 45*a + 1200*a^2; y
4*a*5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4
sage: E = y.expansion(); E
5-adic expansion of 4*a*5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4
sage: list(E)
[[], [0, 4], [3, 1, 3], [0, 0, 4], [0, 0, 1]]
sage: list(y.expansion(lift_mode='smallest'))
[[], [0, -1], [-2, 2, -2], [1], [0, 0, 2]]
sage: 5*((-2*5 + 25) + (-1 + 2*5)*a + (-2*5 + 2*125)*a^2)
4*a^5 + (3*a^2 + a + 3)*5^2 + 4*a^2*5^3 + a^2*5^4
sage: W(0).expansion()
[]
sage: list(A(0, 4).expansion())
[]
```
Check that trac ticket #25879 has been resolved:

```python
sage: K = ZpCA(3, 5)
sage: R.<a> = K[]
sage: L.<a> = K.extension(a^2 - 3)
sage: a.residue()
0
```

### is_equal_to(right, absprec=None)

Return whether `self` is equal to `right` modulo `self.uniformizer()^absprec`.

If `absprec` is `None`, returns if `self` is equal to `right` modulo the precision cap.

**EXAMPLES:**

```python
sage: R = Zp(5, 5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(47); b = W(47 + 25)
sage: a.is_equal_to(b)
False
sage: a.is_equal_to(b, 7)
True
```

### is_zero(absprec=None)

Return whether the valuation of `self` is at least `absprec`; if `absprec` is `None`, return whether `self` is indistinguishable from zero.

**EXAMPLES:**

```python
sage: R = ZpFM(5, 5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: O(w^189).is_zero()
True
sage: W(0).is_zero()
True
sage: a = W(675)
sage: a.is_zero()
False
sage: a.is_zero(7)
True
sage: a.is_zero(21)
False
```

### lift_to_precision(absprec=None)

Return `self`.

**EXAMPLES:**

```python
sage: R = ZpFM(5, 5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
```
matrix_mod_pn()

Return the matrix of right multiplication by the element on the power basis $1, x, x^2, \ldots, x^{d-1}$ for this extension field.

The rows of this matrix give the images of each of the $x^i$. The entries of the matrices are IntegerMod elements, defined modulo $p^{(\text{self.absprec() / e})}$.

Raises an error if \texttt{self} has negative valuation.

EXAMPLES:

```python
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (3+w)^7
sage: a.matrix_mod_pn()
[[2757 333 1068 725 2510]
 [ 50 1507 483 318 725]

[2415 590 2370 2970 1032]]
```

norm(\texttt{base=None})

Return the absolute or relative norm of this element.

\textbf{Note:} This is not the $p$-adic absolute value. This is a field theoretic norm down to a ground ring.

If you want the $p$-adic absolute value, use the \texttt{abs()} function instead.

If $K$ is given then $K$ must be a subfield of the parent $L$ of \texttt{self}, in which case the norm is the relative norm from $L$ to $K$. In all other cases, the norm is the absolute norm down to $\mathbb{Q}_p$ or $\mathbb{Z}_p$.

EXAMPLES:

```python
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: ((1+2*w)^5).norm() 1 + 5^2 + O(5^5)
sage: ((1+2*w)).norm()^5 1 + 5^2 + O(5^5)
```

polynomial(\texttt{var=’x’})

Return a polynomial over the base ring that yields this element when evaluated at the generator of the parent.

INPUT:

- \texttt{var} – string, the variable name for the polynomial

EXAMPLES:
```python
sage: S.<x> = ZZ[]
sage: W.<w> = ZpFM(5).extension(x^2 - 5)
sage: (w + 5).polynomial()
x + 5
```

**precision_absolute()**

Return the absolute precision of self, i.e., the precision cap of self.parent().

EXAMPLES:

```python
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + 3*w^19 + 2*w^21 + 3*w^22 + 3*w^23
sage: a.valuation()
10
sage: a.precision_absolute()
25
sage: a.precision_relative()
15
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + 3*w^9 + 2*w^11 + 3*w^12 + 3*w^13 + w^15 + 4*w^16 + 2*w^17 + w^18 + 3*w^21 + w^22 + 3*w^24
```

**precision_relative()**

Return the relative precision of self, i.e., the precision cap of self.parent() minus the valuation of self.

EXAMPLES:

```python
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + 3*w^19 + 2*w^21 + 3*w^22 + 3*w^23
sage: a.valuation()
10
sage: a.precision_absolute()
25
sage: a.precision_relative()
15
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + 3*w^9 + 2*w^11 + 3*w^12 + 3*w^13 + w^15 + 4*w^16 + 2*w^17 + w^18 + 3*w^21 + w^22 + 3*w^24
```

**teichmuller_expansion(n=None)**

Return a list \([a_0, a_1, \ldots, a_n]\) such that

- \(a_q^q = a_i\)
- \(\text{self.unit_part()} = \sum_{i=0}^{n} a_i \pi^i\), where \(\pi\) is a uniformizer of self.parent()
**INPUT:**

- \( n \) – integer (default None); \( f \) given, returns the corresponding entry in the expansion

**EXAMPLES:**

```python
sage: R.<a> = ZqFM(5^4,4)
sage: E = a.teichmuller_expansion(); E
5-adic expansion of a (teichmuller)
sage: list(E)
[(a + (2*a^3 + 2*a^2 + 3*a + 4)*5 + (4*a^3 + 3*a^2 + 3*a + 2)*5^2 + (4*a^2 + 2*a + 1)*5^3,
  (3*a^3 + 3*a^2 + 2*a + 1) + (a^3 + 4*a^2 + 1)*5 + (a^2 + 4*a + 4)*5^2 + (4*a^2 + 2*a + 1)*5^3,
  (4*a^3 + 2*a^2 + a + 1) + (2*a^3 + 2*a^2 + 2*a + 4)*5 + (3*a^3 + 2*a^2 + 2*a + 1)*5^2 + (4*a^2 + 2*a + 1)*5^3,
  (a^3 + a^2 + 2*a + 4) + (3*a^3 + 3*a^2 + a + 2)*5^2 + (3*a^3 + 3*a^2 + 2*a + 1)*5^3,
  (4*a^3 + 3*a^2 + 3*a + 2)*5 + (4*a^2 + 2*a + 1)*5^2)]
sage: sum([c * 5^i for i, c in enumerate(E)])
a
sage: all(c^625 == c for c in E)
True
sage: S.<x> = ZZ[]
sage: f = x^3 - 98*x + 7
sage: W.<w> = ZpFM(7,3).ext(f)
sage: b = (1+w)^5; L = b.teichmuller_expansion(); L
[(1, 5 + 5*w^3 + w^6 + 4*w^7,
  3 + 3*w^3 + w^7,
  3 + 3*w^3 + w^7,
  0,
  4 + 5*w^3 + w^6 + 4*w^7,
  3 + 3*w^3 + w^7,
  6 + w^3 + 5*w^7,
  6 + w^3 + 5*w^7)]
sage: sum([w^i*L[i] for i in range(len(L))]) == b
True
sage: all(L[i]^(7^3) == L[i] for i in range(9))
True
sage: L = W(3).teichmuller_expansion(); L
[(3 + 3*w^3 + w^7,
  0,
  0,
  4 + 5*w^3 + w^6 + 4*w^7,
  0,
  0,
  3 + 3*w^3 + w^7,
  6 + w^3 + 5*w^7)]
sage: sum([w^i*L[i] for i in range(len(L))])
3
```

**trace** (base=None)

Return the absolute or relative trace of this element.
If $K$ is given then $K$ must be a subfield of the parent $L$ of self, in which case the norm is the relative norm from $L$ to $K$. In all other cases, the norm is the absolute norm down to $\mathbb{Q}_p$ or $\mathbb{Z}_p$.

**EXAMPLES:**

```python
sage: R = ZpCR(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = (2+3*w)^7
sage: b = (6+w^3)^5
sage: a.trace()
3*5 + 2*5^2 + 3*5^3 + 2*5^4 + O(5^5)
```

```python
sage: a.trace() + b.trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
```

```python
sage: (a+b).trace()
4*5 + 5^2 + 5^3 + 2*5^4 + O(5^5)
```

**unit_part()**

Return the unit part of self, ie self / uniformizer^(self.valuation())

**Warning:** If this element has positive valuation then the unit part is not defined to the full precision of the ring. Asking for the unit part of $\mathbb{Z}_p(5)(0)$ will not raise an error, but rather return itself.

**EXAMPLES:**

```python
sage: R = ZpFM(5,5)
sage: S.<x> = R[]
sage: f = x^5 + 75*x^3 - 15*x^2 +125*x - 5
sage: W.<w> = R.ext(f)
sage: a = W(75); a
3*w^10 + 2*w^12 + w^14 + w^16 + w^17 + 3*w^18 + 3*w^19 + 2*w^21 + 3*w^22 + 3*w^...
˓→23
sage: a.valuation()
10
sage: a.precision_absolute()
25
sage: a.precision_relative()
15
sage: a.unit_part()
3 + 2*w^2 + w^4 + w^6 + w^7 + 3*w^8 + 3*w^9 + 2*w^11 + 3*w^12 + 3*w^13 + w^15 + 4*w^16 + 2*w^17 + w^18 + 3*w^21 + w^22 + 3*w^24
```

The unit part inserts nonsense digits if this element has positive valuation:

```python
sage: (a-a).unit_part()
0
```
A class for computing and caching powers of the same integer.

This class is designed to be used as a field of p-adic rings and fields. Since elements of p-adic rings and fields need to use powers of p over and over, this class precomputes and stores powers of p. There is no reason that the base has to be prime however.

EXAMPLES:

```sage
sage: X = PowComputer(3, 4, 10)
sage: X(3)
27
sage: X(10) == 3^10
True
```

AUTHORS:

- David Roe

`sage.rings.padics.pow_computer.PowComputer(m, cache_limit, prec_cap, in_field=False, prec_type=None)`

Returns a PowComputer that caches the values $1, m, m^2, \ldots, m^C$, where $C$ is `cache_limit`.

Once you create a PowComputer, merely call it to get values out.

You can input any integer, even if it’s outside of the precomputed range.

INPUT:

- m – An integer, the base that you want to exponentiate.
- cache_limit – A positive integer that you want to cache powers up to.

EXAMPLES:

```sage
sage: PC = PowComputer(3, 5, 10)
sage: PC
PowComputer for 3
sage: PC(4)
81
sage: PC(6)
729
sage: PC(-1)
1/3
```

class `sage.rings.padics.pow_computer.PowComputer_base`

Bases: `sage.rings.padics.pow_computer.PowComputer_class`

Initialization.
class sage.rings.padics.pow_computer.PowComputer_class

Bases: sage.structure.sage_object.SageObject

Initializes self.

INPUT:

- prime – the prime that is the base of the exponentials stored in this pow_computer.
- cache_limit – how high to cache powers of prime.
- prec_cap – data stored for p-adic elements using this pow_computer (so they have C-level access to fields common to all elements of the same parent).
- ram_prec_cap – prec_cap * e
- in_field – same idea as prec_cap
- poly – same idea as prec_cap
- shift_seed – same idea as prec_cap

EXAMPLES:

sage: PC = PowComputer(3, 5, 10)
sage: PC.pow_Integer_Integer(2)
9

pow_Integer_Integer(n)

Tests the pow_Integer function.

EXAMPLES:

sage: PC = PowComputer(3, 5, 10)
sage: PC.pow_Integer_Integer(4)
81
sage: PC.pow_Integer_Integer(6)
729
sage: PC.pow_Integer_Integer(0)
1
sage: PC.pow_Integer_Integer(10)
59049
sage: PC = PowComputer_ext_maker(3, 5, 10, 20, False, ntl.ZZ_pX([-3,0,1], 3^10), → 'big','e',ntl.ZZ_pX([1],3^10))
sage: PC.pow_Integer_Integer(4)
81
sage: PC.pow_Integer_Integer(6)
729
sage: PC.pow_Integer_Integer(0)
1
sage: PC.pow_Integer_Integer(10)
59049
The classes in this file are designed to be attached to p-adic parents and elements for Cython access to properties of the parent.

In addition to storing the defining polynomial (as an NTL polynomial) at different precisions, they also cache powers of p and data to speed right shifting of elements.

The hierarchy of PowComputers splits first at whether it's for a base ring (Qp or Zp) or an extension.

Among the extension classes (those in this file), they are first split by the type of NTL polynomial (ntl_ZZ_pX or ntl_ZZ_pEX), then by the amount and style of caching (see below). Finally, there are subclasses of the ntl_ZZ_pX PowComputers that cache additional information for Eisenstein extensions.

There are three styles of caching:

- **FM**: caches powers of p up to the cache_limit, only caches the polynomial modulus and the ntl_ZZ_pContext of precision prec_cap.
- **small**: Requires cache_limit = prec_cap. Caches p^k for every k up to the cache_limit and caches a polynomial modulus and a ntl_ZZ_pContext for each such power of p.
- **big**: Caches as the small does up to cache_limit and caches prec_cap. Also has a dictionary that caches values above the cache_limit when they are computed (rather than at ring creation time).

**AUTHORS:**
- David Roe (2008-01-01) initial version

```python
class sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX:
    Bases: sage.rings.padics.pow_computer_ext.PowComputer_ext

    polynomial()
    Returns the polynomial (with coefficient precision prec_cap) associated to this PowComputer.

    The polynomial is output as an ntl_ZZ_pX.

    EXAMPLES:
    
    sage: PC = PowComputer_ext_maker(5, 5, 10, 20, False, ntl.ZZ_pX([-5,0,1],5^10),
    "FM", 'e',ntl.ZZ_pX([1],5^10))
    sage: PC.polynomial()
    [9765620 0 1]

    speed_test(n, runs)
    Runs a speed test.

    INPUT:
    * n – input to a function to be tested (the function needs to be set in the source code).
```
- runs – The number of runs of that function

**OUTPUT:**

- The time in seconds that it takes to call the function on \( n \), \( \text{runs} \) times.

**EXAMPLES:**

```python
sage: PC = PowComputer_ext_maker(5, 10, 10, 20, False, ntl.ZZ_pX([-5, 0, 1], 5^→10), 'small', 'e', ntl.ZZ_pX([1], 5^10))
sage: PC.speed_test(10, 10^6) # random
0.0090679999999991878
```

**class** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_FM*

**Bases:** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX*  
This class only caches a context and modulus for \( p^{\text{prec\_cap}} \).

- Designed for use with fixed modulus p-adic rings, in Eisenstein and unramified extensions of \( \mathbb{Z}_p \).

**class** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_FM_Eis*

**Bases:** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_FM*  
This class computes and stores low\_shifter and high\_shifter, which aid in right shifting elements.

**class** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_big*

**Bases:** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX*  
This class caches all contexts and moduli between 1 and cache\_limit, and also caches for prec\_cap. In addition, it stores a dictionary of contexts and moduli of

**reset_dictionaries()**

- Resets the dictionaries. Note that if there are elements lying around that need access to these dictionaries, calling this function and then doing arithmetic with those elements could cause trouble (if the context object gets garbage collected for example. The bugs introduced could be very subtle, because NTL will generate a new context object and use it, but there’s the potential for the object to be incompatible with the different context object).

**EXAMPLES:**

```python
sage: A = PowComputer_ext_maker(5, 6, 10, 20, False, ntl.ZZ_pX([-5,0,1],5^→10), 'big', 'e', ntl.ZZ_pX([1],5^10))
sage: P = A._get_context_test(8)
sage: A._context_dict()  
{8: NTL modulus 390625}
sage: A.reset_dictionaries()  
sage: A._context_dict()  
{}```

**class** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_big_Eis*

**Bases:** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_big*  
This class computes and stores low\_shifter and high\_shifter, which aid in right shifting elements. These are only stored at maximal precision: in order to get lower precision versions just reduce mod \( p^n \).

**class** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_small*

**Bases:** *sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX*  
This class caches contexts and moduli densely between 1 and cache\_limit. It requires cache\_limit == prec\_cap. It is intended for use with capped relative and capped absolute rings and fields, in Eisenstein and unramified extensions of the base p-adic fields.
class sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_small_Eis
    Bases: sage.rings.padics.pow_computer_ext.PowComputer_ZZ_pX_small

This class computes and stores low_shifter and high_shifter, which aid in right shifting elements. These are only stored at maximal precision: in order to get lower precision versions just reduce mod $p^\text{n}$.

class sage.rings.padics.pow_computer_ext.PowComputer_ext
    Bases: sage.rings.padics.pow_computer.PowComputer_class

sage.rings.padics.pow_computer_ext.PowComputer_ext_maker

Returns a PowComputer that caches the values $1, p, p^2, \ldots, p^C$, where $C$ is cache_limit.

Once you create a PowComputer, merely call it to get values out. You can input any integer, even if it’s outside of the precomputed range.

INPUT:

- prime – An integer, the base that you want to exponentiate.
- cache_limit – A positive integer that you want to cache powers up to.
- prec_cap – The cap on precisions of elements. For ramified extensions, $p^((\text{prec_cap - 1})//e)$ will be the largest power of $p$ distinguishable from zero.
- in_field – Boolean indicating whether this PowComputer is attached to a field or not.
- poly – An ntl-ZZ_pX or ntl-ZZ_pEX defining the extension. It should be defined modulo $p^((\text{prec_cap - 1})//e + 1)$.
- prec_type – ‘FM’, ‘small’, or ‘big’, defining how caching is done.
- ext_type – ‘u’ = unramified, ‘e’ = Eisenstein, ‘t’ = two-step
- shift_seed – (required only for Eisenstein and two-step) For Eisenstein and twostep extensions, if $f = a_n x^n - p a_{n-1} x^{n-1} - \ldots - p a_0$ with $a_n$ a unit, then shift_seed should be $1/a_n (a_{n-1} x^{n-1} + \ldots + a_0)$

EXAMPLES:

```
sage: PC = PowComputer_ext_maker(5, 10, 10, 20, False, ntl.ZZ_pX([-5, 0, 1], 5^10),
    \"small\", \"e\", ntl.ZZ_pX([1], 5^10))
sage: PC
PowComputer_ext for 5, with polynomial [9765620 0 1]
```

sage.rings.padics.pow_computer_ext.ZZ_pX_eis_shift_test(_shifter, _a, _n, _finalprec)

Shifts _a right _n x-adic digits, where x is considered modulo the polynomial in _shifter.

EXAMPLES:

```
sage: from sage.rings.padics.pow_computer_ext import ZZ_pX_eis_shift_test
sage: A = PowComputer_ext_maker(5, 3, 10, 40, False, ntl.ZZ_pX([-5, 75, 15, 0, 1], 5^10),
    \"big\", \"e\", ntl.ZZ_pX([1, -15, -3], 5^10))
sage: ZZ_pX_eis_shift_test(A, [0, 1], 1, 5)
[1]
sage: ZZ_pX_eis_shift_test(A, [0, 0, 1], 1, 5)
[0 1]
sage: ZZ_pX_eis_shift_test(A, [5], 1, 5)
[75 15 0 1]
```
sage: ZZ_pX_eis_shift_test(A, [1], 1, 5)
[]
sage: ZZ_pX_eis_shift_test(A, [17, 91, 8, -2], 1, 5)
[316 53 3123 3]
sage: ZZ_pX_eis_shift_test(A, [316, 53, 3123, 3], -1, 5)
[15 91 8 3123]
sage: ZZ_pX_eis_shift_test(A, [15, 91, 8, 3123], 1, 5)
[316 53 3123 3]
This file contains code for printing p-adic elements. It has been moved here to prevent code duplication and make finding the relevant code easier.

AUTHORS:

• David Roe

`sage.rings.padics.padic_printing.PAdicPrinter(ring, options={})`

Creates a pAdicPrinter.

INPUT:

• ring – a p-adic ring or field.

EXAMPLES:

```
sage: from sage.rings.padics.padic_printing import PAdicPrinter
sage: R = Zp(5)
sage: PAdicPrinter(R, {'sep': '&'})
series printer for 5-adic Ring with capped relative precision 20
```

class `sage.rings.padics.padic_printing.PAdicPrinterDefaults`

Bases: `sage.structure.sage_object.SageObject`

This class stores global defaults for p-adic printing.

`allow_negatives(neg=None)`

Controls whether or not to display a balanced representation.

neg=None returns the current value.

EXAMPLES:

```
sage: padic_printing.allow_negatives(True)
sage: padic_printing.allow_negatives()
True
sage: Qp(29)(-1)
-1 + 0(29^20)
```

(continues on next page)
alphabet(alphabet=None)
Controls the alphabet used to translate p-adic digits into strings (so that no separator need be used in 'digits' mode).

alphabet should be passed in as a list or tuple.
alphabet=None returns the current value.

EXAMPLES:

```
sage: padic_printing.alphabet("abc")
sage: padic_printing.mode('digits')
's...bcaacab'
sage: padic_printing.mode('series')
```

max_poly_terms(max=None)
Controls the number of terms appearing when printing polynomial representations in 'terse' or 'val-unit' modes.

max=None returns the current value.
max=-1 encodes 'no limit.'

EXAMPLES:

```
sage: padic_printing.max_poly_terms(3)
sage: padic_printing.max_poly_terms()
3
sage: padic_printing.mode('terse')
sage: Zq(7^5, 5, names='a')([(2, 3, 4)])^8
2570 + 15808*a + 9018*a^2 + ... + O(7^5)
sage: padic_printing.max_poly_terms(-1)
sage: padic_printing.mode('series')
```

max_series_terms(max=None)
Controls the maximum number of terms shown when printing in 'series', 'digits' or 'bars' mode.

max=None returns the current value.
max=-1 encodes 'no limit.'

EXAMPLES:

```
sage: padic_printing.max_series_terms(2)
sage: padic_printing.max_series_terms()
2
```
max_unram_terms(max=None)
For rings with non-prime residue fields, controls how many terms appear in the coefficient of each pi^n when printing in 'series' or 'bar' modes.

max=None returns the current value.
max=-1 encodes ‘no limit.’

EXAMPLES:

sage: padic_printing.max_unram_terms(2)
sage: padic_printing.max_unram_terms()
2
sage: Zq(5^6, 5, names='a')([1,2,3,-1])^17
(3*a^4 + ... + 3) + (a^5 + ... + a)*5 + (3*a^3 + ... + 2)*5^2 + (3*a^5 + ... + 2)*5^3 + (4*a^5 + ... + 4)*5^4 + O(5^5)
sage: padic_printing.max_unram_terms(-1)

mode(mode=None)
Set the default printing mode.
mode=None returns the current value.
The allowed values for mode are: ‘val-unit’, ‘series’, ‘terse’, ‘digits’ and ‘bars’.

EXAMPLES:

sage: padic_printing.mode('terse')
sage: padic_printing.mode()
'terse'
sage: Qp(7)(100)
100 + O(7^20)
sage: padic_printing.mode('series')
sage: Qp(11)(100)
1 + 9*11 + O(11^20)
sage: padic_printing.mode('val-unit')
sage: Qp(13)(130)
13 * 10 + O(13^21)
sage: padic_printing.mode('digits')
sage: repr(Qp(17)(100))
'...5F'
sage: repr(Qp(17)(1000))
'...37E'
sage: padic_printing.mode('bars')
sage: repr(Qp(19)(1000))
'...2|14|12'
sage: padic_printing.mode('series')
**sep** *(sep=None)*

Controls the separator used in ‘bars’ mode.

sep=None returns the current value.

**EXAMPLES:**

```python
sage: padic_printing.sep(']')['
sage: padic_printing.sep()
'[

sage: padic_printing.mode('bars')
sage: repr(Qp(61)(-1))
'...
˓→60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60][60
˓→'

sage: padic_printing.sep('|')
sage: padic_printing.mode('series')
```

**class** `sage.rings.padics.padic_printing.PAdicPrinter_class`

**Bases:** `sage.structure.sage_object.SageObject`

This class stores the printing options for a specific p-adic ring or field, and uses these to compute the representations of elements.

**dict()**

Returns a dictionary storing all of self’s printing options.

**EXAMPLES:**

```python
sage: D = Zp(5)._printer.dict(); D['sep']
'|'
```

**repr_gen** *(elt, do_latex, pos=None, mode=None, ram_name=None)*

The entry point for printing an element.

**INPUT:**

- elt – a p-adic element of the appropriate ring to print.
- do_latex – whether to return a latex representation or a normal one.

**EXAMPLES:**

```python
sage: R = Zp(5,5); P = R._printer; a = R(-5); a
4*5 + 4*5^2 + 4*5^3 + 4*5^4 + 4*5^5 + O(5^6)
sage: P.repr_gen(a, False, pos=False)
'-5 + O(5^6)'
sage: P.repr_gen(a, False, ram_name='p')
'4*p + 4*p^2 + 4*p^3 + 4*p^4 + 4*p^5 + O(p^6)'
```

**richcmp_modes** *(other, op)*

Return a comparison of the printing modes of self and other.

Return 0 if and only if all relevant modes are equal (max_unram_terms is irrelevant if the ring is totally ramified over the base for example). This does not check if the rings are equal (to prevent infinite recursion in the comparison functions of p-adic rings), but it does check if the primes are the same (since the prime affects whether pos is relevant).

**EXAMPLES:**
```
sage: R = Qp(7, print_mode='digits', print_pos=True)
sage: S = Qp(7, print_mode='digits', print_pos=False)
sage: R._printer == S._printer
True
sage: R = Qp(7)
sage: S = Qp(7, print_mode='val-unit')
sage: R == S
False
sage: R._printer < S._printer
True
```
The errors in this file indicate various styles of precision problems that can go wrong for $p$-adics and power series.

AUTHORS:

- David Roe

```python
exception sage.rings.padics.precision_error.PrecisionError
   Bases: ArithmeticError
```
This file contains several miscellaneous functions used by $p$-adics.

- *gauss_sum* – compute Gauss sums using the Gross-Koblitz formula.
- *min* – a version of $\min$ that returns $\infty$ on empty input.
- *max* – a version of $\max$ that returns $-\infty$ on empty input.

**AUTHORS:**

- David Roe
- Adriana Salerno
- Ander Steele
- Kiran Kedlaya (modified gauss_sum 2017/09)

```python
sage.rings.padics.misc.gauss_sum(a, p, f, prec=20, factored=False, algorithm='pari', parent=None)
```

Return the Gauss sum $g_q(a)$ as a $p$-adic number.

The Gauss sum $g_q(a)$ is defined by

$$g_q(a) = \sum_{u \in F_q^*} \omega(u)^{-a} \zeta_q^u,$$

where $q = p^f$, $\omega$ is the Teichmüller character and $\zeta_q$ is some arbitrary choice of primitive $q$-th root of unity.

Let $p$ be a prime, $f$ a positive integer, $q = p^f$, and $\pi$ be the unique root of $f(x) = x^{p-1} + p$ congruent to $\zeta_p - 1$ modulo $(\zeta_p - 1)^2$. Let $0 \leq a < q - 1$. Then the Gross-Koblitz formula gives us the value of the Gauss sum $g_q(a)$ as a product of $p$-adic Gamma functions as follows:

$$g_q(a) = -\pi^s \prod_{0 \leq i < f} \Gamma_p(a^{(i)}/(q-1)),$$

where $s$ is the sum of the digits of $a$ in base $p$ and the $a^{(i)}$ have $p$-adic expansions obtained from cyclic permutations of that of $a$.

**INPUT:**

- *a* – integer
- *p* – prime
- *f* – positive integer
- *prec* – positive integer (optional, 20 by default)
\textbullet{} \textit{factored} - boolean (optional, False by default)

\textbullet{} \textit{algorithm} - flag passed to \( p \)-adic Gamma function (optional, “pari” by default)

\textbf{OUTPUT:}

If \texttt{factored} is \textit{False}, returns a \( p \)-adic number in an \( \text{Eisenstein extension of } \mathbb{Q}_p \). This number has the form \( p^e \cdot z \) where \( p^i \) is as above, \( e \) is some nonnegative integer, and \( z \) is an element of \( \mathbb{Z}_p \); if \texttt{factored} is \textit{True}, the pair \((e, z)\) is returned instead, and the Eisenstein extension is not formed.

\textbf{Note:} This is based on GP code written by Adriana Salerno.

\textbf{EXAMPLES:}

In this example, we verify that \( g_3(0) = -1 \):

\begin{verbatim}
sage: from sage.rings.padics.misc import gauss_sum
sage: -gauss_sum(0,3,1)
1 + O(pi^40)
\end{verbatim}

Next, we verify that \( g_5(a)g_5(-a) = 5(-1)^a \):

\begin{verbatim}
sage: from sage.rings.padics.misc import gauss_sum
sage: 2*(gauss_sum(2,5,1)^2-5)
O(pi^84)
sage: 5*(gauss_sum(1,5,1)*gauss_sum(3,5,1)+5)
O(pi^84)
\end{verbatim}

Finally, we compute a non-trivial value:

\begin{verbatim}
sage: from sage.rings.padics.misc import gauss_sum
sage: gauss_sum(2,13,2)
6*pi^2 + 7*pi^14 + 11*pi^26 + 3*pi^62 + 6*pi^74 + 3*pi^86 + 5*pi^98 + pi^110 + 7*pi^134 + 9*pi^146 + 4*pi^158 + 6*pi^170 + 4*pi^194 + pi^206 + 6*pi^218 + 9*pi^230 + O(pi^242)
sage: max(2,13,2,prec=5,factored=True)
(2, 6 + 6*13 + 10*13^2 + O(13^5))
\end{verbatim}

\textbf{See also:}

- \texttt{sage.arith.misc.gauss_sum()} for general finite fields
- \texttt{sage.modular.dirichlet.DirichletCharacter.gauss_sum()} for prime finite fields
- \texttt{sage.modular.dirichlet.DirichletCharacter.gauss_sum_numerical()} for prime finite fields

\texttt{sage.rings.padics.misc.max(*L)}

Return the maximum of the inputs, where the maximum of the empty list is \(-\infty\).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.rings.padics.misc import max
sage: max()
-\infty
sage: max(2,3)
3
\end{verbatim}
sage.rings.padics.misc.min(*L)
Return the minimum of the inputs, where the minimum of the empty list is $\infty$.

EXAMPLES:

```python
sage: from sage.rings.padics.misc import min
sage: min()
+Infinity
sage: min(2,3)
2
```

sage.rings.padics.misc.precprint(prec_type, prec_cap, p)
String describing the precision mode on a $p$-adic ring or field.

EXAMPLES:

```python
sage: from sage.rings.padics.misc import precprint
sage: precprint('capped-rel', 12, 2)
'with capped relative precision 12'
sage: precprint('capped-abs', 11, 3)
'with capped absolute precision 11'
sage: precprint('floating-point', 1234, 5)
'with floating precision 1234'
sage: precprint('fixed-mod', 1, 17)
'of fixed modulus $17^1$'
```

sage.rings.padics.misc.trim_zeros(L)
Strips trailing zeros/empty lists from a list.

EXAMPLES:

```python
sage: from sage.rings.padics.misc import trim_zeros
sage: trim_zeros([1,0,1,0])
[1, 0, 1]
sage: trim_zeros([[1],[],[2],[[],[]]])
[[1], [], [2]]
sage: trim_zeros([[[],[]]])
[]
sage: trim_zeros([])
[]
```

Zeros are also trimmed from nested lists (one deep):

```python
sage: trim_zeros([[1,0]])
[[1]]
sage: trim_zeros([[0],[1]])
[[0], [1]]
```
THE FUNCTIONS IN THIS FILE ARE USED IN CREATING NEW P-ADIC ELEMENTS.

When creating a p-adic element, the user can specify that the absolute precision be bounded and/or that the relative precision be bounded. Moreover, different p-adic parents impose their own bounds on the relative or absolute precision of their elements. The precision determines to what power of \( p \) the defining data will be reduced, but the valuation of the resulting element needs to be determined before the element is created. Moreover, some defining data can impose their own precision bounds on the result.

AUTHORS:

- David Roe (2012-03-01)
Chapter 27. The functions in this file are used in creating new p-adic elements.
FROBENIUS ENDOMORPHISMS ON P-ADIC FIELDS

class sage.rings.padics.morphism.FrobeniusEndomorphism_padics
    Bases: sage.rings.morphism.RingHomomorphism

    A class implementing Frobenius endomorphisms on padic fields.

    is_identity()
    Return true if this morphism is the identity morphism.

    EXAMPLES:

    sage: K.<a> = Qq(5^3)
    sage: Frob = K.frobenius_endomorphism()
    sage: Frob.is_identity()
    False
    sage: (Frob^3).is_identity()
    True

    is_injective()
    Return true since any power of the Frobenius endomorphism over an unramified padic field is always in-
    jective.

    EXAMPLES:

    sage: K.<a> = Qq(5^3)
    sage: Frob = K.frobenius_endomorphism()
    sage: Frob.is_injective()
    True

    is_surjective()
    Return true since any power of the Frobenius endomorphism over an unramified padic field is always sur-
    jective.

    EXAMPLES:

    sage: K.<a> = Qq(5^3)
    sage: Frob = K.frobenius_endomorphism()
    sage: Frob.is_surjective()
    True

    order()
    Return the order of this endomorphism.

    EXAMPLES:
power()

Return the smallest integer $n$ such that this endomorphism is the $n$-th power of the absolute (arithmetic) Frobenius.

EXAMPLES:

```
sage: K.<a> = Qq(5^12)
sage: Frob = K.frobenius_endomorphism()
sage: Frob.power()
1
sage: (Frob^9).power()
9
sage: (Frob^13).power()
1
```
