Python Module Index 177

Index 179
1.1 Ring \( \mathbb{Z} \) of Integers

The \texttt{IntegerRing} class represents the ring \( \mathbb{Z} \) of (arbitrary precision) integers. Each integer is an instance of \texttt{Integer}, which is defined in a Pyrex extension module that wraps GMP integers (the \texttt{mpz_t} type in GMP).

```
sage: Z = IntegerRing(); Z
Integer Ring
sage: Z.characteristic()
0
sage: Z.is_field()
False
```

There is a unique instance of the \texttt{integer ring}. To create an \texttt{Integer}, coerce either a Python int, long, or a string. Various other types will also coerce to the integers, when it makes sense.

```
sage: a = Z(1234); a
1234
sage: b = Z(5678); b
5678
sage: type(a)
<type 'sage.rings.integer.Integer'>
sage: a + b
6912
sage: Z('94803849083985934859834583945394')
94803849083985934859834583945394
```

\texttt{sage.rings.integer_ring.IntegerRing()}  
Return the integer ring.

\textbf{EXAMPLES:}

```
sage: IntegerRing()
Integer Ring
sage: ZZ==IntegerRing()
True
```

\texttt{class sage.rings.integer_ring.IntegerRing_class}  
\texttt{Bases: sage.rings.ring.PrincipalIdealDomain}

The ring of integers.

In order to introduce the ring \( \mathbb{Z} \) of integers, we illustrate creation, calling a few functions, and working with its elements.
sage: Z = IntegerRing(); Z
Integer Ring
sage: Z.characteristic()
0
sage: Z.is_field()
False
sage: Z.category()
Join of Category of euclidean domains
   and Category of infinite enumerated sets
   and Category of metric spaces
sage: Z(2^(2^5) + 1)
4294967297

One can give strings to create integers. Strings starting with 0x are interpreted as hexadecimal, and strings starting with 0o are interpreted as octal:
sage: parent('37')
<... 'str'>
sage: parent(Z('37'))
Integer Ring
sage: Z('0x10')
16
sage: Z('0x1a')
26
sage: Z('0o20')
16

As an inverse to digits(), lists of digits are accepted, provided that you give a base. The lists are interpreted in little-endian order, so that entry \text{i} of the list is the coefficient of base^{\text{i}}:
sage: Z([4,1,7],base=100)
70104
sage: Z([4,1,7],base=10)
714
sage: Z([3, 7], 10)
73
sage: Z([3, 7], 9)
66
sage: Z([], 10)
0

Alphanumeric strings can be used for bases 2..36; letters a to z represent numbers 10 to 36. Letter case does not matter.
sage: Z("sage",base=32)
928270
sage: Z("SAGE",base=32)
928270
sage: Z("Sage",base=32)
928270
sage: Z([14, 16, 10, 28],base=32)
928270
sage: 14 + 16*32 + 10*32^2 + 28*32^3
928270

We next illustrate basic arithmetic in \text{Z}:
When we divide two integers using `/`, the result is automatically coerced to the field of rational numbers, even if the result is an integer.

```
sage: a / b
617/2839
sage: type(a/b)
<type 'sage.rings.rational.Rational'>
sage: a/a
1
sage: type(a/a)
<type 'sage.rings.rational.Rational'>
```

For floor division, use the `//` operator instead:

```
sage: a // b
0
sage: type(a//b)
<type 'sage.rings.integer.Integer'>
```

Next we illustrate arithmetic with automatic coercion. The types that coerce are: str, int, long, Integer.

```
sage: a + 17
1251
sage: a * 374
461516
sage: 374 * a
461516
sage: a/19
1234/19
sage: 0 + Z(-64)
-64
```

Integers can be coerced:

```
sage: a = Z(-64)
sage: int(a)
-64
```

We can create integers from several types of objects:

1.1. Ring $\mathbb{Z}$ of Integers
Arbitrary numeric bases are supported; strings or list of integers are used to provide the digits (more details in `IntegerRing_class`):

```
sage: Z("sage",base=32)
sage: Z([14, 16, 10, 28],base=32)
```

The `digits` method allows you to get the list of digits of an integer in a different basis (note that the digits are returned in little-endian order):

```
sage: b = Z([4,1,7],base=100)
sage: b.digits(base=71)
sage: Z(15).digits(2)
sage: Z(15).digits(3)
```

The `str` method returns a string of the digits, using letters a to z to represent digits 10..36:

```
sage: Z(928270).str(base=32)
```

Note that `str` only works with bases 2 through 36.

**absolute_degree()**

Return the absolute degree of the integers, which is 1.

Here, absolute degree refers to the rank of the ring as a module over the integers.

**characteristic()**

Return the characteristic of the integers, which is 0.

**completion (p, prec, extras=())**

Return the metric completion of the integers at the prime \( p \).

**INPUT:**

* \( p \) – a prime (or `infinity`)
• **prec** – the desired precision
• **extras** – any further parameters to pass to the method used to create the completion.

**OUTPUT:**
• The completion of \( \mathbb{Z} \) at \( p \).

**EXAMPLES:**

```python
sage: ZZ.completion(infinity, 53)
Integer Ring
sage: ZZ.completion(5, 15, {'print_mode': 'bars'})
5-adic Ring with capped relative precision 15
```

**degree()**

Return the degree of the integers, which is 1.

Here, degree refers to the rank of the ring as a module over the integers.

**EXAMPLES:**

```python
sage: ZZ.degree()
1
```

**extension** (*poly*, *names*, **kwds**)

Return the order generated by the specified list of polynomials.

**INPUT:**
• **poly** – a list of one or more polynomials
• **names** – a parameter which will be passed to EquationOrder().
• **embedding** – a parameter which will be passed to EquationOrder().

**OUTPUT:**
• Given a single polynomial as input, return the order generated by a root of the polynomial in the field generated by a root of the polynomial.
• Given a list of polynomials as input, return the relative order generated by a root of the first polynomial in the list, over the order generated by the roots of the subsequent polynomials.

**EXAMPLES:**

```python
sage: ZZ.extension(x^2-5, 'a')
Order in Number Field in a with defining polynomial x^2 - 5
sage: ZZ.extension([x^2 + 1, x^2 + 2], 'a,b')
Relative Order in Number Field in a with defining polynomial x^2 + 1 over its base field
```

**fraction_field()**

Return the field of rational numbers - the fraction field of the integers.

**EXAMPLES:**

```python
sage: ZZ.fraction_field()
Rational Field
sage: ZZ.fraction_field() == QQ
True
```
gen \((n=0)\)
Return the additive generator of the integers, which is 1.

**INPUT:**

- \(n\) (default: 0) – In a ring with more than one generator, the optional parameter \(n\) indicates which generator to return; since there is only one generator in this case, the only valid value for \(n\) is 0.

**EXAMPLES:**

```python
sage: ZZ.gen()
1
sage: type(ZZ.gen())
<type 'sage.rings.integer.Integer'>
```

gens()
Return the tuple \((1,)\) containing a single element, the additive generator of the integers, which is 1.

**EXAMPLES:**

```python
sage: ZZ.gens(); ZZ.gens()[0]
(1,)
1
sage: type(ZZ.gens()[0])
<type 'sage.rings.integer.Integer'>
```

is_field \((proof=True)\)
Return False since the integers are not a field.

**EXAMPLES:**

```python
sage: ZZ.is_field()
False
```

is_integrally_closed()
Return that the integer ring is, in fact, integrally closed.

**EXAMPLES:**

```python
sage: ZZ.is_integrally_closed()
True
```

is_noetherian()
Return True since the integers are a Noetherian ring.

**EXAMPLES:**

```python
sage: ZZ.is_noetherian()
True
```

krull_dimension()
Return the Krull dimension of the integers, which is 1.

**EXAMPLES:**

```python
sage: ZZ.krull_dimension()
1
```

ngens()
Return the number of additive generators of the ring, which is 1.
EXAMPLES:

```python
sage: ZZ.ngens()
1
sage: len(ZZ.gens())
1
```

**order** ()
Return the order (cardinality) of the integers, which is `+Infinity`.

EXAMPLES:

```python
sage: ZZ.order()
+Infinity
```

**parameter** ()
Return an integer of degree 1 for the Euclidean property of $\mathbb{Z}$, namely 1.

EXAMPLES:

```python
sage: ZZ.parameter()
1
```

**quotient** ($I$, names=None, **kwds)
Return the quotient of $\mathbb{Z}$ by the ideal or integer $I$.

EXAMPLES:

```python
sage: ZZ.quo(6*ZZ)
Ring of integers modulo 6
sage: ZZ.quo(0*ZZ)
Integer Ring
sage: ZZ.quo(3)
Ring of integers modulo 3
sage: ZZ.quo(3*QQ)
Traceback (most recent call last):
...  
TypeError: I must be an ideal of ZZ
```

**random_element** ($x$=None, $y$=None, distribution=None)
Return a random integer.

**INPUT:**

- $x, y$ integers – bounds for the result.
- **distribution** – a string:
  - 'uniform'
  - 'mpz_rrandomb'
  - '1/n'
  - 'gaussian'

**OUTPUT:**

- With no input, return a random integer.
  
  If only one integer $x$ is given, return an integer between 0 and $x - 1$.
  
  If two integers are given, return an integer between $x$ and $y - 1$ inclusive.
If at least one bound is given, the default distribution is the uniform distribution; otherwise, it is the distribution described below.

If the distribution '1/n' is specified, the bounds are ignored.

If the distribution 'mpz_rrandomb' is specified, the output is in the range from 0 to \(2^x - 1\).

If the distribution 'gaussian' is specified, the output is sampled from a discrete Gaussian distribution with parameter \(\sigma = x\) and centered at zero. That is, the integer \(v\) is returned with probability proportional to \(\exp(-v^2/(2\sigma^2))\). See \texttt{sage.stats.distributions.discrete_gaussian_integer} for details. Note that if many samples from the same discrete Gaussian distribution are needed, it is faster to construct a \texttt{sage.stats.distributions.discrete_gaussian_integer.DiscreteGaussianDistributionIntegerSampler} object which is then repeatedly queried.

The default distribution for \texttt{ZZ.random_element()} is based on \(X = \text{trunc}(4/(5R))\), where \(R\) is a random variable uniformly distributed between \(-1\) and \(1\). This gives \(\Pr(X = 0) = 1/5\), and \(\Pr(X = n) = 2/(5|n|(|n| + 1))\) for \(n \neq 0\). Most of the samples will be small; \(-1, 0,\) and \(1\) occur with probability \(1/5\) each. But we also have a small but non-negligible proportion of “outliers”; \(\Pr(|X| \geq n) = 4/(5n)\), so for instance, we expect that \(|X| \geq 1000\) on one in 1250 samples.

We actually use an easy-to-compute truncation of the above distribution; the probabilities given above hold fairly well up to about \(|n| \approx 10000\), but around \(|n| \approx 30000\) some values will never be returned at all, and we will never return anything greater than \(2^{30}\).

**EXAMPLES:**

```python
sage: [ZZ.random_element() for _ in range(10)]
[-8, 2, 0, 0, 1, -1, 2, 1, -95, -1]
```

The default uniform distribution is integers in \([-2, 2]\):

```python
sage: [ZZ.random_element(distribution="uniform") for _ in range(10)]
[2, -2, 2, -2, -1, 1, -1, 2, 1, 0]
```

Here we use the distribution '1/n':

```python
sage: [ZZ.random_element(distribution="1/n") for _ in range(10)]
[-6, 1, -1, 1, -1, 1, -1, -3, 1]
```

If a range is given, the default distribution is uniform in that range:

```python
sage: ZZ.random_element(-10,10)
-2
sage: ZZ.random_element(10)
2
sage: ZZ.random_element(10^50)
9531604786291536727294723328622110901973365898988
sage: [ZZ.random_element(5) for _ in range(10)]
[3, 1, 2, 3, 0, 0, 3, 4, 0, 3]
```

Notice that the right endpoint is not included:

```python
sage: [ZZ.random_element(-2,2) for _ in range(10)]
[1, -2, -2, -1, -2, -1, -2, 0, -2]
```

We compute a histogram over 1000 samples of the default distribution:
sage: from collections import defaultdict
sage: d = defaultdict(lambda: 0)

sage: for _ in range(1000):
    ....:     samp = ZZ.random_element()
    ....:     d[samp] = d[samp] + 1

sage: sorted(d.items())
[(-1955, 1), (-1026, 1), (-357, 1), (-248, 1), (-145, 1), (-81, 1), (-80, 1), ...
 (-79, 1), (-75, 1), (-69, 1), (-68, 1), (-63, 2), (-61, 1), (-57, 1), (-50, 2), ...
 (-41), (-37, 1), (-35, 1), (-33, 1), (-29, 2), (-27, 1), (-25, 1), (-23, 2), ...
 (-22, 3), (-20, 1), (-19, 1), (-18, 1), (-16, 4), (-15, 3), (-14, 1), (-13, 2), ...
 (-12, 2), (-11, 2), (-10, 7), (-9, 3), (-8, 3), (-7, 7), (-6, 8), (-5, 3), ...
 (-4, 24), (-3, 34), (-2, 75), (-1, 206), (0, 208), (1, 189), (2, 63), ...
 (3, 35), (4, 13), (5, 11), (6, 10), (7, 4), (8, 3), (10, 1), (11, 1), (12, 3), ...
 (13, 1), (14, 1), (16, 3), (18, 2), (19, 1), (26, 2), (27, 1), (28, 2), ...
 (29, 1), (30, 1), (32, 1), (33, 2), (35, 1), (37, 1), (39, 1), (41, 1), (42, 1), ...
 (52, 1), (91, 1), (94, 1), (106, 1), (111, 1), (113, 2), (132, 1), ...
 (134, 1), (232, 1), (240, 1), (2133, 1), (3636, 1)]

We return a sample from a discrete Gaussian distribution:

sage: ZZ.random_element(11.0, distribution="gaussian")
5

range (start, end=None, step=None)
Optimized range function for Sage integers.

AUTHORS:
• Robert Bradshaw (2007-09-20)

EXAMPLES:

sage: ZZ.range(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
sage: ZZ.range(-5,5)
[-5, -4, -3, -2, -1, 0, 1, 2, 3, 4]
sage: ZZ.range(0,50,5)
[0, 5, 10, 15, 20, 25, 30, 35, 40, 45]
sage: ZZ.range(0,50,-5)
[]
sage: ZZ.range(50,0,-5)
[50, 45, 40, 35, 30, 25, 20, 15, 10, 5]
sage: ZZ.range(50,0,5)
[]
sage: ZZ.range(50,-1,-5)
[50, 45, 40, 35, 30, 25, 20, 15, 10, 5, 0]

It uses different code if the step doesn’t fit in a long:

sage: ZZ.range(0,2^83,2^80)
[0, 1208925819614629174706176, 2417851639229258349412352, ...
 ¬362677748384387524118528, 4835703278458516698824704, ...
 ¬6044629098073145873530880, 7253554917687775048237056, ...
 ¬8462480737302404222943232]}

Make sure trac ticket #8818 is fixed:
```python
sage: ZZ.range(1r, 10r)
[1, 2, 3, 4, 5, 6, 7, 8, 9]
```

**residue_field** *(prime, check=True, names=None)*

Return the residue field of the integers modulo the given prime, i.e. \( \mathbb{Z}/p\mathbb{Z} \).

**INPUT:**
- prime - a prime number
- check - (boolean, default True) whether or not to check the primality of prime
- names - ignored (for compatibility with number fields)

**OUTPUT:** The residue field at this prime.

**EXAMPLES:**

```python
sage: F = ZZ.residue_field(61); F
Residue field of Integers modulo 61
sage: pi = F.reduction_map(); pi
Partially defined reduction map:
  From: Rational Field
  To:   Residue field of Integers modulo 61
sage: pi(123/234)
6
sage: pi(1/61)
Traceback (most recent call last):
  ... ZeroDivisionError: Cannot reduce rational 1/61 modulo 61:
  it has negative valuation
sage: lift = F.lift_map(); lift
Lifting map:
  From: Residue field of Integers modulo 61
  To:   Integer Ring
sage: lift(F(12345/67890))
33
sage: (12345/67890) % 61
33
```

Construction can be from a prime ideal instead of a prime:

```python
sage: ZZ.residue_field(ZZ.ideal(97))
Residue field of Integers modulo 97
```

**valuation** *(p)*

Return the discrete valuation with uniformizer p.

**EXAMPLES:**

```python
sage: v = ZZ.valuation(3); v
3-adic valuation
sage: v(3)
1
```

See also:

*Order.valuation()*, *RationalField.valuation()*

**zeta** *(n=2)*

Return a primitive n-th root of unity in the integers, or raise an error if none exists.
INPUT:
• \(n\) – (default 2) a positive integer

OUTPUT:
• an \(n\)-th root of unity in \(\mathbb{Z}\).

EXAMPLES:
```python
sage: ZZ.zeta()
-1
sage: ZZ.zeta(1)
1
sage: ZZ.zeta(3)
Traceback (most recent call last):
...  
ValueError: no nth root of unity in integer ring
sage: ZZ.zeta(0)
Traceback (most recent call last):
...  
ValueError: n must be positive in zeta()
```

```python
sage.rings.integer_ring.crt_basis(X, xgcd=None)
Computes and returns a Chinese Remainder Theorem basis for the list \(X\) of coprime integers.
```

INPUT:
• \(X\) – a list of Integers that are coprime in pairs.
• \(xgcd\) – an optional parameter which is ignored.

OUTPUT:
• \(E\) - a list of Integers such that \(E[i] = 1 \mod X[i]\) and \(E[i] = 0 \mod X[j]\) for all \(j \neq i\).

For this explanation, let \(E[i]\) be denoted by \(E_i\).

The \(E_i\) have the property that if \(A\) is a list of objects, e.g., integers, vectors, matrices, etc., where \(A_i\) is understood modulo \(X_i\), then a CRT lift of \(A\) is simply

\[
\sum_i E_i A_i.
\]

ALGORITHM: To compute \(E_i\), compute integers \(s\) and \(t\) such that

\[
sX_i + t \prod_{i \neq j} X_j = 1.()
\]

Then

\[
E_i = t \prod_{i \neq j} X[j].
\]

Notice that equation (*) implies that \(E_i\) is congruent to 1 modulo \(X_i\) and to 0 modulo the other \(X_j\) for \(j \neq i\).

COMPLEXITY: We compute \(\text{len}(X)\) extended GCD’s.

EXAMPLES:
```python
sage: X = [11, 20, 31, 51]
sage: E = crt_basis([11, 20, 31, 51])
sage: E[0]%X[0], E[1]%X[0], E[2]%X[0], E[3]%X[0]
```
Sage has highly optimized and extensive functionality for arithmetic with integers and the ring of integers.

EXAMPLES:

Add 2 integers:

```
sage: a = Integer(3) ; b = Integer(4)
sage: a + b == 7
True
```

Add an integer and a real number:

```
sage: a + 4.0
7.00000000000000
```

Add an integer and a rational number:

```
sage: a + Rational(2)/5
17/5
```

Add an integer and a complex number:

```
sage: b = ComplexField().0 + 1.5
sage: loads((a+b).dumps()) == a+b
True
sage: z = 32
sage: -z
-32
sage: z = 0; -z
0
sage: z = -1; -z
1
```

Multiplication:

```
sage: a = Integer(3) ; b = Integer(4)
sage: a * b == 12
True
sage: loads((a * 4.0).dumps()) == a*b
```

### 1.2 Elements of the ring $\mathbb{Z}$ of integers

Sage has an internal function to determine if an object is the ring of integers.

```
sage.rings.integer_ring.is_IntegerRing(x)
```

Internal function: return True iff $x$ is the ring $\mathbb{Z}$ of integers.
True

```python
sage: a * Rational(2)/5
6/5
```

```python
sage: list([2,3]) * 4
[2, 3, 2, 3, 2, 3, 2, 3]
```

```python
sage: 'sage'*Integer(3)
'sagesagesage'
```

**COERCIONS:**

Return version of this integer in the multi-precision floating real field $R$:

```python
sage: n = 9390823
sage: RR = RealField(200)
sage: RR(n)
9.3908230000000000000000000000000000000000000000000000000000e6
```

**AUTHORS:**

- William Stein (2005): initial version
- Gonzalo Tornaria (2006-03-02): vastly improved python/GMP conversion; hashing
- Didier Deshommes (2006-03-06): numerous examples and docstrings
- William Stein (2006-03-31): changes to reflect GMP bug fixes
- William Stein (2006-04-14): added GMP factorial method (since it’s now very fast).
- David Harvey (2006-09-15): added nth_root, exact_log
- David Harvey (2006-09-16): attempt to optimise Integer constructor
- Rishikesh (2007-02-25): changed quo_rem so that the rem is positive
- Robert Bradshaw, Martin Albrecht, Robert Bradshaw (2007-03-01): optimized Integer constructor and pool
- Pablo De Napoli (2007-04-01): multiplicative_order should return +infinity for non zero numbers
- Robert Bradshaw (2007-04-12): is_perfect_power, Jacobi symbol (with Kronecker extension). Convert some methods to use GMP directly rather than PARI, Integer(), PY_NEW(Integer)
- David Roe (2007-03-21): sped up valuation and is_square, added val_unit, is_power, is_power_of and divide_knowing_divisible_by
- Robert Bradshaw (2008-03-26): gamma function, multifactorials
- Robert Bradshaw (2008-10-02): bounded squarefree part
- David Loeffler (2011-01-15): fixed bug #10625 (inverse_mod should accept an ideal as argument)
- Vincent Delecroix (2010-12-28): added unicode in Integer.__init__
- David Roe (2012-03): deprecate is_power() in favour of is_perfect_power() (see trac ticket #12116)
- Vincent Delecroix (2017-05-03): faster integer-rational comparisons
- Vincent Klein (2017-05-11): add __mpz__() to class Integer
- Vincent Klein (2017-05-22): Integer constructor support gmpy2.mpz parameter
- Samuel Lelièvre (2018-08-02): document that divisors are sorted (trac ticket #25983)

1.2. Elements of the ring $\mathbb{Z}$ of integers
sage.rings.integer.GCD_list(v)

Return the greatest common divisor of a list of integers.

INPUT:

• v – list or tuple

Elements of v are converted to Sage integers. An empty list has GCD zero.

This function is used, for example, by rings/arith.py.

EXAMPLES:

sage: from sage.rings.integer import GCD_list
sage: w = GCD_list([3, 9, 30]); w
3
sage: type(w)
<type 'sage.rings.integer.Integer'>

Check that the bug reported in trac ticket #3118 has been fixed:

sage: sage.rings.integer.GCD_list([2, 2, 3])
1

The inputs are converted to Sage integers.

sage: w = GCD_list([int(3), int(9), '30']); w
3
sage: type(w)
<type 'sage.rings.integer.Integer'>

Check that the GCD of the empty list is zero (trac ticket #17257):

sage: GCD_list([])
0

class sage.rings.integer.Integer

Bases: sage.structure.element.EuclideanDomainElement

The Integer class represents arbitrary precision integers. It derives from the Element class, so integers can be used as ring elements anywhere in Sage.

Integer() interprets strings that begin with 0o as octal numbers, strings that begin with 0x as hexadecimal numbers and strings that begin with 0b as binary numbers.

The class Integer is implemented in Cython, as a wrapper of the GMP mpz_t integer type.

EXAMPLES:

sage: Integer(123)
123
sage: Integer("123")
123

Sage Integers support PEP 3127 literals:

sage: Integer('0x12')
18
sage: Integer('-0o12')
-10
Conversion from PARI:

```python
sage: Integer(pari('-10380104371593008048799446356441519384'))
-10380104371593008048799446356441519384
sage: Integer(pari('Pol([-3])))
-3
```

Conversion from gmpy2:

```python
sage: from gmpy2 import mpz
sage: Integer mpz(3)
3
```

```python
__pow__(left, right, modulus)
Return (left ^ right) % modulus.
```

**EXAMPLES:**

```python
sage: 2^-6
1/64
sage: 2^6
64
sage: 2^0
1
sage: 2^-0
1
sage: (-1)^(1/3)
(-1)^(1/3)
```

For consistency with Python and MPFR, \(0^0\) is defined to be 1 in Sage:

```python
sage: 0^0
1
```

See also [http://www.faqs.org/faqs/sci-math-faq/0to0/](http://www.faqs.org/faqs/sci-math-faq/0to0/) and [https://math.stackexchange.com/questions/11150/zero-to-the-zero-power-is-00-1](https://math.stackexchange.com/questions/11150/zero-to-the-zero-power-is-00-1).

The base need not be a Sage integer. If it is a Python type, the result is a Python type too:

```python
sage: r = int(2) ^ 10; r; type(r)
1024
<... 'int'>
sage: r = int(3) ^ -3; r; type(r)
0.037037037037037035
<... 'float'>
sage: r = float(2.5) ^ 10; r; type(r)
9536.7431640625
<... 'float'>
```

We raise 2 to various interesting exponents:

```python
sage: 2^x  # symbolic x
2^x
sage: 2^1.5  # real number
```

**1.2. Elements of the ring \(\mathbb{Z}\) of integers**
2^float(1.5)  # python float abs tol 3e-16
sage: 2^I         # complex number
2^I

r = 2^int(-3); r; type(r)
1/8
<type 'sage.rings.rational.Rational'>

f = 2^(sin(x)-cos(x)); f
2^(-cos(x) + sin(x))
f(x=3)
2^(-cos(3) + sin(3))

A symbolic sum:

additive_order()
Return the additive order of self.

EXAMPLES:

sage: ZZ(0).additive_order()
1
sage: ZZ(1).additive_order()
+Infinity

as_integer_ratio()
Return the pair (self.numerator(), self.denominator()), which is (self, 1).

EXAMPLES:

sage: x = -12
sage: x.as_integer_ratio()
(-12, 1)

balanced_digits (base=10, positive_shift=True)
Return the list of balanced digits for self in the given base.

The balanced base b uses b digits centered around zero. Thus if b is odd, there is only one possibility, namely digits between \(-b/2\) and \(b/2\) (both included). For instance in base 9, one uses digits from -4 to 4. If b is even, one has to choose between digits from \(-b/2\) to \(b/2 - 1\) or \(-b/2 + 1\) to \(b/2\) (base 10 for instance: either -5 to 4 or -4 to 5), and this is defined by the value of positive_shift.

INPUT:

- base – integer (default: 10); when base is 2, only the nonnegative or the nonpositive integers can be represented by balanced_digits. Thus we say base must be greater than 2.

- positive_shift – boolean (default: True); for even bases, the representation uses digits from \(-b/2 + 1\) to \(b/2\) if set to True, and from \(-b/2\) to \(b/2 - 1\) otherwise. This has no effect for odd bases.
EXAMPLES:

```
sage: 8.balanced_digits(3)
[-1, 0, 1]
sage: (-15).balanced_digits(5)
[0, 2, -1]
sage: 17.balanced_digits(6)
[-1, 3]
sage: 17.balanced_digits(6, positive_shift=False)
[-1, -3, 1]
sage: (-46).balanced_digits()
[4, 5, -1]
sage: (-46).balanced_digits(positive_shift=False)
[4, -5]
sage: (-23).balanced_digits(12)
[1, -2]
sage: (-23).balanced_digits(12, positive_shift=False)
[1, -2]
sage: 0.balanced_digits(7)
[]
sage: 14.balanced_digits(5.8)
Traceback (most recent call last):
  ... ValueError: base must be an integer
sage: 14.balanced_digits(2)
Traceback (most recent call last):
  ... ValueError: base must be > 2
```

See also:

digits

binary()

Return the binary digits of self as a string.

EXAMPLES:

```
sage: print(Integer(15).binary())
1111
sage: print(Integer(16).binary())
10000
sage: print(Integer(16938402384092843092843098243).binary())
11011011011111010001111011010110001011010001011110110010000000101111000010000011
```

binomial(m, algorithm='mpir')

Return the binomial coefficient “self choose m”.

INPUT:

- m – an integer
- algorithm = 'mpir' (default) or ' pari '; 'mpir ' is faster for small m, and ' pari ' tends to be faster for large m

OUTPUT:

- integer

EXAMPLES:
sage: 10.binomial(2)
45
sage: 10.binomial(2, algorithm='pari')
45
sage: 10.binomial(-2)
0
sage: (-2).binomial(3)
-4
sage: (-3).binomial(0)
1

The argument m or (self-m) must fit into unsigned long:

sage: (2**256).binomial(2**256)
1
sage: (2**256).binomial(2**256-1)
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: (2**256).binomial(2**128)
Traceback (most recent call last):
  ...OverflowError: m must fit in an unsigned long

bits()
Return the bits in self as a list, least significant first. The result satisfies the identity

\[ x = \sum (b \times 2^e \text{ for } e, b \text{ in enumerate(x.bits())}) \]

Negative numbers will have negative “bits”. (So, strictly speaking, the entries of the returned list are not
really members of \( \mathbb{Z}/2\mathbb{Z} \).

This method just calls digits() with base=2.

See also:

nbits() (number of bits; a faster way to compute len(x.bits())); and binary(), which returns a
string in more-familiar notation.

EXAMPLES:

sage: 500.bits()
[0, 0, 1, 0, 1, 1, 1, 1]
sage: 11.bits()
[1, 1, 0, 1]
sage: (-99).bits()
[-1, -1, 0, 0, 0, -1, -1]

ceil()
Return the ceiling of self, which is self since self is an integer.

EXAMPLES:

sage: n = 6
sage: n.ceil()
6

class_number(proof=True)
Return the class number of the quadratic order with this discriminant.

INPUT:
• **self** – an integer congruent to 0 or 1 mod 4 which is not a square

• **proof** (boolean, default True) – if False then for negative discriminants a faster algorithm is used by the PARI library which is known to give incorrect results when the class group has many cyclic factors.

**OUTPUT:**

(integer) the class number of the quadratic order with this discriminant.

**Note:** This is not always equal to the number of classes of primitive binary quadratic forms of discriminant \( D \), which is equal to the narrow class number. The two notions are the same when \( D < 0 \), or \( D > 0 \) and the fundamental unit of the order has negative norm; otherwise the number of classes of forms is twice this class number.

**EXAMPLES:**

```python
sage: (-163).class_number()
1
sage: (-104).class_number()
6
sage: [((4*n+1),(4*n+1).class_number()) for n in [21..29]]
[(85, 2),
 (89, 1),
 (93, 1),
 (97, 1),
 (101, 1),
 (105, 2),
 (109, 1),
 (113, 1),
 (117, 1)]
```

**conjugate()**

Return the complex conjugate of this integer, which is the integer itself.

**EXAMPLES:**

```python
sage: n = 205
sage: n.conjugate()
205
```

**coprime_integers \( (m) \)**

Return the non-negative integers \(< m\) that are coprime to this integer.

**EXAMPLES:**

```python
sage: n = 8
sage: n.coprime_integers(8)
[1, 3, 5, 7]
sage: n.coprime_integers(11)
[1, 3, 5, 7, 9]
sage: n = 5; n.coprime_integers(10)
[1, 2, 3, 4, 6, 7, 8, 9]
sage: n.coprime_integers(5)
[1, 2, 3, 4]
sage: n = 99; n.coprime_integers(99)
[1, 2, 4, 5, 7, 8, 10, 13, 14, 16, 17, 19, 20, 23, 25, 26, 28, 29, 31, 32, 34, 35, 37, 38, 40, 41, 43, 46, 47, 49, 50, 52, 53, 56, 58, 59, 61, 62, 64, 65, 67, 68, 70, 71, 73, 74, 76, 79, 80, 82, 83, 85, 86, 89, 91, 97, 98]
```
AUTHORS:

- Naqi Jaffery (2006-01-24): examples
- David Roe (2017-10-02): Use sieving
- Jeroen Demeyer (2018-06-25): allow returning zero (only relevant for \texttt{1.coprime_integers(n)})

ALGORITHM:

Create an integer with \( m \) bits and set bits at every multiple of a prime \( p \) that divides this integer and is less than \( m \). Then return a list of integers corresponding to the unset bits.

\( \texttt{crt}(y, m, n) \)

Return the unique integer between 0 and \( mn \) that is congruent to the integer modulo \( m \) and to \( y \) modulo \( n \). We assume that \( m \) and \( n \) are coprime.

EXAMPLES:

```
sage: n = 17
sage: m = n.crt(5, 23, 11); m
247
sage: m\%23
17
sage: m\%11
5
```

denominator()  

Return the denominator of this integer, which of course is always 1.

EXAMPLES:

```
sage: x = 5
sage: x.denominator()
1
sage: x = 0
sage: x.denominator()
1
```

digits\,(base=10, digits=None, padto=0)  

Return a list of digits for \texttt{self} in the given base in little endian order.

The returned value is unspecified if \texttt{self} is a negative number and the digits are given.

INPUT:

- \texttt{base} - integer (default: 10)
- \texttt{digits} - optional indexable object as source for the digits
- \texttt{padto} - the minimal length of the returned list, sufficient number of zeros are added to make the list minimum that length (default: 0)

As a shorthand for \texttt{digits(2)}, you can use \texttt{bits()}.

Also see \texttt{ndigits()}.

EXAMPLES:
We support large bases.

```
sage: a=9939082340; a.digits(10)
[0, 4, 3, 2, 8, 0, 9, 3, 9, 9]
sage: a.digits(512)
[100, 302, 26, 74]
sage: (-12).digits(10)
[-2, -1]
sage: (-12).digits(2)
[0, 0, -1, -1]
```

The inverse of this method – constructing an integer from a list of digits and a base – can be done using the above method or by simply using \(\mathbb{Z}()\) with a base:

```
sage: x = 123; ZZ(x.digits(), 10)
123
sage: x == ZZ(x.digits(6), 6)
True
sage: x == ZZ(x.digits(25), 25)
True
```

Using `sum()` and `enumerate()` to do the same thing is slightly faster in many cases (and `balanced_sum()` may be faster yet). Of course it gives the same result:

```
1.2. Elements of the ring \(\mathbb{Z}\) of integers
Note: In some cases it is faster to give a digits collection. This would be particularly true for computing the digits of a series of small numbers. In these cases, the code is careful to allocate as few python objects as reasonably possible.

This function is comparable to \texttt{str} for speed.

AUTHORS:

- Joel B. Mohler (2008-03-02): significantly rewrote this entire function

\texttt{divide\_knowing\_divisible\_by} (left)

Returns the integer \texttt{self} / \texttt{right} when \texttt{self} is divisible by \texttt{right}.

If \texttt{self} is not divisible by \texttt{right}, the return value is undefined, and may not even be close to \texttt{self/float(right)} for multi-word integers.

\texttt{AUTHORS}:  
- Joel B. Mohler (2008-03-02): significantly rewrote this entire function

\texttt{divide\_knowing\_divisible\_by} (right)

Returns the integer self / right when self is divisible by right.

If self is not divisible by right, the return value is undefined, and may not even be close to self/right for multi-word integers.

\texttt{AUTHORS}:
- Joel B. Mohler (2008-03-02): significantly rewrote this entire function

\texttt{divides} (n)

Return True if self divides n.

\texttt{AUTHORS}:
- Joel B. Mohler (2008-03-02): significantly rewrote this entire function
sage: Z = IntegerRing()
sage: Z(5).divides(Z(10))
True
sage: Z(0).divides(Z(5))
False
sage: Z(10).divides(Z(5))
False

**divisors** *(method=None)*

Return the list of all positive integer divisors of this integer, sorted in increasing order.

**EXAMPLES:**

```
sage: (-3).divisors()
[1, 3]
sage: 6.divisors()
[1, 2, 3, 6]
sage: 28.divisors()
[1, 2, 4, 7, 14, 28]
sage: (2^5).divisors()
[1, 2, 4, 8, 16, 32]
sage: 100.divisors()
[1, 2, 4, 5, 10, 20, 25, 50, 100]
sage: 1.divisors()
[1]
sage: 0.divisors()
Traceback (most recent call last):
...  
ValueError: n must be nonzero
```

```
sage: (2^3 * 3^2 * 17).divisors()
[1, 2, 3, 4, 6, 8, 9, 12, 17, 18, 24, 34, 36, 51, 68, 72, 102, 153, 204, 306, 408, 612, 1224]
sage: a = odd_part(factorial(31))
sage: v = a.divisors()
sage: len(v)
172800
sage: prod(e + 1 for p, e in factor(a))
172800
sage: all(t.divides(a) for t in v)
True
```

```
sage: n = 2^551 - 1
sage: L = n.divisors()
sage: len(L)
256
sage: L[-1] == n
True
```

**Note:** If one first computes all the divisors and then sorts it, the sorting step can easily dominate the runtime. Note, however, that (non-negative) multiplication on the left preserves relative order. One can leverage this fact to keep the list in order as one computes it using a process similar to that of the merge sort algorithm.

**euclidean_degree**

Return the degree of this element as an element of an Euclidean domain.
If this is an element in the ring of integers, this is simply its absolute value.

EXAMPLES:

```python
sage: ZZ(1).euclidean_degree()
1
```

**exact_log** ($m$)

Returns the largest integer $k$ such that $m^k \leq$ self, i.e., the floor of $\log_m$(self).

This is guaranteed to return the correct answer even when the usual log function doesn’t have sufficient precision.

**INPUT:**

- $m$ - integer $\geq 2$

**AUTHORS:**

- David Harvey (2006-09-15)
- Joel B. Mohler (2009-04-08) – rewrote this to handle small cases and/or easy cases up to 100x faster.

**EXAMPLES:**

```python
sage: Integer(125).exact_log(5)
3
sage: Integer(124).exact_log(5)
2
sage: Integer(126).exact_log(5)
3
sage: Integer(3).exact_log(5)
0
sage: Integer(1).exact_log(5)
0
sage: Integer(178^1700).exact_log(178)
1700
sage: Integer(178^1700-1).exact_log(178)
1699
sage: Integer(178^1700+1).exact_log(178)
1700
sage: # we need to exercise the large base code path too
sage: Integer(1780^1700-1).exact_log(1780)
1699
```

**sage:** Integer(125).exact_log(5)

3

**sage:** Integer(124).exact_log(5)

2

**sage:** Integer(126).exact_log(5)

3

**sage:** Integer(3).exact_log(5)

0

**sage:** Integer(1).exact_log(5)

0

**sage:** Integer(178^1700).exact_log(178)

1700

**sage:** Integer(178^1700-1).exact_log(178)

1699

**sage:** Integer(178^1700+1).exact_log(178)

1700

**sage:** # we need to exercise the large base code path too

**sage:** Integer(1780^1700-1).exact_log(1780)

1699

**sage:** # The following are very very fast.

**sage:** # Note that for base $m$ a perfect power of 2, we get the exact log by counting bits.

**sage:** n=2983579823750185701375109835; m=32

**sage:** n.exact_log(m)

18

**sage:** # The next is a favorite of mine. The log2 approximate is exact and immediately provable.

**sage:** n=90153710570912709517902579010793251709257901270941709247901209742124; m=213509721309572

**sage:** n.exact_log(m)

4
```python
sage: x = 3^100000
sage: RR(log(RR(x), 3))
100000.000000000
sage: RR(log(RR(x + 100000), 3))
100000.000000000
sage: x.exact_log(3)
100000
sage: (x+1).exact_log(3)
100000
sage: (x-1).exact_log(3)
99999
sage: x.exact_log(2.5)
Traceback (most recent call last):
...  
TypeError: Attempt to coerce non-integral RealNumber to Integer
```

**exp** *(prec=None)*

Returns the exponential function of self as a real number.

This function is provided only so that Sage integers may be treated in the same manner as real numbers when convenient.

**INPUT:**

- prec - integer (default: None): if None, returns symbolic, else to given bits of precision as in RealField

**EXAMPLES:**

```python
sage: Integer(8).exp()
e^8
sage: Integer(8).exp(prec=100)
2980.95798704172827435920995
sage: exp(Integer(8))
e^8
```

For even fairly large numbers, this may not be useful.

```python
sage: y=Integer(145^145)
sage: y.exp()
e^1022
```

**factor** *(algorithm='pari', proof=None, limit=None, int_=False, verbose=0)*

Return the prime factorization of this integer as a formal Factorization object.

**INPUT:**

- algorithm - string
  - 'pari' - (default) use the PARI library
  - 'kash' - use the KASH computer algebra system (requires kash)
  - 'magma' - use the MAGMA computer algebra system (requires an installation of MAGMA)
- 'qsieve' - use Bill Hart’s quadratic sieve code; WARNING: this may not work as expected, see qsieve? for more information
- 'ecm' - use ECM-GMP, an implementation of Hendrik Lenstra’s elliptic curve method.

• proof - bool (default: True) whether or not to prove primality of each factor (only applicable for 'pari' and 'ecm').
• limit - int or None (default: None) if limit is given it must fit in a signed int, and the factorization is done using trial division and primes up to limit.

OUTPUT:
• a Factorization object containing the prime factors and their multiplicities

EXAMPLES:

```
 sage: n = 2^100 - 1; n.factor()
 3 * 5^3 * 11 * 31 * 41 * 101 * 251 * 601 * 1801 * 4051 * 8101 * 268501
```

This factorization can be converted into a list of pairs \((p, e)\), where \(p\) is prime and \(e\) is a positive integer. Each pair can also be accessed directly by its index (ordered by increasing size of the prime):

```
 sage: f = 60.factor()
 sage: list(f)
 [(2, 2), (3, 1), (5, 1)]
 sage: f[2]
 (5, 1)
```

Similarly, the factorization can be converted to a dictionary so the exponent can be extracted for each prime:

```
 sage: f = (3^6).factor()
 sage: dict(f)
 {3: 6}
 sage: dict(f)[3]
 6
```

We use proof=False, which doesn’t prove correctness of the primes that appear in the factorization:

```
 sage: n = 920384092842390423848290348203948092384082349082
 sage: n.factor(proof=False)
 2 * 11 * 1531 * 4402903 * 10023679 * 619162955472170540533894518173
 sage: n.factor(proof=True)
 2 * 11 * 1531 * 4402903 * 10023679 * 619162955472170540533894518173
```

We factor using trial division only:

```
 sage: n.factor(limit=1000)
 2 * 11 * 41835640583745019265831379463815822381094652231
```

We factor using a quadratic sieve algorithm:

```
 sage: p = next_prime(10^20)
 sage: q = next_prime(10^21)
 sage: n = p*q
 sage: n.factor(algorithm='qsieve')
 doctest:... RuntimeWarning: the factorization returned by qsieve may be incomplete (the factors may not be prime)
```
(continues on next page)
We factor using the elliptic curve method:

```python
sage: p = next_prime(10^15)
sage: q = next_prime(10^21)
sage: n = p*q
sage: n.factor(algorithm='ecm')
1000000000000037 * 1000000000000000000117
```

**factorial()**

Return the factorial \( n! = 1 \cdot 2 \cdot 3 \cdots n \).

If the input does not fit in an unsigned long int an OverflowError is raised.

**EXAMPLES:**

```python
sage: for n in srange(7):
    ....:     print("{} {}").format(n, n.factorial()))
0 1
1 1
2 2
3 6
4 24
5 120
6 720
```

Large integers raise an OverflowError:

```python
sage: (2**64).factorial()
Traceback (most recent call last):
  ...
OverflowError: argument too large for factorial
```

And negative ones a ValueError:

```python
sage: (-1).factorial()
Traceback (most recent call last):
  ...
ValueError: factorial only defined for non-negative integers
```

**floor()**

Return the floor of self, which is just self since self is an integer.

**EXAMPLES:**

```python
sage: n = 6
sage: n.floor()
6
```

**gamma()**

The gamma function on integers is the factorial function (shifted by one) on positive integers, and \( \pm \infty \) on non-positive integers.

**EXAMPLES:**
\begin{VerbatimBox} {1} sage: gamma(5) 24 \end{VerbatimBox} \begin{VerbatimBox} {1} sage: gamma(0) Infinity \end{VerbatimBox} \begin{VerbatimBox} {1} sage: gamma(-1) Infinity \end{VerbatimBox} \begin{VerbatimBox} {1} sage: gamma(-2^150) Infinity \end{VerbatimBox}

\noindent \textbf{gcd}\((n)\)

Return the greatest common divisor of self and \textit{n}.

\textbf{EXAMPLES:}

\begin{VerbatimBox} {1} sage: gcd(-1,1) 1 \end{VerbatimBox}
\begin{VerbatimBox} {1} sage: gcd(0,1) 1 \end{VerbatimBox}
\begin{VerbatimBox} {1} sage: gcd(0,0) 0 \end{VerbatimBox}
\begin{VerbatimBox} {1} sage: gcd(2,2^6) 2 \end{VerbatimBox}
\begin{VerbatimBox} {1} sage: gcd(21,2^6) 1 \end{VerbatimBox}

\noindent \textbf{global\_height\(\)}\(( prec=\text{None})\)

Returns the absolute logarithmic height of this rational integer.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{prec} \text{(int)} – desired floating point precision (default: default RealField precision).
\end{itemize}

\textbf{OUTPUT:}

(real) The absolute logarithmic height of this rational integer.

\textbf{ALGORITHM:}

The height of the integer \textit{n} is \(\log|n|\).

\textbf{EXAMPLES:}

\begin{VerbatimBox} {1} sage: ZZ(5).global_height() 1.60943791243410 \end{VerbatimBox}
\begin{VerbatimBox} {1} sage: ZZ(-2).global_height(\text{prec=}100) 0.69314718055994530941723212146 \end{VerbatimBox}
\begin{VerbatimBox} {1} sage: \exp(_2) 2.0000000000000000000000000000
\end{VerbatimBox}

\noindent \textbf{hex\(()\)}

Return the hexadecimal digits of \texttt{self} in lower case.

\textbf{Note:} ‘0x’ is \textit{not} prepended to the result like is done by the corresponding Python function on \texttt{int} or \texttt{long}. This is for efficiency sake--adding and stripping the string wastes time; since this function is used for conversions from integers to other C-library structures, it is important that it be fast.

\textbf{EXAMPLES:}
sage: print(Integer(15).hex())
f
sage: print(Integer(16).hex())
10
sage: print(Integer(16938402384092843092843098243).hex())
36bb1e3929d1a8fe2802f083
sage: hex(Integer(16))  # py2
doctest:warning...:
DeprecationWarning: use the method .hex instead
See https://trac.sagemath.org/26756 for details.
'10'

imag()

Returns the imaginary part of self, which is zero.

EXAMPLES:

sage: Integer(9).imag()
0

inverse_mod(n)

Returns the inverse of self modulo n, if this inverse exists. Otherwise, raises a ZeroDivisionError exception.

INPUT:

- self - Integer
- n - Integer, or ideal of integer ring

OUTPUT:

- x - Integer such that x*self = 1 (mod m), or raises ZeroDivisionError.

IMPLEMENTATION:

Call the mpz_invert GMP library function.

EXAMPLES:

sage: a = Integer(189)
sage: a.inverse_mod(10000)
4709
sage: a.inverse_mod(-10000)
4709
sage: a.inverse_mod(1890)
Traceback (most recent call last):
  ... ZeroDivisionError: inverse of Mod(189, 1890) does not exist
sage: a = Integer(19)**100000  # long time
sage: c = a.inverse_mod(a*a)  # long time
Traceback (most recent call last):
  ... ZeroDivisionError: inverse of Mod(..., ...) does not exist

We check that trac ticket #10625 is fixed:

sage: ZZ(2).inverse_mod(ZZ.ideal(3))
2

1.2. Elements of the ring \( \mathbb{Z} \) of integers
We check that trac ticket \#9955 is fixed:

```
sage: Rational(3) % Rational(-1)
0
```

**inverse_of_unit()**

Return inverse of self if self is a unit in the integers, i.e., self is -1 or 1. Otherwise, raise a ZeroDivisionError.

**EXAMPLES:**

```
sage: (1).inverse_of_unit()
1
sage: (-1).inverse_of_unit()
-1
sage: 5.inverse_of_unit()
Traceback (most recent call last):
  ... ArithmeticError: inverse does not exist
sage: 0.inverse_of_unit()
Traceback (most recent call last):
  ... ArithmeticError: inverse does not exist
```

**is_integer()**

Returns \texttt{True} as they are integers

**EXAMPLES:**

```
sage: sqrt(4).is_integer()
True
```

**is_integral()**

Return \texttt{True} since integers are integral, i.e., satisfy a monic polynomial with integer coefficients.

**EXAMPLES:**

```
sage: Integer(3).is_integral()
True
```

**is_irreducible()**

Returns \texttt{True} if self is irreducible, i.e. +/- prime

**EXAMPLES:**

```
sage: z = 2^31 - 1
sage: z.is_irreducible()
True
sage: z = 2^31
sage: z.is_irreducible()
False
sage: z = 7
sage: z.is_irreducible()
True
sage: z = -7
sage: z.is_irreducible()
True
```

**is_norm(K, element=False, proof=True)**

See \texttt{QQ(self).is_norm()}. 

EXAMPLES:

```
sage: K = NumberField(x^2 - 2, 'beta')
sage: n = 4
sage: n.is_norm(K)
True
sage: 5.is_norm(K)
False
sage: 7.is_norm(QQ)
True
sage: n.is_norm(K, element=True)
(True, -4*beta + 6)
sage: n.is_norm(K, element=True)[1].norm()
4
sage: n = 5
sage: n.is_norm(K, element=True)
(False, None)
sage: n = 7
sage: n.is_norm(QQ, element=True)
(True, 7)
```

```
is_one()
Returns True if the integer is 1, otherwise False.

EXAMPLES:

```
sage: Integer(1).is_one()
True
sage: Integer(0).is_one()
False
```

```
is_perfect_power()
Returns True if self is a perfect power, ie if there exist integers a and b, b > 1 with self = a^b.

See also:

• perfect_power(): Finds the minimal base for which this integer is a perfect power.

• is_power_of(): If you know the base already this method is the fastest option.

• is_prime_power(): Checks whether the base is prime.

EXAMPLES:

```
sage: Integer(-27).is_perfect_power()
True
sage: Integer(12).is_perfect_power()
False
sage: z = 8
sage: z.is_perfect_power()
True
sage: 144.is_perfect_power()
True
sage: 10.is_perfect_power()
False
sage: (-8).is_perfect_power()
True
```
```
sage: (-4).is_perfect_power()
False

is_power_of(n)

Returns True if there is an integer b with self = n^b.

See also:

- perfect_power(): Finds the minimal base for which this integer is a perfect power.
- is_perfect_power(): If you don’t know the base but just want to know if this integer is a perfect power, use this function.
- is_prime_power(): Checks whether the base is prime.

EXAMPLES:

sage: Integer(64).is_power_of(4)
True
sage: Integer(64).is_power_of(16)
False

Note: For large integers self, is_power_of() is faster than is_perfect_power(). The following examples gives some indication of how much faster.

sage: b = lcm(range(1,10000))
sage: b.exact_log(2)
14446
sage: t=cputime()
sage: for a in range(2, 1000): k = b.is_perfect_power()
sage: cputime(t) # random
0.53203299999999976
sage: t=cputime()
sage: for a in range(2, 1000): k = b.is_power_of(2)
sage: cputime(t) # random
0.0
sage: t=cputime()
sage: for a in range(2, 1000): k = b.is_power_of(3)
sage: cputime(t) # random
0.032002000000000308

sage: b = lcm(range(1, 1000))
sage: b.exact_log(2)
1437
sage: t=cputime()
sage: for a in range(2, 1000): k = b.is_perfect_power() # note that we
--> change the range from the example above
sage: cputime(t) # random
0.17201100000000036
sage: t=cputime(); TWO=int(2)
sage: for a in range(2, 10000): k = b.is_power_of(TWO)
sage: cputime(t) # random
0.00400000000000036
sage: t=cputime()
is_prime (proof=None)
Test whether self is prime.

INPUT:

• proof – Boolean or None (default). If False, use a strong pseudo-primality test (see is_pseudoprime()). If True, use a provable primality test. If unset, use the default arithmetic proof flag.

Note: Integer primes are by definition positive! This is different than Magma, but the same as in PARI. See also the is_irreducible() method.

EXAMPLES:

```python
sage: z = 2^31 - 1
sage: z.is_prime()
True
sage: z = 2^31
sage: z.is_prime()
False
sage: z = 7
sage: z.is_prime()
True
sage: z = -7
sage: z.is_prime()
False
sage: z.is_irreducible()
True
```

```python
sage: z = 10^80 + 129
sage: z.is_prime(proof=False)
True
sage: z.is_prime(proof=True)
True
```

When starting Sage the arithmetic proof flag is True. We can change it to False as follows:

```python
sage: proof.arithmetic()
True
sage: n = 10^100 + 267
sage: timeit("n.is_prime()")  # not tested
5 loops, best of 3: 163 ms per loop
sage: proof.arithmetic(False)
False
sage: timeit("n.is_prime()")  # not tested
1000 loops, best of 3: 573 us per loop
```
ALGORITHM:

Calls the PARI isprime function.

\texttt{is\_prime\_power(proof=None, get\_data=False)}

Return True if this integer is a prime power, and False otherwise.

A prime power is a prime number raised to a positive power. Hence 1 is not a prime power.

For a method that uses a pseudoprimality test instead see \texttt{is\_pseudoprime\_power()}.

INPUT:

\begin{itemize}
  \item proof – Boolean or None (default). If False, use a strong pseudo-primality test (see \texttt{is\_pseudoprime()}). If True, use a provable primality test. If unset, use the default arithmetic proof flag.
  \item get\_data – (default False), if True return a pair \((p,k)\) such that this integer equals \(p^k\) with \(p\) a prime and \(k\) a positive integer or the pair \((self,0)\) otherwise.
\end{itemize}

See also:

\begin{itemize}
  \item \texttt{perfect\_power()}: Finds the minimal base for which integer is a perfect power.
  \item \texttt{is\_perfect\_power()}: Doesn’t test whether the base is prime.
  \item \texttt{is\_power\_of()}: If you know the base already this method is the fastest option.
  \item \texttt{is\_pseudoprime\_power()}: If the entry is very large.
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: 17.is_prime_power()
True
sage: 10.is_prime_power()
False
sage: 64.is_prime_power()
True
sage: (3^10000).is_prime_power()
True
sage: (10000).is_prime_power()
False
sage: (-3).is_prime_power()
False
sage: 0.is_prime_power()
False
sage: 1.is_prime_power()
False
sage: p = next_prime(10^20); p
100000000000000000039
sage: p.is_prime_power()
True
sage: (p^97).is_prime_power()
True
sage: (p+1).is_prime_power()
False
\end{verbatim}

With the get\_data keyword set to True:

\begin{verbatim}
sage: (3^100).is_prime_power(get\_data=True)
(3, 100)
\end{verbatim}
sage: 12.is_prime_power(get_data=True)
(12, 0)
sage: (p^97).is_prime_power(get_data=True)
(100000000000000000039, 97)
sage: q = p.next_prime(); q
100000000000000000129
sage: (p*q).is_prime_power(get_data=True)
(10000000000000000016800000000000531, 0)

The method works for large entries when proof = False:

sage: proof.arithmetic(False)
sage: ((10^500 + 961)^4).is_prime_power()
True
sage: proof.arithmetic(True)

We check that trac ticket #4777 is fixed:

sage: n = 150607571^14
sage: n.is_prime_power()
True

is_pseudoprime()
Test whether self is a pseudoprime.

This uses PARI’s Baillie-PSW probabilistic primality test. Currently, there are no known pseudoprimes for Baillie-PSW that are not actually prime. However it is conjectured that there are infinitely many.

See Wikipedia article Baillie-PSW_primality_test

EXAMPLES:

sage: z = 2^31 - 1
sage: z.is_pseudoprime()
True
sage: z = 2^31
sage: z.is_pseudoprime()
False

is_pseudoprime_power(get_data=False)
Test if this number is a power of a pseudoprime number.

For large numbers, this method might be faster than is_prime_power().

INPUT:

• get_data – (default False) if True return a pair \((p, k)\) such that this number equals \(p^k\) with \(p\) a pseudoprime and \(k\) a positive integer or the pair \((self, 0)\) otherwise.

EXAMPLES:

sage: x = 10^200 + 357
sage: x.is_pseudoprime()
True
sage: x.is_pseudoprime_power()
True
sage: (x^12).is_pseudoprime_power()
True
sage: (x^12).is_pseudoprime_power(get_data=True)
(1000000000000000357, 12)
sage: (997^100).is_pseudoprime_power()
is_rational()
Return True as an integer is a rational number.

EXAMPLES:

```
sage: 5.is_rational()
True
```

is_square()
Returns True if self is a perfect square.

EXAMPLES:

```
sage: Integer(4).is_square()
True
sage: Integer(41).is_square()
False
```

is_squarefree()
Returns True if this integer is not divisible by the square of any prime and False otherwise.

EXAMPLES:

```
sage: 100.is_squarefree()
False
sage: 102.is_squarefree()
True
sage: 0.is_squarefree()
False
```

is_unit()
Returns true if this integer is a unit, i.e., 1 or −1.

EXAMPLES:

```
sage: for n in srange(-2,3):
    ....:     print("{} {}".format(n, n.is_unit()))
-2 False
-1 True
0 False
1 True
2 False
```

isqrt()
Returns the integer floor of the square root of self, or raises an ValueError if self is negative.

EXAMPLES:

```
sage: a = Integer(5)
sage: a.isqrt()
2
```
sage: Integer(-102).isqrt()  
Traceback (most recent call last):  
...  
ValueError: square root of negative integer not defined.

jacobi(b)

Calculate the Jacobi symbol \( \left( \frac{\text{self}}{b} \right) \).

EXAMPLES:

sage: z = -1  
sage: z.jacobi(17)  
1  
sage: z.jacobi(19)  
-1  
sage: z.jacobi(17*19)  
-1  
sage: (2).jacobi(17)  
1  
sage: (3).jacobi(19)  
-1  
sage: (6).jacobi(17*19)  
-1  
sage: (6).jacobi(33)  
0  
sage: a = 3; b = 7  
sage: a.jacobi(b) == -b.jacobi(a)  
True

kronecker(b)

Calculate the Kronecker symbol \( \left( \frac{\text{self}}{b} \right) \) with the Kronecker extension \( \left( \frac{\text{self}/2}{\text{self}} \right) = \left( \frac{2}{\text{self}} \right) \) when \( \text{self} \) is odd, or \( \left( \frac{\text{self}/2}{\text{self}} \right) = 0 \) when \( \text{self} \) is even.

EXAMPLES:

sage: z = 5  
sage: z.kronecker(41)  
1  
sage: z.kronecker(43)  
-1  
sage: z.kronecker(5)  
-1  
sage: z.kronecker(15)  
0  
sage: a = 2; b = 5  
sage: a.kronecker(b) == b.kronecker(a)  
True

list()

Return a list with this integer in it, to be compatible with the method for number fields.

EXAMPLES:

sage: m = 5  
sage: m.list()  
[5]

log(m=None, prec=None)
Returns symbolic \log by default, unless the logarithm is exact (for an integer argument). When precision
is given, the RealField approximation to that bit precision is used.

This function is provided primarily so that Sage integers may be treated in the same manner as real numbers
when convenient. Direct use of exact_log is probably best for arithmetic log computation.

INPUT:
- \(m\) - default: natural log base \(e\)
- \(\text{prec}\) - integer (default: None): if None, returns symbolic, else to given bits of precision as in Real-
  Field

EXAMPLES:

```sage
sage: Integer(124).log(5)
log(124)/log(5)
sage: Integer(124).log(5,100)
2.9950093311241087454822446806
sage: Integer(125).log(5)
3
sage: Integer(125).log(5, prec=53)
3.00000000000000
sage: log(Integer(125))
3*log(5)
```

For extremely large numbers, this works:

```sage
sage: x = 3^100000
sage: log(x, 3)
100000
```

With the new Pynac symbolic backend, \(\log(x)\) also works in a reasonable amount of time for this \(x\):

```sage
sage: x = 3^100000
sage: log(x)
log(1334971414230...5522000001)
```

But approximations are probably more useful in this case, and work to as high a precision as we desire:

```sage
sage: x.log(3,53) # default precision for RealField
100000.000000000
sage: (x+1).log(3,53)
100000.000000000
sage: (x+1).log(3,1000)
100000.
```

We can use non-integer bases, with default \(e\):

```sage
sage: x.log(2.5, prec=53)
119897.784671579
```

We also get logarithms of negative integers, via the symbolic ring, using the branch from \(-\pi\) to \(\pi\):

```sage
sage: log(-1)
I*pi
```

The logarithm of zero is done likewise:
Some rational bases yield integer logarithms (trac ticket #21517):

```
sage: ZZ(8).log(1/2)
-3
```

Check that Python ints are accepted (trac ticket #21518):

```
sage: ZZ(8).log(int(2))
3
```

**multifactorial**(*k*)

Compute the *k*-th factorial *n*!(*k*) of self.

The multifactorial number *n*!(*k*) is defined for non-negative integers *n* as follows. For *k* = 1 this is the standard factorial, and for *k* greater than 1 it is the product of every *k*-th terms down from *n* to 1. The recursive definition is used to extend this function to the negative integers *n*.

This function uses direct call to GMP if *k* and *n* are non-negative and uses simple transformation for other cases.

**EXAMPLES:**

```
sage: 5.multifactorial(1)
120
sage: 5.multifactorial(2)
15
sage: 5.multifactorial(3)
10
sage: 23.multifactorial(2)
316234143225
sage: prod([1..23, step=2])
316234143225
sage: (-29).multifactorial(7)
1/2640
sage: (-3).multifactorial(5)
1/2
sage: (-9).multifactorial(3)
Traceback (most recent call last):
  ... ValueError: multifactorial undefined
```

When entries are too large an OverflowError is raised:

```
sage: (2**64).multifactorial(2)
Traceback (most recent call last):
  ... OverflowError: argument too large for multifactorial
```

**multiplicative_order**()

Return the multiplicative order of self.

**EXAMPLES:**
sage: ZZ(1).multiplicative_order()
1
sage: ZZ(-1).multiplicative_order()
2
sage: ZZ(0).multiplicative_order()
+Infinity
sage: ZZ(2).multiplicative_order()
+Infinity

\textbf{nbits}()

Return the number of bits in \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: 500.nbits()
9
sage: 5.nbits()
3
sage: 0.nbits() == len(0.bits()) == 0.ndigits(base=2)
True
sage: 12345.nbits() == len(12345.binary())
True
\end{verbatim}

\textbf{ndigits} (\texttt{base}=10)

Return the number of digits of \texttt{self} expressed in the given base.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{base} - integer (default: 10)
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: n = 52
sage: n.ndigits()
2
sage: n = -10003
sage: n.ndigits()
5
sage: n = 15
sage: n.ndigits(2)
4
sage: n = 1000**1000000+1
sage: n.ndigits()
3000001
sage: n = 1000**1000000-1
sage: n.ndigits()
3000000
sage: n = 10**10000000-10**9999990
sage: n.ndigits()
10000000
\end{verbatim}

\textbf{next\_prime} (\texttt{proof}=\texttt{None})

Return the next prime after \texttt{self}.

This method calls the PARI \texttt{nextprime} function.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{proof} - bool or \texttt{None} (default: \texttt{None}, see \texttt{proof.arithmetic} or \texttt{sage.structure.proof}) Note that the global Sage default is \texttt{proof=\texttt{True}}
EXAMPLES:

```
sage: 100.next_prime()
101
sage: (10^50).next_prime()
100000000000000000000000000000000000000000000000151
```

Use `proof=False`, which is way faster since it does not need a primality proof:

```
sage: b = (2^1024).next_prime(proof=False)
sage: b - 2^1024
643
```

```
sage: Integer(0).next_prime()
2
sage: Integer(1001).next_prime()
1009
```

`next_prime_power(proof=None)`

Return the next prime power after self.

INPUT:

- `proof`: if `True` ensure that the returned value is the next prime power and if set to `False` uses probabilistic methods (i.e. the result is not guaranteed). By default it uses global configuration variables to determine which alternative to use (see `proof.arithmetic` or `sage.structure.proof`).

ALGORITHM:

The algorithm is naive. It computes the next power of 2 and go through the odd numbers calling `is_prime_power()`.

See also:

- `previous_prime_power()`
- `is_prime_power()`
- `next_prime()`
- `previous_prime()`

EXAMPLES:

```
sage: (-1).next_prime_power()
2
sage: 2.next_prime_power()
3
sage: 103.next_prime_power()
107
sage: 107.next_prime_power()
109
sage: 2044.next_prime_power()
2048
```

`next_probable_prime()`

Return the next probable prime after self, as determined by PARI.

EXAMPLES:
nth_root \( n, \text{truncate\_mode}=0 \)

Returns the (possibly truncated) \( n \)’th root of self.

**INPUT:**

- \( n \) - integer \( \geq 1 \) (must fit in C int type).
- \( \text{truncate\_mode} \) - boolean, whether to allow truncation if self is not an \( n \)’th power.

**OUTPUT:**

If truncate_mode is 0 (default), then returns the exact \( n \)’th root if self is an \( n \)’th power, or raises a \( \text{ValueError} \) if it is not.

If truncate_mode is 1, then if either \( n \) is odd or self is positive, returns a pair (root, exact_flag) where root is the truncated nth root (rounded towards zero) and exact_flag is a boolean indicating whether the root extraction was exact; otherwise raises a \( \text{ValueError} \).

**AUTHORS:**

- David Harvey (2006-09-15)
- Interface changed by John Cremona (2009-04-04)

**EXAMPLES:**

```python
sage: Integer(125).nth_root(3)
5
sage: Integer(124).nth_root(3)
Traceback (most recent call last):
  ...  
ValueError: 124 is not a 3rd power
sage: Integer(124).nth_root(3, truncate_mode=1)
(4, False)
sage: Integer(125).nth_root(3, truncate_mode=1)
(5, True)
sage: Integer(126).nth_root(3, truncate_mode=1)
(5, False)
```

```python
sage: Integer(-125).nth_root(3)
-5
sage: Integer(-125).nth_root(3, truncate_mode=1)
(-5, True)
sage: Integer(-124).nth_root(3, truncate_mode=1)
(-4, False)
sage: Integer(-126).nth_root(3, truncate_mode=1)
(-5, False)
```
sage: Integer(125).nth_root(2, True)
(11, False)
sage: Integer(125).nth_root(3, True)
(5, True)

sage: Integer(125).nth_root(-5)
Traceback (most recent call last):
...
ValueError: n (-5) must be positive

sage: Integer(-25).nth_root(2)
Traceback (most recent call last):
...
ValueError: cannot take even root of negative number

sage: a=9
sage: a.nth_root(3)
Traceback (most recent call last):
...
ValueError: 9 is not a 3rd power

sage: a.nth_root(22)
Traceback (most recent call last):
...
ValueError: 9 is not a 22nd power

sage: ZZ(2^20).nth_root(21)
Traceback (most recent call last):
...
ValueError: 1048576 is not a 21st power

sage: ZZ(2^20).nth_root(21, truncate_mode=1)
(1, False)

numerator()
Return the numerator of this integer.

EXAMPLES:

sage: x = 5
sage: x.numerator()
5

sage: x = 0
sage: x.numerator()
0

eoct()
Return the digits of self in base 8.

Note: ‘0’ (or ‘0o’) is not prepended to the result like is done by the corresponding Python function on int or long. This is for efficiency sake—adding and stripping the string wastes time; since this function is used for conversions from integers to other C-library structures, it is important that it be fast.

EXAMPLES:
sage: print(Integer(800).oct())
1440
sage: print(Integer(8).oct())
10
sage: print(Integer(-50).oct())
-62
sage: print(Integer(-899).oct())
-1603
sage: print(Integer(16938402384092843092843098243).oct())
15535436162247215217705000570203

Behavior of Sage integers vs. Python integers (Python 2 and Python 3):

sage: Integer(10).oct()
'12'
sage: oct(Integer(10))  # py2
doctest:warning...:
DeprecationWarning: use the method .oct instead
See https://trac.sagemath.org/26756 for details.
'12'
sage: oct(int(10))  # py2
'012'
sage: oct(int(10))  # py3
'0o12'
sage: Integer(-23).oct()
'-27'
sage: oct(int(-23))  # py2
'-027'
sage: oct(int(-23))  # py3
'-0o27'

odd_part()

The odd part of the integer \( n \). This is \( n/2^v \), where \( v = \text{valuation}(n, 2) \).

IMPLEMENTATION:

Currently returns 0 when self is 0. This behaviour is fairly arbitrary, and in Sage 4.6 this special case was not handled at all, eventually propagating a TypeError. The caller should not rely on the behaviour in case self is 0.

EXAMPLES:

sage: odd_part(5)
5
sage: odd_part(4)
1
sage: odd_part(factorial(31))
122529844256906551386796875

ord\( (p) \)

Return the \( p \)-adic valuation of self.

INPUT:

- \( p \) - an integer at least 2.

EXAMPLES:
We do not require that \( p \) is a prime:

```
sage: (2^11).valuation(4)
sage: 5
```

**ordinal_str()**

Returns a string representation of the ordinal associated to self.

**EXAMPLES:**

```
sage: [ZZ(n).ordinal_str() for n in range(25)]
sage: ['0th',
    '1st',
    '2nd',
    '3rd',
    '4th',
    ...
    '10th',
    '11th',
    '12th',
    '13th',
    '14th',
    ...
    '20th',
    '21st',
    '22nd',
    '23rd',
    '24th']
sage: ZZ(1001).ordinal_str()
sage: '1001st'
sage: ZZ(113).ordinal_str()
sage: '113th'
sage: ZZ(112).ordinal_str()
sage: '112th'
sage: ZZ(111).ordinal_str()
sage: '111th'
```

**p_primary_part\((p)\)**

Return the \( p \)-primary part of self.

**INPUT:**

- \( p \) – a prime integer.
OUTPUT: Largest power of \( p \) dividing \( \text{self} \).

EXAMPLES:

```python
sage: n = 40
sage: n.p_primary_part(2)
8
sage: n.p_primary_part(5)
5
sage: n.p_primary_part(7)
1
sage: n.p_primary_part(6)
Traceback (most recent call last):
...
ValueError: 6 is not a prime number
```

**perfect_power()**

Returns \( (a, b) \), where this integer is \( a^b \) and \( b \) is maximal.

If called on \(-1, 0\) or \(1\), \( b \) will be \(1\), since there is no maximal value of \( b \).

See also:

- **is_perfect_power()**: testing whether an integer is a perfect power is usually faster than finding \( a \) and \( b \).
- **is_prime_power()**: checks whether the base is prime.
- **is_power_of()**: if you know the base already, this method is the fastest option.

EXAMPLES:

```python
sage: 144.perfect_power()
(12, 2)
sage: 1.perfect_power()
(1, 1)
sage: 0.perfect_power()
(0, 1)
sage: (-1).perfect_power()
(-1, 1)
sage: (-8).perfect_power()
(-2, 3)
sage: (-4).perfect_power()
(-4, 1)
sage: (101^29).perfect_power()
(101, 29)
sage: (-243).perfect_power()
(-3, 5)
sage: (-64).perfect_power()
(-4, 3)
```

**popcount()**

Return the number of 1 bits in the binary representation. If \( \text{self} < 0 \), we return Infinity.

EXAMPLES:

```python
sage: n = 123
sage: n.str(2)
'1111011'
```
\begin{verbatim}
sage: n.popcount()
6

sage: n = -17
sage: n.popcount()
+Infinity

\end{verbatim}

\textbf{powermod (exp, mod)}

Compute self**exp modulo mod.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: z = 2
sage: z.powermod(31,31)
2
sage: z.powermod(0,31)
1
sage: z.powermod(-31,31) == 2^-31 % 31
True

As expected, the following is invalid:

\begin{verbatim}
sage: z.powermod(31,0)
Traceback (most recent call last):
...
ZeroDivisionError: cannot raise to a power modulo 0
\end{verbatim}

\textbf{previous_prime (proof=None)}

Returns the previous prime before self.

This method calls the PARI \texttt{precprime} function.

\textbf{INPUT:}

- proof - if True ensure that the returned value is the next prime power and if set to False uses probabilistic methods (i.e. the result is not guaranteed). By default it uses global configuration variables to determine which alternative to use (see \texttt{proof.arithmetic} or \texttt{sage.structure.proof}).

\textbf{See also:}

- \texttt{next_prime()}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: 10.previous_prime()
7
sage: 7.previous_prime()
5
sage: 14376485.previous_prime()
14376463
sage: 2.previous_prime()
Traceback (most recent call last):
...
ValueError: no prime less than 2
\end{verbatim}

An example using proof=False, which is way faster since it does not need a primality proof:

\section{1.2. Elements of the ring $\mathbb{Z}$ of integers}
```
sage: b = (2^1024).previous_prime(proof=False)
sage: 2^1024 - b
105
```

**previous_prime_power** *(proof=None)*  
Return the previous prime power before self.

**INPUT:**

- **proof** - if True ensure that the returned value is the next prime power and if set to False uses probabilistic methods (i.e. the result is not guaranteed). By default it uses global configuration variables to determine which alternative to use (see proof.arithmetic or sage.structure.proof).

**ALGORITHM:**

The algorithm is naive. It computes the previous power of 2 and go through the odd numbers calling the method `is_prime_power()`.

**See also:**

- `next_prime_power()`  
- `is_prime_power()`  
- `previous_prime()`  
- `next_prime()`

**EXAMPLES:**

```
sage: 3.previous_prime_power()
2
sage: 103.previous_prime_power()
101
sage: 107.previous_prime_power()
103
sage: 2044.previous_prime_power()
2039
sage: 2.previous_prime_power()
Traceback (most recent call last):
  ...  
ValueError: no prime power less than 2
```

**prime_divisors()**

Return the prime divisors of this integer, sorted in increasing order.

If this integer is negative, we do not include -1 among its prime divisors, since -1 is not a prime number.

**EXAMPLES:**

```
sage: a = 1; a.prime_divisors()
[]
sage: a = 100; a.prime_divisors()
[2, 5]
sage: a = -100; a.prime_divisors()
[2, 5]
sage: a = 2004; a.prime_divisors()
[2, 3, 167]
```
**prime_factors()**
Return the prime divisors of this integer, sorted in increasing order.

If this integer is negative, we do not include -1 among its prime divisors, since -1 is not a prime number.

EXAMPLES:
```
sage: a = 1; a.prime_divisors()
[]
sage: a = 100; a.prime_divisors()
[2, 5]
sage: a = -100; a.prime_divisors()
[2, 5]
sage: a = 2004; a.prime_divisors()
[2, 3, 167]
```

**prime_to_m_part(m)**
Returns the prime-to-m part of self, i.e., the largest divisor of self that is coprime to m.

**INPUT:**
- m - Integer

**OUTPUT:** Integer

EXAMPLES:
```
sage: 43434.prime_to_m_part(20)
21717
sage: 2048.prime_to_m_part(2)
1
sage: 2048.prime_to_m_part(3)
2048
sage: 0.prime_to_m_part(2)
Traceback (most recent call last):
  ...
ArithmeticError: self must be nonzero
```

**quo_rem(other)**
Returns the quotient and the remainder of self divided by other. Note that the remainder returned is always either zero or of the same sign as other.

**INPUT:**
- other - the divisor

**OUTPUT:**
- q - the quotient of self/other
- r - the remainder of self/other

EXAMPLES:
```
sage: z = Integer(231)
sage: z.quo_rem(2)
(115, 1)
sage: z.quo_rem(-2)
(-116, -1)
sage: z.quo_rem(0)
Traceback (most recent call last):
```

(continues on next page)
ZeroDivisionError: Integer division by zero

```
sage: a = ZZ.random_element(10**50)
sage: b = ZZ.random_element(10**15)
sage: q, r = a.quo_rem(b)
sage: q*b + r == a
True
sage: 3.quo_rem(ZZ['x'].0)
(0, 3)
```

**rational_reconstruction** \((m)\)
Return the rational reconstruction of this integer modulo \(m\), i.e., the unique (if it exists) rational number that reduces to self modulo \(m\) and whose numerator and denominator is bounded by \(\sqrt{m/2}\).

**INPUT:**
- \(\text{self} - \) Integer
- \(\text{m} - \) Integer

**OUTPUT:**
- A **Rational**

**EXAMPLES:**
```
sage: (3/7)%100
29
sage: (29).rational_reconstruction(100)
3/7
```

**real** ()
Returns the real part of self, which is self.

**EXAMPLES:**
```
sage: Integer(-4).real()
-4
```

**round** \((\text{mode}=\text{’away’})\)
Returns the nearest integer to self, which is self since self is an integer.

**EXAMPLES:**
This example addresses trac ticket #23502:
```
sage: n = 6
sage: n.round()
6
```

**sign** ()
Returns the sign of this integer, which is -1, 0, or 1 depending on whether this number is negative, zero, or positive respectively.

**OUTPUT:** Integer

**EXAMPLES:**

---

50 Chapter 1. Integers
sage: 500.sign()
1
sage: 0.sign()
0
sage: (-10^43).sign()
-1

**sqrt** *(prec=None, extend=True, all=False)*

The square root function.

**INPUT:**

- **prec** - integer (default: None): if None, return an exact square root; otherwise return a numerical square root, to the given bits of precision.
- **extend** - bool (default: True): if True, return a square root in an extension ring, if necessary. Otherwise, raise a ValueError if the square is not in the base ring. Ignored if prec is not None.
- **all** - bool (default: False): if True, return all square roots of self (a list of length 0, 1 or 2).

**EXAMPLES:**

```plaintext
sage: Integer(144).sqrt()
12
sage: sqrt(Integer(144))
12
sage: Integer(102).sqrt()
sqrt(102)
sage: n = 2
sage: n.sqrt(all=True)
[1.4142135623730950488016887242, -1.4142135623730950488016887242]
sage: n.sqrt(prec=10)
1.4
sage: n.sqrt(prec=100)
1.4142135623730950488016887242
sage: n.sqrt(prec=100, all=True)
[1.4142135623730950488016887242, -1.4142135623730950488016887242]
sage: n.sqrt(extend=False)
Traceback (most recent call last):
  ... ArithmeticError: square root of 2 is not an integer
```

**sqrtrem()**

Return \((s, r)\) where \(s\) is the integer square root of self and \(r\) is the remainder such that \(self = s^2 + r\). Raises ValueError if self is negative.

**EXAMPLES:**

```plaintext
sage: 25.sqrtrem()
(5, 0)
(continues on next page)```
sage: 27.sqrtrem()
(5, 2)
sage: 0.sqrtrem()
(0, 0)

sage: Integer(-102).sqrtrem()
Traceback (most recent call last):
...
ValueError: square root of negative integer not defined.

**squarefree_part** *(bound=-1)*

Return the square free part of \( x (=self) \), i.e., the unique integer \( z \) that \( x = zy^2 \), with \( y^2 \) a perfect square and \( z \) square-free.

Use \( self.radical() \) for the product of the primes that divide \( self \).

If \( self \) is 0, just returns 0.

**EXAMPLES:**

```
sage: squarefree_part(100)
1
sage: squarefree_part(12)
3
sage: squarefree_part(17*37*37)
17
sage: squarefree_part(-17*32)
-34
sage: squarefree_part(1)
1
sage: squarefree_part(-1)
-1
sage: squarefree_part(-2)
-2
sage: squarefree_part(-4)
-1
sage: a = 8 * 5^6 * 101^2
sage: a.squarefree_part(bound=1000)
2
sage: a = 7^3 * next_prime(2^100)^2 * next_prime(2^200)
sage: a / a.squarefree_part(bound=1000)
49
```

**str** *(base=10)*

Return the string representation of \( self \) in the given base.

**EXAMPLES:**

```
sage: Integer(2^10).str(2)
'10000000000'
```
sage: Integer(2^10).str(17)
'394'

sage: two=Integer(2)
sage: two.str(1)
Traceback (most recent call last):
...
ValueError: base (=1) must be between 2 and 36

sage: two.str(37)
Traceback (most recent call last):
...
ValueError: base (=37) must be between 2 and 36

sage: big = 10^5000000
sage: s = big.str()
# long time (2s on sage.math, 2014)

sage: len(s)
# long time (depends on above defn of s)
5000001

sage: s[:10]
# long time (depends on above defn of s)
'1000000000'

support()
Return a sorted list of the primes dividing this integer.

OUTPUT: The sorted list of primes appearing in the factorization of this rational with positive exponent.

EXAMPLES:

sage: factorial(10).support()
[2, 3, 5, 7]

sage: (-999).support()
[3, 37]

Trying to find the support of 0 gives an arithmetic error:

sage: 0.support()
Traceback (most recent call last):
...
ArithmeticError: Support of 0 not defined.

test_bit(index)
Return the bit at index.

If the index is negative, returns 0.

Although internally a sign-magnitude representation is used for integers, this method pretends to use a two’s complement representation. This is illustrated with a negative integer below.

EXAMPLES:

sage: w = 6
sage: w.str(2)
'110'
sage: w.test_bit(2)
1
sage: w.test_bit(-1)
0
sage: x = -20
sage: x.str(2)
'-10100'
sage: x.test_bit(4)
0
sage: x.test_bit(5)
1
sage: x.test_bit(6)
1

**trailing_zero_bits()**
Return the number of trailing zero bits in self, i.e. the exponent of the largest power of 2 dividing self.

**EXAMPLES:**

```python
sage: 11.trailing_zero_bits()
0
sage: (-11).trailing_zero_bits()
0
sage: (11<<5).trailing_zero_bits()
5
sage: (-11<<5).trailing_zero_bits()
5
sage: 0.trailing_zero_bits()
0
```

**trial_division** *(bound='LONG_MAX', start=2)*
Return smallest prime divisor of self up to bound, beginning checking at start, or abs(self) if no such divisor is found.

**INPUT:**
- bound – a positive integer that fits in a C signed long
- start – a positive integer that fits in a C signed long

**OUTPUT:**
- a positive integer

**EXAMPLES:**

```python
sage: n = next_prime(10^6)*next_prime(10^7); n.trial_division()
1000003
sage: (-n).trial_division()
1000003
sage: n.trial_division(bound=100)
10000049000057
sage: n.trial_division(bound=-10)
Traceback (most recent call last):
  ... ValueError: bound must be positive
sage: n.trial_division(bound=0)
Traceback (most recent call last):
  ... ValueError: bound must be positive
sage: ZZ(0).trial_division()
Traceback (most recent call last):
  ...
ValueError: self must be nonzero

```
sage: n = next_prime(10^5) * next_prime(10^40); n.trial_division()
sage: n.trial_division(bound=10^4)
100003
```

You can specify a starting point:

```
sage: n = 3*5*101*103
sage: n.trial_division(start=50)
101
```

**trunc()**

Round this number to the nearest integer, which is self since self is an integer.

**EXAMPLES:**

```
sage: n = 6
sage: n.trunc()
6
```

**val_unit** *(p)*

**INPUT:**

• p - an integer at least 2.

**OUTPUT:**

• v_p(self) - the p-adic valuation of self
• u_p(self) - self / p^{v_p(self)}

**EXAMPLES:**

```
sage: n = 60
sage: n.val_unit(2)
(2, 15)
sage: n.val_unit(3)
(1, 20)
sage: n.val_unit(7)
```

(continues on next page)
valuation ($p$)
Return the $p$-adic valuation of self.

**INPUT:**

- $p$ - an integer at least 2.

**EXAMPLES:**

```python
sage: n = 60
sage: n.valuation(2)
2
sage: n.valuation(3)
1
sage: n.valuation(7)
0
sage: n.valuation(1)
Traceback (most recent call last):
  ...  
ValueError: You can only compute the valuation with respect to a integer
    \rightarrow larger than 1.
```

We do not require that $p$ is a prime:

```python
sage: (2^11).valuation(4)
5
```

xgcd ($n$)
Return the extended gcd of this element and $n$.

**INPUT:**

- $n$ – an integer

**OUTPUT:**

A triple $(g, s, t)$ such that $g$ is the non-negative gcd of self and $n$, and $s$ and $t$ are cofactors satisfying the Bezout identity

$$g = s \cdot \text{self} + t \cdot n.$$  

**Note:** There is no guarantee that the cofactors will be minimal. If you need the cofactors to be minimal use _xgcd(). Also, using _xgcd() directly might be faster in some cases, see trac ticket #13628.

**EXAMPLES:**

```python
sage: 6.xgcd(4)
(2, 1, -1)
```

```python
class sage.rings.integer.IntegerWrapper
Bases: sage.rings.integer.Integer
```
Rationale for the `IntegerWrapper` class:

With `Integers`, the allocation/deallocation function slots are hijacked with custom functions that stick already allocated `Integers` (with initialized `parent` and `mpz_t` fields) into a pool on “deallocation” and then pull them out whenever a new one is needed. Because `Integers` are so common, this is actually a significant savings. However, this does cause issues with subclassing a Python class directly from `Integer` (but that’s ok for a Cython class).

As a workaround, one can instead derive a class from the intermediate class `IntegerWrapper`, which sets statically its alloc/dealloc methods to the original `Integer` alloc/dealloc methods, before they are swapped manually for the custom ones.

The constructor of `IntegerWrapper` further allows for specifying an alternative parent to `IntegerRing()`.

```python
sage.rings.integer.free_integer_pool()

class sage.rings.integer.int_to_Z
    Bases: sage.categories.morphism.Morphism

    Morphism from Python ints to Sage integers.

    EXAMPLES:

    sage: f = ZZ.coerce_map_from(int)
sage: type(f)
<class 'sage.rings.integer.long_to_Z'>
sage: f(5r)
5
sage: type(f(5r))
<type 'sage.rings.integer.Integer'>
sage: 1 + 2r
3
sage: type(1 + 2r)
<type 'sage.rings.integer.Integer'>
```

This is intended for internal use by the coercion system, to facilitate fast expressions mixing ints and more complex Python types. Note that (as with all morphisms) the input is forcibly coerced to the domain `int` if it is not already of the correct type which may have undesirable results:

```python
sage: f = ZZ.coerce_map_from(int)
sage: f.domain()
Set of Python objects of class 'int'
sage: f(1/3)
0
sage: f(1.7)
1
sage: f("10")
10
```

A pool is used for small integers:

```python
sage: f(10) is f(10)
True
sage: f(-2) is f(-2)
True
```

This is intended for internal use by the coercion system, to facilitate fast expressions mixing ints and more complex Python types. Note that (as with all morphisms) the input is forcibly coerced to the domain `int` if it is not already of the correct type which may have undesirable results:

```python
sage: f = ZZ.coerce_map_from(int)
```

This is intended for internal use by the coercion system, to facilitate fast expressions mixing ints and more complex Python types. Note that (as with all morphisms) the input is forcibly coerced to the domain `int` if it is not already of the correct type which may have undesirable results:

```python
sage: f = ZZ.coerce_map_from(int)
```
sage: from sage.rings.integer import is_Integer

sage: is_Integer(2)
True

sage: is_Integer(2/1)
False

sage: is_Integer(int(2))
False

sage: is_Integer('5')
False

class sage.rings.integer.long_to_Z
Bases: sage.categories.morphism.Morphism

EXAMPLES:

sage: f = ZZ.coerce_map_from(int)
sage: f
Native morphism:
  From: Set of Python objects of class 'int'
  To:   Integer Ring
sage: f(1rL)
1

sage.rings.integer.make_integer(s)
Create a Sage integer from the base-32 Python string s. This is used in unpickling integers.

EXAMPLES:

sage: from sage.rings.integer import make_integer

sage: make_integer('-29')
-73

sage: make_integer(29)
Traceback (most recent call last):
  ...TypeError: expected str...Integer found

1.3 Cython wrapper for bernmm library

AUTHOR:
- David Harvey (2008-06): initial version

sage.rings.bernmm.bernmm_bern_modp(p, k)
Computes $B_k \mod p$, where $B_k$ is the k-th Bernoulli number.

If $B_k$ is not $p$-integral, returns -1.

INPUT:
- p – a prime
- k – non-negative integer

COMPLEXITY:
- Pretty much linear in $p$$p$.

EXAMPLES:
sage: from sage.rings.bernmm import bernmm_bern_modp

sage: bernoulli(0) % 5, bernmm_bern_modp(5, 0)
(1, 1)
sage: bernoulli(1) % 5, bernmm_bern_modp(5, 1)
(2, 2)
sage: bernoulli(2) % 5, bernmm_bern_modp(5, 2)
(1, 1)
sage: bernoulli(3) % 5, bernmm_bern_modp(5, 3)
(0, 0)
sage: bernoulli(4), bernmm_bern_modp(5, 4)
(-1/30, -1)
sage: bernoulli(18) % 5, bernmm_bern_modp(5, 18)
(4, 4)
sage: bernoulli(19) % 5, bernmm_bern_modp(5, 19)
(0, 0)

sage: p = 10000019; k = 1000
sage: bernoulli(k) % p
1972762
sage: bernmm_bern_modp(p, k)
1972762

sage.rings.bernmm.bernmm_bern_rat \(k, \text{num\_threads}=1\)

Computes \(k\)-th Bernoulli number using a multimodular algorithm. (Wrapper for bernmm library.)

INPUT:

- \(k\) – non-negative integer
- \text{num\_threads} – integer \(\geq 1\), number of threads to use

COMPLEXITY:

Pretty much quadratic in \(k\). See the paper “A multimodular algorithm for computing Bernoulli numbers”, David Harvey, 2008, for more details.

EXAMPLES:

sage: from sage.rings.bernmm import bernmm_bern_rat

sage: bernmm_bern_rat(0)
1
sage: bernmm_bern_rat(1)
-1/2
sage: bernmm_bern_rat(2)
1/6
sage: bernmm_bern_rat(3)

1.4 Bernoulli numbers modulo $p$

AUTHOR:
- David Harvey (2006-07-26): initial version
- David Harvey (2006-08-06): new, faster algorithm, also using faster NTL interface
- David Harvey (2007-08-31): algorithm for a single Bernoulli number mod $p$
- David Harvey (2008-06): added interface to bernmm, removed old code

sage.rings.bernoulli_mod_p.bernoulli_mod_p($p$)
Return the Bernoulli numbers $B_0, B_2, \ldots, B_{p-3}$ modulo $p$.

INPUT:
- $p$ – integer, a prime

OUTPUT:
list – Bernoulli numbers modulo $p$ as a list of integers $[B(0), B(2), \ldots, B(p-3)]$.

ALGORITHM:
Described in accompanying latex file.

PERFORMANCE:
Should be complexity $O(p \log p)$.

EXAMPLES:
Check the results against PARI’s C-library implementation (that computes exact rationals) for $p = 37$:

```
sage: bernoulli_mod_p(37)
[1, 31, 16, 15, 16, 4, 17, 32, 31, 15, 15, 17, 12, 29, 2, 0, 2]
sage: [bernoulli(n) % 37 for n in range(0, 36, 2)]
[1, 31, 16, 15, 16, 4, 17, 32, 31, 15, 15, 17, 12, 29, 2, 0, 2]
```

Boundary case:
```
sage: bernoulli_mod_p(3)
[1]
```

AUTHOR:
- David Harvey (2006-08-06)

sage.rings.bernoulli_mod_p.bernoulli_mod_p_single($p, k$)
Return the Bernoulli number $B_k$ mod $p$.

If $B_k$ is not $p$-integral, an ArithmeticError is raised.

INPUT:
- $p$ – integer, a prime
- $k$ – non-negative integer

OUTPUT:
The $k$-th Bernoulli number mod $p$.

EXAMPLES:
sage: bernoulli_mod_p_single(1009, 48)
628
sage: bernoulli(48) % 1009
628

sage: bernoulli_mod_p_single(1, 5)
Traceback (most recent call last):
... ValueError: p (=1) must be a prime >= 3
sage: bernoulli_mod_p_single(100, 4)
Traceback (most recent call last):
... ValueError: p (=100) must be a prime
sage: bernoulli_mod_p_single(19, 5)
0
sage: bernoulli_mod_p_single(19, 18)
Traceback (most recent call last):
... ArithmeticError: B_k is not integral at p
sage: bernoulli_mod_p_single(19, -4)
Traceback (most recent call last):
... ValueError: k must be non-negative

Check results against bernoulli_mod_p:

sage: bernoulli_mod_p(37)
[1, 31, 16, 15, 16, 4, 17, 32, 22, 31, 15, 15, 17, 12, 29, 2, 0, 2]
sage: [bernoulli_mod_p_single(37, n) % 37 for n in range(0, 36, 2)]
[1, 31, 16, 15, 16, 4, 17, 32, 22, 31, 15, 15, 17, 12, 29, 2, 0, 2]

sage: bernoulli_mod_p(31)
[1, 26, 1, 17, 1, 9, 11, 27, 14, 23, 13, 22, 14, 8, 14]
sage: [bernoulli_mod_p_single(31, n) % 31 for n in range(0, 30, 2)]
[1, 26, 1, 17, 1, 9, 11, 27, 14, 23, 13, 22, 14, 8, 14]

sage: bernoulli_mod_p(3)
[1]
sage: [bernoulli_mod_p_single(3, n) % 3 for n in range(0, 2, 2)]
[1]

sage: bernoulli_mod_p(5)
[1, 1]
sage: [bernoulli_mod_p_single(5, n) % 5 for n in range(0, 4, 2)]
[1, 1]

sage: bernoulli_mod_p(7)
[1, 6, 3]
sage: [bernoulli_mod_p_single(7, n) % 7 for n in range(0, 6, 2)]
[1, 6, 3]

AUTHOR:
– David Harvey (2007-08-31) – David Harvey (2008-06): rewrote to use bernmm library

1.4. Bernoulli numbers modulo p
sage.rings.bernoulli_mod_p.verify_bernoulli_mod_p(data)

Computes checksum for Bernoulli numbers.

It checks the identity
\[
\sum_{n=0}^{(p-3)/2} 2^{2n}(2n + 1)B_{2n} \equiv -2 \pmod{p}
\]
(see “Irregular Primes to One Million”, Buhler et al)

**INPUT:**
- data – list, same format as output of bernoulli_mod_p function

**OUTPUT:**
- bool – True if checksum passed

**EXAMPLES:**

```python
sage: from sage.rings.bernoulli_mod_p import verify_bernoulli_mod_p
sage: verify_bernoulli_mod_p(bernoulli_mod_p(next_prime(3)))
True
sage: verify_bernoulli_mod_p(bernoulli_mod_p(next_prime(1000)))
True
sage: verify_bernoulli_mod_p([1, 2, 4, 5, 4])
True
sage: verify_bernoulli_mod_p([1, 2, 3, 4, 5])
False
```

This one should test that long longs are working:

```
sage: verify_bernoulli_mod_p(bernoulli_mod_p(next_prime(20000)))
True
```

**AUTHOR:** David Harvey

### 1.5 Integer factorization functions

**AUTHORS:**
- Andre Apitzsch (2011-01-13): initial version

sage.rings.factorint.aurifeuillian(n, m, F=None, check=True)

Return the Aurifeuillian factors $F_n^\pm(m^2n)$.

This is based off Theorem 3 of [Bre1993].

**INPUT:**
- n – integer
- m – integer
- F – integer (default: None)
- check – boolean (default: True)

**OUTPUT:**
A list of factors.

**EXAMPLES:**
```python
sage: from sage.rings.factorint import aurifeuillian
sage: aurifeuillian(2,2)
[5, 13]
sage: aurifeuillian(2,2^5)
[1985, 2113]
sage: aurifeuillian(5,3)
[1471, 2851]
sage: aurifeuillian(15,1)
[19231, 142111]
sage: aurifeuillian(12,3)
Traceback (most recent call last):
 ... ValueError: n has to be square-free
sage: aurifeuillian(1,2)
Traceback (most recent call last):
 ... ValueError: n has to be greater than 1
sage: aurifeuillian(2,0)
Traceback (most recent call last):
 ... ValueError: m has to be positive
```

**Note:** There is no need to set $F$. It’s only for increasing speed of `factor_aurifeuillian()`.

`sage.rings.factorint.factor_aurifeuillian(n, check=True)`

Return Aurifeuillian factors of $n$ if $n = x^{(2k-1)}x ± 1$ (where the sign is ‘-‘ if $x = 1 \mod 4$, and ‘+’ otherwise) else $n$

**INPUT:**

- $n$ – integer

**OUTPUT:**

List of factors of $n$ found by Aurifeuillian factorization.

**EXAMPLES:**

```python
sage: from sage.rings.factorint import factor_aurifeuillian as fa
sage: fa(2^6+1)
[5, 13]
sage: fa(2^58+1)
[536838145, 536903681]
sage: fa(3^3+1)
[4, 1, 7]
sage: fa(5^5-1)
[4, 11, 71]
sage: prod(_) == 5^5-1
True
sage: fa(2^4+1)
[17]
sage: fa((6^2+3)^3+1)
[109, 91, 127]
```

**REFERENCES:**

- [Bre1993] Theorem 3

---

1.5. Integer factorization functions 63
sage.rings.factorint.factor_cunningham(m, proof=None)

Return factorization of self obtained using trial division for all primes in the so called Cunningham table. This is efficient if self has some factors of type $b^n + 1$ or $b^n - 1$, with $b$ in $\{2, 3, 5, 6, 7, 10, 11, 12\}$.

You need to install an optional package to use this method, this can be done with the following command line:
sage -i cunningham_tables.

**INPUT:**

- **proof** – bool (default: None); whether or not to prove primality of each factor, this is only for factors not in the Cunningham table

**EXAMPLES:**

```python
sage: from sage.rings.factorint import factor_cunningham
sage: factor_cunningham(2^257-1)
# optional - cunningham_tables
535006138814359 * 11556839524661982673033
    ←374550598501810936581776630096313181393
sage: factor_cunningham((3^101+1)*(2^60).next_prime(),proof=False)
# optional - cunningham_tables
2^2 * 379963 * 1152921504606847009 * 1017291527198723292208309354658785077827527
```

sage.rings.factorint.factor_trial_division(m, limit='LONG_MAX')

Return partial factorization of self obtained using trial division for all primes up to limit, where limit must fit in a C signed long.

**INPUT:**

- **limit** – integer (default: LONG_MAX) that fits in a C signed long

**EXAMPLES:**

```python
sage: from sage.rings.factorint import factor_trial_division
sage: n = 920384092842390423848290348203948092384082349082
sage: factor_trial_division(n, 1000)
2 * 11 * 41835640583745019265831379463815822381094652231
sage: factor_trial_division(n, 2000)
2 * 11 * 41835640583745019265831379463815822381094652231
```

sage.rings.factorint.factor_using_pari(n, int_=False, debug_level=0, proof=None)

Factor this integer using PARI.

This function returns a list of pairs, not a Factorization object. The first element of each pair is the factor, of type Integer if int_ is False or int otherwise, the second element is the positive exponent, of type int.

**INPUT:**

- **int_** – (default: False), whether the factors are of type int instead of Integer
- **debug_level** – (default: 0), debug level of the call to PARI
- **proof** – (default: None), whether the factors are required to be proven prime; if None, the global default is used

**OUTPUT:**

A list of pairs.

**EXAMPLES:**

```python
sage: factor(-2**72 + 3, algorithm='pari')  # indirect doctest
-1 * 83 * 131 * 294971519 * 1472414939
```
Check that PARI’s debug level is properly reset (trac ticket #18792):

```
sage: alarm(0.5); factor(2^1000 - 1, verbose=5)
Traceback (most recent call last):
  ...  
AlarmInterrupt
sage: pari.get_debug_level()  
0
```

1.6 Basic arithmetic with C integers

```python
class sage.rings.fast_arith.arith_int
    Bases: object
    gcd_int (a, b)
    inverse_mod_int (a, m)
    rational_recon_int (a, m)
        Rational reconstruction of a modulo m.
xgcd_int (a, b)
class sage.rings.fast_arith.arith_llong
    Bases: object
    gcd_longlong (a, b)
    inverse_mod_longlong (a, m)
    rational_recon_longlong (a, m)
        Rational reconstruction of a modulo m.
```

`sage.rings.fast_arith.prime_range (start, stop=None, algorithm='pari_primes', py_ints=False)`

Return a list of all primes between `start` and `stop - 1`, inclusive.

If the second argument is omitted, this returns the primes up to the first argument.

This function is closely related to (and can use) the primes iterator. Use algorithm "pari_primes" when both `start` and `stop` are not too large, since in all cases this function makes a table of primes up to `stop`. If both are large, use algorithm "pari_isprime" instead.

Algorithm "pari_primes" is faster for most input, but crashes for larger input. Algorithm "pari_isprime" is slower but will work for much larger input.

**INPUT:**

- `start` – integer, lower bound
- `stop` – integer, upper bound
- `algorithm` – optional string, one of:
  - "pari_primes" - Uses PARI’s `pari:primes` function. Generates all primes up to stop. Depends on PARI’s `pari:primepi` function.
  - “pari_isprime” - Uses a mod 2 wheel and PARI’s `pari:isprime` function by calling the primes iterator.
- `py_ints` – optional boolean (default False), return Python ints rather than Sage Integers (faster)

**EXAMPLES:**
AUTHORS:

- William Stein (original version)
- Craig Citro (rewrote for massive speedup)
- Kevin Stueve (added primes iterator option) 2010-10-16
- Robert Bradshaw (speedup using Pari prime table, py_ints option)

1.7 Fast decomposition of small integers into sums of squares

Implement fast version of decomposition of (small) integers into sum of squares by direct method not relying on factorisation.

AUTHORS:

- Vincent Delecroix (2014): first implementation (trac ticket #16374)

\[
sage\text{.rings.sum_of_squares}\text{.four_squares\_pyx}(n)
\]

Return a 4-tuple of non-negative integers \((i, j, k, l)\) such that \(i^2 + j^2 + k^2 + l^2 = n\) and \(i \leq j \leq k \leq l\).

The input must be lesser than \(2^{32} = 4294967296\), otherwise an \texttt{OverflowError} is raised.

See also:

\texttt{four_squares()} is much more suited for large input

EXAMPLES:

\[
sage: \text{from sage.rings.sum_of_squares import four_squares\_pyx}
sage: \text{four_squares\_pyx}(15447)
(2, 5, 17, 123)
sage: 2^2 + 5^2 + 17^2 + 123^2
\]

(continues on next page)
sage: four_squares_pyx(523439)
(3, 5, 26, 723)
sage: 3^2 + 5^2 + 26^2 + 723^2
523439
sage: four_squares_pyx(2**32)
Traceback (most recent call last):
... OverflowError: ...

sage.rings.sum_of_squares.is_sum_of_two_squares_pyx(n)
Return True if n is a sum of two squares and False otherwise.
The input must be smaller than $2^{32} = 4294967296$, otherwise an OverflowError is raised.

EXAMPLES:

sage: from sage.rings.sum_of_squares import is_sum_of_two_squares_pyx
sage: [x for x in range(30) if is_sum_of_two_squares_pyx(x)]
[0, 1, 2, 4, 5, 8, 9, 10, 13, 16, 17, 18, 20, 25, 26, 29]
sage: is_sum_of_two_squares_pyx(2**32)
Traceback (most recent call last):
... OverflowError: ...

sage.rings.sum_of_squares.three_squares_pyx(n)
If n is a sum of three squares return a 3-tuple $(i, j, k)$ of Sage integers such that $i^2 + j^2 + k^2 = n$ and $i \leq j \leq k$. Otherwise raise a ValueError.
The input must be lesser than $2^{32} = 4294967296$, otherwise an OverflowError is raised.

EXAMPLES:

sage: from sage.rings.sum_of_squares import three_squares_pyx
sage: three_squares_pyx(0)
(0, 0, 0)
sage: three_squares_pyx(1)
(0, 0, 1)
sage: three_squares_pyx(2)
(0, 1, 1)
sage: three_squares_pyx(3)
(1, 1, 1)
sage: three_squares_pyx(4)
(0, 0, 2)
sage: three_squares_pyx(5)
(0, 1, 2)
sage: three_squares_pyx(6)
(1, 1, 2)
sage: three_squares_pyx(7)
Traceback (most recent call last):
... ValueError: 7 is not a sum of 3 squares
sage: three_squares_pyx(107)
(1, 5, 9)
sage: three_squares_pyx(2**32)
Traceback (most recent call last):
...
OverflowError: ...

sage.rings.sum_of_squares.two_squares_pyx(n)
Return a pair of non-negative integers \((i, j)\) such that \(i^2 + j^2 = n\).

If \(n\) is not a sum of two squares, a ValueError is raised. The input must be lesser than \(2^{32} = 4294967296\), otherwise an OverflowError is raised.

See also:
two_squares() is much more suited for large inputs

EXAMPLES:

```
sage: from sage.rings.sum_of_squares import two_squares_pyx
sage: two_squares_pyx(0)
(0, 0)
sage: two_squares_pyx(1)
(0, 1)
sage: two_squares_pyx(2)
(1, 1)
sage: two_squares_pyx(3)
Traceback (most recent call last):
...  
ValueError: 3 is not a sum of 2 squares
sage: two_squares_pyx(106)
(5, 9)
sage: two_squares_pyx(2**32)
Traceback (most recent call last):
...  
OverflowError: ...
```

### 1.8 Fast Arithmetic Functions

sage.arith.functions.LCM_list(v)
Return the LCM of an iterable \(v\).

Elements of \(v\) are converted to Sage objects if they aren’t already.

This function is used, e.g., by lcm().

INPUT:

- \(v\) – an iterable

OUTPUT: integer

EXAMPLES:

```
sage: from sage.arith.functions import LCM_list
sage: w = LCM_list([3, 9, 30]); w
90
sage: type(w)
<type 'sage.rings.integer.Integer'>
```
The inputs are converted to Sage integers:

```
sage: w = LCM_list([int(3), int(9), int(30)]); w
90
sage: type(w)
<type 'sage.rings.integer.Integer'>
```

`sage.arith.functions.lcm(a, b=None)`
The least common multiple of a and b, or if a is a list and b is omitted the least common multiple of all elements of a.

Note that LCM is an alias for lcm.

**INPUT:**
- a, b – two elements of a ring with lcm or
- a – a list or tuple of elements of a ring with lcm

**OUTPUT:**
First, the given elements are coerced into a common parent. Then, their least common multiple in that parent is returned.

**EXAMPLES:**

```
sage: lcm(97,100)
9700
sage: LCM(97,100)
9700
sage: LCM(0,2)
0
sage: LCM(-3,-5)
15
sage: LCM([1,2,3,4,5])
60
sage: v = LCM(range(1,10000))  # *very* fast!
sage: len(str(v))
4349
```

1.9 Generic implementation of powering

This implements powering of arbitrary objects using a square-and-multiply algorithm.

`sage.arith.power.generic_power(a, n)`
Return $a^n$.

If $n$ is negative, return $(1/a)^{(-n)}$.

**INPUT:**
- a – any object supporting multiplication (and division if $n < 0$)
- n – any integer (in the duck typing sense)

**EXAMPLES:**

```
sage: from sage.arith.power import generic_power
sage: generic_power(int(12), int(0))
1
```
sage: generic_power(int(0), int(100))
0
sage: generic_power(Integer(10), Integer(0))
1
sage: generic_power(Integer(0), Integer(23))
0
sage: sum([generic_power(2,i) for i in range(17)]) #test all 4-bit combinations
131071
sage: F = Zmod(5)
sage: a = generic_power(F(2), 5); a
2
sage: a.parent() is F
True
sage: a = generic_power(F(1), 2)
sage: a.parent() is F
True
sage: generic_power(int(5), 0)
1
sage: generic_power(2, 5/4)
Traceback (most recent call last):
  ... Not ImplementedError: non-integral exponents not supported

sage: class SymbolicMul(str):
    ....:    def __mul__(self, other):
    ....:        s = "({}*{})".format(self, other)
    ....:        return type(self)(s)
sage: x = SymbolicMul("x")
sage: print(generic_power(x, 7))
((x*x)*(x*x))*(x*x)*x

1.10 Utility classes for multi-modular algorithms

class sage.arith.multi_modular.MultiModularBasis
    Bases: sage.arith.multi_modular.MultiModularBasis_base

    Class used for storing a MultiModular bases of a fixed length.

class sage.arith.multi_modular.MultiModularBasis_base
    Bases: object

    This class stores a list of machine-sized prime numbers, and can do reduction and Chinese Remainder Theorem lifting modulo these primes.

    Lifting implemented via Garner’s algorithm, which has the advantage that all reductions are word-sized. For each \( i \), precompute \( \prod_j = 1^{i-1}m_j \) and \( \prod_j = 1^{i-1}m_j^{-1}(modm_i) \).

    This class can be initialized in two ways, either with a list of prime moduli or an upper bound for the product of the prime moduli. The prime moduli are generated automatically in the second case.

    EXAMPLES:

    sage: from sage.arith.multi_modular import MultiModularBasis_base
    sage: mm = MultiModularBasis_base([3, 5, 7]); mm

MultiModularBasis with moduli [3, 5, 7]

```
sage: height = 52348798724
sage: mm = MultiModularBasis_base(height); mm
MultiModularBasis with moduli [31051, 16981, 6007]
```
```
sage: mm = MultiModularBasis_base(height); mm
MultiModularBasis with moduli [21419, 13751, 15901]
```
```
sage: mm = MultiModularBasis_base(height); mm
MultiModularBasis with moduli [14369, 31379, 10067]
```
```
sage: mm.prod()//height
86
```

```
crt (b)
```
Calculate lift mod $\prod_{i=0}^{\text{len}(b)-1} m_i$.

In the case that offset > 0, $z[j]$ remains unchanged mod $\prod_{i=0}^{\text{offset}-1} m_i$

INPUT:

- $b$ - a list of length at most self.n

OUTPUT:

Integer $z$ where $z = b[i] mod m_i$ for $0 <= i < \text{len}(b)$

EXAMPLES:

```
sage: from sage.arith.multi_modular import MultiModularBasis_base
sage: mm = MultiModularBasis_base([10007, 10009, 10037, 10039, 17351])
sage: res = mm.crt([3,5,7,9]); res
8474803647063985
sage: res % 10007
3
sage: res % 10009
5
sage: res % 10037
7
sage: res % 10039
9
```

```
extend_with_primes (plist, partial_products=None, check=True)
```
Extend the stored list of moduli with the given primes in plist.

EXAMPLES:

```
sage: from sage.arith.multi_modular import MultiModularBasis_base
sage: mm = MultiModularBasis_base([1009, 10007]); mm
MultiModularBasis with moduli [1009, 10007]
sage: mm.extend_with_primes([10037, 10039])
4
sage: mm
MultiModularBasis with moduli [1009, 10007, 10037, 10039]
```

```
list ()
```
Return a list with the prime moduli.

EXAMPLES:
sage: from sage.arith.multi_modular import MultiModularBasis_base
sage: mm = MultiModularBasis_base([46307, 10007])
sage: mm.list()
[46307, 10007]

partial_product (n)
Return a list containing precomputed partial products.

EXAMPLES:

sage: from sage.arith.multi_modular import MultiModularBasis_base
sage: mm = MultiModularBasis_base([46307, 10007]); mm
MultiModularBasis with moduli [46307, 10007]
sage: mm.partial_product(0)
46307
sage: mm.partial_product(1)
463394149

precomputation_list()
Return a list of the precomputed coefficients \( \prod_{j=1}^{i-1} m_j^{-1} (mod m_i) \) where \( m_i \) are the prime moduli.

EXAMPLES:

sage: from sage.arith.multi_modular import MultiModularBasis_base
sage: mm = MultiModularBasis_base([46307, 10007]); mm
MultiModularBasis with moduli [46307, 10007]
sage: mm.precomputation_list()
[1, 4013]

prod()
Return the product of the prime moduli.

EXAMPLES:

sage: from sage.arith.multi_modular import MultiModularBasis_base
sage: mm = MultiModularBasis_base([46307]); mm
MultiModularBasis with moduli [46307]
sage: mm.prod()
46307
sage: mm = MultiModularBasis_base([46307, 10007]); mm
MultiModularBasis with moduli [46307, 10007]
sage: mm.prod()
463394149

class sage.arith.multi_modular.MutableMultiModularBasis
Bases: sage.arith.multi_modular.MultiModularBasis

Class used for performing multi-modular methods, with the possibility of removing bad primes.

next_prime()
Pick a new random prime between the bounds given during the initialization of this object, update the
precomputed data, and return the new prime modulus.

EXAMPLES:

sage: from sage.arith.multi_modular import MultiModularBasis
sage: mm = MultiModularBasis([10007])
}
replace_prime(ix)

Replace the prime moduli at the given index with a different one, update the precomputed data accordingly, and return the new prime.

INPUT:

• ix – index into list of moduli

OUTPUT: the new prime modulus

EXAMPLES:

```
sage: from sage.arith.multi_modular import MutableMultiModularBasis
sage: mm = MutableMultiModularBasis([10007, 10009, 10037, 10039])
sage: mm
MultiModularBasis with moduli [10007, 10009, 10037, 10039]
sage: mm.prod()
10092272478850909
sage: mm.precomputation_list()
[1, 5004, 6536, 6060]
sage: mm.partial_product(2)
1005306552331
sage: mm.replace_prime(1)
31051 # 64-bit
31051L # 32-bit
sage: mm
MultiModularBasis with moduli [10007, 31051, 10037, 10039]
sage: mm.prod()
3130936870896151
sage: mm.precomputation_list()
[1, 17274, 1770, 2170]
sage: mm.partial_product(2)
3118770482209
```
See also:

- \texttt{CRT\_list()}

EXAMPLES:

Using \texttt{crt} by giving it pairs of residues and moduli:

\begin{verbatim}
sage: \texttt{crt(2, 1, 3, 5)}
11
sage: \texttt{crt(13, 20, 100, 301)}
28013
sage: \texttt{crt([2, 1], [3, 5])}
11
sage: \texttt{crt([13, 20], [100, 301])}
28013
\end{verbatim}

You can also use upper case:

\begin{verbatim}
sage: \texttt{c = CRT(2,3, 3, 5)}; c
8
sage: \texttt{c} \mod 3 == 2
True
sage: \texttt{c} \mod 5 == 3
True
\end{verbatim}

Note that this also works for polynomial rings:

\begin{verbatim}
sage: \texttt{K.<a> = NumberField(x^3 - 7)}
sage: \texttt{R.<y> = K[]}
sage: \texttt{f} = y^2 + 3
sage: \texttt{g} = y^3 - 5
sage: \texttt{CRT(1,3,f,g)}
-3/26*y^4 + 5/26*y^3 + 15/26*y + 53/26
sage: \texttt{CRT(1,a,f,g)}
(-3/52*a + 3/52)*y^4 + (5/52*a - 5/52)*y^3 + (15/52*a - 15/52)*y + 27/52*a + 25/52
\end{verbatim}

You can also do this for any number of moduli:

\begin{verbatim}
sage: \texttt{K.<a> = NumberField(x^3 - 7)}
sage: \texttt{R.<x> = K[]}
sage: \texttt{CRT([a], [x])}
a
sage: \texttt{f} = x^2 + 3
sage: \texttt{g} = x^3 - 5
sage: \texttt{h} = x^5 + x^2 - 9
sage: \texttt{k = CRT([1, a, 3], [f, g, h]); k}
(12/19988*a - 5087/386828)*x^9 + (1005/8996*a + 386828)*x^8 + (2/173*a - 6/173)*x^7 + (133/6747*a - 5373/96707)*x^6 + (-6/2249*a + 18584/290121)*x^5 + (-277/8996*a + 386828)*x^4 + (-135/4498*a + 42673/193414)*x^3 + (-1005/8996*a + 470245/1160484)*x^2 + (-1215/8996*a + 141165/386828)*x + 621/8996*a + 836445/386828
sage: \texttt{k} \mod (f)
1
sage: \texttt{k} \mod (g)
a
\end{verbatim}

(continues on next page)
If the moduli are not coprime, a solution may not exist:

\begin{verbatim}
sage: crt(4, 8, 12)
20
sage: crt(4, 6, 8, 12)
Traceback (most recent call last):
...
ValueError: No solution to crt problem since gcd(8,12) does not divide 4-6
\end{verbatim}

\begin{verbatim}
sage: import numpy
sage: from gmpy2 import mpz
\end{verbatim}
crt also work with numpy and gmpy2 numbers:

\begin{verbatim}
sage: import numpy
sage: import numpy
sage: from gmpy2 import mpz
sage: import numpy
sage: from gmpy2 import mpz
sage: import numpy
sage: from gmpy2 import mpz
sage: import numpy
sage: from gmpy2 import mpz
sage: import numpy
sage: from gmpy2 import mpz
sage: import numpy
sage: from gmpy2 import mpz
\end{verbatim}

\texttt{sage.arith.misc.CRT\_basis}(moduli)

Return a CRT basis for the given moduli.

INPUT:

- moduli - list of pairwise coprime moduli m which admit an extended Euclidean algorithm

OUTPUT:

- a list of elements \( a_i \) of the same length as \( m \) such that \( a_i \) is congruent to 1 modulo \( m_i \) and to 0 modulo \( m_j \) for \( j \neq i \).

Note: The pairwise coprimality of the input is not checked.

EXAMPLES:

\begin{verbatim}
sage: a1 = ZZ(mod(42,5))
sage: a2 = ZZ(mod(42,13))
sage: c1, c2 = CRT\_basis([5,13])
\end{verbatim}
A polynomial example:

```sage
sage: x = polygen(QQ)
sage: mods = [x, x^2 + 1, 2 + x - 3]
sage: b = CRT_basis(mods)
sage: b
[-2/3*x^3 + x^2 - 2/3*x + 1, 6/13*x^3 - x^2 + 6/13*x, 8/39*x^3 + 8/39*x]
sage: [[bi % mj for mj in mods] for bi in b]
[[1, 0, 0], [0, 1, 0], [0, 0, 1]]
```

`sage.arith.misc.CRT_list(v, moduli)`
Given a list `v` of elements and a list of corresponding moduli, find a single element that reduces to each element of `v` modulo the corresponding moduli.

**See also:**

- `crt()`

**EXAMPLES:**

```sage
sage: CRT_list([2, 3, 2], [3, 5, 7])
23
sage: x = polygen(QQ)
sage: c = CRT_list([3], [x]); c
3
sage: c.parent()
Univariate Polynomial Ring in x over Rational Field
```

It also works if the moduli are not coprime:

```sage
sage: CRT_list([32, 2, 2], [60, 90, 150])
452
```

But with non coprime moduli there is not always a solution:

```sage
sage: CRT_list([32, 2, 1], [60, 90, 150])
Traceback (most recent call last):
... ValueError: No solution to crt problem since gcd(180,150) does not divide 92-1
```

The arguments must be lists:

```sage
sage: CRT_list([1, 2, 3], "not a list")
Traceback (most recent call last):
... ValueError: Arguments to CRT_list should be lists
sage: CRT_list("not a list", [2, 3])
Traceback (most recent call last):
... ValueError: Arguments to CRT_list should be lists
```

The list of moduli must have the same length as the list of elements:
sage: CRT_list([1,2,3],[2,3,5])
23
sage: CRT_list([1,2,3],[2,3])
Traceback (most recent call last):
...  
ValueError: Arguments to CRT_list should be lists of the same length
sage: CRT_list([1,2,3],[2,3,5,7])
Traceback (most recent call last):
...  
ValueError: Arguments to CRT_list should be lists of the same length

sage.arith.misc.CRT_vectors(X, moduli)
Vector form of the Chinese Remainder Theorem: given a list of integer vectors \( v_i \) and a list of coprime moduli \( m_i \), find a vector \( w \) such that \( w = v_i \pmod{m_i} \) for all \( i \). This is more efficient than applying \( \text{CRT()} \) to each entry.

INPUT:
- \( X \) - list or tuple, consisting of lists/tuples/vectors/etc of integers of the same length
- moduli - list of \( \text{len}(X) \) moduli

OUTPUT:
- list - application of CRT componentwise.

EXAMPLES:

sage: CRT_vectors([[3,5,7],[3,5,11]], [2,3])
[3, 5, 5]
sage: CRT_vectors([vector(ZZ, [2,3,1]), Sequence([1,7,8],ZZ)], [8,9])
[10, 43, 17]

class sage.arith.misc.Euler_Phi

Bases: object

Return the value of the Euler phi function on the integer \( n \). We defined this to be the number of positive integers \( \leq n \) that are relatively prime to \( n \). Thus if \( n \leq 0 \) then \( \text{euler\_phi}(n) \) is defined and equals 0.

INPUT:
- \( n \) - an integer

EXAMPLES:

sage: euler_phi(1)
1
sage: euler_phi(2)
1
sage: euler_phi(3)
2
sage: euler_phi(12)
4
sage: euler_phi(37)
36

Notice that euler\_phi is defined to be 0 on negative numbers and 0.
We verify directly that the phi function is correct for 21.

```
sage: euler_phi(21)
12
sage: [i for i in range(21) if gcd(21,i) == 1]
[1, 2, 4, 5, 8, 10, 11, 13, 16, 17, 19, 20]
```

The length of the list of integers ‘i’ in range(n) such that the gcd(i,n) == 1 equals euler_phi(n).

```
sage: len([i for i in range(21) if gcd(21,i) == 1]) == euler_phi(21)
True
```

The phi function also has a special plotting method.

```
sage: P = plot(euler_phi, -3, 71)
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int8
sage: euler_phi(int8(37))
36
sage: from gmpy2 import mpz
sage: euler_phi(mpz(37))
36
```

AUTHORS:

- William Stein
- Alex Clemesha (2006-01-10): some examples

**plot** (*xmin=1, xmax=50, pointsize=30, rgbcolor=0, 0, 1, join=True, **kwds*)

Plot the Euler phi function.

**INPUT:**

- **xmin** - default: 1
- **xmax** - default: 50
- **pointsize** - default: 30
- **rgbcolor** - default: (0,0,1)
- **join** - default: True: whether to join the points.
- ****kwds** - passed on

**EXAMPLES:**

```
sage: from sage.arith.misc import Euler_Phi
sage: p = Euler_Phi().plot()
sage: p.ymax()
46.0
```
sage.arith.misc.GCD(a, b=None, **kwargs)

Return the greatest common divisor of \(a\) and \(b\).

If \(a\) is a list and \(b\) is omitted, return instead the greatest common divisor of all elements of \(a\).

INPUT:

- \(a, b\) – two elements of a ring with gcd or
- \(a\) – a list or tuple of elements of a ring with gcd

Additional keyword arguments are passed to the respectively called methods.

OUTPUT:

The given elements are first coerced into a common parent. Then, their greatest common divisor \(\text{in that common parent}\) is returned.

EXAMPLES:

```python
sage: GCD(97, 100)
1
sage: GCD(97*10^15, 19^20*97^2)
97
sage: GCD(2/3, 4/5)
2/15
sage: GCD([2, 4, 6, 8])
2
sage: GCD(srange(0,10000,10))  # fast !!!!
10
```

Note that to take the gcd of \(n\) elements for \(n \neq 2\) you must put the elements into a list by enclosing them in \([..]\). Before trac ticket #4988 the following wrongly returned 3 since the third parameter was just ignored:

```python
sage: gcd(3, 6, 2)
Traceback (most recent call last):
  ... TypeError: gcd() takes ...
sage: gcd([3, 6, 2])
1
```

Similarly, giving just one element (which is not a list) gives an error:

```python
sage: gcd(3)
Traceback (most recent call last):
  ... TypeError: 'sage.rings.integer.Integer' object is not iterable
```

By convention, the gcd of the empty list is (the integer) 0:

```python
sage: gcd([])
0
sage: type(gcd([]))
<type 'sage.rings.integer.Integer'>
```

class sage.arith.misc.Moebius

Bases: object

Return the value of the Möbius function of abs(n), where \(n\) is an integer.

**DEFINITION:** \(\mu(n)\) is 0 if \(n\) is not square free, and otherwise equals \((-1)^{r}\), where \(n\) has \(r\) distinct prime factors.
For simplicity, if \( n = 0 \) we define \( \mu(n) = 0 \).

**IMPLEMENTATION:** Factors or - for integers - uses the PARI C library.

**INPUT:**
- \( n \) - anything that can be factored.

**OUTPUT:** 0, 1, or -1

**EXAMPLES:**

```sage
sage: moebius(-5)
-1
sage: moebius(9)
0
sage: moebius(12)
0
sage: moebius(-35)
1
sage: moebius(-1)
1
sage: moebius(7)
-1
sage: moebius(0)  # potentially nonstandard!
0
```

The \( \text{moebius} \) function even makes sense for non-integer inputs.

```sage
sage: x = GF(7)['x'].0
sage: moebius(x+2)
-1
```

Tests with numpy and gmpy2 numbers:

```sage
sage: from numpy import int8
sage: moebius(int8(-5))
-1
sage: from gmpy2 import mpz
sage: moebius(mpz(-5))
-1
```

**plot** (\( \text{xmin}=0, \text{xmax}=50, \text{pointsize}=30, \text{rgbcolor}=(0,0,1), \text{join}=True, **kwds \))

Plot the Möbius function.

**INPUT:**
- \( \text{xmin} \) - default: 0
- \( \text{xmax} \) - default: 50
- \( \text{pointsize} \) - default: 30
- \( \text{rgbcolor} \) - default: (0,0,1)
- \( \text{join} \) - default: True; whether to join the points (very helpful in seeing their order).
- **kwds** - passed on

**EXAMPLES:**
```python
from sage.arith.misc import Moebius
p = Moebius().plot()
p.ymax()
1.0
```

**range** *(start, stop=None, step=None)*

Return the Möbius function evaluated at the given range of values, i.e., the image of the list `range(start, stop, step)` under the Möbius function.

This is much faster than directly computing all these values with a list comprehension.

**EXAMPLES:**

```python
v = moebius.range(-10, 10); v
[1, 0, 0, -1, 1, -1, 0, -1, -1, 1, 0, 1, -1, -1, 0, -1, 1, -1, 0, 0]
v == [moebius(n) for n in range(-10,10)]
True
v = moebius.range(-1000, 2000, 4)
v == [moebius(n) for n in range(-1000,2000, 4)]
True
```

class sage.arith.misc.Sigma

Return the sum of the k-th powers of the divisors of n.

**INPUT:**

- n - integer
- k - integer (default: 1)

**OUTPUT:** integer

**EXAMPLES:**

```python
sigma(5)
6
sigma(5,2)
26
```

The sigma function also has a special plotting method.

```python
P = plot(sigma, 1, 100)
```

This method also works with k-th powers.

```python
P = plot(sigma, 1, 100, k=2)
```

**AUTHORS:**

- William Stein: original implementation
- Craig Citro (2007-06-01): rewrote for huge speedup

**plot** *(xmin=1, xmax=50, k=1, pointsize=30, rgbcolor=0, 0, 1, join=True, **kwds)*

Plot the sigma (sum of k-th powers of divisors) function.

**INPUT:**

- xmin - default: 1
- xmax - default: 50
EXAMPLES:

\begin{verbatim}
sage: from sage.arith.misc import Sigma
sage: p = Sigma().plot()
\end{verbatim}

\begin{verbatim}
sage.arith.misc.XGCD(a, b)
\end{verbatim}

Return a triple \((g, s, t)\) such that \(g = s \cdot a + t \cdot b = \gcd(a, b)\).

**Note:** One exception is if \(a\) and \(b\) are not in a principal ideal domain (see Wikipedia article Principal_ideal_domain), e.g., they are both polynomials over the integers. Then this function can't in general return \((g, s, t)\) as above, since they need not exist. Instead, over the integers, we first multiply \(g\) by a divisor of the resultant of \(a/g\) and \(b/g\), up to sign.

**INPUT:**

- \(a, b\) - integers or more generally, element of a ring for which the xgcd make sense (e.g. a field or univariate polynomials).

**OUTPUT:**

- \(g, s, t\) - such that \(g = s \cdot a + t \cdot b\)

**Note:** There is no guarantee that the returned cofactors (\(s\) and \(t\)) are minimal.

**EXAMPLES:**

\begin{verbatim}
sage: xgcd(56, 44)
(4, 4, -5)
sage: 4*56 + (-5)*44
4
sage: g, a, b = xgcd(5/1, 7/1); g, a, b
(1, 3, -2)
sage: a*(5/1) + b*(7/1) == g
True
sage: x = polygen(QQ)
sage: xgcd(x^3 - 1, x^2 - 1)
(x - 1, 1, -x)
sage: K.<g> = NumberField(x^2-3)
sage: g.xgcd(g+2)
(1, 1/3*g, 0)
sage: R.<a,b> = K[]
\end{verbatim}

(continues on next page)
Here is an example of a \texttt{xgcd} for two polynomials over the integers, where the linear combination is not the gcd but the gcd multiplied by the resultant:

\begin{verbatim}
sage: R.<x> = ZZ[]
sage: gcd(2*x*(x-1), x^2)
x
sage: (2*x, -1, 2)
sage: (2*(x-1)).resultant(x)
2
\end{verbatim}

Tests with numpy and gmpy2 types:

\begin{verbatim}
sage: from numpy import int8
sage: xgcd(4,int8(8))
(4, 1, 0)
sage: xgcd(int8(4),int8(8))
(4, 1, 0)
sage: from gmpy2 import mpz
sage: xgcd(mpz(4), mpz(8))
(4, 1, 0)
sage: xgcd(4, mpz(8))
(4, 1, 0)
\end{verbatim}

\texttt{sage.arith.misc.algdep}(z, degree, known_bits=None, use_bits=None, known_digits=None, use_digits=None, height_bound=None, proof=False)

Return an irreducible polynomial of degree at most \texttt{degree} which is approximately satisfied by the number \texttt{z}.

You can specify the number of known bits or digits of \texttt{z} with \texttt{known_bits=k} or \texttt{known_digits=k}. PARI is then told to compute the result using $0.8k$ of these bits/digits. Or, you can specify the precision to use directly with \texttt{use_bits=k} or \texttt{use_digits=k}. If none of these are specified, then the precision is taken from the input value.

A height bound may be specified to indicate the maximum coefficient size of the returned polynomial; if a sufficiently small polynomial is not found, then \texttt{None} will be returned. If \texttt{proof=True} then the result is returned only if it can be proved correct (i.e. the only possible minimal polynomial satisfying the height bound, or no such polynomial exists). Otherwise a \texttt{ValueError} is raised indicating that higher precision is required.

ALGORITHM: Uses LLL for real/complex inputs, PARI C-library \texttt{algdep} command otherwise.

Note that \texttt{algebraic_dependency} is a synonym for \texttt{algdep}.

INPUT:

- \texttt{z} - real, complex, or \texttt{p}-adic number
- \texttt{degree} - an integer
- \texttt{height_bound} - an integer (default: \texttt{None}) specifying the maximum coefficient size for the returned polynomial
- \texttt{proof} - a boolean (default: \texttt{False}), requires \texttt{height_bound} to be set

EXAMPLES:
This example involves a complex number:

```
sage: z = (1/2)*(1 + RDF(sqrt(3)) * CC.0); z
0.500000000000000 + 0.866025403784439*I
sage: algdep(z, 6)
x^2 - x + 1
```

This example involves a \(p\)-adic number:

```
sage: K = Qp(3, print_mode = 'series')
sage: a = K(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2*3^19 + O(3^20)
sage: algdep(a, 1)
19*x - 7
```

These examples show the importance of proper precision control. We compute a 200-bit approximation to \(\sqrt{2}\) which is wrong in the 33\text{rd} bit:

```
sage: z = sqrt(RealField(200)(2)) + (1/2)^33
sage: p = algdep(z, 4); p
-227004321085*x^4 - 216947902586*x^3 - 99411220986*x^2 + 82234881648*x - 211871195088
sage: factor(p)
-227004321085*x^4 - 216947902586*x^3 - 99411220986*x^2 + 82234881648*x - 211871195088
sage: algdep(z, 4, known_bits=32)
x^2 - 2
sage: algdep(z, 4, known_digits=10)
x^2 - 2
sage: algdep(z, 4, use_bits=25)
x^2 - 2
sage: algdep(z, 4, use_digits=8)
x^2 - 2
```

Using the `height_bound` and `proof` parameters, we can see that \(\pi\) is not the root of an integer polynomial of degree at most 5 and coefficients bounded above by 10:

```
sage: algdep(pi.n(), 5, height_bound=10, proof=True) is None
True
```

For stronger results, we need more precision:

```
sage: algdep(pi.n(), 5, height_bound=100, proof=True) is None
Traceback (most recent call last):
  ...  
ValueError: insufficient precision for non-existence proof
sage: algdep(pi.n(200), 5, height_bound=100, proof=True) is None
True
```

(continues on next page)
```python
sage: algdep(pi.n(), 10, height_bound=10, proof=True) is None
Traceback (most recent call last):
  ... ValueError: insufficient precision for non-existence proof
sage: algdep(pi.n(200), 10, height_bound=10, proof=True) is None
True
```

We can also use `proof=True` to get positive results:

```python
sage: a = sqrt(2) + sqrt(3) + sqrt(5)
sage: algdep(a.n(), 8, height_bound=1000, proof=True)
Traceback (most recent call last):
  ... ValueError: insufficient precision for uniqueness proof
sage: f = algdep(a.n(1000), 8, height_bound=1000, proof=True); f
x^8 - 40*x^6 + 352*x^4 - 960*x^2 + 576
sage: f(a).expand()
0
```

```python
sage.arith.misc.algebraic_dependency(z, degree, known_bits=None, use_bits=None, known_digits=None, use_digits=None, height_bound=None, proof=False)
```

Return an irreducible polynomial of degree at most `degree` which is approximately satisfied by the number `z`.

You can specify the number of known bits or digits of `z` with `known_bits=k` or `known_digits=k`. PARI is then told to compute the result using $0.8k$ of these bits/digits. Or, you can specify the precision to use directly with `use_bits=k` or `use_digits=k`. If none of these are specified, then the precision is taken from the input value.

A height bound may be specified to indicate the maximum coefficient size of the returned polynomial; if a sufficiently small polynomial is not found, then `None` will be returned. If `proof=True` then the result is returned only if it can be proved correct (i.e. the only possible minimal polynomial satisfying the height bound, or no such polynomial exists). Otherwise a `ValueError` is raised indicating that higher precision is required.

**ALGORITHM:** Uses LLL for real/complex inputs, PARI C-library `algdep` command otherwise.

Note that `algebraic_dependency` is a synonym for `algdep`.

**INPUT:**

- `z` - real, complex, or $p$-adic number
- `degree` - an integer
- `height_bound` - an integer (default: `None`) specifying the maximum coefficient size for the returned polynomial
- `proof` - a boolean (default: `False`), requires `height_bound` to be set

**EXAMPLES:**

```python
sage: algdep(1.888888888888888, 1)
9*x - 17
sage: algdep(0.121212121212121, 1)
33*x - 4
sage: algdep(sqrt(2), 2)
x^2 - 2
```

This example involves a complex number:
This example involves a $p$-adic number:

```
sage: K = Qp(3, print_mode = 'series')
sage: a = K(7/19); a
1 + 2*3 + 3^2 + 3^3 + 2*3^4 + 2*3^5 + 3^8 + 2*3^9 + 3^11 + 3^12 + 2*3^15 + 2*3^16 + 3^17 + 2*3^19 + O(3^20)
sage: algdep(a, 1)
19*x - 7
```

These examples show the importance of proper precision control. We compute a 200-bit approximation to $\sqrt{2}$ which is wrong in the 33'rd bit:

```
sage: z = sqrt(RealField(200)(2)) + (1/2)^33
sage: p = algdep(z, 4); p
227004321085*x^4 - 216947902586*x^3 - 99411220986*x^2 + 82234881648*x - 211871195088
sage: factor(p)
227004321085*x^4 - 216947902586*x^3 - 99411220986*x^2 + 82234881648*x - 211871195088
sage: algdep(z, 4, known_bits=32)
x^2 - 2
sage: algdep(z, 4, known_digits=10)
x^2 - 2
sage: algdep(z, 4, use_bits=25)
x^2 - 2
sage: algdep(z, 4, use_digits=8)
x^2 - 2
```

Using the `height_bound` and `proof` parameters, we can see that $\pi$ is not the root of an integer polynomial of degree at most 5 and coefficients bounded above by 10:

```
sage: algdep(pi.n(), 5, height_bound=10, proof=True) is None
True
```

For stronger results, we need more precision:

```
sage: algdep(pi.n(), 5, height_bound=100, proof=True) is None
Traceback (most recent call last):
  ... ValueError: insufficient precision for non-existence proof
sage: algdep(pi.n(200), 5, height_bound=100, proof=True) is None
True
```

We can also use `proof=True` to get positive results:

```
sage: algdep(pi.n(), 10, height_bound=10, proof=True) is None
Traceback (most recent call last):
  ... ValueError: insufficient precision for non-existence proof
sage: algdep(pi.n(200), 10, height_bound=10, proof=True) is None
True
```

We can also use `proof=True` to get positive results:
\begin{verbatim}
  sage: a = sqrt(2) + sqrt(3) + sqrt(5)
sage: algdep(a.n(), 8, height_bound=1000, proof=True)
Traceback (most recent call last):
  ...  
ValueError: insufficient precision for uniqueness proof
sage: f = algdep(a.n(1000), 8, height_bound=1000, proof=True); f
x^8 - 40*x^6 + 352*x^4 - 960*x^2 + 576
sage: f(a).expand()
0
\end{verbatim}

```

sage.arith.misc.bernoulli \((n, \text{algorithm='default', num_threads=1})\)

Return the \(n\)-th Bernoulli number, as a rational number.

INPUT:

- \(n\) - an integer
- \text{algorithm}:
  - 'default' - use 'flint' for \(n \leq 20000\), then 'arb' for \(n \leq 300000\) and 'bernmm' for larger values (this is just a heuristic, and not guaranteed to be optimal on all hardware)
  - 'arb' - use the arb library
  - 'flint' - use the FLINT library
  - 'pari' - use the PARI C library
  - 'gap' - use GAP
  - 'gp' - use PARI/GP interpreter
  - 'magma' - use MAGMA (optional)
  - 'bernmm' - use bernmm package (a multimodular algorithm)
- \text{num_threads} - positive integer, number of threads to use (only used for bernmm algorithm)

EXAMPLES:

\begin{verbatim}
sage: bernoulli(12)
-691/2730
sage: Bernoulli(50)
495057205241079648212477525/66
\end{verbatim}

We demonstrate each of the alternative algorithms:

\begin{verbatim}
sage: bernoulli(12, algorithm='arb')
-691/2730
sage: bernoulli(12, algorithm='flint')
-691/2730
sage: bernoulli(12, algorithm='gap')
-691/2730
sage: bernoulli(12, algorithm='gp')
-691/2730
sage: bernoulli(12, algorithm='magma') # optional - magma
-691/2730
sage: bernoulli(12, algorithm='pari')
-691/2730
sage: bernoulli(12, algorithm='bernmm')
-691/2730
\end{verbatim}

(continues on next page)

1.11. Miscellaneous arithmetic functions
AUTHOR:

- David Joyner and William Stein

```
sage: bernoulli(12, algorithm='bernmm', num_threads=4)
-691/2730
```

sage.arith.misc.\texttt{binomial}(x, m, **kwds)

Return the binomial coefficient

\[
\binom{x}{m} = \frac{x(x-1) \cdots (x-m+1)}{m!}
\]

which is defined for \( m \in \mathbb{Z} \) and any \( x \). We extend this definition to include cases when \( x - m \) is an integer but \( m \) is not by

\[
\binom{x}{m} = \binom{x}{x-m}
\]

If \( m < 0 \), return 0.

INPUT:

- \( x, m \) - numbers or symbolic expressions. Either \( m \) or \( x-m \) must be an integer.

OUTPUT: number or symbolic expression (if input is symbolic)

EXAMPLES:

```
sage: from sage.arith.misc import binomial
sage: binomial(5,2)
10
sage: binomial(2,0)
1
sage: binomial(1/2, 0)
1
sage: binomial(3,-1)
0
sage: binomial(20,10)
184756
sage: binomial(-2, 5)
-6
sage: binomial(-5, -2)
0
sage: binomial(RealField()('2.5'), 2)
1.87500000000000
sage: n=var('n'); binomial(n,2)
1/2*(n - 1)*n
sage: n=var('n'); binomial(n,n)
1
sage: binomial(n,n-1)
n
sage: binomial(2^100, 2^100)
1
sage: x = polygen(ZZ)
sage: binomial(x, 3)
1/6*x^3 - 1/2*x^2 + 1/3*x
sage: binomial(x, x-3)
1/6*x^3 - 1/2*x^2 + 1/3*x
```
If \( x \in \mathbb{Z} \), there is an optional ‘algorithm’ parameter, which can be ‘mpir’ (faster for small values) or ‘pari’ (faster for large values):

```python
sage: a = binomial(100, 45, algorithm='mpir')
sage: b = binomial(100, 45, algorithm='pari')
sage: a == b
True
```

`sage.arith.misc.binomial_coefficients(n)`

Return a dictionary containing pairs \( \{(k_1, k_2) : C_{k_1 k_2}\} \) where \( C_{k_1 k_2} \) are binomial coefficients and \( n = k_1 + k_2 \).

**INPUT:**

- \( n \) - an integer

**OUTPUT:** dict

**EXAMPLES:**

```python
sage: sorted(binomial_coefficients(3).items())
[((0, 3), 1), ((1, 2), 3), ((2, 1), 3), ((3, 0), 1)]
```

Notice the coefficients above are the same as below:

```python
sage: R.<x,y> = QQ[]
sage: (x+y)^3
x^3 + 3*x^2*y + 3*x*y^2 + y^3
```

Tests with numpy and gmpy2 numbers:

```python
sage: from numpy import int8
sage: sorted(binomial_coefficients(int8(3)).items())
[((0, 3), 1), ((1, 2), 3), ((2, 1), 3), ((3, 0), 1)]
sage: from gmpy2 import mpz
sage: sorted(binomial_coefficients(mpz(3)).items())
[((0, 3), 1), ((1, 2), 3), ((2, 1), 3), ((3, 0), 1)]
```

**AUTHORS:**

- Fredrik Johansson

`sage.arith.misc.continuant(v, n=None)`

Function returns the continuant of the sequence \( v \) (list or tuple).

Definition: see Graham, Knuth and Patashnik, *Concrete Mathematics*, section 6.7: Continuants. The continuant is defined by

- \( K_0() = 1 \)
- \( K_1(x_1) = x_1 \)
- \( K_n(x_1, \ldots, x_n) = K_{n-1}(x_n, \ldots, x_{n-1})x_n + K_{n-2}(x_1, \ldots, x_{n-2}) \)

If \( n = \text{None} \) or \( n > \text{len}(v) \) the default \( n = \text{len}(v) \) is used.

**INPUT:**

- \( v \) - list or tuple of elements of a ring
- \( n \) - optional integer

**OUTPUT:** element of ring (integer, polynomial, etcetera).

**EXAMPLES:**
We verify the identity
\[ K_n(z, z, \cdots, z) = \sum_{k=0}^{n} \binom{n-k}{k} z^{n-2k} \]
for \( n = 6 \) using polynomial arithmetic:

```
sage: z = QQ['z'].0
sage: continuant((z,z,z,z,z,z,z,z,z,z,z,z,z,z,z),6)
z^6 + 5*z^4 + 6*z^2 + 1
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int8
sage: continuant([int8(1),int8(2),int8(3)])
10
sage: from gmpy2 import mpz
sage: continuant([mpz(1),mpz(2),mpz(3)])
mpz(10)
```

AUTHORS:
• Jaap Spies (2007-02-06)

sage.arith.misc.crt \( (a, b, m=\text{None}, n=\text{None}) \)
Return a solution to a Chinese Remainder Theorem problem.

INPUT:
• \( a, b \) - two residues (elements of some ring for which extended gcd is available), or two lists, one of residues and one of moduli.
• \( m, n \) - (default: None) two moduli, or None.

OUTPUT:
If \( m, n \) are not None, returns a solution \( x \) to the simultaneous congruences \( x \equiv a \pmod{m} \) and \( x \equiv b \pmod{n} \), if one exists. By the Chinese Remainder Theorem, a solution to the simultaneous congruences exists if and only if \( a \equiv b \pmod{\gcd(m, n)} \). The solution \( x \) is only well-defined modulo \( \text{lcm}(m, n) \).
If \( a \) and \( b \) are lists, returns a simultaneous solution to the congruences \( x \equiv a_i \pmod{b_i} \), if one exists.

See also:

- \( \text{CRT\_list()} \)

EXAMPLES:

Using \( \text{crt} \) by giving it pairs of residues and moduli:

```plaintext
sage: crt(2, 1, 3, 5)
11
sage: crt(13, 20, 100, 301)
28013
sage: crt([2, 1], [3, 5])
11
sage: crt([13, 20], [100, 301])
28013
```

You can also use upper case:

```plaintext
sage: c = CRT(2,3, 3, 5); c
8
sage: c % 3 == 2
True
sage: c % 5 == 3
True
```

Note that this also works for polynomial rings:

```plaintext
sage: K.<a> = NumberField(x^3 - 7)
sage: R.<y> = K[

sage: f = y^2 + 3
sage: g = y^3 - 5
sage: CRT(1,3,f,g)
-3/26*y^4 + 5/26*y^3 + 15/26*y + 53/26

sage: CRT(1,a,f,g)
(-3/52*a + 3/52)*y^4 + (5/52*a - 5/52)*y^3 + (15/52*a - 15/52)*y + 27/52*a + 25/52
```

You can also do this for any number of moduli:

```plaintext
sage: K.<a> = NumberField(x^3 - 7)
sage: R.<x> = K[

sage: f = x^2 + 3
sage: g = x^3 - 5
sage: h = x^5 + x^2 - 9
sage: k = CRT([1, a, 3], [f, g, h]); k
(127/26988*a - 5807/386828)*x^9 + (45/8996*a - 33677/1160484)*x^8 + (2/173*a - 6/

-173)*x^7 + (133/6747*a - 5373/96707)*x^6 + (-6/2249*a + 18584/290121)*x^5 + (-

-277/8996*a + 38847/386828)*x^4 + (-135/4498*a + 42673/193414)*x^3 + (-1005/

-8996*a + 470245/1160484)*x^2 + (-1215/8996*a + 141165/386828)*x + 621/8996*a +

836445/386828

sage: k.mod(f)
1
```

(continues on next page)
If the moduli are not coprime, a solution may not exist:

```
sage: crt(4,8,8,12)
20
sage: crt(4,6,8,12)
Traceback (most recent call last):
  ...  
ValueError: No solution to crt problem since gcd(8,12) does not divide 4-6
```

```
sage: x = polygen(QQ)
sage: crt(2,3,x-1,x+1)
-1/2*x + 5/2
sage: crt(2,x,x^2-1,x^3-1)
Traceback (most recent call last):
  ...  
ValueError: No solution to crt problem since gcd(x^2 - 1,x^3 - 1) does not divide 2-x
```

crt also work with numpy and gmpy2 numbers:

```
sage: import numpy
sage: crt(numpy.int8(2), numpy.int8(3), numpy.int8(7), numpy.int8(11))
58
sage: from gmpy2 import mpz
sage: crt(mpz(2), mpz(3), mpz(7), numpy.int8(11))
58
```

sage.arith.misc.dedekind_psi(N)

Return the value of the Dedekind psi function at N.

**INPUT:**

- N – a positive integer

**OUTPUT:**

an integer

The Dedekind psi function is the multiplicative function defined by

\[
\psi(n) = n \prod_{p \mid n, p \text{prime}} (1 + 1/p).
\]

See Wikipedia article Dedekind_psi_function and OEIS sequence A001615.

**EXAMPLES:**
```python
sage: from sage.arith.misc import dedekind_psi
sage: [dedekind_psi(d) for d in range(1, 12)]
[1, 3, 4, 6, 6, 12, 8, 12, 12, 18, 12]
```

```python
sage.arith.misc.dedekind_sum(p, q, algorithm='default')
```

Return the Dedekind sum $s(p,q)$ defined for integers $p, q$ as

$$s(p,q) = \sum_{i=0}^{q-1} \left( \left( \frac{i}{q} \right) \left( \frac{pi}{q} \right) \right)$$

where

$$\left( x \right) = \begin{cases} 
    x - \lfloor x \rfloor - \frac{1}{2} & \text{if } x \in \mathbb{Q} \setminus \mathbb{Z} \\
    0 & \text{if } x \in \mathbb{Z}.
\end{cases}$$

**Warning:** Caution is required as the Dedekind sum sometimes depends on the algorithm or is left undefined when $p$ and $q$ are not coprime.

**INPUT:**

- $p, q$ – integers
- algorithm – must be one of the following
  - 'default' - (default) use FLINT
  - 'flint' - use FLINT
  - 'pari' - use PARI (gives different results if $p$ and $q$ are not coprime)

**OUTPUT:** a rational number

**EXAMPLES:**

Several small values:

```python
sage: for q in range(10): print([dedekind_sum(p,q) for p in range(q+1)])
[0]
[0, 0]
[0, 0, 0]
[0, 1/18, -1/18, 0]
[0, 1/8, 0, -1/8, 0]
[0, 1/5, 0, 0, -1/5, 0]
[0, 5/18, 1/18, 0, -1/18, -5/18, 0]
[0, 5/14, 1/14, -1/14, 1/14, -1/14, -5/14, 0]
[0, 7/16, 1/8, 1/16, 0, -1/16, -1/8, -7/16, 0]
[0, 14/27, 4/27, 1/18, -4/27, 4/27, -1/18, -4/27, -14/27, 0]
```

Check relations for restricted arguments:

```python
sage: q = 23; dedekind_sum(1, q); (q-1)*(q-2)/(12*q)
77/46
77/46
sage: p, q = 100, 723 # must be coprime
sage: dedekind_sum(p, q) + dedekind_sum(q, p)
31583/86760
sage: -1/4 + (p/q + q/p + 1/(p*q))/12
31583/86760
```

### 1.11. Miscellaneous arithmetic functions
We check that evaluation works with large input:

```
sage: dedekind_sum(3^54 - 1, 2^93 + 1)
459340694971839990630374299870/29710560942849126597578981379
sage: dedekind_sum(3^54 - 1, 2^93 + 1, algorithm='pari')
459340694971839990630374299870/29710560942849126597578981379
```

We check consistency of the results:

```
sage: dedekind_sum(5, 7, algorithm='default')
-1/14
sage: dedekind_sum(5, 7, algorithm='flint')
-1/14
sage: dedekind_sum(5, 7, algorithm='pari')
-1/14
sage: dedekind_sum(6, 8, algorithm='default')
-1/8
sage: dedekind_sum(6, 8, algorithm='flint')
-1/8
sage: dedekind_sum(6, 8, algorithm='pari')
-1/8
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int8
sage: dedekind_sum(int8(5), int8(7), algorithm='default')
-1/14
sage: from gmpy2 import mpz
sage: dedekind_sum(mpz(5), mpz(7), algorithm='default')
-1/14
```

REFERENCES:

- [Ap1997]
- Wikipedia article Dedekind_sum

```
sage.arith.misc.differences(lis, n=1)
```

Return the $n$ successive differences of the elements in $lis$.

EXAMPLES:

```
sage: differences(prime_range(50))
[1, 2, 2, 4, 2, 4, 2, 4, 6, 2, 6, 4, 2, 4]
sage: differences([i^2 for i in range(1,11)])
[3, 5, 7, 9, 11, 13, 15, 17, 19]
sage: differences([i^3 + 3*i for i in range(1,21)])
[10, 22, 40, 94, 130, 172, 220, 274, 334, 400, 472, 550, 634, 724, 820, 922, ...
sage: differences([p - i^2 for i, p in enumerate(prime_range(50))], 3)
[-1, 2, -4, 4, -4, 4, 0, -6, 8, -6, 0, 4]
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int8
sage: differences([int8(1),int8(4),int8(6),int8(19)])
[3, 2, 13]
```
sage: from gmpy2 import mpz
sage: differences([mpz(1), mpz(4), mpz(6), mpz(19)])
[mpz(3), mpz(2), mpz(13)]

• Timothy Clemans (2008-03-09)

sage.arith.misc.divisors(n)
Return the list of all divisors (up to units) of this element of a unique factorization domain.

For an integer, the list of all positive integer divisors of this integer, sorted in increasing order, is returned.

INPUT:
• n - the element

EXAMPLES:
Divisors of integers:

sage: divisors(-3)
[1, 3]
sage: divisors(6)
[1, 2, 3, 6]
sage: divisors(28)
[1, 2, 4, 7, 14, 28]
sage: divisors(2^5)
[1, 2, 4, 8, 16, 32]
sage: divisors(100)
[1, 2, 4, 5, 10, 20, 25, 50, 100]
sage: divisors(1)
[1]
sage: divisors(0)
Traceback (most recent call last):
...
ValueError: n must be nonzero

sage: divisors(2^3 * 3^2 * 17)
[1, 2, 3, 4, 6, 8, 9, 12, 17, 18, 24, 34, 36, 51, 68, 72, 102, 136, 153, 204, 306, 408, 612, 1224]

This function works whenever one has unique factorization:

sage: K.<a> = QuadraticField(7)
sage: divisors(K.ideal(7))
[Fractional ideal (1), Fractional ideal (a), Fractional ideal (7)]
sage: divisors(K.ideal(3))
[Fractional ideal (1), Fractional ideal (3), Fractional ideal (-a + 2), Fractional ideal (-a - 2)]
sage: divisors(K.ideal(35))
[Fractional ideal (1), Fractional ideal (5), Fractional ideal (a), Fractional ideal (7), Fractional ideal (5*a), Fractional ideal (35)]

sage.arith.misc.eratosthenes(n)
Return a list of the primes \( \leq n \).

This is extremely slow and is for educational purposes only.

INPUT:
• n - a positive integer

1.11. Miscellaneous arithmetic functions 95
OUTPUT:

• a list of primes less than or equal to n.

EXAMPLES:

```
sage: eratosthenes(3)
[2, 3]
sage: eratosthenes(50)
[2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47]
sage: len(eratosthenes(100))
25
sage: eratosthenes(213) == prime_range(213)
True
```

```
sage.arith.misc.factor(n, proof=None, int_=False, algorithm='pari', verbose=0, **kwds)

Return the factorization of n. The result depends on the type of n. If n is an integer, returns the factorization as an object of type Factorization. If n is not an integer, n.factor(proof=proof, **kwds) gets called. See n.factor?? for more documentation in this case.

Warning: This means that applying factor to an integer result of a symbolic computation will not factor the integer, because it is considered as an element of a larger symbolic ring.

EXAMPLES:

```
sage: f(n)=n^2
sage: is_prime(f(3))
False
sage: factor(f(3))
9
```

INPUT:

• n - an nonzero integer
• proof - bool or None (default: None)
• int_ - bool (default: False) whether to return answers as Python ints
• algorithm - string
  - 'pari' - (default) use the PARI c library
  - 'kash' - use KASH computer algebra system (requires that kash be installed)
  - 'magma' - use Magma (requires magma be installed)
• verbose - integer (default: 0); PARI's debug variable is set to this; e.g., set to 4 or 8 to see lots of output during factorization.

OUTPUT:

• factorization of n

The qsieve and ecm commands give access to highly optimized implementations of algorithms for doing certain integer factorization problems. These implementations are not used by the generic factor command, which currently just calls PARI (note that PARI also implements sieve and ecm algorithms, but they are not as optimized). Thus you might consider using them instead for certain numbers.
The factorization returned is an element of the class `Factorization`; see `Factorization??` for more details, and examples below for usage. A Factorization contains both the unit factor (+1 or -1) and a sorted list of (prime, exponent) pairs.

The factorization displays in pretty-print format but it is easy to obtain access to the (prime,exponent) pairs and the unit, to recover the number from its factorization, and even to multiply two factorizations. See examples below.

**EXAMPLES:**

```
sage: factor(500)
2^2 * 5^3
sage: factor(-20)
-1 * 2^2 * 5
sage: f=factor(-20)
sage: list(f)
[(2, 2), (5, 1)]
sage: f.unit()
-1
sage: f.value()
-20
sage: factor( -next_prime(10^2) * next_prime(10^7) )
-1 * 101 * 10000019
sage: factor(-500, algorithm='kash')  # optional - kash
-1 * 2^2 * 5^3
sage: factor(-500, algorithm='magma')  # optional - magma
-1 * 2^2 * 5^3
sage: factor(0)
Traceback (most recent call last):
 ... ArithmeticError: factorization of 0 is not defined
sage: factor(1)
1
sage: factor(-1)
-1
sage: factor(2^(2^7)+1)
59649589127497217 * 5704689200685129054721
```

Sage calls PARI's `factor`, which has proof False by default. Sage has a global proof flag, set to True by default (see `sage.structure.proof.proof`, or proof.[tab]). To override the default, call this function with proof=False.

```
sage: factor(3^89-1, proof=False)
2 * 179 * 161479891519807 * 5042939439565996049162197
```

Any object which has a factor method can be factored like this:

```
sage: K.<i> = QuadraticField(-1)
sage: factor(122 - 454*i)
(-3*i - 2) * (-i - 2)^3 * (i + 1)^3 * (i + 4)
```

1.11. Miscellaneous arithmetic functions
To access the data in a factorization:

```python
sage: f = factor(420); f
2^2 * 3 * 5 * 7
sage: [x for x in f]
[(2, 2), (3, 1), (5, 1), (7, 1)]
sage: [p for p,e in f]
[2, 3, 5, 7]
sage: [e for p,e in f]
[2, 1, 1, 1]
sage: [p^e for p,e in f]
[4, 3, 5, 7]
```

We can factor Python, numpy and gmpy2 numbers:

```python
sage: factor(math.pi)
3.141592653589793
sage: import numpy
sage: factor(numpy.int8(30))
2 * 3 * 5
sage: import gmpy2
sage: factor(gmpy2.mpz(30))
2 * 3 * 5
```

`sage.arith.misc.factorial(n, algorithm='gmp')`
Compute the factorial of \( n \), which is the product \( 1 \cdot 2 \cdot 3 \cdot \cdots (n - 1) \cdot n \).

**INPUT:**
- \( n \) - an integer
- **algorithm** - string (default: ‘gmp’):
  - ‘gmp’ - use the GMP C-library factorial function
  - ‘pari’ - use PARI’s factorial function

**OUTPUT:** an integer

**EXAMPLES:**

```python
sage: from sage.arith.misc import factorial
sage: factorial(0)
1
sage: factorial(4)
24
sage: factorial(10)
3628800
sage: factorial(1) == factorial(0)
True
sage: factorial(6) == 6*5*4*3*2
True
sage: factorial(1) == factorial(0)
True
sage: factorial(71) == 71* factorial(70)
True
sage: factorial(-32)
Traceback (most recent call last):
...
ValueError: factorial -- must be nonnegative
```
Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int8
sage: factorial(int8(4))
24
sage: from gmpy2 import mpz
sage: factorial(mpz(4))
24
```

PERFORMANCE: This discussion is valid as of April 2006. All timings below are on a Pentium Core Duo 2Ghz MacBook Pro running Linux with a 2.6.16.1 kernel.

- It takes less than a minute to compute the factorial of $10^7$ using the GMP algorithm, and the factorial of $10^6$ takes less than 4 seconds.
- The GMP algorithm is faster and more memory efficient than the PARI algorithm. E.g., PARI computes $10^7$ factorial in 100 seconds on the core duo 2Ghz.
- For comparison, computation in Magma $\leq 2.12-10$ of $n!$ is best done using $\ast [1..n]$. It takes 113 seconds to compute the factorial of $10^7$ and 6 seconds to compute the factorial of $10^6$. Mathematica V5.2 compute the factorial of $10^7$ in 136 seconds and the factorial of $10^6$ in 7 seconds. (Mathematica is notably very efficient at memory usage when doing factorial calculations.)

```
sage.arith.misc.falling_factorial(x, a)
Return the falling factorial $(x)_a$.

The notation in the literature is a mess: often $(x)_a$, but there are many other notations: GKP: Concrete Mathematics uses $x^a$.

Definition: for integer $a \geq 0$ we have $x(x - 1) \cdots (x - a + 1)$. In all other cases we use the GAMMA-function:

$$\frac{\Gamma(x+1)}{\Gamma(x-a+1)}.$$ 

INPUT:

- $x$ – element of a ring
- $a$ – a non-negative integer or
- $x$ and $a$ – any numbers

OUTPUT: the falling factorial

See also:

`rising_factorial()`

EXAMPLES:

```
sage: falling_factorial(10, 3)
720
sage: falling_factorial(10, RR('3.0'))
720.000000000000
sage: falling_factorial(10, RR('3.3'))
1310.11633396601
sage: falling_factorial(10, 10)
3628800
sage: factorial(10)
3628800
sage: a = falling_factorial(1+i, I)
; a
gamma(I + 2)
sage: CC(a)
0.652965496420167 + 0.343065839816545*I
```
AUTHORS:

• Jaap Spies (2006-03-05)

`sage.arith.misc.four_squares(n)`

Write the integer \( n \) as a sum of four integer squares.

INPUT:

- \( n \) – an integer

OUTPUT: a tuple \((a, b, c, d)\) of non-negative integers such that \( n = a^2 + b^2 + c^2 + d^2 \) with \( a \leq b \leq c \leq d \).

EXAMPLES:

```python
sage: four_squares(3)
(0, 1, 1, 1)
sage: four_squares(13)
(0, 0, 2, 3)
sage: four_squares(130)
(0, 0, 3, 11)
sage: four_squares(1101011011004)
(90, 102, 1220, 1049290)
sage: four_squares(10^100-1)
(155024616290, 2612183768627, 14142135623730950488016887, ˓→99999999999999999999999999999999999999999999999999)
sage: for i in range(2^129, 2^129+10000):  # long time
....:     S = four_squares(i)
....:     assert sum(x^2 for x in S) == i
```

`sage.arith.misc.fundamental_discriminant(D)`

Return the discriminant of the quadratic extension \( K = \mathbb{Q}(\sqrt{D}) \), i.e. an integer \( d \) congruent to either 0 or 1, mod 4, and such that, at most, the only square dividing it is 4.

INPUT:

- \( D \) - an integer

OUTPUT:

- an integer, the fundamental discriminant

EXAMPLES:
Tests with numpy and gmpy2 numbers:

```python
sage: from numpy import int8
sage: fundamental_discriminant(int8(102))
408
sage: from gmpy2 import mpz
sage: fundamental_discriminant(mpz(102))
408
```

`sage.arith.misc.gauss_sum(char_value, finite_field)`
Return the Gauss sums for a general finite field.

**INPUT:**

- `char_value` – choice of multiplicative character, given by its value on the `finite_field`
  - `multiplicative_generator()`
- `finite_field` – a finite field

**OUTPUT:**

an element of the parent ring of `char_value`, that can be any field containing enough roots of unity, for example the `UniversalCyclotomicField`, `QQbar` or `ComplexField`

For a finite field $F$ of characteristic $p$, the Gauss sum associated to a multiplicative character $\chi$ (with values in a ring $K$) is defined as

$$\sum_{x \in F^\times} \chi(x) \zeta_p^{\text{Tr} x},$$

where $\zeta_p \in K$ is a primitive root of unity of order $p$ and $\text{Tr}$ is the trace map from $F$ to its prime field $F_p$.

For more info on Gauss sums, see [Wikipedia article Gauss_sum](https://en.wikipedia.org/wiki/Gauss_sum).

**Todo:** Implement general Gauss sums for an arbitrary pair `(multiplicative_character, additive_character)`

**EXAMPLES:**

```python
sage: from sage.arith.misc import gauss_sum
sage: F = GF(5); q = 5
sage: zq = UniversalCyclotomicField().zeta(q-1)
sage: L = [gauss_sum(zq**i,F) for i in range(5)]; L
[-1, E(20)^4 + E(20)^13 - E(20)^16 - E(20)^17,
 E(5) - E(5)^2 - E(5)^3 + E(5)^4,
 E(20)^4 - E(20)^13 - E(20)^16 + E(20)^17,
 -1]
sage: [g*g.conjugate() for g in L]
[1, 5, 5, 5, 1]
```

(continues on next page)
See also:

- `sage.rings.padics.misc.gauss_sum()` for a \( p \)-adic version
- `sage.modular.dirichlet.DirichletCharacter.gauss_sum()` for prime finite fields
- `sage.modular.dirichlet.DirichletCharacter.gauss_sum_numerical()` for prime finite fields

```
sage: F = GF(11**2); q = 11**2
sage: zq = UniversalCyclotomicField().zeta(q-1)
sage: g = gauss_sum(zq**4,F)
sage: g*g.conjugate()
121
```

```
sage: gcd(97,100)
1
sage: gcd(97*10^15, 19^20*97^2)
97
sage: gcd(2/3, 4/5)
2/15
sage: gcd([2,4,6,8])
2
sage: gcd(srange(0,10000,10))  # fast !
10
```

Note that to take the gcd of \( n \) elements for \( n \neq 2 \) you must put the elements into a list by enclosing them in `[]`. Before trac ticket #4988 the following wrongly returned 3 since the third parameter was just ignored:

```
sage: gcd(3, 6, 2)
Traceback (most recent call last):
...
TypeError: gcd() takes ...
sage: gcd([3, 6, 2])
1
```

Similarly, giving just one element (which is not a list) gives an error:
By convention, the gcd of the empty list is (the integer) 0:

```python
sage: gcd([])
0
sage: type(gcd([]))
<type 'sage.rings.integer.Integer'>
```

`sage.arith.misc.get_gcd(order)`
Return the fastest gcd function for integers of size no larger than order.

**EXAMPLES:**

```python
sage: sage.arith.misc.get_gcd(4000)
<built-in method gcd_int of sage.rings.fast_arith.arith_int object at ...>
sage: sage.arith.misc.get_gcd(400000)
<built-in method gcd_longlong of sage.rings.fast_arith.arith_llong object at ...>
sage: sage.arith.misc.get_gcd(4000000000)
<function gcd at ...>
```

`sage.arith.misc.get_inverse_mod(order)`
Return the fastest inverse_mod function for integers of size no larger than order.

**EXAMPLES:**

```python
sage: sage.arith.misc.get_inverse_mod(6000)
<built-in method inverse_mod_int of sage.rings.fast_arith.arith_int object at ...>
sage: sage.arith.misc.get_inverse_mod(600000)
<built-in method inverse_mod_longlong of sage.rings.fast_arith.arith_llong object at ...>
sage: sage.arith.misc.get_inverse_mod(6000000000)
<function inverse_mod at ...>
```

`sage.arith.misc.hilbert_conductor(a, b)`
This is the product of all (finite) primes where the Hilbert symbol is -1.

What is the same, this is the (reduced) discriminant of the quaternion algebra \((a, b)\) over \(\mathbb{Q}\).

**INPUT:**
- \(a, b\) – integers

**OUTPUT:**
- squarefree positive integer

**EXAMPLES:**

```python
sage: hilbert_conductor(-1, -1)
2
sage: hilbert_conductor(-1, -11)
11
sage: hilbert_conductor(-2, -5)
5
sage: hilbert_conductor(-3, -17)
17
```
Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int8
sage: hilbert_conductor(int8(-3), int8(-17))
17
sage: from gmpy2 import mpz
sage: hilbert_conductor(mpz(-3), mpz(-17))
17
```

AUTHOR:
- Gonzalo Tornaria (2009-03-02)

```
sage.arith.misc.hilbert_conductor_inverse(d)
```

Finds a pair of integers \((a, b)\) such that \(\text{hilbert_conductor}(a, b) == d\).

The quaternion algebra \((a, b)\) over \(\mathbb{Q}\) will then have (reduced) discriminant \(d\).

INPUT:
- \(d\) — square-free positive integer

OUTPUT: pair of integers

EXAMPLES:

```
sage: hilbert_conductor_inverse(2)
(-1, -1)
sage: hilbert_conductor_inverse(3)
(-1, -3)
sage: hilbert_conductor_inverse(6)
(-1, 3)
sage: hilbert_conductor_inverse(-30)
(-3, -10)
sage: hilbert_conductor_inverse(4)
Traceback (most recent call last):
  ... ValueError: d needs to be squarefree
sage: hilbert_conductor_inverse(-1)
Traceback (most recent call last):
  ... ValueError: d needs to be positive
```

AUTHOR:
- Gonzalo Tornaria (2009-03-02)

```
sage.arith.misc.hilbert_symbol(a, b, p, algorithm='pari')
```

Return 1 if \(ax^2 + by^2\) \(p\)-adically represents a nonzero square, otherwise returns \(-1\). If either \(a\) or \(b\) is 0, returns 0.

INPUT:
- \(a, b\) - integers
- \(p\) - integer; either prime or -1 (which represents the archimedean place)
- \(algorithm\) - string
  - 'pari' - (default) use the PARI C library
  - 'direct' - use a Python implementation
  - 'all' - use both PARI and direct and check that the results agree, then return the common answer
OUTCOME: integer (0, -1, or 1)

EXAMPLES:

```sage
sage: hilbert_symbol (-1, -1, -1, algorithm='all')
-1
sage: hilbert_symbol (2, 3, 5, algorithm='all')
1
sage: hilbert_symbol (4, 3, 5, algorithm='all')
1
sage: hilbert_symbol (0, 3, 5, algorithm='all')
0
sage: hilbert_symbol (-1, -1, 2, algorithm='all')
-1
sage: hilbert_symbol (1, -1, 2, algorithm='all')
1
sage: hilbert_symbol (3, -1, 2, algorithm='all')
-1
sage: hilbert_symbol(QQ(-1)/QQ(4), -1, 2) == -1
True
sage: hilbert_symbol(QQ(-1)/QQ(4), -1, 3) == 1
True
```

Tests with numpy and gmpy2 numbers:

```sage
sage: from numpy import int8
sage: hilbert_symbol(int8(2), int8(3), int8(5), algorithm='all')
1
sage: from gmpy2 import mpz
sage: hilbert_symbol(mpz(2), mpz(3), mpz(5), algorithm='all')
1
```

AUTHORS:

- William Stein and David Kohel (2006-01-05)

sage.arith.misc.integer_ceil(x)
Return the ceiling of x.

EXAMPLES:

```sage
sage: integer_ceil(5.4)
6
sage: integer_ceil(x)
Traceback (most recent call last):
... NotImplementedError: computation of ceil of x not implemented
```

Tests with numpy and gmpy2 numbers:

```sage
sage: from numpy import float32
sage: integer_ceil(float32(5.4))
6
sage: from gmpy2 import mpfr
sage: integer_ceil(mpfr(5.4))
6
```

sage.arith.misc.integer_floor(x)
Return the largest integer ≤ x.
INPUT:

- \( x \) - an object that has a floor method or is coercible to \( \text{int} \)

OUTPUT: an \( \text{Integer} \)

EXAMPLES:

```
sage: integer_floor(5.4)
5
sage: integer_floor(float(5.4))
5
sage: integer_floor(-5/2)
-3
sage: integer_floor(RDF(-5/2))
-3
sage: integer_floor(x)
Traceback (most recent call last):
  ...
NotImplementedError: computation of floor of x not implemented
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import float32
sage: integer_floor(float32(5.4))
5
sage: from gmpy2 import mpfr
sage: integer_floor(mpfr(5.4))
5
```

```
sage.arith.misc.inverse_mod(a, m)
The inverse of the ring element \( a \) modulo \( m \).

If no special inverse_mod is defined for the elements, it tries to coerce them into integers and perform the inversion there

```
sage: inverse_mod(7,1)
0
sage: inverse_mod(5,14)
3
sage: inverse_mod(3,-5)
2
```

Tests with numpy and mpz numbers:

```
sage: from numpy import int8
sage: inverse_mod(int8(5),int8(14))
3
sage: from gmpy2 import mpz
sage: inverse_mod(mpz(5),mpz(14))
3
```

```
sage.arith.misc.is_power_of_two(n)
Return whether \( n \) is a power of 2.

INPUT:

- \( n \) – integer

OUTPUT:
```
EXAMPLES:

```python
sage: is_power_of_two(1024)
    True
sage: is_power_of_two(1)
    True
sage: is_power_of_two(24)
    False
sage: is_power_of_two(0)
    False
sage: is_power_of_two(-4)
    False
```

Tests with numpy and gmpy2 numbers:

```python
sage: from numpy import int8
sage: is_power_of_two(int8(16))
    True
sage: is_power_of_two(int8(24))
    False
sage: from gmpy2 import mpz
sage: is_power_of_two(mpz(16))
    True
sage: is_power_of_two(mpz(24))
    False
```

```python
sage.arith.misc.is_prime(n)
    Return True if \( n \) is a prime number, and False otherwise.

Use a provable primality test or a strong pseudo-primality test depending on the global arithmetic proof flag.

INPUT:

- \( n \) - the object for which to determine primality

See also:

- is_pseudoprime()
- sage.rings.integer.Integer.is_prime()```

AUTHORS:

- Kevin Stueve kstueve@uw.edu (2010-01-17): delegated calculation to \( n.is_prime() \)

EXAMPLES:

```python
sage: is_prime(389)
    True
sage: is_prime(2000)
    False
sage: is_prime(2)
    True
sage: is_prime(-1)
    False
sage: is_prime(1)
    False
```

(continues on next page)
sage: is_prime(-2)
False
sage: a = 2**2048 + 981
sage: is_prime(a)  # not tested - takes ~ 1min
sage: proof.arithmetic(False)
sage: is_prime(a)  # instantaneous!
True
sage: proof.arithmetic(True)

sage.arith.misc.is_prime_power(n, get_data=False)
Test whether $n$ is a positive power of a prime number

This function simply calls the method Integer.is_prime_power() of Integers.

INPUT:

• n – an integer

• get_data – if set to True, return a pair $(p, k)$ such that this integer equals $p^k$ instead of True or $(self, 0)$ instead of False

EXAMPLES:

sage: is_prime_power(389)
True
sage: is_prime_power(2000)
False
sage: is_prime_power(2)
True
sage: is_prime_power(1024)
True
sage: is_prime_power(1024, get_data=True)
(2, 10)

The same results can be obtained with:

sage: 389.is_prime_power()
True
sage: 2000.is_prime_power()
False
sage: 2.is_prime_power()
True
sage: 1024.is_prime_power()
True
sage: 1024.is_prime_power(get_data=True)
(2, 10)

sage.arith.misc.is_pseudoprime(n)
Test whether $n$ is a pseudo-prime

The result is NOT proven correct - this is a pseudo-primality test!.

INPUT:

• n – an integer

Note: We do not consider negatives of prime numbers as prime.
EXAMPLES:

```python
sage: is_pseudoprime(389)
True
sage: is_pseudoprime(2000)
False
sage: is_pseudoprime(2)
True
sage: is_pseudoprime(-1)
False
sage: factor(-6)
-1 * 2 * 3
sage: is_pseudoprime(1)
False
sage: is_pseudoprime(-2)
False
```

`sage.arith.misc.is_pseudoprime_power(n, get_data=False)`

Test if $n$ is a power of a pseudoprime.

The result is NOT proven correct - this IS a pseudo-primality test!. Note that a prime power is a positive power of a prime number so that 1 is not a prime power.

INPUT:

- $n$ - an integer
- `get_data` - (boolean) instead of a boolean return a pair $(p, k)$ so that $n$ equals $p^k$ and $p$ is a pseudoprime or $(n, 0)$ otherwise.

EXAMPLES:

```python
sage: is_pseudoprime_power(389)
True
sage: is_pseudoprime_power(2000)
False
sage: is_pseudoprime_power(2)
True
sage: is_pseudoprime_power(1024)
True
sage: is_pseudoprime_power(-1)
False
sage: is_pseudoprime_power(1)
False
sage: is_pseudoprime_power(997^100)
True
```

Use of the `get_data` keyword:

```python
sage: is_pseudoprime_power(3^1024, get_data=True)
(3, 1024)
sage: is_pseudoprime_power(2^256, get_data=True)
(2, 256)
sage: is_pseudoprime_power(31, get_data=True)
(31, 1)
sage: is_pseudoprime_power(15, get_data=True)
(15, 0)
```

Tests with numpy and gmpy2 numbers:
sage: from numpy import int16
sage: is_pseudoprime_power(int16(1024))
True
sage: from gmpy2 import mpz
sage: is_pseudoprime_power(mpz(1024))
True

sage.arith.misc.is_square(n, root=False)
Return whether or not \( n \) is square.
If \( n \) is a square also return the square root. If \( n \) is not square, also return None.

INPUT:
- \( n \) – an integer
- root – whether or not to also return a square root (default: False)

OUTPUT:
- bool – whether or not a square
- object – (optional) an actual square if found, and None otherwise.

EXAMPLES:

sage: is_square(2)
False
sage: is_square(4)
True
sage: is_square(2.2)
True
sage: is_square(-2.2)
False
sage: is_square(CDF(-2.2))
True
sage: is_square((x-1)^2)
Traceback (most recent call last):
  ... NotImplementedError: is_square() not implemented for non numeric elements of Symbolic Ring

sage: is_square(4, True)
(True, 2)

Tests with numpy and gmpy2 numbers:

sage: from numpy import int8
sage: is_square(int8(4))
True
sage: from gmpy2 import mpz
sage: is_square(mpz(4))
True

Tests with Polynomial:

sage: R.<v> = LaurentPolynomialRing(QQ, 'v')
sage: H = IwahoriHeckeAlgebra('A3', v**2)
sage: R.<a,b,c,d> = QQ[]
sage: p = a*b + c*d*a*d*a + 5

(continues on next page)
sage: is_square(p**2)
True

sage.arith.misc.is_squarefree(n)
Test whether n is square free.

EXAMPLES:

sage: is_squarefree(100)
False
sage: is_squarefree(101)
True
sage: R = ZZ['x']
sage: x = R.gen()
sage: is_squarefree((x^2+x+1) * (x-2))
True
sage: is_squarefree((x-1)**2 * (x-3))
False
sage: O = ZZ[sqrt(-1)]
sage: I = O.gen(1)
sage: is_squarefree(I+1)
True
sage: is_squarefree(O(2))
False
sage: O(2).factor()
(-I) * (I + 1)^2

This method fails on domains which are not Unique Factorization Domains:

sage: O = ZZ[sqrt(-5)]
sage: a = O.gen(1)
sage: is_squarefree(a - 3)
Traceback (most recent call last):
  ...
ArithmeticError: non-principal ideal in factorization

Tests with numpy and gmpy2 numbers:

sage: from numpy import int8
sage: is_squarefree(int8(100))
False
sage: is_squarefree(int8(101))
True
sage: from gmpy2 import mpz
sage: is_squarefree(mpz(100))
False
sage: is_squarefree(mpz(101))
True

sage.arith.misc.jacobi_symbol(a, b)
The Jacobi symbol of integers a and b, where b is odd.

Note: The kronecker_symbol() command extends the Jacobi symbol to all integers b.
If
\[ b = p_1^{e_1} \cdots p_r^{e_r} \]
then
\[ (a|b) = (a|p_1)^{e_1} \cdots (a|p_r)^{e_r} \]
where \((a|p_j)\) are Legendre Symbols.

**INPUT:**
- a - an integer
- b - an odd integer

**EXAMPLES:**

```
sage: jacob_symbol(10, 777)
-1
sage: jacob_symbol(10, 5)
0
sage: jacob_symbol(10, 2)
Traceback (most recent call last):
...
ValueError: second input must be odd, 2 is not odd
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int16
sage: jacob_symbol(int16(10), int16(777))
-1
sage: from gmpy2 import mpz
sage: jacob_symbol(mpz(10), mpz(777))
-1
```

`sage.arith.misc.kronecker(x, y)`
The Kronecker symbol \((x|y)\).

**INPUT:**
- x – integer
- y – integer

**OUTPUT:**
- an integer

**EXAMPLES:**

```
sage: kronecker_symbol(13, 21)
-1
sage: kronecker_symbol(101, 4)
1
```

This is also available as `kronecker()`:

```
sage: kronecker(3, 5)
-1
sage: kronecker(3, 15)
0
sage: kronecker(2, 15)
```

(continues on next page)
Tests with numpy and gmpy2 numbers:

```python
sage: from numpy import int8
sage: kronecker_symbol(int8(13), int8(21))
-1
sage: from gmpy2 import mpz
sage: kronecker_symbol(mpz(13), mpz(21))
-1
```

`sage.arith.misc.kronecker_symbol(x, y)`

The Kronecker symbol \((x|y)\).

**INPUT:**
- \(x\) – integer
- \(y\) – integer

**OUTPUT:**
- an integer

**EXAMPLES:**

```python
sage: kronecker_symbol(13, 21)
-1
sage: kronecker_symbol(101, 4)
1
```

This is also available as `kronecker()`:

```python
sage: kronecker(3, 5)
-1
sage: kronecker(3, 15)
0
sage: kronecker(2, 15)
1
sage: kronecker(-2, 15)
-1
sage: kronecker(2/3, 5)
1
```

Tests with numpy and gmpy2 numbers:

```python
sage: from numpy import int8
sage: kronecker_symbol(int8(13), int8(21))
-1
sage: from gmpy2 import mpz
sage: kronecker_symbol(mpz(13), mpz(21))
-1
```

`sage.arith.misc.legendre_symbol(x, p)`

The Legendre symbol \((x|p)\), for \(p\) prime.
Note: The kronecker_symbol() command extends the Legendre symbol to composite moduli and \(p = 2\).

INPUT:
- \(x\) - integer
- \(p\) - an odd prime number

EXAMPLES:

```
sage: legendre_symbol(2,3)
-1
sage: legendre_symbol(1,3)
1
sage: legendre_symbol(1,2)
Traceback (most recent call last):
...  
ValueError: p must be odd
sage: legendre_symbol(2,15)
Traceback (most recent call last):
...  
ValueError: p must be a prime
sage: kronecker_symbol(2,15)
1
sage: legendre_symbol(2/3,7)
-1
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int8
sage: legendre_symbol(int8(2),int8(3))
-1
sage: from gmpy2 import mpz
sage: legendre_symbol(mpz(2),mpz(3))
-1
```

```
sage: from sage.arith.misc import mqrr_rational_reconstruction
sage: mqrr_rational_reconstruction(u, m, T)
Maximal Quotient Rational Reconstruction.
For research purposes only - this is pure Python, so slow.

INPUT:
- \(u\), \(m\), \(T\) - integers such that \(m > u \geq 0\), \(T > 0\).

OUTPUT:
Either integers \(n, d\) such that \(d > 0\), \(\gcd(n, d) = 1\), \(n/d = u \mod m\), and \(T \cdot d \cdot |n| < m\), or None.

Reference: Monagan, Maximal Quotient Rational Reconstruction: An Almost Optimal Algorithm for Rational Reconstruction (page 11)

This algorithm is probabilistic.

EXAMPLES:

```
sage: mqrr_rational_reconstruction(21,3100,13)
(21, 1)
```

Tests with numpy and gmpy2 numbers:
```python
sage: from numpy import int16
sage: mqrr_rational_reconstruction(int16(21), int16(3100), int16(13))
(21, 1)
sage: from gmpy2 import mpz
sage: mqrr_rational_reconstruction(mpz(21), mpz(3100), mpz(13))
(21, 1)
```

```
sage.arith.misc.multinomial(*ks)
Return the multinomial coefficient

INPUT:

- An arbitrary number of integer arguments \(k_1, \ldots, k_n\)
- An iterable (e.g. a list) of integers \([k_1, \ldots, k_n]\)

OUTPUT:

Return the integer:

\[
\binom{k_1 + \cdots + k_n}{k_1, \ldots, k_n} = \frac{(\sum_{i=1}^{n} k_i)!}{\prod_{i=1}^{n} k_i!} = \prod_{i=1}^{n} \binom{\sum_{j=1}^{i} k_j}{k_i}
\]

EXAMPLES:

```python
sage: multinomial(0, 0, 2, 1, 0, 0)
3
sage: multinomial([0, 0, 2, 1, 0, 0])
3
sage: multinomial(3, 2)
10
sage: multinomial(2^30, 2, 1)
618970023101454657175683075
sage: multinomial([2^30, 2, 1])
618970023101454657175683075
sage: multinomial(Composition([1, 3]))
4
sage: multinomial(Partition([4, 2]))
15
```

Tests with numpy and gmpy2 numbers:

```python
sage: from numpy import int8
sage: multinomial(int8(3), int8(2))
10
sage: from gmpy2 import mpz
sage: multinomial(mpz(3), mpz(2))
mpz(10)
```

AUTHORS:

- Gabriel Ebner

```
sage.arith.misc.multinomial_coefficients(m, n)
Return a dictionary containing pairs \{\((k_1, k_2, \ldots, k_m) : C_{k,n}\)\} where \(C_{k,n}\) are multinomial coefficients such that \(n = k_1 + k_2 + \ldots + k_m\).

INPUT:

- \(m\) - integer
```
• \( n \) - integer

OUTPUT: dict

EXAMPLES:

```python
sage: sorted(multinomial_coefficients(2, 5).items())
[((0, 5), 1), ((1, 4), 5), ((2, 3), 10), ((3, 2), 10), ((4, 1), 5), ((5, 0), 1)]
```

Notice that these are the coefficients of \((x + y)^5\):

```python
sage: R.<x,y> = QQ[]
sage: (x+y)^5
x^5 + 5*x^4*y + 10*x^3*y^2 + 10*x^2*y^3 + 5*x*y^4 + y^5
```

```python
sage: sorted(multinomial_coefficients(3, 2).items())
[((0, 0, 2), 1), ((0, 1, 1), 2), ((0, 2, 0), 1), ((1, 0, 1), 2), ((1, 1, 0), 2), ((2, 0, 0), 1)]
```

ALGORITHM: The algorithm we implement for computing the multinomial coefficients is based on the following result:

\[
\binom{n}{k_1, \ldots, k_m} = \frac{k_1 + 1}{n - k_1} \sum_{i=2}^{m} \binom{n}{k_1 + 1, \ldots, k_i - 1, \ldots}
\]

e.g.:

```python
sage: k = (2, 4, 1, 0, 2, 6, 0, 0, 3, 5, 7, 1) # random value
sage: n = sum(k)
sage: s = 0
sage: for i in range(1, len(k)):
    ..:            ki = list(k)
    ..:            ki[0] += 1
    ..:            ki[i] -= 1
    ..:            s += multinomial(n, *ki)
sage: multinomial(n, *k) == (k[0] + 1) / (n - k[0]) * s
True
```

sage.arith.misc.next_prime \((n, proof=None)\)

The next prime greater than the integer \( n \). If \( n \) is prime, then this function does not return \( n \), but the next prime after \( n \). If the optional argument proof is False, this function only returns a pseudo-prime, as defined by the PARI nextprime function. If it is None, uses the global default (see sage.structure.proof.proof)

INPUT:

• \( n \) - integer

• \( proof \) - bool or None (default: None)

EXAMPLES:

```python
sage: next_prime(-100)
2
sage: next_prime(1)
2
sage: next_prime(2)
3
sage: next_prime(3)
5
```
Notice that the next_prime(5) is not 5 but 7.

sage: next_prime(5)
7
2011

sage.arith.misc.next_prime_power(n)
Return the smallest prime power greater than n.

Note that if n is a prime power, then this function does not return n, but the next prime power after n.

This function just calls the method Integer.next_prime_power() of Integers.

See also:

• is_prime_power() (and Integer.is_prime_power())
• previous_prime_power() (and Integer.previous_prime_power())

EXAMPLES:

sage: next_prime_power(1)
2
sage: next_prime_power(2)
3
sage: next_prime_power(10)
11
sage: next_prime_power(7)
8
sage: next_prime_power(99)
101

The same results can be obtained with:

sage: 1.next_prime_power()
2
sage: 2.next_prime_power()
3
sage: 10.next_prime_power()
11

Note that 2 is the smallest prime power:

sage: next_prime_power(-10)
2
sage: next_prime_power(0)
2

sage.arith.misc.next_probable_prime(n)
Return the next probable prime after self, as determined by PARI.

INPUT:

• n - an integer
EXAMPLES:

```
sage: next_probable_prime(-100)
2
sage: next_probable_prime(19)
23
sage: next_probable_prime(int(999999999))
1000000007
sage: next_probable_prime(2^768)
1552518092300708935148979488462502555256886017116696611139052038026050952686376886330878408828644
```
sage: number_of_divisors(mpz(100))
9

\texttt{sage.arith.misc.odd\_part}(n)
The odd part of the integer \(n\). This is \(n/2^v\), where \(v = \text{valuation}(n, 2)\).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: odd_part(5)
5
sage: odd_part(4)
1
sage: odd_part(factorial(31))
122529844256906551386796875
\end{verbatim}

Tests with numpy and gmpy2 numbers:

\begin{verbatim}
sage: from numpy import int8
sage: odd_part(int8(5))
5
sage: from gmpy2 import mpz
sage: odd_part(mpz(5))
5
\end{verbatim}

\texttt{sage.arith.misc.power\_mod}(a, n, m)
Return the \(n\)-th power of \(a\) modulo the integer \(m\).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: power_mod(0,0,5)
Traceback (most recent call last):
...
ArithmeticError: 0^0 is undefined.
sage: power_mod(2,390,391)
285
sage: power_mod(2,-1,7)
4
sage: power_mod(11,1,7)
4
sage: R.<x> = ZZ[]
sage: power_mod(3*x, 10, 7)
4*x^10
sage: power_mod(11,1,0)
Traceback (most recent call last):
...
ZeroDivisionError: modulus must be nonzero.
\end{verbatim}

Tests with numpy and gmpy2 numbers:

\begin{verbatim}
sage: from numpy import int32
sage: power_mod(int32(2),int32(390),int32(391))
285
sage: from gmpy2 import mpz
sage: power_mod(mpz(2),mpz(390),mpz(391))
mpz(285)
\end{verbatim}
sage.arith.misc.\texttt{previous\_prime} (n)

The largest prime < n. The result is provably correct. If \( n \leq 1 \), this function raises a ValueError.

\textbf{EXAMPLES:}

```
sage: previous_prime(10)
7
sage: previous_prime(7)
5
sage: previous_prime(8)
7
sage: previous_prime(7)
5
sage: previous_prime(5)
3
sage: previous_prime(3)
2
sage: previous_prime(2)
Traceback (most recent call last):
  ... ValueError: no previous prime
sage: previous_prime(1)
Traceback (most recent call last):
  ... ValueError: no previous prime
sage: previous_prime(-20)
Traceback (most recent call last):
  ... ValueError: no previous prime
```

sage.arith.misc.\texttt{previous\_prime\_power} (n)

Return the largest prime power smaller than n.

The result is provably correct. If \( n \) is smaller or equal than 2 this function raises an error.

This function simply call the method \texttt{Integer.previous\_prime\_power()} of Integers.

\textbf{See also:}

- \texttt{is\_prime\_power()} (and \texttt{Integer.is\_prime\_power()})
- \texttt{next\_prime\_power()} (and \texttt{Integer.next\_prime\_power()})

\textbf{EXAMPLES:}

```
sage: previous_prime_power(3)
2
sage: previous_prime_power(10)
9
sage: previous_prime_power(7)
5
sage: previous_prime_power(127)
125
```

The same results can be obtained with:

```
sage: 3.previous_prime_power()
2
sage: 10.previous_prime_power()
```
sage: 7.previous_prime_power()
sage: 127.previous_prime_power()

Input less than or equal to 2 raises errors:

sage: previous_prime_power(2)
Traceback (most recent call last):
...
ValueError: no prime power less than 2

sage: previous_prime_power(-10)
Traceback (most recent call last):
...
ValueError: no prime power less than 2

sage: n = previous_prime_power(2^16 - 1)
sage: while is_prime(n):
....:
    n = previous_prime_power(n)
sage: factor(n)
251^2

\texttt{sage.arith.misc.prime\_divisors}(n)

Return the list of prime divisors (up to units) of this element of a unique factorization domain.

INPUT:

\begin{itemize}
\item n – any object which can be decomposed into prime factors
\end{itemize}

OUTPUT:

A list of prime factors of \( n \). For integers, this list is sorted in increasing order.

EXAMPLES:

Prime divisors of positive integers:

sage: prime_divisors(1)
[]
sage: prime_divisors(100)
[2, 5]
[2, 3, 167]

If \( n \) is negative, we do \textit{not} include -1 among the prime divisors, since -1 is not a prime number:

sage: prime_divisors(-100)
[2, 5]

For polynomials we get all irreducible factors:

sage: R.<x> = PolynomialRing(QQ)
sage: prime_divisors(x^12 - 1)
[x - 1, x + 1, x^2 - x + 1, x^2 + 1, x^2 + x + 1, x^4 - x^2 + 1]

Tests with numpy and gmpy2 numbers:
sage: from numpy import int8
sage: prime_divisors(int8(-100))
[2, 5]
sage: from gmpy2 import mpz
sage: prime_divisors(mpz(-100))
[2, 5]

sage.arith.misc.prime_factors(n)
Return the list of prime divisors (up to units) of this element of a unique factorization domain.

INPUT:

• n – any object which can be decomposed into prime factors

OUTPUT:
A list of prime factors of n. For integers, this list is sorted in increasing order.

EXAMPLES:
Prime divisors of positive integers:

sage: prime_divisors(1)
[]
sage: prime_divisors(100)
[2, 5]
[2, 3, 167]

If n is negative, we do not include -1 among the prime divisors, since -1 is not a prime number:

sage: prime_divisors(-100)
[2, 5]

For polynomials we get all irreducible factors:

sage: R.<x> = PolynomialRing(QQ)
sage: prime_divisors(x^12 - 1)
[x - 1, x + 1, x^2 - x + 1, x^2 + 1, x^2 + x + 1, x^4 - x^2 + 1]

Tests with numpy and gmpy2 numbers:

sage: from numpy import int8
sage: prime_divisors(int8(-100))
[2, 5]
sage: from gmpy2 import mpz
sage: prime_divisors(mpz(-100))
[2, 5]

sage.arith.misc.prime_powers(start, stop=None)
List of all positive primes powers between start and stop-1, inclusive. If the second argument is omitted, returns the prime powers up to the first argument.

INPUT:

• start - an integer. If two inputs are given, a lower bound for the returned set of prime powers. If this is the only input, then it is an upper bound.
• stop - an integer (default: None). An upper bound for the returned set of prime powers.
OUTPUT:
The set of all prime powers between start and stop or, if only one argument is passed, the set of all prime powers between 1 and start. The number \( n \) is a prime power if \( n = p^k \), where \( p \) is a prime number and \( k \) is a positive integer. Thus, 1 is not a prime power.

EXAMPLES:

```
sage: prime_powers(20)
[2, 3, 4, 5, 7, 8, 9, 11, 13, 16, 17, 19]
sage: len(prime_powers(1000))
193
sage: len(prime_range(1000))
168

sage: a = [z for z in range(95,1234) if is_prime_power(z)]
sage: b = prime_powers(95,1234)
sage: len(b)
194
sage: len(a)
194
sage: a[:10]
[97, 101, 103, 107, 109, 113, 121, 125, 127, 128]
sage: b[:10]
[97, 101, 103, 107, 109, 113, 121, 125, 127, 128]
sage: a == b
True
sage: prime_powers(100) == [i for i in range(100) if is_prime_power(i)]
True
sage: prime_powers(10,7)
[]
sage: prime_powers(-5)
[]
sage: prime_powers(-1,3)
[2]
```

```
sage.arith.misc.prime_to_m_part(n, m)
Return the prime-to-m part of \( n \).
This is the largest divisor of \( n \) that is coprime to \( m \).

INPUT:

- \( n \) – Integer (nonzero)
- \( m \) – Integer

OUTPUT: Integer

EXAMPLES:

```
sage: prime_to_m_part(240,2)
15
sage: prime_to_m_part(240,3)
80
sage: prime_to_m_part(240,5)
48
sage: prime_to_m_part(43434,20)
21717
```
```
Note that integers also have a method with the same name:

```
sage: 240.prime_to_m_part(2)
15
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int16
sage: prime_to_m_part(int16(240), int16(2))
15
sage: from gmpy2 import mpz
sage: prime_to_m_part(mpz(240), mpz(2))
15
```

```
sage.arith.misc.primes(start, stop=None, proof=None)
Return an iterator over all primes between start and stop-1, inclusive. This is much slower than prime_range, but potentially uses less memory. As with next_prime(), the optional argument proof controls whether the numbers returned are guaranteed to be prime or not.

This command is like the Python 2 xrange command, except it only iterates over primes. In some cases it is better to use primes than prime_range, because primes does not build a list of all primes in the range in memory all at once. However, it is potentially much slower since it simply calls the next_prime() function repeatedly, and next_prime() is slow.

**INPUT:**

- `start` - an integer - lower bound for the primes
- `stop` - an integer (or infinity) optional argument - giving upper (open) bound for the primes
- `proof` - bool or None (default: None) If True, the function yields only proven primes. If False, the function uses a pseudo-primality test, which is much faster for really big numbers but does not provide a proof of primality. If None, uses the global default (see sage.structure.proof.proof)

**OUTPUT:**

- an iterator over primes from start to stop-1, inclusive

**EXAMPLES:**

```
sage: for p in primes(5,10):
    ....:     print(p)
5
7
```

```
sage: list(primes(13))
[2, 3, 5, 7, 11]
sage: list(primes(10000000000, 10000000100))
[10000000019, 10000000033, 10000000061, 10000000069, 10000000097]
sage: max(primes(10^100, 10^100+10^4, proof=False))
10000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000000009631
sage: next(p for p in primes(10^20, infinity) if is_prime(2*p+1))
100000000000000001243
```

```
sage.arith.misc.primes_first_n(n, leave pari=False)
Return the first \( n \) primes.

**INPUT:**

- `n` - a nonnegative integer

**OUTPUT:**

```
• a list of the first \( n \) prime numbers.

EXAMPLES:

```
sage: primes_first_n(10)
[2, 3, 5, 7, 11, 13, 17, 19, 23, 29]
sage: len(primes_first_n(1000))
1000
sage: primes_first_n(0)
[]
```

```
sage.arith.misc.primitive_root(n, check=True)
Return a positive integer that generates the multiplicative group of integers modulo \( n \), if one exists; otherwise, raise a ValueError.

A primitive root exists if \( n = 4 \) or \( n = p^k \) or \( n = 2p^k \), where \( p \) is an odd prime and \( k \) is a nonnegative number.

INPUT:

• \( n \) – a non-zero integer

• check – bool (default: True); if False, then \( n \) is assumed to be a positive integer possessing a primitive root, and behavior is undefined otherwise.

OUTPUT:

A primitive root of \( n \). If \( n \) is prime, this is the smallest primitive root.

EXAMPLES:

```
sage: primitive_root(23)
5
sage: primitive_root(-46)
5
sage: primitive_root(25)
2
sage: print([primitive_root(p) for p in primes(100)])
[1, 2, 3, 2, 2, 3, 2, 5, 2, 3, 2, 6, 3, 5, 2, 2, 2, 2, 7, 5, 3, 2, 3, 5]
sage: primitive_root(8)
Traceback (most recent call last):
... ValueError: no primitive root
```

**Note:** It takes extra work to check if \( n \) has a primitive root; to avoid this, use check=False, which may slightly speed things up (but could also result in undefined behavior). For example, the second call below is an order of magnitude faster than the first:

```
sage: n = 10^50 + 151  # a prime
sage: primitive_root(n)
11
sage: primitive_root(n, check=False)
11
```

```
sage.arith.misc.quadratic_residues(n)
Return a sorted list of all squares modulo the integer \( n \) in the range \( 0 \leq x < |n| \).

EXAMPLES:
```
sage: quadratic_residues(11)
[0, 1, 3, 4, 5, 9]
sage: quadratic_residues(1)
[0]
sage: quadratic_residues(2)
[0, 1]
sage: quadratic_residues(8)
[0, 1, 4]
sage: quadratic_residues(-10)
[0, 1, 4, 5, 6, 9]
sage: v = quadratic_residues(1000); len(v)
159

Tests with numpy and gmpy2 numbers:

sage: from numpy import int8
sage: quadratic_residues(int8(11))
[0, 1, 3, 4, 5, 9]
sage: from gmpy2 import mpz
sage: quadratic_residues(mpz(11))
[0, 1, 3, 4, 5, 9]

sage.arith.misc.radical(n, *args, **kwds)
Return the product of the prime divisors of n.
This calls n.radical(*args, **kwds).

EXAMPLES:

sage: radical(2 * 3^2 * 5^5)
30
sage: radical(0)
Traceback (most recent call last):
...
ArithmeticError: Radical of 0 not defined.
sage: K.<i> = QuadraticField(-1)
sage: radical(K(2))
i + 1

Tests with numpy and gmpy2 numbers:

sage: from numpy import int8
sage: radical(int8(50))
10
sage: from gmpy2 import mpz
sage: radical(mpz(50))
10

sage.arith.misc.random_prime(n, proof=None, lbound=2)
Return a random prime p between lbound and n.
The returned prime p satisfies lbound ≤ p ≤ n.
The returned prime p is chosen uniformly at random from the set of prime numbers less than or equal to n.

INPUT:
• n - an integer >= 2.
• proof - bool or None (default: None) If False, the function uses a pseudo-primality test, which is much faster for really big numbers but does not provide a proof of primality. If None, uses the global default (see sage.structure.proof.proof)

• lbound - an integer >= 2, lower bound for the chosen primes

EXAMPLES:

```
sage: random_prime(100000)
30029
sage: random_prime(2)
2
```

Here we generate a random prime between 100 and 200:

```
sage: random_prime(200, lbound=100)
167
```

If all we care about is finding a pseudo prime, then we can pass in proof=False

```
sage: random_prime(200, proof=False, lbound=100)
197
```

`sage.arith.misc.rational_reconstruction(a, m, algorithm='fast')`

This function tries to compute \( x/y \), where \( x/y \) is a rational number in lowest terms such that the reduction of \( x/y \) modulo \( m \) is equal to \( a \) and the absolute values of \( x \) and \( y \) are both \( \leq \sqrt{m}/2 \). If such \( x/y \) exists, that pair is unique and this function returns it. If no such pair exists, this function raises ZeroDivisionError.

An efficient algorithm for computing rational reconstruction is very similar to the extended Euclidean algorithm. For more details, see Knuth, Vol 2, 3rd ed, pages 656-657.

INPUT:

• \( a \) – an integer
• \( m \) – a modulus
• \( \text{algorithm} \) – (default: ‘fast’)
  • ‘fast’ - a fast implementation using direct MPIR calls in Cython.

OUTPUT:

Numerator and denominator \( n, d \) of the unique rational number \( r = n/d \), if it exists, with \( n \) and \( |d| \leq \sqrt{N}/2 \). Return \((0, 0)\) if no such number exists.

The algorithm for rational reconstruction is described (with a complete nontrivial proof) on pages 656-657 of Knuth, Vol 2, 3rd ed. as the solution to exercise 51 on page 379. See in particular the conclusion paragraph right in the middle of page 657, which describes the algorithm thus:

This discussion proves that the problem can be solved efficiently by applying Algorithm 4.5.2X with \( u = m \) and \( v = a \), but with the following replacement for step X2: If \( v^3 \leq \sqrt{m}/2 \), the algorithm terminates. The pair \((x, y) = (|v^2|, v^3 * \text{sign}(v^2))\) is then the unique solution, provided that \( x \) and \( y \) are coprime and \( x \leq \sqrt{m}/2 \); otherwise there is no solution. (Alg 4.5.2X is the extended Euclidean algorithm.)
Knuth remarks that this algorithm is due to Wang, Kornerup, and Gregory from around 1983.

EXAMPLES:

```python
sage: m = 100000
sage: (119*inverse_mod(53,m))%m
11323
sage: rational_reconstruction(11323,m)
119/53
sage: rational_reconstruction(400,1000)
Traceback (most recent call last):
  ... ArithmeticError: rational reconstruction of 400 (mod 1000) does not exist
sage: rational_reconstruction(3, 292393)
3
sage: a = Integers(292393)(45/97); a
204977
sage: rational_reconstruction(a, 292393, algorithm='fast')
45/97
sage: rational_reconstruction(293048, 292393)
Traceback (most recent call last):
  ... ArithmeticError: rational reconstruction of 655 (mod 292393) does not exist
sage: rational_reconstruction(0, 0)
Traceback (most recent call last):
  ... ZeroDivisionError: rational reconstruction with zero modulus
sage: rational_reconstruction(0, 1, algorithm="foobar")
Traceback (most recent call last):
  ... ValueError: unknown algorithm 'foobar'
```

Tests with numpy and gmpy2 numbers:

```python
sage: from numpy import int32
sage: rational_reconstruction(int32(3), int32(292393))
3
sage: from gmpy2 import mpz
sage: rational_reconstruction(mpz(3), mpz(292393))
3
```

```
sage.arith.misc.rising_factorial(x, a)
Return the rising factorial \((x)\).

The notation in the literature is a mess: often \((x)^n\), but there are many other notations: GKP: Concrete Mathematics uses \(x^n\).

The rising factorial is also known as the Pochhammer symbol, see Maple and Mathematica.

Definition: for integer \(a \geq 0\) we have \(x(x+1) \cdots (x+a-1)\). In all other cases we use the GAMMA-function: \(\Gamma(x+a)/\Gamma(x)\).

**INPUT:**

- \(x\) – element of a ring
- \(a\) – a non-negative integer or
```
* x and a – any numbers

**OUTPUT:** the rising factorial

**See also:**

`falling_factorial()`

**EXAMPLES:**

```sage
rising_factorial(10, 3)
1320
```

```sage
rising_factorial(10, RR('3.0'))
1320.00000000000
```

```sage
rising_factorial(10, RR('3.3'))
2826.38895824964
```

```sage
a = rising_factorial(1+I, I); a
```

```
gamma(2*I + 1)/gamma(I + 1)
```

```sage
CC(a)
```

```
0.266816390637832 + 0.122783354006372*I
```

```sage
a = rising_factorial(I, 4); a
```

```
-10
```

```sage
x = polygen(ZZ)
```

```sage
rising_factorial(x, 4)
```

```
x^4 + 6*x^3 + 11*x^2 + 6*x
```

**AUTHORS:**

- Jaap Spies (2006-03-05)

`sage.arith.misc.sort_complex_numbers_for_display(nums)`

Given a list of complex numbers (or a list of tuples, where the first element of each tuple is a complex number), we sort the list in a "pretty" order. First come the real numbers (with zero imaginary part), then the complex numbers sorted according to their real part. If two complex numbers have the same real part, then they are sorted according to their imaginary part.

This is not a useful function mathematically (not least because there is no principled way to determine whether the real components should be treated as equal or not). It is called by various polynomial root-finders; its purpose is to make doctest printing more reproducible.

We deliberately choose a cumbersome name for this function to discourage use, since it is mathematically meaningless.

**EXAMPLES:**

```sage
import sage.arith.misc
```

```sage
sort_c = sort_complex_numbers_for_display
```

```sage
ums = [CDF(i) for i in range(3)]
```

```sage
for i in range(3):
    ....:     nums.append(CDF(i + RDF.random_element(-3e-11, 3e-11),
    ....:                        RDF.random_element()))
```

```sage
shuffle(nums)
```

```
[1.0000000000138833 - 0.7238965893336062*I, 1.9999999999869107 + 0.
˓→6090836283134269*I, 0.9999999999760288 - 0.7238965893336062*I, 1.
˓→9999999999874383 - 0.4560801012073723*I, 1.266816390637832 + 0.1227833
˓→54006372\*I, 0.266816390637832 + 0.122783354006372*I, 0.9999999999760288
˓→ - 0.7238965893336062*I, 1.0000000000138833 - 0.7238965893336062*I]
```

---

1.11. Miscellaneous arithmetic functions

129
sage.arith.misc.squarefree_divisors(x)
Return an iterator over the squarefree divisors (up to units) of this ring element.

Depends on the output of the prime_divisors function.
Squarefree divisors of an integer are not necessarily yielded in increasing order.

INPUT:

• x – an element of any ring for which the prime_divisors function works.

EXAMPLES:
Integers with few prime divisors:

```
sage: list(squarefree_divisors(7))
[1, 7]
sage: list(squarefree_divisors(6))
[1, 2, 3, 6]
sage: list(squarefree_divisors(12))
[1, 2, 3, 6]
```

Squarefree divisors are not yielded in increasing order:

```
sage: list(squarefree_divisors(30))
[1, 2, 3, 6, 5, 10, 15, 30]
```

sage.arith.misc.subfactorial(n)
Subfactorial or rencontres numbers, or derangements: number of permutations of \(n\) elements with no fixed points.

INPUT:

• \(n\) - non negative integer

OUTPUT:

• integer - function value

EXAMPLES:

```
sage: subfactorial(0)
1
sage: subfactorial(1)
0
sage: subfactorial(8)
14833
```

Tests with numpy and gmpy2 numbers:

```
sage: from numpy import int8
sage: subfactorial(int8(8))
14833
sage: from gmpy2 import mpz
sage: subfactorial(mpz(8))
14833
```

AUTHORS:

• Jaap Spies (2007-01-23)
Write the integer \( n \) as a sum of \( k \) integer squares if possible; otherwise raise a `ValueError`.

**INPUT:**
- \( k \) – a non-negative integer
- \( n \) – an integer

**OUTPUT:** a tuple \((x_1, \ldots, x_k)\) of non-negative integers such that their squares sum to \( n \).

**EXAMPLES:**

```python
sage: sum_of_k_squares(2, 9634)
(15, 97)
sage: sum_of_k_squares(3, 9634)
(0, 15, 97)
sage: sum_of_k_squares(4, 9634)
(1, 2, 5, 98)
sage: sum_of_k_squares(5, 9634)
(0, 1, 2, 5, 98)
sage: sum_of_k_squares(6, 11^1111-1)
(19215400822645944253860920437586326284, 37204645194585992174252915693267578306,

sage: sum_of_k_squares(1, -10)
Traceback (most recent call last):
  ... ValueError: -10 is not a sum of 1 square
sage: sum_of_k_squares(0, 9)
Traceback (most recent call last):
  ... ValueError: 9 is not a sum of 0 squares
sage: sum_of_k_squares(0, 0)
()
sage: sum_of_k_squares(7, -1)
Traceback (most recent call last):
  ... ValueError: -1 is not a sum of 7 squares
sage: sum_of_k_squares(-1, 0)
Traceback (most recent call last):
  ... ValueError: k = -1 must be non-negative
```

Tests with numpy and gmpy2 numbers:
sage: from numpy import int16
sage: sum_of_k_squares(int16(2), int16(9634))
(15, 97)

sage: from gmpy2 import mpz
sage: sum_of_k_squares(mpz(2), mpz(9634))
(15, 97)

sage.arith.misc.three_squares(n)

Write the integer \( n \) as a sum of three integer squares if possible; otherwise raise a ValueError.

INPUT:

• \( n \) – an integer

OUTPUT: a tuple \((a, b, c)\) of non-negative integers such that \( n = a^2 + b^2 + c^2 \) with \( a \leq b \leq c \).

EXAMPLES:

sage: three_squares(389)
(1, 8, 18)
sage: three_squares(946)
(9, 9, 28)
sage: three_squares(2986)
(3, 24, 49)
sage: three_squares(7^100)
(0, 0, 1798465042647412146620280340569649349251249)
sage: three_squares(11^111-1)
(61627416065597534150706462680, 901582938385735143295060746161, \ldots)
sage: three_squares(7 * 2^41)
(1048576, 2097152, 3145728)
sage: three_squares(7 * 2^42)
Traceback (most recent call last):
... ValueError: 30786325577728 is not a sum of 3 squares

sage: three_squares(0)
(0, 0, 0)
sage: three_squares(-1)
Traceback (most recent call last):
... ValueError: -1 is not a sum of 3 squares

ALGORITHM:

See http://www.schorn.ch/howto.html

sage.arith.misc.trial_division(n, bound=None)

Return the smallest prime divisor \( \leq \text{bound} \) of the positive integer \( n \), or \( n \) if there is no such prime. If the optional argument \( \text{bound} \) is omitted, then \( \text{bound} \leq n \).

INPUT:

• \( n \) - a positive integer

• \( \text{bound} \) - (optional) a positive integer

OUTPUT:

• \( \text{int} \) - a prime \( p \leq \text{bound} \) that divides \( n \), or \( n \) if there is no such prime.

EXAMPLES:
```python
sage: trial_division(15)
3
sage: trial_division(91)
7
sage: trial_division(11)
11
sage: trial_division(387833, 300)
387833
sage: trial_division(387833, 400)
389
```

Tests with numpy and gmpy2 numbers:

```python
sage: from numpy import int8
sage: trial_division(int8(91))
7
sage: from gmpy2 import mpz
sage: trial_division(mpz(91))
7
```

`sage.arith.misc.two_squares(n)`
Write the integer $n$ as a sum of two integer squares if possible; otherwise raise a `ValueError`.

**INPUT:**

- $n$ – an integer

**OUTPUT:** a tuple $(a, b)$ of non-negative integers such that $n = a^2 + b^2$ with $a \leq b$.

**EXAMPLES:**

```python
sage: two_squares(389)
(10, 17)
sage: two_squares(21)
Traceback (most recent call last):
... ValueError: 21 is not a sum of 2 squares
sage: two_squares(21^2)
(0, 21)
sage: a,b = two_squares(100000000000000000129); a,b
(4418521500, 8970878873)
sage: a^2 + b^2
100000000000000000129
sage: two_squares(2^222+1)
(253801659504708621991421712450521, 2583712713213354898490304645018692)
sage: two_squares(0)
(0, 0)
sage: two_squares(-1)
Traceback (most recent call last):
... ValueError: -1 is not a sum of 2 squares
```

**ALGORITHM:**

See [http://www.schorn.ch/howto.html](http://www.schorn.ch/howto.html)

`sage.arith.misc.valuation(m, *args, **kwds)`
Return the valuation of $m$.  

1.11. Miscellaneous arithmetic functions 133
This function simply calls the m.valuation() method. See the documentation of m.valuation() for a more precise description.

Note that the use of this functions is discouraged as it is better to use m.valuation() directly.

**Note:** This is not always a valuation in the mathematical sense. For more information see: sage.rings.finite_rings.integer_mod.IntegerMod_int.valuation

**EXAMPLES:**

```python
sage: valuation(512, 2)
9
sage: valuation(1, 2)
0
sage: valuation(5/9, 3)
-2
```

Valuation of 0 is defined, but valuation with respect to 0 is not:

```python
sage: valuation(0, 7)
+Infinity
sage: valuation(3, 0)
Traceback (most recent call last):
  ... ValueError: You can only compute the valuation with respect to a integer larger than 1.
```

Here are some other examples:

```python
sage: valuation(100, 10)
2
sage: valuation(200, 10)
2
sage: valuation(243, 3)
5
sage: valuation(243*10007, 3)
5
sage: valuation(243*10007, 10007)
1
sage: y = QQ['y'].gen()
sage: valuation(y^3, y)
3
sage: x = QQ[['x']].gen()
sage: valuation((x^3-x^2)/(x-4))
2
sage: valuation(4r, 2r)
2
sage: valuation(1r, 1r)
Traceback (most recent call last):
  ... ValueError: You can only compute the valuation with respect to a integer larger than 1.
sage: from numpy import int16
sage: valuation(int16(512), int16(2))
9
sage: from gmpy2 import mpz
```

(continues on next page)
sage: valuation(mpz(512), mpz(2))
9

\texttt{sage.arith.misc.} \texttt{xgcd}(a, b)
\texttt{\hspace{1em} Return a triple } \langle g, s, t \rangle \texttt{ such that } g = s \cdot a + t \cdot b = \text{gcd}(a, b).

\textbf{Note:} One exception is if \(a\) and \(b\) are not in a principal ideal domain (see Wikipedia article \texttt{Principal_ideal_domain}), e.g., they are both polynomials over the integers. Then this function can’t in general return \((g, s, t)\) as above, since they need not exist. Instead, over the integers, we first multiply \(g\) by a divisor of the resultant of \(a/g\) and \(b/g\), up to sign.

\textbf{INPUT:}
- \(a, b\) - integers or more generally, element of a ring for which the \texttt{xgcd} make sense (e.g. a field or univariate polynomials).

\textbf{OUTPUT:}
- \(g, s, t\) - such that \(g = s \cdot a + t \cdot b\)

\textbf{Note:} There is no guarantee that the returned cofactors \((s\) and \(t)\) are minimal.

\textbf{EXAMPLES:}

\begin{verbatim}
\texttt{sage: xgcd(56, 44)}
(4, 4, -5)
\texttt{sage: 4*56 + (-5)*44}
4
\texttt{sage: g, a, b = xgcd(5/1, 7/1); g, a, b}
(1, 3, -2)
\texttt{sage: a*(5/1) + b*(7/1) == g}
True
\texttt{sage: x = polygen(QQ)}
\texttt{sage: xgcd(x^3 - 1, x^2 - 1)}
(x - 1, 1, -x)
\texttt{sage: K.<g> = NumberField(x^2-3)}
\texttt{sage: g.xgcd(g+2)}
(1, 1/3*g, 0)
\texttt{sage: R.<a,b> = K[]}\n\texttt{sage: S.<y> = R.fraction_field([])}\n\texttt{sage: xgcd(y^2, a*y+b)}
(1, a^2/b^2, (a+g)*y+b)
\texttt{sage: xgcd((b+g)*y^2, (a+g)*y+b)}
(1, (a^2 + (2*g)*a + 3)/(b^3 + (g)*b^2), (((-a + (-g))/b^2)*y + 1/b)
\end{verbatim}

Here is an example of a \texttt{xgcd} for two polynomials over the integers, where the linear combination is not the \texttt{gcd} but the \texttt{gcd} multiplied by the resultant:

\begin{verbatim}
\texttt{sage: R.<x> = ZZ[]}\n\texttt{sage: gcd(2*x*(x-1), x^2)}
\end{verbatim}
Tests with numpy and gmpy2 types:

```
sage: from numpy import int8
sage: xgcd(4, int8(8))
(4, 1, 0)
sage: xgcd(int8(4), int8(8))
(4, 1, 0)
sage: from gmpy2 import mpz
sage: xgcd(mpz(4), mpz(8))
(4, 1, 0)
sage: xgcd(4, mpz(8))
(4, 1, 0)
```

`sage.arith.misc.xkcd(n="")`
This function is similar to the xgcd function, but behaves in a completely different way.

See https://xkcd.com/json.html for more details.

INPUT:
- n – an integer (optional)

OUTPUT: a fragment of HTML

EXAMPLES:

```
sage: xkcd(353)  # optional - internet
<h1>Python</h1><img src="https://imgs.xkcd.com/comics/python.png" title="I wrote 20 short programs in Python yesterday. It was wonderful. Perl, I'm leaving you."
```

`sage.arith.misc.xlcm(m, n)`  
Extended lcm function: given two positive integers $m, n$, returns a triple $(l, m_1, n_1)$ such that $l = \text{lcm}(m, n) = m_1 \cdot n_1$ where $m_1 | m, n_1 | n$ and $\text{gcd}(m_1, n_1) = 1$, all with no factorization.

Used to construct an element of order $l$ from elements of orders $m, n$ in any group: see sage/groups/generic.py for examples.

EXAMPLES:

```
sage: xlcm(120, 36)
(360, 40, 9)
```

- `sage.sets.positive_integers`
- `sage.sets.non_negative_integers`
- `sage.sets.primes`
2.1 Field $\mathbb{Q}$ of Rational Numbers

The class $\texttt{RationalField}$ represents the field $\mathbb{Q}$ of (arbitrary precision) rational numbers. Each rational number is an instance of the class $\texttt{Rational}$.

Interactively, an instance of $\texttt{RationalField}$ is available as $\texttt{QQ}$:

```python
sage: QQ
Rational Field
```

Values of various types can be converted to rational numbers by using the $\texttt{__call__}$ method of $\texttt{RationalField}$ (that is, by treating $\texttt{QQ}$ as a function).

```python
sage: RealField(9).pi()
3.1
sage: QQ(RealField(9).pi())
22/7
sage: QQ(RealField().pi())
245850922/78256779
sage: QQ(35)
35
sage: QQ('12/347')
12/347
sage: QQ(exp(pi*I))
-1
sage: x = polygen(ZZ)
sage: QQ((3*x)/(4*x))
3/4
```

AUTHORS:

- Niles Johnson (2010-08): trac ticket #3893: random_element() should pass on *args and **kwds.
- Travis Scrimshaw (2012-10-18): Added additional docstrings for full coverage. Removed duplicates of discriminant() and signature().
- Anna Haensch (2018-03): Added function quadratic_defect()

```python
sage.rings.rational_field.Q = Rational Field
sage.rings.rational_field.QQ = Rational Field
class sage.rings.rational_field.RationalField
    Bases: sage.misc.fast_methods.Singleton, sage.rings.number_field.
          number_field_base.NumberField
```
The class \texttt{RationalField} represents the field $\mathbb{Q}$ of rational numbers.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: a = 901824309821093812093810928309183091832091
sage: b = QQ(a); b
901824309821093812093810928309183091832091
sage: QQ(b)
901824309821093812093810928309183091832091
sage: QQ(int(93820984323))
93820984323
sage: QQ(ZZ(901824309821093812093810928309183091832091))
901824309821093812093810928309183091832091
sage: QQ('-930482/9320842317')
-930482/9320842317
sage: QQ((-930482, 9320842317))
-930482/9320842317
sage: QQ([9320842317])
9320842317
sage: QQ(pari(39029384023840928309482842098430284398243982394))

sage: QQ(23.2)
116/5
sage: a = 23.2; a
23.2000000000000
sage: QQ(a, 10)
116/5

Here's a nice example involving elliptic curves:

sage: E = EllipticCurve('11a')
sage: L = E.lseries().at1(300)[0]; L
0.2538418608559106843377589233...
sage: O = E.period_lattice().omega(); O
1.26920930427955
sage: t = L/O; t
0.200000000000000
sage: QQ(RealField(45)(t))
1/5
\end{verbatim}
absolute_degree()  
Return the absolute degree of \( \mathbb{Q} \) which is 1.

EXAMPLES:

```python
sage: QQ.absolute_degree()
1
```

absolute_discriminant()  
Return the absolute discriminant, which is 1.

EXAMPLES:

```python
sage: QQ.absolute_discriminant()
1
```

algebraic_closure()  
Return the algebraic closure of self (which is \( \mathbb{Q} \)).

EXAMPLES:

```python
sage: QQ.algebraic_closure()
Algebraic Field
```

automorphisms()  
Return all Galois automorphisms of self.

OUTPUT:

- a sequence containing just the identity morphism

EXAMPLES:

```python
sage: QQ.automorphisms()
[
    Ring endomorphism of Rational Field
    Defn: 1 |--> 1
]
```

characteristic()  
Return 0 since the rational field has characteristic 0.

EXAMPLES:

```python
sage: c = QQ.characteristic(); c
0
sage: parent(c)
Integer Ring
```

class_number()  
Return the class number of the field of rational numbers, which is 1.

EXAMPLES:

```python
sage: QQ.class_number()
1
```

completion \( (p, \text{prec}, \text{extras}=/) \)  
Return the completion of \( \mathbb{Q} \) at \( p \).

EXAMPLES:
complex_embedding\((\text{prec}=53)\)
Return embedding of the rational numbers into the complex numbers.

**EXAMPLES:**

```
sage: QQ.complex_embedding()
Ring morphism:
  From: Rational Field
  To:   Complex Field with 53 bits of precision
        Defn: 1 |--> 1.00000000000000
sage: QQ.complex_embedding(20)
Ring morphism:
  From: Rational Field
  To:   Complex Field with 20 bits of precision
        Defn: 1 |--> 1.0000
```

complex_embedding\((\text{prec}=53)\)

construction\()\nReturns a pair \((\text{functor}, \text{parent})\) such that \(\text{functor}(\text{parent})\) returns self.

This is the construction of \(\mathbb{Q}\) as the fraction field of \(\mathbb{Z}\).

**EXAMPLES:**

```
sage: QQ.construction()
(FractionField, Integer Ring)
```

degree\()\nReturn the degree of \(\mathbb{Q}\) which is 1.

**EXAMPLES:**

```
sage: QQ.degree()
1
```

discriminant\()\nReturn the discriminant of the field of rational numbers, which is 1.

**EXAMPLES:**

```
sage: QQ.discriminant()
1
```

embeddings\((K)\)
Return list of the one embedding of \(\mathbb{Q}\) into \(K\), if it exists.

**EXAMPLES:**

```
sage: QQ.embeddings(QQ)
[Identity endomorphism of Rational Field]
sage: QQ.embeddings(CyclotomicField(5))
[Coercion map:
   From: Rational Field
   To:   Cyclotomic Field of order 5 and degree 4]
```

\(K\) must have characteristic 0:

```
sage: QQ.embeddings(GF(3))
Traceback (most recent call last):
...
ValueError: no embeddings of the rational field into K.
```

### extension \((poly, names, **kwds)\)
Create a field extension of \(\mathbb{Q}\).

EXAMPLES:

We make a single absolute extension:

```
sage: K.<a> = QQ.extension(x^3 + 5); K
Number Field in a with defining polynomial x^3 + 5
```

We make an extension generated by roots of two polynomials:

```
sage: K.<a,b> = QQ.extension([x^3 + 5, x^2 + 3]); K
Number Field in a with defining polynomial x^3 + 5 over its base field
sage: b^2
-3
sage: a^3
-5
```

### gen \((n=0)\)
Return the \(n\)-th generator of \(\mathbb{Q}\).

There is only the 0-th generator which is 1.

EXAMPLES:

```
sage: QQ.gen()
1
```

### gens ()
Return a tuple of generators of \(\mathbb{Q}\) which is only \((1,)\).

EXAMPLES:

```
sage: QQ.gens()
(1,)
```

### hilbert_symbol_negative_at_S \((S, b, check=True)\)
Returns an integer that has a negative Hilbert symbol with respect to a given rational number and a given set of primes (or places).

The function is algorithm 3.4.1 in [Kir2016]. It finds an integer \(a\) that has negative Hilbert symbol with respect to a given rational number exactly at a given set of primes (or places).

INPUT:
- \(S\) – a list of rational primes, the infinite place as real embedding of \(\mathbb{Q}\) or as -1
- \(b\) – a non-zero rational number which is a non-square locally at every prime in \(S\).
- \(check\) – bool (default: True) perform additional checks on input and confirm the output.

OUTPUT:
- An integer \(a\) that has negative Hilbert symbol \((a, b)_p\) for every place \(p\) in \(S\) and no other place.

EXAMPLES:

2.1. Field \(\mathbb{Q}\) of Rational Numbers

141
AUTHORS:

**is_absolute()**

Q is an absolute extension of \( \mathbb{Q} \).

EXAMPLES:

```python
sage: QQ.is_absolute()
True
```

**is_prime_field()**

Return True since \( \mathbb{Q} \) is a prime field.

EXAMPLES:

```python
sage: QQ.is_prime_field()
True
```

**maximal_order()**

Return the maximal order of the rational numbers, i.e., the ring \( \mathbb{Z} \) of integers.

EXAMPLES:

```python
sage: QQ.maximal_order()
Integer Ring
sage: QQ.ring_of_integers()
Integer Ring
```

**ngens()**

Return the number of generators of \( \mathbb{Q} \) which is 1.

EXAMPLES:

```python
sage: QQ.ngens()
1
```

**number_field()**

Return the number field associated to \( \mathbb{Q} \). Since \( \mathbb{Q} \) is a number field, this just returns \( \mathbb{Q} \) again.

EXAMPLES:

```python
sage: QQ.number_field() is QQ
True
```

**order()**

Return the order of \( \mathbb{Q} \) which is \( \infty \).

EXAMPLES:

```python
sage: QQ.order() +Infinity
```
places\( (\text{all\_complex}=\text{False}, \text{prec}=\text{None}) \)

Return the collection of all infinite places of self, which in this case is just the embedding of self into \( \mathbb{R} \).

By default, this returns homomorphisms into \( \mathbb{R} \). If \text{prec} is not None, we simply return homomorphisms into \( \text{RealField} (\text{prec}) \) (or \( \text{RDF} \) if \text{prec}=53).

There is an optional flag \text{all\_complex}, which defaults to False. If \text{all\_complex} is True, then the real embeddings are returned as embeddings into the corresponding complex field.

For consistency with non-trivial number fields.

**EXAMPLES:**

```python
sage: QQ.places()
[Ring morphism:
  From: Rational Field
  To: Real Field with 53 bits of precision
  Defn: 1 |--> 1.0000000000000000000000000000000000000000000000000000000000]
sage: QQ.places(prec=53)
[Ring morphism:
  From: Rational Field
  To: Real Double Field
  Defn: 1 |--> 1.0]
sage: QQ.places(prec=200, all_complex=True)
[Ring morphism:
  From: Rational Field
  To: Complex Field with 200 bits of precision
  Defn: 1 |--> 1.0000000000000000000000000000000000000000000000000000000000]
```

power\text{\_basis}()

Return a power basis for this number field over its base field.

The power basis is always \([1]\) for the rational field. This method is defined to make the rational field behave more like a number field.

**EXAMPLES:**

```python
sage: QQ.power_basis()
[1]
```

primes\text{\_of\_bounded\_norm\_iter}(B)

Iterator yielding all primes less than or equal to \( B \).

**INPUT:**

- \( B \) – a positive integer; upper bound on the primes generated.

**OUTPUT:**

An iterator over all integer primes less than or equal to \( B \).

**Note:** This function exists for compatibility with the related number field method, though it returns prime integers, not ideals.

**EXAMPLES:**

```python
sage: it = QQ.primes_of_bounded_norm_iter(10)
sage: list(it)
[2, 3, 5, 7]
```
sage: list(QQ.primes_of_bounded_norm_iter(1))
[]

quadratic_defect \((a, p, check=True)\)
Return the valuation of the quadratic defect of \(a\) at \(p\).

INPUT:
- \(a\) – an element of \(\text{self}\)
- \(p\) – a prime ideal or a prime number
- \(\text{check}=(\text{default: True}); \text{check if } p \text{ is prime}

REFERENCE:
[Kir2016]

EXAMPLES:

```
sage: QQ.quadratic_defect(0, 7)
+Infinity
sage: QQ.quadratic_defect(5, 7)
0
sage: QQ.quadratic_defect(5, 2)
2
sage: QQ.quadratic_defect(5, 5)
1
```

random_element \((\text{num_bound=None, den_bound=None, } \ast \text{args, } \ast \text{kwds}\)\)
Return a random element of \(\mathbb{Q}\).

Elements are constructed by randomly choosing integers for the numerator and denominator, not necessarily coprime.

INPUT:
- \(\text{num_bound}\) – a positive integer, specifying a bound on the absolute value of the numerator. If absent, no bound is enforced.
- \(\text{den_bound}\) – a positive integer, specifying a bound on the value of the denominator. If absent, the bound for the numerator will be reused.

Any extra positional or keyword arguments are passed through to \(\text{sage.rings.integer_ring. IntegerRing_class.random_element()\).}

EXAMPLES:

```
sage: QQ.random_element()
-4
sage: QQ.random_element()
0
sage: QQ.random_element()
-1/2
```

In the following example, the resulting numbers range from -5/1 to 5/1 (both inclusive), while the smallest possible positive value is 1/10:

```
sage: QQ.random_element(5, 10)
-2/7
```
Extra positional or keyword arguments are passed through:

```python
sage: QQ.random_element(distribution='1/n')
0
sage: QQ.random_element(distribution='1/n')
-1
```

**range_by_height (start, end=None)**

Range function for rational numbers, ordered by height.

Returns a Python generator for the list of rational numbers with heights in `range(start, end)`.

Folows the same convention as Python range, see `range?` for details.

See also `__iter__()`.  

**EXAMPLES:**

All rational numbers with height strictly less than 4:

```python
sage: list(QQ.range_by_height(4))
[0, 1, -1, 1/2, -1/2, 2, -2, 1/3, -1/3, 3, -3, 2/3, -2/3, 3/2, -3/2]
sage: [a.height() for a in QQ.range_by_height(4)]
[1, 1, 1, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, 3]
```

All rational numbers with height 2:

```python
sage: list(QQ.range_by_height(2, 3))
[1/2, -1/2, 2, -2]
```

Nonsensical integer arguments will return an empty generator:

```python
sage: list(QQ.range_by_height(3, 3))
[]
sage: list(QQ.range_by_height(10, 1))
[]
```

There are no rational numbers with height \leq 0:

```python
sage: list(QQ.range_by_height(-10, 1))
[]
```

**relative_discriminant ()**

Return the relative discriminant, which is 1.

**EXAMPLES:**

```python
sage: QQ.relative_discriminant()
1
```

**residue_field (p, check=True)**

Return the residue field of \( \mathbb{Q} \) at the prime \( p \), for consistency with other number fields.

**INPUT:**

- \( p \) - a prime integer.
- \( \text{check} \) (default True) - if True check the primality of \( p \), else do not.

**OUTPUT:** The residue field at this prime.

**EXAMPLES:**
sage: QQ.residue_field(5)
Residue field of Integers modulo 5
sage: QQ.residue_field(next_prime(10^9))
Residue field of Integers modulo 1000000007

\textbf{selmer\_group} \((S, m, proof=True, orders=False)\)

Compute the group \(Q(S, m)\).

\textbf{INPUT:}

- \(S\) – a set of primes
- \(m\) – a positive integer
- \(\text{proof} – \text{ignored}\)
- \(\text{orders} \ (\text{default False}) – \text{if True, output two lists, the generators and their orders}\)

\textbf{OUTPUT:}

A list of generators of \(Q(S, m)\) (and, optionally, their orders in \(Q^\times/(Q^\times)^m\)). This is the subgroup of \(Q^\times/(Q^\times)^m\) consisting of elements \(a\) such that the valuation of \(a\) is divisible by \(m\) at all primes not in \(S\). It is equal to the group of \(S\)-units modulo \(m\)-th powers. The group \(Q(S, m)\) contains the subgroup of those \(a\) such that \(Q(\sqrt[m]{a})/Q\) is unramified at all primes of \(Q\) outside of \(S\), but may contain it properly when not all primes dividing \(m\) are in \(S\).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: QQ.selmer_group((,), 2)
[-1]
sage: QQ.selmer_group((3,), 2)
[-1, 3]
sage: QQ.selmer_group((5,), 2)
[-1, 5]
\end{verbatim}

The previous examples show that the group generated by the output may be strictly larger than the ‘true’ Selmer group of elements giving extensions unramified outside \(S\).

When \(m\) is even, \(-1\) is a generator of order 2:

\begin{verbatim}
sage: QQ.selmer_group((2,3,5,7,), 2, orders=True)
([[-1, 2, 3, 5, 7], [2, 2, 2, 2, 2]])
sage: QQ.selmer_group((2,3,5,7,), 3, orders=True)
([[-1, 2, 3, 5, 7], [3, 3, 3, 3]])
\end{verbatim}

\textbf{selmer\_group\_iterator} \((S, m, proof=True)\)

Return an iterator through elements of the finite group \(Q(S, m)\).

\textbf{INPUT:}

- \(S\) – a set of primes
- \(m\) – a positive integer
- \(\text{proof} – \text{ignored}\)

\textbf{OUTPUT:}

An iterator yielding the distinct elements of \(Q(S, m)\). See the docstring for \textit{selmer\_group()} for more information.

\textbf{EXAMPLES:}
signature()
Return the signature of the rational field, which is (1, 0), since there are 1 real and no complex embeddings.

EXAMPLES:

```python
sage: QQ.signature()
(1, 0)
```

some_elements()
Return some elements of \( \mathbb{Q} \).

See TestSuite() for a typical use case.

OUTPUT:
An iterator over 100 elements of \( \mathbb{Q} \).

EXAMPLES:

```python
sage: tuple(QQ.some_elements())
(1/2, -1/2, 2, -2,
0, 1, -1, 42,
2/3, -2/3, 3/2, -3/2,
4/5, -4/5, 5/4, -5/4,
6/7, -6/7, 7/6, -7/6,
8/9, -8/9, 9/8, -9/8,
10/11, -10/11, 11/10, -11/10,
12/13, -12/13, 13/12, -13/12,
14/15, -14/15, 15/14, -15/14,
16/17, -16/17, 17/16, -17/16,
18/19, -18/19, 19/18, -19/18,
20/441, -20/441, 441/20, -441/20,
22/529, -22/529, 529/22, -529/22,
24/625, -24/625, 625/24, -625/24,
...)```  

valuation(p)
Return the discrete valuation with uniformizer \( p \).

EXAMPLES:

```python
sage: v = QQ.valuation(3); v
3-adic valuation
sage: v(1/3)
-1
```

See also:

NumberField_generic.valuation(), IntegerRing_class.valuation()

zeta(n=2)
Return a root of unity in \( \text{self} \).
INPUT:

- \( n \) – integer (default: 2) order of the root of unity

EXAMPLES:

```
sage: QQ.zeta()
-1
sage: QQ.zeta(2)
-1
sage: QQ.zeta(1)
1
sage: QQ.zeta(3)
Traceback (most recent call last):
... ValueError: no n-th root of unity in rational field
```

```
sage.rings.rational_field.frac(n, d)
Return the fraction \( n/d \).

EXAMPLES:

```
sage: from sage.rings.rational_field import frac
sage: frac(1,2)
1/2
```

```
sage.rings.rational_field.is_RationalField(x)
Check to see if \( x \) is the rational field.

EXAMPLES:

```
sage: from sage.rings.rational_field import is_RationalField as is_RF
sage: is_RF(QQ)
True
sage: is_RF(ZZ)
False
```

# 2.2 Rational Numbers

AUTHORS:

- William Stein (2005): first version
- Gonzalo Tornaria and William Stein (2006-03-02): greatly improved python/GMP conversion; hashing
- David Harvey (2006-09-15): added nth_root
- Pablo De Napoli (2007-04-01): corrected the implementations of multiplicative_order, is_one; optimized __nonzero__; documented: lcm, gcd
- Travis Scrimshaw (2012-10-18): Added doctests for full coverage.
- Vincent Delecroix (2013): continued fraction
- Vincent Delecroix (2017-05-03): faster integer-rational comparison
• Vincent Klein (2017-05-11): add __mpq__() to class Rational

• Vincent Klein (2017-05-22): Rational constructor support gmpy2.mpq or gmpy2.mpz parameter. Add __mpz__ to class Rational.

class sage.rings.rational.Q_to_Z
   Bases: sage.categories.map.Map
   
   A morphism from Q to Z.

   section()
       Return a section of this morphism.

   EXAMPLES:

   sage: sage.rings.rational.Q_to_Z(QQ, ZZ).section()
   Natural morphism:
   From: Integer Ring
   To:  Rational Field

class sage.rings.rational.Rational
   Bases: sage.structure.element.FieldElement
   
   A rational number.

   Rational numbers are implemented using the GMP C library.

   EXAMPLES:

   sage: a = -2/3
   sage: type(a)
   <type 'sage.rings.rational.Rational'>
   sage: parent(a)
   Rational Field
   sage: Rational('1/0')
   Traceback (most recent call last):
     ...
   TypeError: unable to convert '1/0' to a rational
   sage: Rational(1.5)
   3/2
   sage: Rational('9/6')
   3/2
   sage: Rational((2^99,2^100))
   1/2
   sage: Rational("2", "10", 16)
   1/8
   sage: Rational(QQbar(125/8).nth_root(3))
   5/2
   sage: Rational(AA(209735/343 - 17910/49*golden_ratio).nth_root(3) + 3*AA(golden_ratio))
   53/7
   sage: QQ(float(1.5))
   3/2
   sage: QQ(RDF(1.2))
   6/5

   Conversion from fractions:

   sage: import fractions
   sage: f = fractions.Fraction(1r, 2r)
Conversion from PARI:

\begin{verbatim}
sage: Rational(pari('-939082/3992923'))
-939082/3992923
sage: Rational(pari('Pol([-1/2]')))  #9595
-1/2
\end{verbatim}

Conversions from numpy:

\begin{verbatim}
sage: import numpy as np
sage: QQ(np.int8('-15'))
-15
sage: QQ(np.int16('-32'))
-32
sage: QQ(np.int32('-19'))
-19
sage: QQ(np.uint32('1412'))
1412
sage: QQ(np.float16('12'))
12
\end{verbatim}

Conversions from gmpy2:

\begin{verbatim}
sage: from gmpy2 import *
sage: QQ(mpq('3/4'))
3/4
sage: QQ(mpz(42))
42
sage: Rational(mpq(2/3))
2/3
sage: Rational(mpz(5))
5
\end{verbatim}

 absol ute_n orm() 

Return the norm from Q to Q of x (which is just x). This was added for compatibility with NumberFields

EX A MPLE S:

\begin{verbatim}
sage: (6/5).absolute_norm()
6/5
sage: QQ(7/5).absolute_norm()
7/5
\end{verbatim}

additive_order() 

Return the additive order of self.

OUTPUT: integer or infinity

EX A MPLE S:

\begin{verbatim}
sage: QQ(0).additive_order()
1
\end{verbatim}
sage: QQ(1).additive_order()
+Infinity

as_integer_ratio()

Return the pair (self.numerator(), self.denominator()).

EXAMPLES:

sage: x = -12/29
sage: x.as_integer_ratio()
(-12, 29)

ceil()

Return the ceiling of this rational number.

OUTPUT: Integer

If this rational number is an integer, this returns this number, otherwise it returns the floor of this number +1.

EXAMPLES:

sage: n = 5/3; n.ceil()
2
sage: n = -17/19; n.ceil()
0
sage: n = -7/2; n.ceil()
-3
sage: n = 7/2; n.ceil()
4
sage: n = 10/2; n.ceil()
5

ccharpoly(var='x')

Return the characteristic polynomial of this rational number. This will always be just var - self; this is really here so that code written for number fields won’t crash when applied to rational numbers.

INPUT:

• var - a string

OUTPUT: Polynomial

EXAMPLES:

sage: (1/3).charpoly('x')
x - 1/3

The default is var='x'. (trac ticket #20967):

sage: a = QQ(2); a.charpoly('x')
x - 2

AUTHORS:

• Craig Citro

conjugate()

Return the complex conjugate of this rational number, which is the number itself.

EXAMPLES:
content(other)

Return the content of self and other, i.e. the unique positive rational number $c$ such that $\text{self}/c$ and $\text{other}/c$ are coprime integers.

other can be a rational number or a list of rational numbers.

EXAMPLES:

```
sage: a = 2/3
sage: a.content(2/3)
2/3
sage: a.content(1/5)
1/15
sage: a.content([2/5, 4/9])
2/45
```

continued_fraction()

Return the continued fraction of that rational.

EXAMPLES:

```
sage: (641/472).continued_fraction()
[1; 2, 1, 3, 1, 4, 1, 5]
sage: a = (355/113).continued_fraction(); a
[3, 7, 16]
sage: a.n(digits=10)
3.141592920
sage: pi.n(digits=10)
3.141592654
```

It’s almost pi!

continued_fraction_list(type='std')

Return the list of partial quotients of this rational number.

INPUT:

- type - either “std” (the default) for the standard continued fractions or “hj” for the Hirzebruch-Jung ones.

EXAMPLES:

```
sage: (13/9).continued_fraction_list()
[1, 2, 4]
sage: 1 + 1/(2 + 1/4)
13/9

sage: (225/157).continued_fraction_list()
[1, 2, 3, 4, 5]
sage: 1 + 1/(2 + 1/(3 + 1/(4 + 1/5)))
225/157

sage: (fibonacci(20)/fibonacci(19)).continued_fraction_list()
[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 2]
```

(continues on next page)
Check that the partial quotients of an integer \( n \) is simply \( [n] \):

```python
sage: QQ(1).continued_fraction_list()
[1]
sage: QQ(0).continued_fraction_list()
[0]
sage: QQ(-1).continued_fraction_list()
[-1]
```

Hirzebruch-Jung continued fractions:

```python
sage: (11/19).continued_fraction_list("hj")
[1, 3, 2, 3, 2]
sage: 1 - 1/(3 - 1/(2 - 1/(3 - 1/2)))
11/19
sage: (225/137).continued_fraction_list("hj")
[2, 3, 5, 10]
sage: 2 - 1/(3 - 1/(5 - 1/10))
225/137
sage: (-23/19).continued_fraction_list("hj")
[-1, 5, 4]
sage: -1 - 1/(5 - 1/4)
-23/19
```

denom()

Return the denominator of this rational number. denom is an alias of denominator.

EXAMPLES:

```python
sage: x = -5/11
sage: x.denominator()
11
```

```python
sage: x = 9/3
sage: x.denominator()
1
```

```python
sage: x = 5/13
sage: x.denom()
13
```

denominator()

Return the denominator of this rational number. denom is an alias of denominator.

EXAMPLES:

```python
sage: x = -5/11
sage: x.denominator()
11
```

```python
sage: x = 9/3
```
sage: x.denominator()
1
sage: x = 5/13
sage: x.denom()
13

factor()
Return the factorization of this rational number.

OUTPUT: Factorization

EXAMPLES:

sage: (-4/17).factor()
-1 * 2^2 * 17^-1

Trying to factor 0 gives an arithmetic error:

sage: (0/1).factor()
Traceback (most recent call last):
...  
ArithmeticError: factorization of 0 is not defined

floor()
Return the floor of this rational number as an integer.

OUTPUT: Integer

EXAMPLES:

sage: n = 5/3; n.floor()
1
sage: n = -17/19; n.floor()
-1
sage: n = -7/2; n.floor()
-4
sage: n = 7/2; n.floor()
3
sage: n = 10/2; n.floor()
5

gamma(prec=None)
Return the gamma function evaluated at self. This value is exact for integers and half-integers, and returns a symbolic value otherwise. For a numerical approximation, use keyword prec.

EXAMPLES:

sage: gamma(1/2)
sqrt(pi)
sage: gamma(7/2)
15/8*sqrt(pi)
sage: gamma(-3/2)
4/3*sqrt(pi)
sage: gamma(6/1)
120
sage: gamma(1/3)
gamma(1/3)
This function accepts an optional precision argument:

```
sage: (1/3).gamma(prec=100)
2.678938534707747633656929410
sage: (1/2).gamma(prec=100)
1.7724538509055160272981674833
```

**global_height** (*prec=None*)
Return the absolute logarithmic height of this rational number.

INPUT:

• *prec* (int) – desired floating point precision (default: default RealField precision).

OUTPUT:

(real) The absolute logarithmic height of this rational number.

ALGORITHM:
The height is the sum of the total archimedean and non-archimedean components, which is equal to 
\[
\max(\log(n), \log(d))
\]
where \(n, d\) are the numerator and denominator of the rational number.

EXAMPLES:

```
sage: a = QQ(6/25)
sage: a.global_height_arch() + a.global_height_non_arch()
3.21887582486820
sage: a.global_height()
3.21887582486820
sage: (1/a).global_height()
3.21887582486820
sage: QQ(0).global_height()
0.000000000000000
sage: QQ(1).global_height()
0.000000000000000
```

**global_height_arch** (*prec=None*)
Return the total archimedean component of the height of this rational number.

INPUT:

• *prec* (int) – desired floating point precision (default: default RealField precision).

OUTPUT:

(real) The total archimedean component of the height of this rational number.

ALGORITHM:
Since \(\mathbb{Q}\) has only one infinite place this is just the value of the local height at that place. This separate
function is included for compatibility with number fields.

EXAMPLES:

```
sage: a = QQ(6/25)
sage: a.global_height_arch()
0.000000000000000
sage: (1/a).global_height_arch()
1.4271163556401457483890413081
sage: (1/a).global_height_arch(100)
1.4271163556401457483890413081
```
**global_height_non_arch**(prec=None)

Return the total non-archimedean component of the height of this rational number.

**INPUT:**

- prec (int) – desired floating point precision (default: default RealField precision).

**OUTPUT:**

(real) The total non-archimedean component of the height of this rational number.

**ALGORITHM:**

This is the sum of the local heights at all primes \( p \), which may be computed without factorization as the log of the denominator.

**EXAMPLES:**

```
sage: a = QQ(5/6)
sage: a.support()
[2, 3, 5]
sage: a.global_height_non_arch()
1.79175946922805
```

**height()**

The max absolute value of the numerator and denominator of self, as an \( \text{Integer} \).

**OUTPUT:** Integer

**EXAMPLES:**

```
sage: a = 2/3
sage: a.height()
3
sage: a = 34/3
sage: a.height()
34
sage: a = -97/4
sage: a.height()
97
```

**AUTHORS:**

- Naqi Jaffery (2006-03-05): examples

**Note:** For the logarithmic height, use **global_height()**.

**imag()**

Return the imaginary part of self, which is zero.

**EXAMPLES:**

```
sage: (1/239).imag()
0
```

**is_S_integral**(S=\( S=\emptyset \))

Determine if the rational number is \( S \)-integral.
x is S-integral if \( x.\text{valuation}(p) \geq 0 \) for all \( p \) not in \( S \), i.e., the denominator of \( x \) is divisible only by the primes in \( S \).

**INPUT:**
- \( S \) – list or tuple of primes.

**OUTPUT:** bool

**Note:** Primality of the entries in \( S \) is not checked.

**EXAMPLES:**
```
sage: QQ(1/2).is_S_integral()
False
sage: QQ(1/2).is_S_integral([2])
True
sage: [a for a in range(1,11) if QQ(101/a).is_S_integral([2,5])]
[1, 2, 4, 5, 8, 10]
```

### is_S_unit \((S=None)\)
Determines if the rational number is an \( S \)-unit.

\( x \) is an \( S \)-unit if \( x.\text{valuation}(p) = 0 \) for all \( p \) not in \( S \), i.e., the numerator and denominator of \( x \) are divisible only by the primes in \( S \).

**INPUT:**
- \( S \) – list or tuple of primes.

**OUTPUT:** bool

**Note:** Primality of the entries in \( S \) is not checked.

**EXAMPLES:**
```
sage: QQ(1/2).is_S_unit()
False
sage: QQ(1/2).is_S_unit([2])
True
sage: [a for a in range(1,11) if QQ(10/a).is_S_unit([2,5])]
[1, 2, 4, 5, 8, 10]
```

### is_integer
Determines if a rational number is integral (i.e. is in \( \mathbb{Z} \)).

**OUTPUT:** bool

**EXAMPLES:**
```
sage: QQ(1/2).is_integral()
False
sage: QQ(4/4).is_integral()
True
```

### is_integral
Determines if a rational number is integral (i.e. is in \( \mathbb{Z} \)).

**OUTPUT:** bool
EXAMPLES:

```python
sage: QQ(1/2).is_integral()
False
sage: QQ(4/4).is_integral()
True
```

**is_norm**(\(L, \text{element=True, proof=True}\))

Determine whether \(self\) is the norm of an element of \(L\).

**INPUT:**
- \(L\) – a number field
- \(element\) – (default: \(False\)) boolean whether to also output an element of which \(self\) is a norm
- \(proof\) – If \(True\), then the output is correct unconditionally. If \(False\), then the output assumes GRH.

**OUTPUT:**
If \(element\) is \(False\), then the output is a boolean \(B\), which is \(True\) if and only if \(self\) is the norm of an element of \(L\). If \(element\) is \(False\), then the output is a pair \((B, x)\), where \(B\) is as above. If \(B\) is \(True\), then \(x\) an element of \(L\) such that \(self == x.\text{norm()}\). Otherwise, \(x\) is \(None\).

**ALGORITHM:**
Uses PARI’s `bnfisnorm`. See `_bnfisnorm()`.

**EXAMPLES:**

```python
sage: K = NumberField(x^2 - 2, 'beta')
sage: (1/7).is_norm(K)
True
sage: (1/10).is_norm(K)
False
sage: 0.is_norm(K)
True
sage: (1/7).is_norm(K, element=True)
(True, 1/7*beta + 3/7)
```

The number field doesn’t have to be defined by an integral polynomial:

```python
sage: B, e = (1/5).is_norm(QuadraticField(5/4, 'a'), element=True)
sage: B
True
```

A non-Galois number field:

```python
sage: K.<a> = NumberField(x^3-2)
sage: B, e = (3/5).is_norm(K, element=True); B
True
```

(continues on next page)
AUTHORS:

• Craig Citro (2008-04-05)
• Marco Streng (2010-12-03)

**is_nth_power (n)**

Return True if self is an \( n \)-th power, else False.

INPUT:

• \( n \) - integer (must fit in C int type)

**Note:** Use this function when you need to test if a rational number is an \( n \)-th power, but do not need to know the value of its \( n \)-th root. If the value is needed, use `nth_root()`.

AUTHORS:

• John Cremona (2009-04-04)

**EXAMPLES:**

```sage
sage: QQ(25/4).is_nth_power(2)
True
sage: QQ(125/8).is_nth_power(3)
True
sage: QQ(-125/8).is_nth_power(3)
True
sage: QQ(25/4).is_nth_power(-2)
True
sage: QQ(9/2).is_nth_power(2)
False
sage: QQ(-25).is_nth_power(2)
False
```

**is_one ()**

Determine if a rational number is one.

OUTPUT: bool

**EXAMPLES:**

```sage
sage: QQ(1/2).is_one()
False
sage: QQ(4/4).is_one()
True
```

**is_padic_square (p, check=True)**

Determines whether this rational number is a square in \( \mathbb{Q}_p \) (or in \( R \) when \( p = \text{infinity} \)).

INPUT:
• $p$ - a prime number, or infinity
• check – (default: True); check if $p$ is prime

EXAMPLES:

```python
sage: QQ(2).is_padic_square(7)
True
sage: QQ(98).is_padic_square(7)
True
sage: QQ(2).is_padic_square(5)
False
```

`is_perfect_power(expected_value=False)`

Return True if `self` is a perfect power.

**INPUT:**

• expected_value - (bool) whether or not this rational is expected be a perfect power. This does not affect the correctness of the output, only the runtime.

If `expected_value` is `False` (default) it will check the smallest of the numerator and denominator is a perfect power as a first step, which is often faster than checking if the quotient is a perfect power.

**EXAMPLES:**

```python
sage: (4/9).is_perfect_power()
True
sage: (144/1).is_perfect_power()
True
sage: (4/3).is_perfect_power()
False
sage: (2/27).is_perfect_power()
False
sage: (4/27).is_perfect_power()
False
sage: (-1/25).is_perfect_power()
False
sage: (-1/27).is_perfect_power()
True
sage: (0/1).is_perfect_power()
True
```

The second parameter does not change the result, but may change the runtime.

```python
sage: (-1/27).is_perfect_power(True)
True
sage: (-1/25).is_perfect_power(True)
False
sage: (2/27).is_perfect_power(True)
False
sage: (144/1).is_perfect_power(True)
True
```

This test makes sure we workaround a bug in GMP (see trac ticket #4612):

```python
sage: [-a for a in srange(100) if not QQ(-a^3).is_perfect_power() ]
[]
sage: [-a for a in srange(100) if not QQ(-a^3).is_perfect_power(True) ]
[]
```
is_rational()  
Return True since this is a rational number.

EXAMPLES:

```sage
sage: (3/4).is_rational()
True
```

is_square()  
Return whether or not this rational number is a square.

OUTPUT: bool

EXAMPLES:

```sage
sage: x = 9/4
sage: x.is_square()
True
sage: x = (7/53)^100
sage: x.is_square()
True
sage: x = 4/3
sage: x.is_square()
False
sage: x = -1/4
sage: x.is_square()
False
```

list()  
Return a list with the rational element in it, to be compatible with the method for number fields.

OUTPUT:

- list - the list [self]

EXAMPLES:

```sage
sage: m = 5/3
sage: m.list()
[5/3]
```

local_height(p, prec=None)  
Return the local height of this rational number at the prime $p$.

INPUT:

- $p$ – a prime number
- prec (int) – desired floating point precision (default: default RealField precision).

OUTPUT:

(real) The local height of this rational number at the prime $p$.

EXAMPLES:

```sage
sage: a = QQ(25/6)
sage: a.local_height(2)
0.693147180559945
sage: a.local_height(3)
1.09861228866811
(continues on next page)```
local_height_arch \((\text{prec}=\text{None})\)
Return the Archimedean local height of this rational number at the infinite place.

**INPUT:**

- \(\text{prec}\) (int) – desired floating point precision (default: default RealField precision).

**OUTPUT:**

(real) The local height of this rational number \(x\) at the unique infinite place of \(\mathbb{Q}\), which is \(\max(\log(\left|x\right|), 0)\).

**EXAMPLES:**

```
sage: a = QQ(6/25)
sage: a.local_height_arch()
0.000000000000000
sage: (1/a).local_height_arch()
1.42711635564015
sage: (1/a).local_height_arch(100)
1.4271163556401457483890413081
```

log \((\text{m}=\text{None}, \text{prec}=\text{None})\)
Return the log of \(\text{self}\).

**INPUT:**

- \(\text{m}\) – the base (default: natural log base e)
- \(\text{prec}\) – integer (optional); the precision in bits

**OUTPUT:**

When \(\text{prec}\) is not given, the log as an element in symbolic ring unless the logarithm is exact. Otherwise the log is a RealField approximation to \(\text{prec}\) bit precision.

**EXAMPLES:**

```
sage: (124/345).log(5)
log(124/345)/log(5)
sage: (124/345).log(5,100)
-0.63578895602025611710391773754
sage: log(QQ(125))
3*log(5)
sage: log(QQ(125), 5)
3
sage: log(QQ(125), 3)
3*\log(5)/\log(3)
sage: QQ(8).log(1/2)
-3
sage: (1/8).log(1/2)
3
sage: (1/2).log(1/8)
1/3
sage: (1/2).log(8)
-1/3
sage: (16/81).log(8/27)
4/3
```

(continues on next page)
\begin{verbatim}
sage: (8/27).log(16/81)
3/4
sage: log(27/8, 16/81)
-3/4
sage: log(16/81, 27/8)
-4/3
sage: (125/8).log(5/2)
3
sage: (125/8).log(5/2, prec=53)
3.00000000000000
\end{verbatim}

**minpoly**\(^{(var='x')}\)

Return the minimal polynomial of this rational number. This will always be just \(x - \text{self};\) this is really here so that code written for number fields won’t crash when applied to rational numbers.

**INPUT:**

- \(\text{var} -\) a string

**OUTPUT:** Polynomial

**EXAMPLES:**

\begin{verbatim}
sage: (1/3).minpoly()
x - 1/3
sage: (1/3).minpoly('y')
y - 1/3
\end{verbatim}

**AUTHORS:**

- Craig Citro

**mod_ui**\(^{(n)}\)

Return the remainder upon division of \(\text{self}\) by the unsigned long integer \(n\).

**INPUT:**

- \(\text{n} -\) an unsigned long integer

**OUTPUT:** integer

**EXAMPLES:**

\begin{verbatim}
sage: (-4/17).mod_ui(3)
1
sage: (-4/17).mod_ui(17)
Traceback (most recent call last):
...
ArithmeticError: The inverse of 0 modulo 17 is not defined.
\end{verbatim}

**multiplicative_order**\(^{}()\)

Return the multiplicative order of \(\text{self}\).

**OUTPUT:** Integer or infinity

**EXAMPLES:**

\begin{verbatim}
sage: QQ(1).multiplicative_order()
1
sage: QQ('1/-1').multiplicative_order()
1
\end{verbatim}
norm()  
Return the norm from \( \mathbb{Q} \) to \( \mathbb{Q} \) of \( x \) (which is just \( x \)). This was added for compatibility with NumberFields.

OUTPUT:

- Rational - reference to self

EXAMPLES:

```
sage: (1/3).norm()
sage: 1/3
```

AUTHORS:

- Craig Citro

nth_root(\( n \))  
Computes the \( n \)-th root of self, or raises a ValueError if self is not a perfect \( n \)-th power.

INPUT:

- \( n \) - integer (must fit in C int type)

AUTHORS:

- David Harvey (2006-09-15)

EXAMPLES:

```
sage: (25/4).nth_root(2)
sage: 5/2
sage: (125/8).nth_root(3)
sage: 5/2
sage: (-125/8).nth_root(3)
sage: -5/2
sage: (25/4).nth_root(-2)
sage: 2/5
```

```
sage: (9/2).nth_root(2)
Traceback (most recent call last):
  ...
ValueError: not a perfect 2nd power
```

```
sage: (-25/4).nth_root(2)
Traceback (most recent call last):
  ...
ValueError: cannot take even root of negative number
```

numer()  
Return the numerator of this rational number. numer is an alias of numerator.
EXAMPLES:

```
sage: x = 5/11
sage: x.numerator()
5

sage: x = 9/3
sage: x.numerator()
3

sage: x = -5/11
sage: x.numer()
-5
```

`numerator()`

Return the numerator of this rational number. numer is an alias of numerator.

EXAMPLES:

```
sage: x = 5/11
sage: x.numerator()
5

sage: x = 9/3
sage: x.numerator()
3

sage: x = -5/11
sage: x.numer()
-5
```

`ord(p)`

Return the power of \( p \) in the factorization of self.

INPUT:

- \( p \) - a prime number

OUTPUT:

(integer or infinity) \( \text{Infinity} \) if \( \text{self} \) is zero, otherwise the (positive or negative) integer \( e \) such that \( \text{self} = m \cdot p^e \) with \( m \) coprime to \( p \).

Note: See also `val_unit()` which returns the pair \((e,m)\). The function `ord()` is an alias for `valuation()`.

EXAMPLES:

```
sage: x = -5/9
sage: x.valuation(5)
1
sage: x.ord(5)
1
sage: x.valuation(3)
-2
sage: x.valuation(2)
0
```

Some edge cases:
period()

Return the period of the repeating part of the decimal expansion of this rational number.

ALGORITHM:

When a rational number \( \frac{n}{d} \) with \((n, d) = 1\) is expanded, the period begins after \(s\) terms and has length \(t\), where \(s\) and \(t\) are the smallest numbers satisfying \(10^s = 10^s + t \mod d\). In general if \(d = 2^a5^b m\) where \(m\) is coprime to 10, then \(s = \max(a, b)\) and \(t\) is the order of 10 modulo \(m\).

EXAMPLES:

sage: (1/7).period()
sage: RR(1/7)
0.142857142857143
sage: (1/8).period()
sage: RR(1/8)
0.125000000000000
sage: RR(1/6)
0.166666666666667
sage: x = 333/106
sage: x.period()
sage: RealField(200)(x)
3.1415094339622641509433962264150943396226415094339622641509

prime_to_S_part(S=\emptyset)

Return self with all powers of all primes in \(S\) removed.

INPUT:

- \(S\) - list or tuple of primes.

OUTPUT: rational

Note: Primality of the entries in \(S\) is not checked.

EXAMPLES:

sage: QQ(3/4).prime_to_S_part()
sage: QQ(3/4).prime_to_S_part([2])
sage: QQ(-3/4).prime_to_S_part([3])
sage: QQ(700/99).prime_to_S_part([2, 3, 5])
sage: QQ(-700/99).prime_to_S_part([2, 3, 5])
sage: QQ(0).prime_to_S_part([2, 3, 5])
real()

Return the real part of self, which is self.

EXAMPLES:

```
sage: (1/2).real()
1/2
```

relative_norm()

Return the norm from Q to Q of x (which is just x). This was added for compatibility with NumberFields

EXAMPLES:

```
sage: (6/5).relative_norm()
6/5
sage: QQ(7/5).relative_norm()
7/5
```

round(mode='away')

Return the nearest integer to self, rounding away from 0 by default, for consistency with the builtin Python round.

INPUT:

- self - a rational number
- mode - a rounding mode for half integers:
  - ‘toward’ rounds toward zero
  - ‘away’ (default) rounds away from zero
  - ‘up’ rounds up
  - ‘down’ rounds down
  - ‘even’ rounds toward the even integer
  - ‘odd’ rounds toward the odd integer

OUTPUT: Integer

EXAMPLES:

```
sage: (9/2).round()
5
sage: n = 4/3; n.round()
1
sage: n = -17/4; n.round()
-4
sage: n = -5/2; n.round()
-3
sage: n.round("away")
-3
sage: n.round("up")
-2
```

(continues on next page)
sage: n.round("down")
-3
sage: n.round("even")
-2
sage: n.round("odd")
-3

sign()
Return the sign of this rational number, which is -1, 0, or 1 depending on whether this number is negative, zero, or positive respectively.

OUTPUT: Integer

EXAMPLES:

sage: (2/3).sign()
1
sage: (0/3).sign()
0
sage: (-1/6).sign()
-1

sqrt (prec=None, extend=True, all=False)
The square root function.

INPUT:

- prec – integer (default: None): if None, returns an exact square root; otherwise returns a numerical square root if necessary, to the given bits of precision.
- extend – bool (default: True): if True, return a square root in an extension ring, if necessary. Otherwise, raise a ValueError if the square is not in the base ring.
- all – bool (default: False): if True, return all square roots of self, instead of just one.

EXAMPLES:

sage: x = 25/9
sage: x.sqrt()
5/3
sage: sqrt(x)
5/3
sage: x = 64/4
sage: x.sqrt()
4
sage: x = 100/1
sage: x.sqrt()  # all=True
[10, -10]
sage: x = 81/5
sage: x.sqrt()  # 9*sqrt(1/5)
9*sqrt(1/5)
sage: x = -81/3
sage: x.sqrt()  # 3*sqrt(-3)
3*sqrt(-3)
```python
sage: n = 2/3
sage: n.sqrt()
sqrt(2/3)
sage: n.sqrt(prec=10)
0.82
sage: n.sqrt(prec=100)
0.81649658092772603273242802490
sage: n.sqrt(prec=100)^2
0.66666666666666666666666666667
sage: n.sqrt(prec=53, all=True)
[0.816496580927726, -0.816496580927726]
```

**AUTHORS:**

- Naqi Jaffery (2006-03-05): some examples

### squarefree_part()

Return the square free part of \(x\), i.e., an integer \(z\) such that \(x = y^2\), for a perfect square \(y^2\).

**EXAMPLES:**

```python
sage: a = 1/2
sage: a.squarefree_part()
2
```

### str(base=10)

Return a string representation of `self` in the given `base`.

**INPUT:**

- `base` – integer (default: 10); base must be between 2 and 36.

**OUTPUT:** string

**EXAMPLES:**

```python
sage: (-4/17).str()
'-4/17'
sage: (-4/17).str(2)
'-100/10001'
```

Note that the base must be at most 36.
\begin{verbatim}
sage: (-4/17).str(40)
Traceback (most recent call last):
...
ValueError: base (=40) must be between 2 and 36
sage: (-4/17).str(1)
Traceback (most recent call last):
...
ValueError: base (=1) must be between 2 and 36
\end{verbatim}

\textbf{support()}

Return a sorted list of the primes where this rational number has non-zero valuation.

\textbf{OUTPUT:} The set of primes appearing in the factorization of this rational with nonzero exponent, as a sorted list.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: (-4/17).support()
[2, 17]
\end{verbatim}

Trying to find the support of 0 gives an arithmetic error:

\begin{verbatim}
sage: (0/1).support()
Traceback (most recent call last):
...
ArithmeticError: Support of 0 not defined.
\end{verbatim}

\textbf{trace()}

Return the trace from $\mathbb{Q}$ to $\mathbb{Q}$ of $x$ (which is just $x$). This was added for compatibility with \texttt{NumberFields}.

\textbf{OUTPUT:}

- \texttt{Rational} - reference to self

\textbf{EXAMPLES:}

\begin{verbatim}
sage: (1/3).trace()
1/3
\end{verbatim}

\textbf{AUTHORS:}

- Craig Citro

\textbf{trunc()}

Round this rational number to the nearest integer toward zero.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: (5/3).trunc()
1
sage: (-5/3).trunc()
-1
sage: QQ(42).trunc()
42
sage: QQ(-42).trunc()
-42
\end{verbatim}

\textbf{val_unit ($p$)}

Return a pair: the $p$-adic valuation of \texttt{self}, and the $p$-adic unit of \texttt{self}, as a \texttt{Rational}.
We do not require the \( p \) be prime, but it must be at least 2. For more documentation see \texttt{Integer.val_unit()}.

**INPUT:**

- \( p \) - a prime

**OUTPUT:**

- \texttt{int} - the \( p \)-adic valuation of this rational
- \texttt{Rational} - \( p \)-adic unit part of self

**EXAMPLES:**

```python
sage: (-4/17).val_unit(2)
(2, -1/17)
sage: (-4/17).val_unit(17)
(-1, -4)
sage: (0/1).val_unit(17)
(+Infinity, 1)
```

**AUTHORS:**

- David Roe (2007-04-12)

\texttt{valuation(\( p \))}

Return the power of \( p \) in the factorization of self.

**INPUT:**

- \( p \) - a prime number

**OUTPUT:**

(integer or infinity) \texttt{Infinity} if \texttt{self} is zero, otherwise the (positive or negative) integer \( e \) such that \texttt{self} = \( m \times p^e \) with \( m \) coprime to \( p \).

**Note:** See also \texttt{val_unit()} which returns the pair \((e, m)\). The function \texttt{ord()} is an alias for \texttt{valuation()}.

**EXAMPLES:**

```python
sage: x = -5/9
sage: x.valuation(5)
1
sage: x.ord(5)
1
sage: x.valuation(3)
-2
sage: x.valuation(2)
0
```

Some edge cases:

```python
sage: (0/1).valuation(4)
+Infinity
sage: (7/16).valuation(4)
-2
```
class sage.rings.rational.Z_to_Q
    Bases: sage.categories.morphism.Morphism

    A morphism from \( \mathbb{Z} \) to \( \mathbb{Q} \).

    is_surjective()
    Return whether this morphism is surjective.

    EXAMPLES:

    sage: QQ.coerce_map_from(ZZ).is_surjective()
    False

section()
    Return a section of this morphism.

    EXAMPLES:

    sage: f = QQ.coerce_map_from(ZZ).section(); f
    Generic map:
        From: Rational Field
        To:   Integer Ring

    This map is a morphism in the category of sets with partial maps (see trac ticket #15618):

    sage: f.parent()
    Set of Morphisms from Rational Field to Integer Ring in Category of sets with
    partial maps

class sage.rings.rational.int_to_Q
    Bases: sage.categories.morphism.Morphism

    A morphism from Python 2 int to \( \mathbb{Q} \).

sage.rings.rational.integer_rational_power(a, b)
    Compute \( a^b \) as an integer, if it is integral, or return None.

    The nonnegative real root is taken for even denominators.

    INPUT:
    
    • a - an Integer
    • b - a nonnegative Rational

    OUTPUT:

    \( a^b \) as an Integer or None

    EXAMPLES:

    sage: from sage.rings.rational import integer_rational_power
    sage: integer_rational_power(49, 1/2)
    7
    sage: integer_rational_power(27, 1/3)
    3
    sage: integer_rational_power(-27, 1/3) is None
    True
    sage: integer_rational_power(-27, 2/3) is None
    True
    sage: integer_rational_power(512, 7/9)
    128
sage: integer_rational_power(27, 1/4) is None
True
sage: integer_rational_power(-16, 1/4) is None
True
sage: integer_rational_power(0, 7/9)
0
sage: integer_rational_power(1, 7/9)
1
sage: integer_rational_power(-1, 7/9) is None
True
sage: integer_rational_power(-1, 8/9) is None
True
sage: integer_rational_power(-1, 9/8) is None
True

TESTS (trac ticket #11228):

sage: integer_rational_power(-10, QQ(2))
100
sage: integer_rational_power(0, QQ(0))
1

```
sage.rings.rational.is_Rational(x)
```

Return true if x is of the Sage rational number type.

**EXAMPLES:**

```
sage: from sage.rings.rational import is_Rational
sage: is_Rational(2)
False
sage: is_Rational(2/1)
True
sage: is_Rational(int(2))
False
sage: is_Rational('5')
False
```

```
class sage.rings.rational.long_to_Q
```

Bases: sage.categories.morphism.Morphism

A morphism from Python 2 long/Python 3 int to Q.

```
sage.rings.rational.make_rational(s)
```

Make a rational number from s (a string in base 32)

**INPUT:**

- s - string in base 32

**OUTPUT:** Rational

**EXAMPLES:**

```
sage: (-7/15).str(32)
'-7/f'
sage: sage.rings.rational.make_rational('-7/f')
-7/15
```

2.2. Rational Numbers 173
sage.rings.rational.rational_power_parts(a, b, factor_limit=100000)

Compute rationals or integers c and d such that $a^b = c * d^b$ with d small. This is used for simplifying radicals.

**INPUT:**

- a – a rational or integer
- b – a rational
- factor_limit – the limit used in factoring a

**EXAMPLES:**

```python
sage: from sage.rings.rational import rational_power_parts
sage: rational_power_parts(27, 1/2)
(3, 3)
sage: rational_power_parts(-128, 3/4)
(8, -8)
sage: rational_power_parts(-4, 1/2)
(2, -1)
sage: rational_power_parts(-4, 1/3)
(1, -4)
sage: rational_power_parts(9/1000, 1/2)
(3/10, 1/10)
```
